## IT Operations Management

ServiceNow® IT Operations Management solutions help your organization enhance visibility into your infrastructure and services, prevent service outages, and maximize operational agility.

### Watch the video

### See more, know more, do more with IT Operations Management

Move IT operations from a reactive team to one that works intelligently for the business with IT Operations Management. Deliver high-performance business services. Gain visibility across infrastructure and apps, maintain service health, and optimize cloud delivery and spend.

IBM Cloud

CMDB
ITOM Visibility gives you an accurate, up-to-date view of your IT infrastructure and services, spanning both multi-cloud and on-premises environments. It automates the end-to-end infrastructure discovery and service mapping process—including tracking ongoing changes—creating a complete and reliable record in your CMDB. This infrastructure and service information is seamlessly leveraged by other ServiceNow applications such as ITOM Health, ITOM Optimization, and Software Asset Management, and you can easily enrich it with additional configuration information by integrating with third-party applications and data sources.
**ITOM Health** uses the power of AIOps to turn the tidal wave of events into a trickle of actionable alerts—cutting through the noise, pinpointing service issues, and helping you to rapidly identify and remediate the root cause. Unlike legacy event management systems, which are static and rule based, ITOM Health applies machine learning and advanced analytics to correlate events, adapting automatically to rapidly evolving virtualized and cloud environments.

**ITOM Optimization**

![ITOM Optimization Diagram]

**ITOM Optimization** delivers the visibility and control you need while enhancing the agility of the cloud. It provides comprehensive visibility of cloud costs and usage, identifying and automating opportunities to optimize cloud spend. And, it also includes automated cloud provisioning capabilities, allowing you to establish an effective, agile cloud governance model.

Subscriptions for IT Operations Management

The ServiceNow platform uses a new licensing method where your organization is charged for using the following IT Operations Management products: ServiceNow® ITOM Visibility product, ServiceNow® ITOM Health product, and ServiceNow® ITOM Optimization product.

For licensing purposes, CI types are assigned to CI categories. The customer contract for your organization determines the ratios of CI allocation for each CI category. Information from the customer contract is synchronized with the ServiceNow platform. There are the following CI categories:

- Containers
- PaaS
- Servers
- Unresolved monitored objects

**Note:** CI types are the same as CI classes.

ServiceNow charges for the following IT Operations Management applications:

**ITOM Visibility**

The ServiceNow® ITOM Visibility product consists of the ServiceNow® Discovery feature and the ServiceNow® Service Mapping feature, which together give you a unified, connected view of your entire IT network and the services it supports. For licensing purposes, ITOM Visibility provides the count of CIs that it discovers, both during horizontal and top-down discovery. ITOM Visibility reports the count for CIs of the following CI categories: Servers, PaaS, and Containers.

**ITOM Health**

ServiceNow® ITOM Health product includes the ServiceNow® Event Management feature and the ServiceNow® Operational Intelligence feature, which together help you to track and maintain the health of services in your organization. ITOM Health reports the number of CIs, for which it captures alerts, events, and metric data. ITOM Health reports the CI count for all CI categories.

**ITOM Optimization**
ServiceNow® ITOM Optimization product includes two features: The Cloud Management feature gives you tools to provision private and public cloud infrastructure and services and to achieve consistent management and cost visibility. The Cloud Insights application, available in the ServiceNow Store, helps you to analyze the full range of costs associated with cloud assets so you can identify and take action on opportunities to save money and optimize operations. For licensing purposes, ITOM Optimization provides the count of CIs of the following categories: Servers, Containers, and PaaS.

Depending on the needs of your organization, you can purchase subscriptions for each IT Operations Management product separately (a la carte) or together (in bundles). When you purchase subscriptions in bundles, you get the same number of subscriptions for all IT Operations Management applications covered by the bundle. For example, for a bundle of 500 that covers ITOM Visibility and ITOM Health, your organization receives 500 subscriptions for ITOM Visibility and 500 subscriptions for ITOM Health.

Bundle subscriptions cover specific applications. You cannot use bundle subscriptions for other applications, even if these other applications are part of the same bundle. For example, you purchased a bundle of 500 covering ITOM Visibility and ITOM Health, and you used up all 500 ITOM Visibility subscriptions. You cannot use the spare ITOM Health subscriptions for ITOM Visibility.

If your organization consumes more subscriptions than you initially estimated, you can purchase a larger bundle that better suits the needs of your organization. Your organization may consume subscriptions of IT Operations Management applications at different levels. If so, you can purchase a bundle that sufficiently covers most of the required applications and also purchase a la carte subscriptions for the application that consumes more subscriptions.

Note: IT Operations Management bundles also provide entitlement to IntegrationHub for the functionality related to IT Operations Management applications.

View subscription statistics for IT Operations Management

View how many subscriptions for IT Operations Management applications your organization purchased and consumed.

Role required: sn_itom_license.reader

Review the configuration item (CI) allocation and allocation level to see how your organization uses IT Operations Management subscriptions and plan upcoming subscription needs.

View the following statistics on subscriptions purchased a la carte and by bundles:

Name
The name of either subscription bundle or IT Operations Management application, if your organization purchased subscriptions per application separately (a la carte).

Purchased
The number of purchased subscriptions per bundle or application (a la carte).

Allocated
The number of consumed subscriptions from a bundle or application (a la carte). For bundles, this field shows the highest number of consumed subscriptions by applications that are part of the bundle. For example, if ITOM Visibility consumed 300 subscriptions and ITOM Health consumed 200 subscriptions, this field shows 300 for the bundle covering these applications.

The color code indicates the percentage of the subscriptions that your organization consumed. By default, the color code threshold is 90%.

- Green — Your organization has used less than 10% of purchased subscriptions.
- **Yellow** — Your organization has used more than 90%, but less than 100% of purchased subscriptions.
- **Red** — Your organization has used 100% or more and exceeded the number of purchased subscriptions. Purchased subscriptions are overdrawn.

**Start date/End date**

The dates for which this subscription is valid.

The licensing module calculates and displays subscription consumption as follows:

**Subscriptions by bundle only**

When you purchase subscriptions in bundles, you get the same number of subscriptions for all IT Operations Management applications covered by the bundle. For example, for a bundle of 500 that covers ITOM Visibility and ITOM Health, your organization receives 500 subscriptions for ITOM Visibility and 500 subscriptions for ITOM Health.

The licensing module subtracts the number of consumed subscriptions from the bundle subscriptions for the relevant application. Bundle subscriptions cover specific applications. You cannot use bundle subscriptions for other applications, even if these other applications are part of the same bundle. For example, you purchased a bundle of 500 covering ITOM Visibility and ITOM Health, and you used up all 500 ITOM Visibility subscriptions. You cannot use the spare ITOM Health subscriptions for ITOM Visibility.

If your organization exceeds the number of purchased subscriptions, the bundle size is automatically adjusted to the number of consumed subscriptions. When that happens, the licensing module recalculates levels of consumption for all applications covered by the same bundle.
The Subscriptions window displays the actual number of consumed subscriptions under **Allocated**. The red color code indicates that the bundle is overdrawn.

**Subscriptions a la carte only**

The licensing module subtracts the number of consumed subscriptions from the a la carte subscriptions for the relevant application. The Subscriptions window displays the information for purchased and allocated subscriptions for IT Operations Management applications.
If your organization exceeds the number of purchased subscriptions for an IT Operations Management application, you cannot use unconsumed subscriptions for another application.

<table>
<thead>
<tr>
<th>Subscriptions window</th>
<th>ITOM Health</th>
<th>Capacity</th>
<th>ServiceNow</th>
<th>Start date</th>
<th>End date</th>
<th>Display on</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ITOM Health</td>

<td>ServiceNow</td>
<td>2019-03-01</td>
<td>2019-06-28</td>
<td>false</td>
</tr>
<tr>
<td></td>
<td>ITOM Visibility</td>
<td></td>
<td>ServiceNow</td>
<td>2019-03-01</td>
<td>2019-06-28</td>
<td>false</td>
</tr>
</tbody>
</table>

If your organization exceeds the number of subscriptions, the Subscriptions window shows the relevant a la carte subscription is overdrawn. In the following figure, ITOM Health consumed more subscriptions than you purchased for it.
Subscriptions for the same applications both in bundle and a la carte

If you purchased ITOM subscriptions both in bundle and a la carte, the licensing module always subtracts the number of consumed subscriptions from the bundle before deducting from the number of subscriptions purchased a la carte. For example, there is a bundle of 500 subscriptions covering ITOM Visibility and ITOM Health. In addition, there are 250 subscriptions for ITOM Visibility purchased a la carte. The first 500 subscriptions consumed by ITOM Visibility are consumed by the bundle. Only when ITOM Visibility exceeds the number of subscriptions in the bundle, the licensing module starts deducting from subscriptions purchased a la carte and shows them as subscriptions allocated to ITOM Visibility. In the following figure, one or both applications covered by the ITOM Pro bundle consumed 250 subscriptions.

If your organization exceeds the number of subscriptions purchased in bundle and a la carte, the licensing module considers it as overdrawn from the a la carte subscriptions.
In this case, the Subscriptions window indicates that the a la carte subscriptions are overdrawn.

Subscriptions in bundle and subscriptions a la carte for some applications covered by the bundle

If you purchased ITOM subscriptions in bundle and you also purchased a la carte subscriptions for an application that the bundle covers, the licensing module always subtracts the number of consumed subscriptions from the bundle before deducting from the number of subscriptions
purchased a la carte. In the following figure, an organization consumed all subscriptions available by the ITOM Pro bundle for ITOM Health. The licensing module then started subtracting from the a la carte subscriptions for ITOM Health.

If your organization exceeds the overall number of subscriptions both in the bundle and a la carte subscriptions, the licensing module considers it as overdrawn on the a la carte subscription. If your organization exceeds subscriptions for the application covered only by the same bundle, it is considered overdrawn on the bundle.

In this case, the Subscriptions window displays the a la carte subscriptions for this application as overdrawn. If your organization exceeds the overall number of subscriptions for an application
that is covered only by the bundle, the Subscriptions window shows the bundle as overdrawn. In the figure below, ITOM Health consumed 810 subscriptions going over subscriptions provided by the bundle (500) and a la carte (250). The Subscriptions window shows the ITOM Health a la carte subscription as overdrawn. ITOM Visibility consumed 550 subscriptions. Since there are no a la carte subscriptions purchased for ITOM Visibility, the bundle that covers ITOM Visibility appears overdrawn.

To view subscription information for IT Operations Management subscriptions purchased a la carte and in bundles, navigate to ITOM License > License Summary.

Use subscription names to differentiate between subscriptions bought in bundles and a la carte.

Check CI count used for IT Operations Management subscriptions

ITOM Visibility, ITOM Health, and ITOM Optimization provide information on licensable resources that these ITOM applications serve. Resources that IT Operations Management applications discover, monitor, and provision are configuration items (CIs) stored in the CMDB. The ITOM
licensing module combines this information on CIs with the information on subscriptions your organization purchased to produce statistics on subscription use by IT Operations Management applications.

Role required: admin

ServiceNow charges for the following IT Operations Management applications:

**ITOM Visibility**

The ServiceNow® ITOM Visibility product consists of the ServiceNow® Discovery feature and the ServiceNow® Service Mapping feature, which together give you a unified, connected view of your entire IT network and the services it supports. For licensing purposes, ITOM Visibility provides the count of CIs that it discovers, both during horizontal and top-down discovery. ITOM Visibility reports the count for CIs of the following CI categories: Servers, PaaS, and Containers.

**ITOM Health**

ServiceNow® ITOM Health product includes the ServiceNow® Event Management feature and the ServiceNow® Operational Intelligence feature, which together help you to track and maintain the health of services in your organization. ITOM Health reports the number of CIs, for which it captures alerts, events, and metric data. ITOM Health reports the CI count for all CI categories.

**ITOM Optimization**

ServiceNow® ITOM Optimization product includes two features: The Cloud Management feature gives you tools to provision private and public cloud infrastructure and services and to achieve consistent management and cost visibility. The Cloud Insights application, available in the ServiceNow Store, helps you to analyze the full range of costs associated with cloud assets so you can identify and take action on opportunities to save money and optimize operations. For licensing purposes, ITOM Optimization provides the count of CIs of the following categories: Servers, Containers, and PaaS.

The process of collecting and aggregating information for licensing purposes consists of the following interactions:

1. The IT Operations Management applications count CIs and assign them to CI categories daily. For more details, see KB0748149: CI count for licensing purposes by IT Operations Management.

2. The IT Operations Management applications daily report CI count by CI category to the IT Operations Management licensing module. If features of the same application report the same CIs as their resources, the CI count is manipulated to remove the duplication. For example, if Discovery and Service Mapping discover the same CIs, these CIs appear only once in the CI count.

3. The licensing module aggregates CI counts from IT Operations Management applications to get the daily average CI count for the last 90 days.

4. The licensing module correlates the daily average CI counts for IT Operations Management applications with the licensing information from the customer contract to produce license statistics.

As a result, you can view the statistics on how your organization uses purchased subscription units.
You can view the following information on CI count and subscriptions purchased for each IT Operations Management application separately (a la carte):

- **Total Count**: CI count for CIs organized by CI categories, for each IT Operations Management application.
- **Subscription Unit Ratio**: Ratios define how many CIs of a certain CI category require a subscription. The licensing module pulls the information about ratios from customer contracts.
- **Total Subscription Units Consumed**: The number of subscriptions per CI category for each IT Operations Management application that your organization consumed. The licensing module calculates this number by applying the subscriptions ratio to the CI count number for each application's CI category.
- **Total Subscription Units Consumed**: The sum of subscriptions consumed by all IT Operations Management applications.
This information does not include any statistics on subscriptions purchased in bundles. For complete information on subscriptions, view subscription statistics for IT Operations Management.

To view subscription information for each IT Operations Management application separately (a la carte), navigate to ITOM License > License Report.

Check which CI types require an IT Operations Management subscription

View the list of configuration item (CI) types that require IT Operations Management subscriptions.

Role required:

sn_itom_license.reader

For licensing purposes, CI types are assigned to CI categories. The customer contract for your organization determines the ratios of CI allocation for each CI category. Information from the customer contract is synchronized with the ServiceNow platform. There are the following CI categories:

- Containers
- PaaS
- Servers
- Unresolved monitored objects

**Note:** CI types are the same as CI classes.

The system stores information about CI categories and CI types that belong to them in the ITOM Licensing MetaData (itom_lu_metadata) table. This table includes information only about parent CI types. All CI types that are created by extending these parent CI types are included by default. For example, the Apache Web Server CI type is included in the CI count, because it is an extension of the Web Server CI type.

1. Navigate to ITOM License > Licenses by CI Type.
2. Click the arrow next to the CI Category to expand it and view CI types that are associated with it.
   
   CI types that appear under CI categories on this list require IT Operations Management subscriptions.

**ITOM Visibility**

The ServiceNow® ITOM Visibility product consists of the ServiceNow® Discovery feature and the ServiceNow® Service Mapping feature, which together give you a unified, connected view of your entire IT network and the services it supports.

**ITOM Visibility**

The ServiceNow® ITOM Visibility product consists of the ServiceNow® Discovery feature and the ServiceNow® Service Mapping feature, which together give you a unified, connected view of your entire IT network and the services it supports.

Discovery provides a replicable and reliable method to identify your enterprise IT infrastructure. Service Mapping creates an accurate, service-aware view of infrastructure. Service Mapping continuously monitors IT resources for service-affecting changes and updates service maps in real time.

For more information about ITOM Visibility, see the ITOM Visibility release notes.

**Using guided setup to implement IT Operations Management applications**

IT Operations Management Guided Setup provides a sequence of tasks that help you configure IT Operations Management applications on your ServiceNow instance. To open IT Operations...
Management guided setup, navigate to Guided Setup > ITOM Guided Setup. For more information about using the guided setup interface, see.

**Service Mapping**

The ServiceNow® Service Mapping application discovers all application services in your organization and builds a comprehensive map of all devices, applications, and configuration profiles used in these business services. Service Mapping maps dependencies, based on a connection between devices and applications. This method is referred to as top-down mapping. The top-down mapping helps you immediately see the impact of a problematic object on the rest of the application service operation.

Service Mapping is available as a separate subscription and requires activation by Service Mapping personnel.

**Understanding Service Mapping**

Service Mapping discovers all application services in your organization and builds a comprehensive map of all devices, applications, and configuration profiles used in these application services.

**Who uses Service Mapping?**

Service Mapping enables IT departments of companies, organizations, and cloud companies providing platform as a service to create a service-aware view of infrastructure.
How do you use Service Mapping?

An application service is a set of interconnected applications and hosts which are configured to offer a service to the organization. Application services can be internal, like an organization email system or customer-facing, like an organization website. For example, creating financial reports through a web-based application requires a computer, web server, application server, databases, middleware, and network infrastructure. These applications and hosts are all configured to offer the service of financial reporting.

Typically, IT departments create and maintain an inventory that treats devices and applications as standalone, independent objects. Connections between the devices and applications are not included. This is usually referred to as horizontal discovery. This method does not address the biggest challenge for IT departments, which is understanding the connection and dependencies between each object.

Service Mapping maps dependencies, based on a connection between devices and applications. This method is referred to as top-down mapping. The top-down mapping helps you immediately see the impact of a problematic object on the rest of the application service operation.

Comparison of horizontal and top-down mapping results

Application service maps show infrastructure objects and semantic connections between them. Service Mapping regenerates application service maps regularly, to keep them updated and relevant. Any faulty objects are shown along with the devices and applications they affect, providing a visual clue of the state of the application service.
How does Service Mapping work?

The main method of Service Mapping discovering and mapping devices and applications is using patterns. A pattern is a sequence of operations whose purpose is to detect attributes of devices and applications and their outbound connections. Service Mapping can also discover devices and applications by following traffic connections between them. This method is referred to as traffic-based discovery.

What to know before you begin?

You can use Service Mapping only if the Discovery product is activated and set up. You must define users and configure credentials to allow Service Mapping and Discovery access to applications and devices inside your organization network. For more information, see Service Mapping setup.

Service Mapping on the Now Platform

Service Mapping relies on Discovery and the MID Server to discover devices and applications. Service Mapping uses results of horizontal discovery performed by Discovery. The MID Server facilitates communication between Service Mapping and devices and applications it discovers. Data collected and organized by Service Mapping is visible in Event Management, Dependency Views, and Application Portfolio Management (APM). With Event Management, you can view events to take actions for recovering your organization application services. Dependency Views shows relationships between devices and applications in the context of application services they belong to. When integrated with APM, Service Mapping provides information about components making up a business application and helps APM users to monitor business application performance.

Service Mapping supports domain separation. If your Now Platform uses domain separation, administrators and users can only see and manage application services belonging to their own domain.

Pattern-based discovery in Service Mapping

Pattern-based discovery is the main method of Service Mapping collecting data about devices and applications used in application services. After Service Mapping collects data, it then creates a map of application services and stores the collected data in the CMDB. ServiceNow applications refer to devices and applications that comprise an application service as configuration items (CIs).

Service Mapping uses patterns to discover and map CIs. A pattern is a sequence of steps whose purpose is to detect attributes of a CI and its outbound connections. A typical Service Mapping pattern consists of two types of algorithms for identifying CIs and finding CI connections.

The starting point of any discovery process is an entry point. An entry point is how clients access an application service. For example, to map your electronic mailing application service, define an IP address or host name of the email server as an entry point. The discovery and mapping process begins from Discovery performing the horizontal discovery to identify the host. Once the host discovery is complete, Service Mapping starts the top-down discovery to find and map applications running on this host.

Service Mapping uses MID Servers to communicate with CIs in your organization. MID Servers are located inside your organization network and Service Mapping can communicate with them without traversing firewalls.
The discovery and mapping process consists of the following interactions:

1. A user defines an application service with an entry point for an application CI.
   Service Mapping creates a record for the new application service in the Application Service (cmdb_ci_service_discovered) table.

2. The device hosting the application is identified.
   a. Service Mapping checks if the device hosting this application CI exists in the CMDB.
   b. If the device hosting this application CI does not exist, Service Mapping triggers Discovery to detect host.
   c. Discovery creates the first set of probes for port discovery, referred to as Shazzam probes, and places them as a discovery request in the External Communication Channel (ECC) queue.
   d. The MID Server checks the ECC queue and retrieves the discovery request assigned to it.
   e. The MID Server runs the probes against the host and discovers open ports.
f. The MID Server passes information on the host ports to the ECC queue.
g. Discovery checks the ECC queue and receives information on the host ports.
h. These steps are repeated for other types of probes: classification, identification, and exploration.

i. Discovery adds the host to the CMDB.

j. During the host discovery using probes, Service Mapping checks the ECC queue if this process is complete. When the host discovery is complete, Service Mapping checks whether this host exists in the CMDB.

**Note:** For the detailed description of the horizontal discovery flow, refer to [Horizontal discovery process flow with probes and sensors](#).

3. Once the host is found in the CMDB, Service Mapping discovers the application running on this host.

   a. Service Mapping creates an application discovery request for the IP address of the entry point. It then writes the request in the ECC queue and assigns a MID Server to the request.

   b. The MID Server checks the ECC queue and retrieves the discovery request assigned to it.

   c. The MID Server starts running identification sections of the patterns associated with the classifier to find the match for the entry point. When the identification section matches the entry point, the pattern discovers a CI.
d. The MID Server starts running connectivity sections of the pattern to find outgoing connections of the newly discovered CI.

e. The MID Server passes information on the discovered CI, its attributes, and connections to the ECC queue.

f. Service Mapping checks the ECC queue and receives information on the newly discovered CI.

Whenever Service Mapping checks the ECC queue and receives information on a discovered CI, it checks these tables for any data on outbound connections related to the CI: the cmdb_tcp and sa_flow_connection tables. If these two tables contain unique data that patterns did not discover, Service Mapping enriches the information about the CI connections and adds them to the map.

g. Service Mapping writes the information into the CMDB and adds this CI to the application service map.
h. Service Mapping creates the discovery requests for all applications to which the newly discovered CI connects. Mapping is complete after Service Mapping maps a CI that either does not have any outbound connections or is marked as a boundary. A boundary makes Service Mapping stop discovery from this point and not follow outgoing connections.

4. The system regularly runs the service recomputation to query the CMDB for the latest CI changes, add data for network and storage paths, and apply CI impact rules.

Traffic-based discovery in Service Mapping

Service Mapping uses traffic-based connections to collect network statistics and perform traffic-based discovery. Not only can Service Mapping discover CIs using patterns, it can also discover them by following traffic connections between CIs. This method is referred to as traffic-based discovery.

Using traffic-based discovery is like casting a finer net, allowing Service Mapping to find even those CIs that it failed to discover using patterns. The advantage is discovering more CIs, at the same time this method may clutter an application service with irrelevant CIs. Typically, you use traffic-based discovery at the initial stages of discovering an application service and disable it once you completed discovery and fine-tuned the application service.

While using traffic-based discovery creates a more inclusive map, it may also result in mapping many redundant CIs that do not influence the application service operation. You can choose to hide CIs discovered using this method from an application service map. In that case, these CIs are still part of the application service, but they are not on its map.

The system uses commands and network flow logs to collect traffic-related data and saves them in the CMDB tables. Service Mapping retrieves this data from the tables to detect CI inbound and outbound connections.
### Tables containing data collected using traffic-based methods

<table>
<thead>
<tr>
<th>Table</th>
<th>Source</th>
<th>Used by Service Mapping to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Flow Connector (sa_flow_connection)</td>
<td>Netflow and VPC logs</td>
<td>• Discover dependencies, add connections during top-down discovery.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Detect possible entry points for application services and create application service candidates for mapping based on these entry points.</td>
</tr>
<tr>
<td>Flow Services IP/Port and Statistics (sa_flow_service)</td>
<td>Netflow and VPC logs</td>
<td>Discover all services listening on ports. In base system, Service Mapping does not use data from this table.</td>
</tr>
<tr>
<td>Flow Server Communication (sa_flow_server_comm)</td>
<td>Netflow and VPC logs</td>
<td>Discover services communicating to other services. In base system, Service Mapping does not use data from this table.</td>
</tr>
<tr>
<td>TCP Connection (cmdb_tcp)</td>
<td>netstat and lsof commands</td>
<td>Discover connections during top-down discovery.</td>
</tr>
</tbody>
</table>

In base systems, traffic-based discovery uses only TCP-related data collected with the help of the netstat and lsof commands. Discovery based on Netflow and VPC logs requires additional configuration. You can enrich your traffic-based discovery by configuring Service Mapping to perform data collection using Netflow and VPC logs. In addition, Service Mapping has access to TCP connection data collected by enhanced traffic-based horizontal discovery performed by Discovery.

By default, traffic-based discovery using commands is available in Service Mapping allowing it to use this method at all levels. You can enable traffic-based discovery at different levels listed here from the most global to the most specific:

**Product level**

In the base system, traffic-based discovery in Service Mapping is enabled. If necessary, you can fine-tune or disable traffic-based discovery at the product as described in Properties installed with Service Mapping under Components installed with Service Mapping.

**Application service level**

You can enable traffic-based discovery for a specific application service. In this case, Service Mapping uses this method for all CIs making up this application service, unless traffic-based discovery is disabled for some CI types or specific CIs.

**CI type level**

You can create a discovery rule to include or exclude a CI type from traffic-based discovery. This rule prevails over the setting you choose for an application service.

**Specific CI level**

You can create a discovery rule to include or exclude a specific CI from traffic-based discovery. This rule prevails over the setting you choose for an application service.

Rules for specific CIs take precedence over rules for CI types. For example, if you do not want to use traffic-based discovery on any Tomcat servers, you can define a CI type rule disabling the...
traffic-based discovery on the Tomcat table. At the same time, you can create a discovery rule enabling the traffic-based discovery for a specific Tomcat server. In that case, Service Mapping uses the traffic-based discovery only for this specific Tomcat server out of all Tomcat servers.

As traffic-based discovery method may clutter an application service with irrelevant CIs, Service Mapping uses an algorithm to reduce the number of erroneously mapped CI. You can further adjust traffic-based discovery to remove unwanted CIs as described in Remove CIs not belonging to application services.

Domain separation and Service Mapping

This is an overview of domain separation and Service Mapping. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can then control several aspects of this separation, including which users can see and access data.

Overview

Support: Level 1

Domain separation is supported in this application. Not all ServiceNow applications support domain separation; some include limitations on the data and administrative settings that can be domain separated. To learn more, see Application support for domain separation.

In ServiceNow environments where domain separation is configured, customers can view or manage only application services in domains to which customers have access.
How domain separation works in Service Mapping

In domain-separated environments, switch into relevant leaf domains to access actions related to mapping performed by Service Mapping. A leaf domain is a child domain of the lowest level, meaning it does not have any child domains itself.

Domain separation is handled in a slightly different way than simply configuring separate domains. Notice that you must select or specify the relevant leaf domain to perform the following mapping actions in domain-separated environments:

- When creating an application service, the application service is assigned to the user's domain.
- When manually adding a CI to an application service, you can choose only CIs that belong to the service domain.
- When manually adding connections to CIs to an application service, users must belong to the same domain as the application service.
- When transferring service definitions between instances, imported application services and service groups are assigned to the user's domain.

Refer to Discovery patterns used by ITOM Visibility topic and MID Server configuration for Service Mapping for more context. The following topics provide operational information on how to use Service Mapping in deployments with domain separation:

- Enable traffic-based discovery for CI types or specific CIs
- Create or modify patterns
- Create entry point types for Service Mapping
- Enhance patterns without changing their identification sections
- Customize pattern operations

Discovery of application services on cloud using Service Mapping

Service Mapping can discover application services consisting of devices and applications deployed in cloud.

There are two types of cloud computing methods your enterprise may use: infrastructure as a service (IaaS) and platform as a service (PaaS). Service Mapping discovers application services based on IaaS in the same way as any application service based on infrastructure located inside an enterprise private network. It relies on Discovery to find hosts before discovering applications and connections between them using patterns. For more information on this discovery flow, see Pattern-based discovery in Service Mapping.

Discovering application services entirely or partially based on PaaS requires a different paradigm. Applications in such deployments are hosted by network devices on cloud. To discover an application service in such a deployment, you use Discovery and Service Mapping as follows:

- You configure a service account for cloud-computing platform hosting the application service. Service Mapping and Discovery use this service account for accessing devices and applications on this platform.
- Discovery performs the horizontal discovery using probes and finds the infrastructure devices in the cloud.
- Discovery performs the horizontal discovery using patterns and finds applications and services hosted on the cloud.
- Service Mapping performs the top-down discovery to find connections between devices and applications and build the map of the application service.
Applications supported by Discovery and Service Mapping

Discovery and Service Mapping can discover a wide range of operating systems and applications.

Discovery finds computers, servers, printers, a variety of IP-enabled devices, and the applications that run on them. It can then update the CIs in your CMDB with the data it collects. This discovery method is referred to as horizontal discovery. Service Mapping maps dependencies, based on a connection between devices and applications. This method is referred to as top-down mapping. The top-down mapping helps you immediately see the impact of a problematic object on the rest of the application service operation.

On top of hosts and applications supported by default, you can discover additional hosts and applications by deploying patterns available on Store.

If your organization uses devices or applications, which are not supported by default or using patterns available at Store, you can configure Discovery and Service Mapping to discover them as described in Discovery patterns used by ITOM Visibility.

**Components installed with Service Mapping**

Several types of components are installed with activation of the Service Mapping plugin, including tables, user roles, properties, and scheduled jobs.

Demo data is available for this feature.
### Roles installed

<table>
<thead>
<tr>
<th>Role title (name)</th>
<th>Description</th>
<th>Contains roles</th>
</tr>
</thead>
<tbody>
<tr>
<td>(app_service_admin)</td>
<td>Creates and modifies application services, creates service groups, views, and edits application service maps.</td>
<td>(itil)</td>
</tr>
<tr>
<td>(app_service_user)</td>
<td>Views application service maps. The itil role that serves as the basic helpdesk technician role contains the app_service_user role.</td>
<td>cmdb_read</td>
</tr>
<tr>
<td>(itom_admin)</td>
<td>Configure IT Operations Management applications using the ITOM Guided Setup.</td>
<td>(sn_bm_client.benchmark_data_viewer) (sm_itom_license.reader)</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> The ITOM Guided Setup does not cover Service Mapping.</td>
<td></td>
</tr>
<tr>
<td>(sam_core_admin)</td>
<td>An internal role.</td>
<td>(sam_core_user)</td>
</tr>
<tr>
<td>(sam_core_user)</td>
<td>An internal role.</td>
<td>(itil)</td>
</tr>
<tr>
<td>(sm_admin)</td>
<td>SETS UP THE SERVICE MAPPING APPLICATION. Maps, fixes, and maintains application services. Also performs advanced configuration and customization of the product. Assign this role to application administrators.</td>
<td>• (app_service_admin) • (app_service_owner) • (discovery_admin) • (itil_admin) • (itom_admin) • (sam_core_admin) • (personalize_dictionary) • (pd_admin) • (pd_user)</td>
</tr>
<tr>
<td>(sm_app_owner)</td>
<td>PROVIDES INFORMATION NECESSARY FOR SUCCESSFUL MAPPING OF AN APPLICATION SERVICE. Once a service is mapped, this user reviews the results and either approves it or suggests changes. Assign the sm_app_owner role to users who own application services and are familiar with the infrastructure and applications that make up the services.</td>
<td>(sm_user)</td>
</tr>
<tr>
<td>(sm_itom_license.reader)</td>
<td>Views subscription information and statistics for IT Operations Management applications.</td>
<td></td>
</tr>
</tbody>
</table>
### Role title (name) | Description | Contains roles
--- | --- | ---
(sm_user) | Views maps for operational application services to plan change or migration, as well as analyze the continuity and availability of services. Assign this role to application users. | • (sam_core_user.sm_user)  
• (itil.sm_user)

(sn_svc_err.admin) | Fixes discovery errors in bulk using the error framework feature in Service Mapping and Discovery. | (itil)

(pd_admin) | Creates new and modifies existing patterns, which Service Mapping and Discovery use for performing horizontal and top-down discovery. | (pd_user)

### Scheduled jobs installed

<table>
<thead>
<tr>
<th>Scheduled job</th>
<th>Description</th>
</tr>
</thead>
</table>
| Deferred Discovery Cleanup  
(sysauto_script_ba4bee737f0022008f1c3b19be6efa910d) | Runs every minute. Detects and cancels discovery schedules on TCP connections that are not in the active state anymore (5 minutes of no activity). |
| Update Query Based Services  
(sysauto_script_08745913f3113102e6bae4716612b1f) | Runs every 10 minutes. Updates views for all defined technical services. |
| Update Business Service Status  
(sysauto_script_5641702ac32102003e7674e81d3ae26) | Runs every minute. Updates the discovery status attribute for application services. The discovery status is calculated as the overall status over all endpoints that an application service contains. |
| Flow Discovery Scheduler  
(sysauto_script_74c676f00d0b0220060ff742ea966291) | Runs every 10 minutes. Triggers the network flow discovery and writes the data into the (sa_flow_connector) table. |
| Save thread dumps  
(sysauto_script_a49c0d300c032020039a3553a81d3ae2) | Not active by default. When enabled, collects thread dumps and stores the data in the (sys_thread_dump) table. |
| Slow steps stats persist  
(sysauto_script_dc0d6e690c302020039a3553a81d3ae2) | Runs every minute. Collects data on slow execution of pattern steps and writes this data into the (sys_step_pattern) table. |
| Calculate number of servers  
(sys_trigger_db438f407f1502000128134f8d6a91c6) | Runs every Sunday. Updates the licensing metric with the overall number of discovered servers on instance. This information is used for billing. On domain separated instances, the number is updated for each domain. |
| Run DNS Lookup For All Entry Points and Manual Connection Endpoints  
(t178ab457fb213001952baf8be6fa91d3) | Runs the DNS lookup probe on all entry points and manual connection endpoints and updates information on their IP addresses in the CMDB. This scheduled job is disabled by default. |
### Scheduled Job

</tbody>
</table>
| sa.debugger.max_timeout | Maximum timeout (in seconds) since the last server activity during a Pattern Debugger run.  
  - **Type**: integer  
  - **Default value**: 120  
  - **Other possible values**: any number higher than 60  
  - **Location**: Service Mapping > Administration > Properties. |
| sa.service_history.max_allowed_bubbles | Number of changes that the history scale and the Changes tab display.  
  - **Type**: integer  
  - **Default value**: 3000  
  - **Other possible values**: any number higher than 3000  
  - **Attention**: Increasing the value for this property may cause performance issues with loading application service maps.  
  - **Location**: Service Mapping > Administration > Properties. |
| sa.rediscovery.batch_size | Number of discovery tasks executed in a single batch.  
  - **Type**: integer  
  - **Default value**: 100  
  - **Other possible values**: any number higher than 10  
  - **Location**: Service Mapping > Administration > Properties. |
| sa.traffic_based_discovery.active | Traffic-based discovery  
  - **Type**: true/false  
  - **Default value**: true  
  - **Other possible values**: false  
  - **Location**: Service Mapping > Administration > Properties. |
| sa.traffic_based_discovery.conn_aging_time | Time period in hours for a Traffic Based Connection to remain active since last discovered.  
  - **Type**: integer  
  - **Default value**: 72  
  - **Other possible values**: any number higher than 24  
  - **Location**: Service Mapping > Administration > Properties. |
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| sa.traffic_based_discovery.ignored_ports | Ports to ignore when found by traffic-based discovery. This property is available in the System Property (sys_properties) table. Change this property to define ports that Service Mapping ignores while performing traffic-based discovery. It makes discovery more efficient since resources are not wasted on discovering irrelevant connections.  
  - **Type**: string  
  - **Default value**: 445, 139, 111, 2049, 860, 3260, 135, 53  
  - **Other possible values**: any relevant port numbers  
  - **Location**: System Property (sys_properties) table |
| sa.traffic_based_discovery.max_connections | Maximum number of traffic-based connections from a single CI. This property is available in the System Property (sys_properties) table. This property helps to keep the map size reasonable by limiting the number of possible CI connections.  
  - **Type**: integer  
  - **Default value**: 30  
  - **Other possible values**: any number higher than 1  
  - **Location**: System Property (sys_properties) table |
| best_practice.import_csv.max_file_size_in_kb | Maximal size of CSV files in KB. This property is used for importing application service candidates in bulk.  
  - **Type**: integer  
  - **Default value**: 5000  
  - **Other possible values**: any number higher than 1  
  - **Location**: Service Mapping > Service Planner > Properties. |
| glide.ui.sa_dw_business_service_activity.fields | Defines which fields are displayed for the activity feed in the Planner feature.  
  - **Type**: string  
  - **Default value**: *Attachments*, name, work_notes, *Email*, status, Business_service_owner  
  - **Other possible values**: comma-separated list of fields  
  - **Location**: System Property (sys_properties) table |

### Service Mapping roles and flow

Learn about high-level tasks users having different roles perform in Service Mapping.

In Service Mapping, users with the following roles collaborate to map, review, and monitor organization application services:

**sm_admin**

Sets up the Service Mapping application. Maps, fixes, and maintains application services. Also performs advanced configuration and customization of the product. Assign this role to application administrators.

**sm_user**

Views maps for operational application services to plan change or migration, as well as analyze the continuity and availability of services. Assign this role to application users.

**sm_app_owner**

Provides information necessary for successful mapping of an application service. Once a service is mapped, this user reviews the results and either approves it or suggests changes. Assign the sm_app_owner role to users who own application services and are familiar with the infrastructure and applications that make up the services.

**Note:** For a complete list of Service Mapping roles, see Components installed with Service Mapping.

A typical Service Mapping workflow has the following stages:

1. The administrator performs basic obligatory configurations to set up Service Mapping.
2. The administrator maps organization business services in bulk. In addition, the administrator may map some application services individually.
3. The administrator fixes business service errors in bulk.
4. The administrator reviews the results of the initial mapping and fixes errors in individual business services.

<td>Enable automatic discovery on all successfully imported entry points.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Type</strong>: boolean</td>
</tr>
<tr>
<td></td>
<td>- <strong>Default value</strong>: false</td>
</tr>
<tr>
<td></td>
<td>- <strong>Other possible values</strong>: true</td>
</tr>
<tr>
<td></td>
<td>- <strong>Location</strong>: Service Mapping &gt; Administration &gt; Properties.</td>
</tr>
</tbody>
</table>
5. The administrator sends fixed business services to the business service owner for review.

6. The application service owner checks that the application service maps are complete and all major components comprising it are correctly represented. If necessary, the owner leaves comments, referred to as reject messages, on application service maps for the Service Mapping administrator to implement. See Review application service maps.

7. The administrator fine-tunes business service maps with feedback from the business service owner, and then resends them to the owner for review.

8. If the revised application service maps are satisfactory, the application service owner approves them. If not, the owner requests further fixes, which the administrator must address. See Review application service maps.

9. The administrator completes defining the business services by configuring access to them, as well as some advanced attributes like criticality.

10. After application service definition is complete, the Service Mapping user can view business service maps.
1. Set up Service Mapping
2. Map business services in bulk
3. Fix discovery errors in bulk
4. Fix discovery errors in individual maps
5. Send individual business services for review
6. Review business services and provide feedback
7. Implement owner’s requests and resend for review
8. Review and approve individual business services
9. Complete individual business service definition
10. View and analyze business service maps

In addition to these tasks, there may be a need to customize patterns that Service Mapping uses to discover devices and applications forming application services. Users must have the pd_admin role to customize patterns. In the base system, the sm_admin role contains the pd_role. Customizing patterns requires basic knowledge of programming.

Service Mapping setup

You get started with Service Mapping by configuring roles, credentials, and MID Server connections.

Setting up Service Mapping is the first stage in the Service Mapping workflow.
Service Mapping workflow

Service Mapping is part of the Now Platform and deploys some of its platform-wide mechanisms and features. At the same time, there are some configurations that are specific to Service Mapping only.

**Warning:** The Service Mapping setup for the Advance Release is different from the standard Service Mapping setup.
Perform the following tasks in the exact order they are listed below:

1. **Request Service Mapping.**

2. Install and configure MID Server. MID Servers, which are located in the enterprise private network, facilitate communication between servers on the network and some ServiceNow applications, such as Service Mapping, and Discovery. For more information, see [MID Server configuration for Service Mapping](#).

3. Verify that **Discovery** is set up and runs horizontal discovery as expected.

4. Configure **credentials required for host discovery.**

5. Configure credentials required for Service Mapping to access applications inside your organization private network. See [Prerequisites for performing top-down discovery using Service Mapping](#).

6. If your organization network contains load balancers running on a Linux host, create a **discovery behavior for load balancers.**

7. Grant the following Service Mapping roles to relevant users:

   - **sm_admin**
     
     Sets up the Service Mapping application. Maps, fixes, and maintains application services. Also performs advanced configuration and customization of the product. Assign this role to application administrators.

   - **sm_user**
     
     Views maps for operational application services to plan change or migration, as well as analyze the continuity and availability of services. Assign this role to application users.

   - **sm_app_owner**
     
     Provides information necessary for successful mapping of an application service. Once a service is mapped, this user reviews the results and either approves it or suggests changes. Assign the sm_app_owner role to users who own application services and are familiar with the infrastructure and applications that make up the services.

8. **Verify that Service Mapping is set up properly.**

9. If your organization has a ServiceNow deployment with customized Discovery or CMDB attributes, perform additional configuration described in [KB0647574: Preparing customized ServiceNow deployments to work with Service Mapping](#).

In addition to these obligatory setup configurations described here, you may need to perform additional configurations after you complete the initial mapping process. For more information, see [Advanced Service Mapping configuration](#).

---

**Request Service Mapping**

Service Mapping is available under the ITOM Visibility subscription and requires activation by ServiceNow personnel.

To purchase a subscription, contact your ServiceNow account manager. The account manager can arrange to have the plugin activated on your organization’s production and sub-production instances, generally within a few days.

If you do not have an account manager, decide to delay activation after purchase, or want to evaluate the product on a sub-production instance without charge, follow these steps.

Role required: admin
The following plugins are activated automatically when the Service Mapping plugin (com.snc.service-mapping) is activated:

- Discovery (com.snc.discovery)
- Pattern Designer (com.snc.pattern.designer)
- Cloud Management Core (com.snc.cloud.core)
- Performance Analytics – Content Pack – Service Mapping (com.snc.service-mapping.pa.content)
- Event Management and Service Mapping Core (com.snc.service-watch)

**Note:** The Event Management and Service Mapping Core (com.snc.service-watch) plugin is different from the Event Management plugin (com.glideapp.itom.snac).

1. From your instance, navigate to **System Definition > Plugins**.
2. On the All Applications page, click **Request Plugin** to open the request form on HI.
3. On HI, select to be redirected to the HI Service Portal Service Catalog.
Activate Plugin

In order to enhance the user experience, we have redesigned Activate a Plugin service catalog item. You can also use Manage Instances page on Service Portal to Activate a Plugin.

4. On the Activate Plugin request form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target Instance</td>
<td>Instance on which to activate the plugin.</td>
</tr>
<tr>
<td>Plugin Name</td>
<td>Name of the plugin to activate.</td>
</tr>
<tr>
<td>Specify the date and time you would like this plugin to be enabled</td>
<td>Date and time must be at least two business days from the current time.</td>
</tr>
<tr>
<td>Reason/Comments</td>
<td>Information that would be helpful for the ServiceNow personnel who are activating the plugin. For example, if you need the plugin activated at a specific time instead of during one of the default activation windows, specify it in the comments.</td>
</tr>
</tbody>
</table>

5. Click Submit.

MID Server configuration for Service Mapping

Configure Service Mapping and MID Servers to work together.

What is the MID Server

The Management, Instrumentation, and Discovery (MID) Server is a Java application that runs as a Windows service or UNIX daemon on a server. MID Servers, which are located in the enterprise private network, facilitate communication between servers on the network and some ServiceNow applications, such as Service Mapping, and Discovery.

MID Server selection criteria

Most environments require multiple MID Servers, with Service Mapping using the relevant MID Server for discovery. MID Servers have the following mandatory selection criteria that Service Mapping uses to choose the relevant MID Server:

- Application — defines what application a MID Server works with. Set it to Service Mapping to reserve this MID Server exclusively to Service Mapping discovery requests. Alternatively, set it to ALL to allow any ServiceNow application to use this MID Server.
• Capability — defines the network capability. For Service Mapping, set this parameter to ALL or any combination of SSH, WMI, SNMP, and Cloud Management. See Configure MID Server capabilities.
• IP range — limits operation of this MID Server to this IP range. Service Mapping does not choose this MID Server for a discovery request whose endpoint is outside this IP range. See Configure an IP address range for the MID Server.

Important: These selection criteria are mandatory for the new MID Server algorithm. Configure them in every MID Server you are planning to use with Service Mapping.

Service Mapping selects a MID Server using the following algorithm:

• Service Mapping chooses the MID Server whose selection criteria best match the parameters of the discovery request.
• If there are no MID Servers with matching selection criteria, Service Mapping chooses the default MID Server.
• If there are no MID Servers with matching selection criteria or default MID Server, Service Mapping cannot start the discovery process.

While by default Service Mapping uses this algorithm in all deployments upgraded from Istanbul or Jakarta, it can support both new and legacy algorithms for selecting a MID Server. For more information, see Choose MID Server selection algorithm.

Default MID Servers for Service Mapping

In addition to selection criteria, you can configure one of the MID Servers as the default server that Service Mapping uses. If there are no MID Servers with matching application, capability, or IP range, Service Mapping uses the default MID Server. See Configure a default MID Server for each application.

Using PowerShell for discovery

MID Servers can use PowerShell to directly communicate with Windows servers using both WMI and WinRM protocols. For Windows services using the WinRM protocol, the PowerShell process establishes a secure PSSession (PowerShell Remoting session) that stays open until the MID Server finishes querying a Windows server. For Windows servers using the WMI protocol, the PowerShell process sends every PowerShell command with credentials.

If you do not configure MID Servers to use PowerShell and PowerShell Remoting, MID Servers use WMI Collector.

MID Server credential-less discovery with Nmap

If the MID Server does not have sufficient credentials to access a device or application, it can run Network Mapper (Nmap) commands to collect basic information without using credentials. Credential-less discovery with Nmap requires additional configuration as described in Install and uninstall Nmap on a MID Server.

ServiceNow applications refer to devices and applications that comprise an application service as configuration items (CIs).
Placing MID Servers

The number of MID Servers that you require and where you place them depends on your organization needs. If you want to map devices and applications inside your private network, place the MID Servers inside the private network. If you want to map devices and applications located in the DMZ, place the MID Servers both in the DMZ and inside the private network.

In deployments where domain separation is enabled and domains are configured to form a hierarchy, MID Servers must be placed in the lowest domain level, a "leaf domain".
Once MID Servers are installed, configure them to work with Service Mapping for the best discovery results.

*Choose MID Server selection algorithm*
Service Mapping supports the new and the legacy algorithms for selecting a MID Server for a discovery request. Depending on your organization needs, you can choose which algorithm to enable.

*Role required: admin or sm_admin*
Service Mapping selects a MID Server using the following algorithm:

- Service Mapping chooses the MID Server whose selection criteria best match the parameters of the discovery request.
- If there are no MID Servers with matching selection criteria, Service Mapping chooses the default MID Server.
If there are no MID Servers with matching selection criteria or default MID Server, Service Mapping cannot start the discovery process.

By default, Service Mapping uses this algorithm in all fresh installs and deployments upgraded from Istanbul or Jakarta.

In upgraded deployments, Service Mapping selects a MID Server using a legacy algorithm:

- Service Mapping chooses the MID Server whose application criteria is set to ServiceMapping or to ALL.
- By default, Service Mapping selects the MID Server whose IP range matches the IP in the discovery request.
- If Service Mapping cannot find a MID Server with the matching IP range and matching application, it assigns the discovery request to the default MID Server.
- If there is no default MID Server and none of the MID Servers have IP ranges configured for them, Service Mapping uses a random MID Server.
- If there is no default MID Server and no IP range matches the IP in the discovery request, Service Mapping cannot start the discovery process.

By default, Service Mapping uses the legacy algorithm in all deployments upgraded to Istanbul and earlier.

1. Navigate to Service Mapping > Administration > Properties.
2. To enable the new algorithm for deployments upgraded to Istanbul and earlier:
   a) Clear the Enable Legacy MID selection algorithm check box.
   b) Click Save.
   c) Configure MID Server selection criteria as described in MID Server configuration for Service Mapping.

3. To enable the legacy algorithm for the New York deployment:
   a) Select the Enable Legacy MID selection algorithm check box.
   b) Click Save.
   c) Configure MID Server selection criteria as described in MID Server configuration for Service Mapping in upgraded deployments.

MID Server configuration for Service Mapping in upgraded deployments

For ServiceNow deployments upgraded from earlier versions to Istanbul, Service Mapping uses the legacy algorithm to choose a MID Server for a discovery request.

MID Servers have the following selection criteria that Service Mapping in upgraded deployments uses to choose a MID Server for a discovery request:

- Application — defines what application a MID Server works with. Set it to Service Mapping to reserve this MID Server exclusively to Service Mapping discovery requests. Alternatively, set it to ALL to allow any ServiceNow application to use this MID Server.
  
  In earlier releases, you could configure MID Servers to work only with Service Mapping by using the Capability parameter. If you had MID Servers with this configuration, during the upgrade to Istanbul the application parameter is automatically set to ServiceMapping for them.

- IP range — limits operation of this MID Server to this IP range. Service Mapping does not choose this MID Server for a discovery request whose endpoint is outside this IP range.
In addition to the IP range, you can configure one of the MID Servers as the default server that Service Mapping uses. For operational information, see Configure a default MID Server for Service Mapping for upgraded deployments.

In upgraded deployments, Service Mapping selects a MID Server using a legacy algorithm:

- Service Mapping chooses the MID Server whose application criteria is set to **ServiceMapping** or to **ALL**.
- By default, Service Mapping selects the MID Server whose IP range matches the IP in the discovery request.
- If Service Mapping cannot find a MID Server with the matching IP range and matching application, it assigns the discovery request to the default MID Server.
- If there is no default MID Server and none of the MID Servers have IP ranges configured for them, Service Mapping uses a random MID Server.
- If there is no default MID Server and no IP range matches the IP in the discovery request, Service Mapping cannot start the discovery process.

The new algorithm for selecting MID Servers uses an extra selection criteria: capability. It allows Service Mapping to take a network protocol into consideration. For information about updated selection criteria and the new MID Server selection algorithm, see Choose MID Server selection algorithm.

While by default Service Mapping uses the legacy algorithm in upgraded deployments, it can support both new and legacy algorithms for selecting a MID Server. If necessary, you can enable the new MID Server selection algorithm for your upgraded deployment. For more information, see Choose MID Server selection algorithm.

Configure a default MID Server for Service Mapping for upgraded deployments

In deployments upgraded to Istanbul or earlier, Service Mapping uses the default MID Server when it cannot find a MID Server with the matching IP range. Configuring a default MID Server improves the discovery process.

Role required: sm_admin

Perform this procedure only for deployments upgraded to Istanbul or earlier. For fresh installs, perform Configure a default MID Server for each application.

Ensure that you know the name of the MID Server you want to configure as the default MID Server for Service Mapping.

In upgraded deployments, Service Mapping selects a MID Server using a legacy algorithm:

- Service Mapping chooses the MID Server whose application criteria is set to **ServiceMapping** or to **ALL**.
- By default, Service Mapping selects the MID Server whose IP range matches the IP in the discovery request.
- If Service Mapping cannot find a MID Server with the matching IP range and matching application, it assigns the discovery request to the default MID Server.
- If there is no default MID Server and none of the MID Servers have IP ranges configured for them, Service Mapping uses a random MID Server.
- If there is no default MID Server and no IP range matches the IP in the discovery request, Service Mapping cannot start the discovery process.

1. Navigate to System Properties by entering `sys_properties.list` in the navigation filter.
2. Click **New**.
3. Configure values for the new property as follows:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter mid.server.sm_default.</td>
</tr>
</tbody>
</table>
### Property | Description
--- | ---
Description | Enter a free text description of the use of this MID Server.
Type | Select **string**.
Value | Enter the name of the MID Server you want to configure as the default for Service Mapping.

4. **Click Update.**

*Create a dedicated WMI Collector service for MID Servers running on the same server*

A WMI (Windows Management Instrumentation) Collector service (wmi_collector.exe) is a MID Server component that helps it to communicate with Windows servers. If your deployment uses multiple MID Servers, make it more robust by creating a dedicated WMI Collector service for each MID Server.

1. Decide on the port number used by MID Server to communicate with the WMI collector.

2. Check that no other process uses this port.

   For example, to check if any process is already using the port 8585, use this netstat command:
   ```
   C:\temp>netstat -ano | findstr LISTEN | findstr 8585
   ```
   If the port is already in use, the output states it as follows:
   ```
   TCP 0.0.0.0:8585 0.0.0.0:0 LISTENING 4
   TCP [::]:8585 [::]:0 LISTENING 4
   ```

**Role required:** sm_admin

As default, MID Servers use a WMI (Windows Management Instrumentation) Collector service that helps MID Servers to communicate with Windows servers. Patterns used to discover Windows servers or applications running on them, contain WMI and WinRM queries and commands to run on Windows servers. A WMI Collector service transfers WMI and WinRM queries and commands from the MID Server to Windows-based CIs and brings the results of the queries to the MID Server.

MID Servers can use PowerShell to directly communicate with Windows servers using both WMI and WinRM protocols. For Windows services using the WinRM protocol, the PowerShell process establishes a secure PSSession (PowerShell Remoting session) that stays open until the MID Server finishes querying a Windows server. For Windows servers using the WMI protocol, the PowerShell process sends every PowerShell command with credentials.

If you do not configure MID Servers to use PowerShell and PowerShell Remoting, MID Servers use WMI Collector.

In some deployments, there is a default WMI Collector service shared by MID Servers installed on the same server, even if these MID Servers belong to different instances. This setup is potentially problematic, since this single WMI Collector service may be in non-operational state, be not upgraded, or experience overload issues.

**Note:** WMI Collector will be deprecated in a future release.
To make your deployment more robust, create a unique WMI Collector service for every MID Server running on the same server.
1. Access one of the instances.
2. Navigate to MID Servers > Servers.
3. Select the MID Server to which you want to add a WMI collector.
4. Create a WMI collector as follows:
   a) On the Configuration Parameters tab, click New.
   b) Define the collector attributes:
      | Field         | Description                                                                 |
      |---------------|-----------------------------------------------------------------------------|
      | Parameter name| Select mid.servicewatch.wmi_collector_service.                              |
      | Domain        | Do not change this setting. The instance retrieves it from the MID Server.  |
      | Value         | Enter the descriptive name for the new WMI Collector service.               |
   c) Click Submit.
5. Define the port for the WMI collector:
   a) On the Configuration Parameters tab, click New.
   b) Define the port attributes:
<pre><code>  | Field         | Description                                                               |
  |---------------|---------------------------------------------------------------------------|
  | Parameter name| Select mid.servicewatch.wmi.port.                                         |
</code></pre>
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Domain</td>
<td>Do not change this setting. The instance retrieves it from the MID Server.</td>
</tr>
<tr>
<td>Value</td>
<td>Enter the port number on which the WMI collector receives data from the MID Server. By default, WMI collector uses port 8585. <strong>Important:</strong> Make sure that no other process uses this port.</td>
</tr>
</tbody>
</table>

3) Click **Submit**.

6. If necessary, repeat this procedure for other MID Servers running on the same server.

**Note:** The new service is not generated immediately. It is only generated upon running WMI steps in a Discovery schedule.

**Prerequisites for performing top-down discovery using Service Mapping**

Learn about credentials, users, and user permissions you must configure to let Service Mapping access and discover applications inside your organization private network.

Configure the relevant requirements to enable successful top-down discovery:

**Host credentials**

Service Mapping uses credentials of the hosts to access applications running on this host. Typically, host credentials are enough for top-down discovery. For example, to discover the HP Service Manager Application Server, configure only credentials for accessing the server hosting this application, SSH credentials, or Windows credentials.

**Applicative credentials**

To discover some applications, Service Mapping needs separate credentials from credentials of the host on which such applications run. This type of credentials is referred to in ServiceNow as applicative credentials. For example, to discover the ABAP SAP Central Services (ASCS), configure applicative credential in addition to the host credentials.

**Elevated rights for Unix-based hosts**

For Unix-based hosts, configure on MID Servers, you must provide a user with sudo-level credentials on all Unix-based hosts in your organization. For example, if the server hosting ASCS is Unix-based, provide a user with elevated rights to be able to run discovery commands against this Unix-based server.

**SNMP community credentials**

Configure SNMP community credentials to allow Service Mapping and Discovery to query network devices using the SNMP protocol. For example, configure SNMP community credentials for A10 Networks Thunder ADC.

**Users or user permissions**

You may need to provide additional users or user permissions to run certain commands or access certain directories. For example, for ASCS, provide a user with permissions to run SOAP on RFC read table function.
The Now Platform provides a centralized way of configuring credentials for Discovery, Service Mapping, and other applications. It allows you to configure credentials for hosts and applications only once. If you have already configured host-related credentials for another application, you do not need to do it again for Service Mapping.

You can assign credentials to specific MID Servers or keep credential generic so all MID Servers can use them. MID Servers retrieve commands and credentials from the ServiceNow instance and apply them to discover CIs inside organization private network.

Use the following guidelines to decide for which MID Server to create credentials:

- If all CIs, belonging to the same CI type, share a credential, you do not need to specify a MID Server for it. In that case, it is used on all MID Servers by default.

  **Note:** Specifying the MID Server when configuring credentials is optional.

- If CIs of the same type and on the same network have different credentials, configure these credentials and define order in which Service Mapping uses them when trying to connect to these CIs.

In addition to generic credentials, you configure on MID Servers, you must configure sudo-level credentials on all Unix-based hosts in your organization.

If the MID Server does not have sufficient credentials to access a device or application, it can run Network Mapper (Nmap) commands to collect basic information without using credentials. Credential-less discovery with Nmap requires additional configuration as described in Install and uninstall Nmap on a MID Server.

Review the list of credentials necessary to discover hosts and applications supported in the base system.

Credentials required for host discovery

There are credentials and permissions that Service Mapping requires for discovering hosts.

Prior to discovering applications, Service Mapping accesses hosts that applications run on and discovers them. Make sure that you provide all necessary credentials to allow host discovery.

The Now Platform provides a centralized way of configuring credentials for Discovery, Service Mapping, and other applications. It allows you to configure credentials for hosts and applications only once. If you have already configured host-related credentials for another application, you do not need to do it again for Service Mapping.

Credentials required for discovery of hosts running on UNIX/Linux:

Discovery, Orchestration, and IntegrationHub explore UNIX and Linux devices by using SSH credentials to execute commands over Secure Shell (SSH).

To provide sufficient permissions, configure one of the following Unix and Linux credentials:

- Non-root user and password and using the `sudo` utility to run selected commands as root
- Root user and password

For information on commands requiring sudo-level rights, see Service Mapping commands requiring a privileged user and Commands that require root privileges for Discovery and Orchestration.

To access Unix-based hosts with non-root credentials, provide the read access to the following files and directories:

- /etc/*release
- /etc/bashrc
- /etc/profile
- /proc/cpuinfo
- /proc/vmware/sched/ncpus
- /var/log/dmesg
- APD directory

Credentials required for discovery of hosts running on Windows Servers:

To provide sufficient permissions, configure one of the following Windows credentials:

- A domain user with local administrator access on the target Windows hosts.
- A domain administrator.

Note: You may need domain administrator credentials only in some cases. For example, when discovering domain controllers.

Configure MID Server to use Windows credentials.

(Optional) For discovering using the WinRM protocol, see Configure WinRM trusted hosts on MID Server.

Service Mapping commands requiring a privileged user

Service Mapping uses commands requiring elevated rights to discover and map Unix-based hosts in your organization. In addition to configuring necessary credentials, configure servers in your organization to allow Service Mapping to run these commands with elevated rights.
You do not run these commands directly. Service Mapping uses commands requiring elevated rights as part of the following processes:

- host detection
- process identification on port
- discovering CIs using patterns

Some commands are mandatory. The discovery process fails if Service Mapping cannot run these commands with elevated rights.

**Warning:** If you do not configure credentials for a mandatory command, a process or a pattern using it fails leading to discovery failure or error.

Some of these commands do not require elevated rights, unless directories that Service Mapping must access are protected.

### Operating system commands requiring elevated rights

#### AIX commands requiring elevated rights

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat</td>
<td>file-name</td>
<td>Mandatory</td>
<td>Shows the file content.</td>
</tr>
<tr>
<td>ls</td>
<td>-F -1, -1HF, -w 1, -l</td>
<td>Mandatory</td>
<td>Lists the directory content.</td>
</tr>
<tr>
<td>procwdx</td>
<td>Process_id</td>
<td>Mandatory</td>
<td>Gets working directory of a process.</td>
</tr>
<tr>
<td>rmsock</td>
<td>Socketname tcpcp</td>
<td>It is mandatory to use either rmsock or lsof.</td>
<td>Finds process listening on a specific port.</td>
</tr>
<tr>
<td>lsof</td>
<td>-Pnl +M -l</td>
<td>It is mandatory to use either rmsock or lsof.</td>
<td>Shows files or connections associated with the process.</td>
</tr>
<tr>
<td>lstat</td>
<td>Various options</td>
<td>Optional</td>
<td>Fetches information about a link.</td>
</tr>
<tr>
<td>ps</td>
<td>eww</td>
<td>Mandatory</td>
<td>Fetches environment variables for the process on AIX.</td>
</tr>
</tbody>
</table>

#### HP-UX commands requiring elevated rights

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat</td>
<td>file-name</td>
<td>Mandatory</td>
<td>Shows the file content.</td>
</tr>
<tr>
<td>Command</td>
<td>Parameter</td>
<td>Mandatory/Optional</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-----------</td>
<td>--------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>ls</td>
<td>-F-1</td>
<td>Mandatory</td>
<td>Lists the directory content.</td>
</tr>
<tr>
<td></td>
<td>-1HF</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>-w 1</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>-1</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>-1HF</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>-w 1</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>-1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>pfiles</td>
<td>Process_id</td>
<td>It is mandatory to use either pfiles or lsol.</td>
<td>Shows files or connections associated with the process.</td>
</tr>
<tr>
<td>lsol</td>
<td>-Pnl +M -i</td>
<td>It is mandatory to use either pfiles or lsol.</td>
<td>Shows files or connections associated with the process.</td>
</tr>
</tbody>
</table>

### Solaris commands requiring elevated rights

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat</td>
<td>File_name</td>
<td>Mandatory</td>
<td>Shows the file content.</td>
</tr>
<tr>
<td>ls</td>
<td>ls -F-1</td>
<td>Mandatory</td>
<td>Lists the directory content.</td>
</tr>
<tr>
<td></td>
<td>ls -1HF</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>ls -w 1</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>ls -1</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>e-l</td>
<td>Optional</td>
<td>Fetches file attributes used for file caching decision.</td>
</tr>
<tr>
<td>dtrace</td>
<td>-C -s</td>
<td></td>
<td>Shows process listening on the given port. Required for Solaris 11.1 or earlier.</td>
</tr>
<tr>
<td></td>
<td>script_name</td>
<td>For Solaris 11.1 and earlier, it is mandatory to use either the dtrace or lsol command.</td>
<td></td>
</tr>
<tr>
<td>lsol</td>
<td>-Pnl +M -i</td>
<td>For Solaris 11.1 and earlier, it is mandatory to use either the dtrace or lsol command.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>For Solaris 11.2 and later, it is mandatory to use either the lsol or netstat command.</td>
<td></td>
</tr>
<tr>
<td>netstat</td>
<td>-anu</td>
<td>For Solaris 11.2 and later, it is mandatory to use either the lsol or netstat command.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Lists the open ports. Required for Solaris version 11.2 or later.</td>
<td></td>
</tr>
<tr>
<td>ifconfig</td>
<td>ifconfig -a</td>
<td>Mandatory</td>
<td>Shows interface information (need sudo to get the MAC addresses).</td>
</tr>
<tr>
<td>pwdx</td>
<td>Process_id</td>
<td>Mandatory</td>
<td>Gets the process information.</td>
</tr>
<tr>
<td>pargs</td>
<td>-e process_id</td>
<td>Mandatory</td>
<td>Gets the process information.</td>
</tr>
</tbody>
</table>
### Command Parameter Mandatory/optional Description

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ps</td>
<td>-eo user, pid, ppid, comm, args</td>
<td>Mandatory</td>
<td>Gets the process list.</td>
</tr>
<tr>
<td>inetadm</td>
<td>-l or without params</td>
<td>Optional</td>
<td>Handles the case of application using the inet daemon.</td>
</tr>
</tbody>
</table>

### Linux commands requiring elevated rights

<table>
<thead>
<tr>
<th>Commands</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat</td>
<td>File_name</td>
<td>Mandatory</td>
<td>Shows the file content.</td>
</tr>
<tr>
<td>ls</td>
<td>ls -F-1</td>
<td>Mandatory</td>
<td>Lists directory content.</td>
</tr>
<tr>
<td></td>
<td>ls -1HF</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>ls -w 1</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>ls -1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>netstat</td>
<td>-lnup</td>
<td>Mandatory</td>
<td>Shows the open network connections.</td>
</tr>
<tr>
<td></td>
<td>-lnp</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>-ntup</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>-an</td>
<td></td>
<td></td>
</tr>
<tr>
<td>stat</td>
<td>--format=&quot;%Y&quot;</td>
<td>Optional</td>
<td>Shows the modification time of the file.</td>
</tr>
<tr>
<td></td>
<td>-L file_name</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Application commands requiring elevated rights

Service Mapping uses some of these commands in patterns.

**Apache Web Server (on Unix)**

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grep</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Extracts strings from the output.</td>
</tr>
<tr>
<td>netstat</td>
<td>Various options</td>
<td>Mandatory only for the OC4J Connectivity - netstat - linux connection section of the pattern. If elevated rights are not configured for this command, Service Mapping does not discover Apache Web Server connections to Oracle Application Server Containers for J2EE.</td>
<td>Lists open ports.</td>
</tr>
<tr>
<td>Command</td>
<td>Parameter</td>
<td>Mandatory/Optional</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-----------</td>
<td>-------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>Is</td>
<td>Various options</td>
<td>Mandatory only for the Create Weblogic Connections connection section of the pattern. If elevated rights are not configured for this command, Service Mapping does not discover Apache Web Server connections to Oracle WebLogic Module.</td>
<td>Lists files and folders in the specified folder.</td>
</tr>
</tbody>
</table>

**Apache Tomcat (on Unix)**

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grep</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Extracts strings from the output.</td>
</tr>
<tr>
<td>ls</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists files and folders in the specified folder.</td>
</tr>
<tr>
<td>cat</td>
<td>-</td>
<td>Mandatory</td>
<td>Shows the file content.</td>
</tr>
<tr>
<td>netstat</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists the open ports.</td>
</tr>
<tr>
<td>find</td>
<td>-name</td>
<td>Optional</td>
<td>This command is used only for creating the web services connections. Finds specific strings in files and folders.</td>
</tr>
</tbody>
</table>

**Apache Tomcat WAR (on Unix)**

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grep</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Extracts strings from the output.</td>
</tr>
<tr>
<td>ls</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists files and folders in the specified folder.</td>
</tr>
<tr>
<td>cat</td>
<td>-</td>
<td>Mandatory</td>
<td>Shows the file content.</td>
</tr>
<tr>
<td>version.sh/version.bat</td>
<td>-</td>
<td>Optional</td>
<td>Gets the Tomcat version.</td>
</tr>
<tr>
<td>netstat</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists the open ports.</td>
</tr>
<tr>
<td>Command</td>
<td>Parameter</td>
<td>Mandatory/Optional</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------</td>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>find</strong></td>
<td>-name</td>
<td>Optional</td>
<td>This command is used in connection sections of the pattern for discovering Apache Tomcat WAR connections. Finds specific strings in files and folders.</td>
</tr>
</tbody>
</table>

**App TNS Service (on Unix)**

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ls</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists files and folders in the specified folder.</td>
</tr>
<tr>
<td>netstat</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists open ports.</td>
</tr>
<tr>
<td>grep</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Extracts strings from the output.</td>
</tr>
</tbody>
</table>

**BIG-IP Global Traffic Manager (GTM) F5 (on F5 BIG-IP)**

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ping</td>
<td>-a -c 1 (url1).host</td>
<td>Mandatory</td>
<td>Gets the host IP.</td>
</tr>
</tbody>
</table>

**BMC CTRL-M Enterprise Manager (on Unix)**

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grep</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Extracts strings from the output.</td>
</tr>
<tr>
<td>netstat</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists open ports.</td>
</tr>
</tbody>
</table>

**BMC CTRL-M Gateway (on Unix)**

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grep</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Extracts strings from the output.</td>
</tr>
<tr>
<td>find</td>
<td>Various options</td>
<td>Optional</td>
<td>This command is used only to create connections to Control M Server. Finds file and folder paths.</td>
</tr>
</tbody>
</table>
### Citrix Netscaler (on Citrix Netscaler)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grep</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Extracts strings from the output.</td>
</tr>
<tr>
<td>show</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Retrieves Netscaler IP address.</td>
</tr>
</tbody>
</table>

### EMC Documentum Broker (on Unix)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>find</td>
<td>Various options</td>
<td>Optional</td>
<td>Finds connections to Docbase.</td>
</tr>
</tbody>
</table>

### FormEngine (on Unix)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grep</td>
<td>Various options</td>
<td>Mandatory</td>
<td>(On Unix only) Extracts strings from the output.</td>
</tr>
<tr>
<td>ls</td>
<td>Various options</td>
<td>Mandatory</td>
<td>(On Unix only) Lists files and folders in the specified folder.</td>
</tr>
<tr>
<td>cat</td>
<td>-</td>
<td>Mandatory</td>
<td>(On Unix only) Shows the file content.</td>
</tr>
</tbody>
</table>

### IBM Customer Information Control System (CICS) (on Unix)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>netstat</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists open ports.</td>
</tr>
<tr>
<td>grep</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Extracts strings from the output.</td>
</tr>
</tbody>
</table>

### IBM CTRL-M Server (on Unix)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grep</td>
<td>Various options</td>
<td>Mandatory</td>
<td>(For Unix only) Extracts strings from the output.</td>
</tr>
<tr>
<td>find</td>
<td>Various options</td>
<td>Mandatory</td>
<td>(For Unix only) Finds file and folder paths.</td>
</tr>
</tbody>
</table>
### IBM CICS Transaction Gateway CTG (on Unix or Windows)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grep</td>
<td>Various options</td>
<td>Optional</td>
<td>(For Unix only) This command is used only to create CICS connections. Extracts strings from the output.</td>
</tr>
<tr>
<td>cat</td>
<td>-</td>
<td>Optional</td>
<td>(For Unix only) This command is used only to create CICS connections. Displays the file content in the output.</td>
</tr>
<tr>
<td>find</td>
<td>Various options</td>
<td>Optional</td>
<td>(For Unix only) This command is used only to create CICS connections. Finds specific strings in files and folders.</td>
</tr>
</tbody>
</table>

### IBM DB2 (on Linux)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grep</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Extracts strings from the output.</td>
</tr>
<tr>
<td>cat</td>
<td>-</td>
<td>Mandatory</td>
<td>Displays the file content in the output.</td>
</tr>
</tbody>
</table>

### IBM J2EE EAR (on Linux)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grep</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Extracts strings from the output.</td>
</tr>
<tr>
<td>netstat</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists open ports.</td>
</tr>
<tr>
<td>find</td>
<td>-name</td>
<td>Mandatory</td>
<td>Finds files and folders in the specified folder.</td>
</tr>
</tbody>
</table>

### IBM Websphere Application Server (on Unix)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grep</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Extracts strings from the output.</td>
</tr>
<tr>
<td>ls</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists files and folders in the specified folder.</td>
</tr>
<tr>
<td>cat</td>
<td>-</td>
<td>Mandatory</td>
<td>Shows the file content.</td>
</tr>
<tr>
<td>Command</td>
<td>Parameter</td>
<td>Mandatory/Optional</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-----------</td>
<td>--------------------</td>
<td>-------------</td>
</tr>
<tr>
<td><code>find</code></td>
<td><code>-name</code></td>
<td>Optional</td>
<td>This command is used only for creating the Web Services connections. Finds files and folders for the specific name.</td>
</tr>
<tr>
<td></td>
<td><code>-type</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### IBM Websphere Portal (on Linux)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ls</code></td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists files and folders in the specified folder.</td>
</tr>
<tr>
<td><code>cat</code></td>
<td>-</td>
<td>Mandatory</td>
<td>Shows the file content.</td>
</tr>
<tr>
<td><code>netstat</code></td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists the open ports.</td>
</tr>
</tbody>
</table>

### IBM WebSphere Message Broker Flow (on Unix)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>grep</code></td>
<td>Various options</td>
<td>Mandatory</td>
<td>Extracts strings from the output.</td>
</tr>
<tr>
<td><code>ls</code></td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists files and folders in the specified folder.</td>
</tr>
<tr>
<td><code>cat</code></td>
<td>-</td>
<td>Mandatory</td>
<td>Shows the file content.</td>
</tr>
<tr>
<td><code>ps</code></td>
<td><code>-ef</code></td>
<td>Mandatory</td>
<td>Gets the process information.</td>
</tr>
<tr>
<td><code>netstat</code></td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists the open ports.</td>
</tr>
</tbody>
</table>

### IBM WebSphere Message Broker (on Unix)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ps</code></td>
<td><code>-ef</code></td>
<td>Mandatory</td>
<td>Gets the process information.</td>
</tr>
<tr>
<td><code>netstat</code></td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists the open ports.</td>
</tr>
<tr>
<td><code>grep</code></td>
<td>Various options</td>
<td>Mandatory</td>
<td>Extracts strings from the output.</td>
</tr>
<tr>
<td><code>ls</code></td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists files and folders in the specified folder.</td>
</tr>
<tr>
<td><code>cat</code></td>
<td>-</td>
<td>Mandatory</td>
<td>Shows the file content.</td>
</tr>
</tbody>
</table>

### IBM WebSphere MQ (on Unix)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>grep</code></td>
<td>Various options</td>
<td>Mandatory</td>
<td>Extracts strings from the output.</td>
</tr>
</tbody>
</table>
### IBM WebSphere MQ Queue (on Unix)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grep</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Extracts strings from the output.</td>
</tr>
</tbody>
</table>

### Jboss Module (on Unix)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grep</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Extracts strings from the output.</td>
</tr>
<tr>
<td>netstat</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists open ports.</td>
</tr>
</tbody>
</table>

### Jboss (on Unix and Windows)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ls</td>
<td>Various options</td>
<td>Mandatory</td>
<td>(On Unix only) Lists files and folders in the specified folder.</td>
</tr>
<tr>
<td>grep</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Extracts strings from the output.</td>
</tr>
<tr>
<td>dir</td>
<td>Various options</td>
<td>Mandatory</td>
<td>(On Windows only) Lists files and folders in the specified folder.</td>
</tr>
<tr>
<td>find</td>
<td>Various options</td>
<td>Mandatory</td>
<td>(For Windows only) Finds specific strings in files and folders.</td>
</tr>
<tr>
<td>netstat</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists open ports.</td>
</tr>
</tbody>
</table>

### JRun (on Unix)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dir</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists files and folders in the specified folder.</td>
</tr>
</tbody>
</table>

### JRun WAR Inc (on Unix)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ls</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists files and folders in the specified folder.</td>
</tr>
<tr>
<td>grep</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Extracts strings from the output.</td>
</tr>
<tr>
<td>netstat</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists open ports.</td>
</tr>
</tbody>
</table>
### Microsoft Exchange Client Access Server (CAS), Microsoft Exchange Hub Transport Server, Microsoft Exchange Mailbox (on Windows)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Get-ExchangeServer</td>
<td>-status -Identity &quot;+ $hostname+&quot;</td>
<td>Mandatory for using PowerShell commands.</td>
<td>Extracts the list of Microsoft Exchange hosts and role</td>
</tr>
<tr>
<td>Get-ExchangeServer</td>
<td>format-table -autosize -HideTableHeaders Name,Fqdn,IsMailboxServer</td>
<td>Mandatory for using PowerShell commands.</td>
<td>Extracts the list of Microsoft Exchange hosts and role in table format</td>
</tr>
<tr>
<td>Get-MailboxServer</td>
<td>format-list</td>
<td>Mandatory for using PowerShell commands.</td>
<td>Extracts the list of Microsoft Exchange Mailbox servers.</td>
</tr>
<tr>
<td>Get-ClusteredMailBoxServerStatus</td>
<td>format-table -Property OperationalMachines</td>
<td>Mandatory for using PowerShell commands.</td>
<td>Extracts information about Microsoft Exchange Mailbox clusters.</td>
</tr>
<tr>
<td>Get-StorageGroup</td>
<td>-server &quot;+Shname+&quot;</td>
<td>Mandatory for discovering storage.</td>
<td>Extracts information about storage and exports it into a file.</td>
</tr>
</tbody>
</table>

- ** grep **
  * Various options
  * Mandatory
  * (On Unix only) Extracts strings from the output.

- ** netstat **
  * Various options
  * Mandatory
  * Lists open ports.

- ** ps **
  * --pid=(process.pid) --no-headers -o %U : %p : %a
  * Optional
  * Gets the userid parameter value.
### MySQL Cluster MGM Node (on Linux)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>netstat</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists open ports.</td>
</tr>
<tr>

### Nginx (on Unix)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>netstat</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists open ports.</td>
</tr>
<tr>
<td>ps</td>
<td>--pid=(process,pid) --no-headers -o &quot;%U : %p : %a&quot;</td>
<td>Optional</td>
<td>Gets the userid parameter value.</td>
</tr>
<tr>
<td>ls</td>
<td>(IncludeTabletmp().files)</td>
<td>Optional</td>
<td>This command is used if necessary to create HTTP connections. Lists files and folders in the specified folder.</td>
</tr>
<tr>
<td>cat</td>
<td>(IncludeTabletmp().files)</td>
<td>Optional</td>
<td>This command is used if necessary to create HTTP connections. Shows the file content.</td>
</tr>
</tbody>
</table>

### Oracle E-Business Suite (on Unix)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ls</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists files and folders in the specified folder.</td>
</tr>
<tr>
<td>grep</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Extracts strings from the output.</td>
</tr>
<tr>
<td>export</td>
<td>-</td>
<td>Mandatory</td>
<td>Sets variables.</td>
</tr>
<tr>
<td>echo</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Prints strings in the output.</td>
</tr>
<tr>
<td>sqlplus</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Creates the connection to the Oracle instance.</td>
</tr>
<tr>
<td>awk</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Manipulates the output.</td>
</tr>
<tr>
<td>netstat</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Gets open ports.</td>
</tr>
</tbody>
</table>

### Oracle Advanced Queue Queue (on Unix)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>netstat</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists open ports.</td>
</tr>
</tbody>
</table>
### Oracle Concurrent Server (on Unix)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grep</td>
<td>Various options</td>
<td>Mandatory</td>
<td>(For Unix only) Extracts strings from the output.</td>
</tr>
<tr>
<td>netstat</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists open ports.</td>
</tr>
<tr>
<td>awk</td>
<td>Various options</td>
<td>Mandatory</td>
<td>(For Unix only) Manipulates the output.</td>
</tr>
<tr>
<td>ls</td>
<td>Various options</td>
<td>Mandatory</td>
<td>(For Unix only) Lists files and folders in the specified folder.</td>
</tr>
<tr>
<td>cat</td>
<td>-</td>
<td>Mandatory</td>
<td>(For Unix only) Displays the file content in the output.</td>
</tr>
<tr>
<td>find</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Finds specific strings in files and folders.</td>
</tr>
</tbody>
</table>

### Oracle Discoverer Engine (on Unix)

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ls</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists files and folders in the specified folder.</td>
</tr>
<tr>
<td>grep</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Extracts strings from the output.</td>
</tr>
<tr>
<td>cat</td>

<tr>
<td>ls</td>
<td>Various options</td>
<td>Mandatory</td>
<td>Lists files and folders in the specified folder.</td>
</tr>
</tbody>
</table>
Service Mapping commands not requiring a privileged user

Most of the commands utilized by Service Mapping for discovery and mapping do not require elevated rights.

Review this list of commands to understand how Service Mapping uses them and to make sure that the virtual security of your company is not compromised.

You do not run these commands directly. Service Mapping uses commands requiring elevated rights as part of the following processes:

- host detection
- process identification on port
- discovering CIs using patterns

Some commands are mandatory. The discovery process fails if Service Mapping cannot run these commands.

**Operating systems**

**AIX commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>awk</td>
<td>various options</td>
<td>Mandatory</td>
<td>Parses the string.</td>
</tr>
<tr>
<td>istat</td>
<td>file_name</td>
<td>Optional</td>
<td>Gets last modification time of file.</td>
</tr>
<tr>
<td>nslookup</td>
<td>hostname</td>
<td>Mandatory</td>
<td>Resolve DNS host name.</td>

<tr>
<td>type</td>
<td>File_name</td>
<td>Mandatory</td>
<td>Shows the text file content.</td>
</tr>
<tr>
<td>nslookup</td>
<td>Host_name</td>
<td>Mandatory</td>
<td>DNS lookup</td>
</tr>
<tr>
<td>arp</td>
<td>-a</td>
<td>Optional (required for network path calculation)</td>
<td>Shows the ARP table.</td>
</tr>
<tr>
<td>netstat</td>
<td>-ano</td>
<td>Mandatory</td>
<td>Shows the network connections.</td>
</tr>
</tbody>
</table>
### Command | Parameter | Mandatory/optional | Description
--- | --- | --- | ---
findstr | Various options | Mandatory | Finds the string in the previous command output.
dir | /q /s /b | Mandatory | Lists files in the directories.
paping | --nocolor -c 1 -p port_num ip_address | Mandatory | Utility to run TCP ping against given host.
ping | -n 1 ip_address/host | Mandatory | Pings the host.
tracert | ip_address | Optional (required for network path calculation) | Shows the layer 3 network route to the target host.

---

**Applications**

**ABAP SAP Central Services (ASCS) (on Unix or Windows)**

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/optional</th>
<th>Description</th>
</tr>
</thead>
</table>
dir | Various options | Mandatory | (For Windows only) Lists files and folders in the specified folder.
msg_server | -V | Optional | Gets the version.
ping | -n 1 | Mandatory | (For Windows only) Verifies that the host is answering.
netstat | Various options | Mandatory | Lists open ports.

**Active Directory Domain Controller (on Windows)**

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>

SNMP-based queries
Service Mapping accesses network infrastructure devices like load balancers and routers using Simple Network Management Protocol (SNMP) v1/v2c/v3. Configure SNMP community credentials to enable this type of access.

Configure SNMP community if you use SNMP v1/v2 or SNMPv3 credentials if you use SNMP v3. For operational information, see SSH credentials.

SNMP-based queries have the format of strings of integers.

General SNMP-based queries

Make sure that the user has credentials for SNMPv3 unless read-only community string is used.

**Create a discovery behavior for Unix-based load balancers**

If your network uses load balancers running on Linux hosts, create a discovery behavior to ensure that Service Mapping and Discovery discover them correctly.

Make sure that Discovery is activated.

Role required: sm_admin or admin

The discovery and mapping process begins with Discovery identifying the host. After the host discovery is complete, Service Mapping starts discovering and mapping applications running on this host.

The default discovery process identifies a configuration item (CI) as a Linux server if it finds an SSH port in use. It may lead to incorrect discovery of load balancers running on Linux as Linux servers. Create a discovery behavior to first discover network devices using SNMP protocol. After Discovery has discovered Unix-based load balancers correctly and created the appropriate CIs for them, you can continue with discovering and mapping application services in Service Mapping.

Discovery performs discovery through a MID Server located in the enterprise private network. A behavior determines:

- What MID Server Discovery is using.
1. Create a new behavior for discovering Unix-based load balancers:
   a) Navigate to Service Mapping > Administration > Behavior.
   b) Click New.
   c) Enter the name for this behavior.
   d) Right-click on the header bar and click Save.
   e) Click New on the Discovery Functionality tab.
   f) Enter 1 in the Phase field.
   g) Select SNMP only from the Functionality definition list.
   h) Select the relevant MID Servers in the MID Servers area.
   i) Check the Active check box.
   j) Click Submit.

2. Create a discovery schedule for the newly defined behavior:
   a) Navigate to Discovery > Discovery Schedules.
   b) Click New.
   c) Fill in the fields as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a unique, descriptive name for your schedule.</td>
</tr>
<tr>
<td>Discover</td>
<td>Select Configuration items.</td>
</tr>
<tr>
<td>MID Server selection method</td>
<td>Select Use behavior.</td>
</tr>
<tr>
<td>Behavior</td>
<td>Select the behavior you created in step 1.</td>
</tr>
<tr>
<td>Active</td>
<td>Select the check box to enable this schedule. If you clear the check box,</td>
</tr>
<tr>
<td></td>
<td>the schedule is disabled, but you can still run a discovery manually from</td>
</tr>
<tr>
<td></td>
<td>this form, using the configured values.</td>
</tr>
<tr>
<td>Max run time</td>
<td>Set a time limit for running this schedule. When the configured time</td>
</tr>
<tr>
<td></td>
<td>elapses, the remaining tasks for the discovery are canceled, even if the</td>
</tr>
<tr>
<td></td>
<td>scan is not complete. Use this field to limit system load to a desirable</td>
</tr>
<tr>
<td></td>
<td>time window. If no value is entered in this field, this schedule runs until</td>
</tr>
<tr>
<td></td>
<td>complete.</td>
</tr>
<tr>
<td>Run and related fields</td>
<td>Determines the run schedule of the discovery. Configure the frequency in</td>
</tr>
<tr>
<td></td>
<td>the Run field and the other fields that appear to specify an exact time.</td>
</tr>
</tbody>
</table>

   Note: The run time always uses the system time zone. If you add the optional Run as tz field, it has no effect on the actual runtime.

3. Create an IP range for the discovery schedule:
The IP range for the schedule must correlate with the IP range of the MID Server that you assigned to the behavior. The MID Server must also have the appropriate application or the ALL application.

a) On the Discovery IP Ranges tab, click New.
b) Enter the name for this IP range.
c) Configure the IP range by entering IP addresses in the Starting IP and Ending IP fields.

4. Click Submit.

Verify that Service Mapping is set up properly

Before you start mapping application services, verify that you configured MID Servers to discover application services and provided all the necessary host and application credentials.

Role required: sm_admin

Service Mapping performs an automatic scan of the following resources and configurations to give you the readiness status:

- (Mandatory) There are MID Servers with correctly configured IP ranges and the applications and capabilities settings. For more information, see MID Server configuration for Service Mapping.
  
  If this check does not recognize correctly configured MID Servers, you cannot perform the bulk discovery.
- (Optional) There are credentials for operating systems and applications as described in Prerequisites for performing top-down discovery using Service Mapping.
- (Optional) There are at least three load balancers recently discovered during horizontal discovery.
- (Optional) There are at least 100 hosts discovered by the horizontal discovery in the last 14 days.
- (Optional) The data collection using Netflow or VPC Flow Logs is configured. This configuration is necessary to enhance the traffic-based discovery in Service Mapping. For more information, see Data collection and discovery using Netflow and Data collection and discovery using VPC Flow Logs.
- (Optional) Cloud Discovery is activated and configured. This setting is necessary to discover application services based on IaaS.

If an optional resource or configuration is missing, you can still map application services, but it may result in partial discovery of some CIs and connections.

1. Navigate to Service Mapping > Home.
   The Home page displays only information on application services that Service Mapping can discover or already discovered. The Home page does not display information on application services that are created manually or using the API.

2. Verify that Service Mapping is set up and ready for discovery.
   If some obligatory configurations are missing, the error displays at the top of the window.
   a) Click the link in the error or click the Readiness Checklist icon.
b) In the Service Mapping Readiness Checklist window, click the link next to the setup category with the error icon (✓). You cannot perform discovery and mapping unless there are no errors in the Readiness Checklist window.

c) Perform the necessary action to complete the setup. For example, configure missing credentials.

3. If more than one setup category has an error, return to the Readiness Checklist window and fix any other errors.

Map business services in bulk

Quick start tests for Service Mapping

Validate that Service Mapping still works after you make any configuration change such as apply an upgrade or develop an application. Copy and customize these quick start tests to pass when using your instance-specific data.

Service Mapping quick start tests require activating the Service Mapping plugin (com.snc.service-mapping) and loading the demo data.

<table>
<thead>
<tr>
<th>Test</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SM OOTB: Tests SM application visibility by roles</td>
<td>Validate the visibility of Service Mapping applications and modules for different roles. For example, the test verifies that a user logged in with the sm_user role, cannot access the Administration module under Service Mapping.</td>
</tr>
</tbody>
</table>
**Application service mapping**

You can perform initial mapping of multiple or single application services in your organization using a method that best suits you.

You can map application services after you complete the Service Mapping setup.

---

**Service Mapping workflow**
A typical organization has hundreds of application services. Mapping each of them individually can be time and effort consuming. With Service Mapping, you can map most IT services in bulk. Mapping multiple application services at once is very effective, but is not precise. You may need to individually map application services omitted during bulk mapping.

A discovery method depends on how you have been managing your application services prior to mapping them and what information about them you gathered:

- **Map multiple application services suggested by Service Mapping**

  Service Mapping uses load balancers on your network to identify possible application services (candidates). You can map all or selected candidate in bulk, creating multiple application services in a single operation. This method suits your organization if you do not have much information about application services.

- **Map multiple application services from a CSV file**

  This method suits you if your organization has performed cross-organization mapping and analysis and collected some information about planned application services. If so, you can organize the collected information in a specific order and save it as a CSV file. Service Mapping extracts information from this file and creates potential application services referred to as service candidates.

- **Map a single application service**

  You can map individual, single application services one by one by defining attributes for each application service. Use this mapping method for application services Service Mapping cannot discover during bulk mapping. You must know or plan to find out application service attributes necessary for mapping.

**Map multiple application services suggested by Service Mapping**

You can map multiple application services identified and suggested by Service Mapping in a single operation. This method suits your organization if you do not have much information about business services.

Role required: sm_admin

You must have Service Mapping enabled to map or review application services.

Immediately after you complete the Service Mapping setup, Service Mapping automatically creates potential application services referred to as candidates:

1. Service Mapping extracts entries directly from load balancers on your network.
2. Service Mapping converts load balancer entries into potential entry points.
   - It also scans tables containing traffic-based connections to identify potential entry points. An entry point is how clients access an application service. Service Mapping starts the mapping process from this point. For example, to map your electronic mailing application service, define an IP address or host name of the email server as an entry point.
3. Service Mapping checks that potential entry points created from traffic-based connections are unique and not in use by any existing application services to avoid duplication.
4. Service Mapping creates an application service candidate for each entry point.
   - Not all candidate application services correlate to actual application services. Service Mapping filters out unlikely candidates by applying an algorithm that takes into account such parameters as empty IP addresses, port numbers, and the load balancer VIP hit counts less than 1000. Service Mapping stores candidates in the Candidate Entry Point (sa_cand_entry_point) table in the CMDB.

During the discovery and mapping process, Service Mapping creates an application service from each candidate and assigns it the entry point retrieved from the candidate. While mapping in
bulk is an effective and fast way to create numerous application services, the result of the bulk mapping is not precise. There may be some false or duplicate application services created by mistake because the data from the load balancer is raw. During the review and approval process, you review all mapped application services and get rid of the ones that were erroneously created.

You can further filter the list of candidates by selecting specific ones to include in or exclude from discovery. Mapping only selected candidates provides the following advantages:

- Reduces the discovery time
- Minimizes the number of potential irrelevant application services

You can remove the unwanted candidates from the list using these methods either by filtering them out or deleting them from the Candidate Entry Point (sa_cand_entry_point) table. In both cases, you can bring hidden or deleted candidates back to the list.

1. Navigate to Service Mapping > Home.
   The Home page displays only information on application services that Service Mapping can discover or already discovered. The Home page does not display information on application services that are created manually or using the API.

2. Verify that Service Mapping is set up and ready for discovery.
   If some obligatory configurations are missing, the error displays at the top of the window.
   a) Click the link in the error or click the Readiness Checklist Icon.
   b) In the Service Mapping Readiness Checklist window, click the link next to the setup category with the error icon (❌).
      You cannot perform discovery and mapping unless there are no errors in the Readiness Checklist window.
   c) Perform the necessary action to complete the setup.
      For example, configure missing credentials.
3. To map all application services suggested by Service Mapping, click **Map**.

4. To map selected application services suggested by Service Mapping:
   a) Click **Additional options** under the **Map** tile.
   b) Select **View Candidates List**.
   c) Optional: Display candidates based on traffic-based connections, remove the condition that filters out candidates retrieved from load balancers or imported from a CSV file.

   ![Candidate Entry Points](image)

   The candidate list shows candidates with the source attribute **netstat**.

d) Review the list of candidates to decide which ones you want to discover as application services.

e) Create application services from the relevant candidates:
If you want to create application services from most of the candidates

1. Filter out irrelevant candidates by selecting them and clicking **Actions on selected rows**, and then clicking **Ignore Selected**.

   The irrelevant candidates are hidden from the list.

   **Note:** To show candidates you previously filtered out, set the **Ignore** filtering condition to **true**.

2. Alternatively, delete irrelevant candidates by selecting them and clicking **Actions on selected rows**, and then selecting **Delete**.

   The irrelevant candidates are removed from the Candidate Entry Point (sa_cand_entry_point) table containing candidates.

   **Note:** Service Mapping recreates deleted candidates every time Discovery performs horizontal discovery of the same load balancers or you reimport candidates from the same CSV file.

3. Click **Discover All**.

If you want to create application services only from several candidates

1. Select the check boxes next to the relevant candidates.

2. Click **Actions on selected rows** at the bottom of the screen.

3. Click **Discover selected**.

Service Mapping starts discovery of all candidates and creates application services from them. If you have many candidates, the discovery may take some time.

After the discovery process finishes, application services, which Service Mapping discovered without errors and with at least one discovered CI, appear under the **Approve** tile. Application services discovered with errors appear under the **Fix** tile.

- Review the list of created application services. If Service Mapping did not create some application services during bulk mapping as you expected, create them manually as described in **Map a single application service**.
- Fix application services discovered with errors. For more information, see **Fix application service errors in bulk**.
- Send application services discovered without errors to their respective owners for approval. For more information, see **Send application service maps for review**.
Map multiple application services from a CSV file

This method suits you if your organization has performed cross-organization mapping and analysis and collected some information about planned application services. If so, you can organize the collected information in a specific order and save it as a CSV file. Service Mapping extracts information from this file and creates potential application services referred to as service candidates.

Perform the procedure described in Prepare a CSV file for mapping your candidates.

⚠️ Warning: If you import planned services using the Service Map Planner module, use the CSV file format described in Import planned application services from the CSV file.

Role required: sm_admin

You must have Service Mapping enabled to map or review application services.

If necessary, you can import service candidates from multiple CSV files.

When reimporting application service candidates, Service Mapping does not import candidates you chose to ignore earlier.

After Service Mapping discovers configuration items (CIs) belonging to your application service for the first time, it then rediscovers CIs to find changes and updates. Create or modify discovery schedules to control how often Service Mapping rediscovers services or CIs.

1. Navigate to Service Mapping > Home.
   The Home page displays only information on application services that Service Mapping can discover or already discovered. The Home page does not display information on application services that are created manually or using the API.
2. Click Additional Options under the Map tile.
3. Click Import Service Map List.
4. In the Import CSV file window, click Choose file.
5. Navigate to the CSV file to use for the import and click Choose.
6. Click Import.
   The imported application service candidates are added to the list of candidates.
7. Check that the overall number of service candidates on the Map tile increased by the expected number.
8. Click Map to create application services from the candidates you imported from the CSV file.

   • Review the list of created application services. If Service Mapping did not create some application services during bulk mapping as you expected, create them manually as described in Map a single application service.
   • Fix application services discovered with errors. For more information, see Fix application service errors in bulk.
   • Send application services discovered without errors to their respective owners for approval. For more information, see Send application service maps for review.

Prepare a CSV file for mapping your candidates

Organize information about potential application services (candidates) in your organization and save it in a CSV file.

Role required: sm_admin
**Warning:** If you import planned services using the Service Map Planner module, use the CSV file format described in *Import planned application services from the CSV file*.

2. Define entry point attributes for service candidates in the .xlsx file. Customers use these entry points to access services. For example, they use http://www.google.com:8080 to access the Google page.

**Warning:** Do not confuse column order in the .xlsx file. Entering attributes in wrong columns causes mapping errors.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>Enter a unique name of the planned application service. For example, NY Public Library or Google. <strong>Warning:</strong> Service Mapping imports only application services with unique names. If there is more than one entry with the same name in CSV files you use, the latest imported record overwrites the previous ones.</td>
</tr>
<tr>
<td>B</td>
<td>(Optional) If you know the URL that serves as the entry point to your application service, enter it in this column. For example, enter <a href="https://www.nypl.org/">https://www.nypl.org/</a> or <a href="http://www.google.com:8080">www.google.com:8080</a>. <strong>Warning:</strong> If you define the URL, you do not have to define the IP address, port, FQDN, and protocol. Service Mapping parses the URL to extract the IP address, port, and FQDN. If there is no URL that serves as the entry point, define other parameters in columns C, and E.</td>
</tr>
<tr>
<td>C</td>
<td>(Optional) The IP address of the entry point in the IPv4 format. Enter this parameter only if you did not enter the URL in column B.</td>
</tr>
<tr>
<td>D</td>
<td>(Optional) The port of the entry point. For example, 8080 for the Google page. Enter this parameter only if you did not enter URL in column B. If you did not enter either URL or the port, Service Mapping uses port 80 for the http protocol and port 443 for the https protocol.</td>
</tr>
<tr>
<td>E</td>
<td>(Optional) The FQDN of the service entry point, for example, <a href="http://www.google.com">www.google.com</a> for Google. Enter this parameter only if you did not enter the URL in column B.</td>
</tr>
</tbody>
</table>
3. Save the file in a drive that you can access during the import with the .csv extension.

Map multiple application services from a CSV file

Map a single application service

In addition to mapping application services in bulk, you can map individual, single application services by defining attributes for each application service. Use this mapping method if you already know or are planning to find out application service details. You must have Service Mapping enabled to map or review application services.

- Verify that Service Mapping is set up properly.
- If the application service relies on PaaS supported by Microsoft Azure or Amazon Web Services, [discover datacenters] and then create [horizontal discovery schedules] on the cloud service account.

Role required: sm_admin

You can map single application services in addition to bulk mapping, which is very effective at mapping multiple application services, but is not precise. You may need to individually map application services omitted during bulk mapping.

The most important attribute you must know and configure for your application service is an entry point.

An entry point is how clients access an application service. Usually, it is either a URL or a combination of the IP address and port. Service Mapping starts the mapping process from this point. For example, to map your electronic mailing application service, define an IP address or host name of the email server as an entry point.

Entry points vary depending on the nature of the application service. Service Mapping comes with a wide range of preconfigured entry point types that cover many commonly used applications.

In addition to entry points that Service Mapping can discover, you may add entry points that Service Mapping cannot discover. You may want to add such an entry point as an indication that your application service contains a device or application.

Also, you must define an owner for your application service. The application service owner is a user who is familiar with the infrastructure and applications making up the service. This user is the application service SME who provides information necessary for a successful creation of an application service. Once a service is mapped, this user reviews the results and either approves it or suggests changes.

After Service Mapping discovers configuration items (CIs) belonging to your application service for the first time, it then rediscovers CIs to find changes and updates. Create or modify discovery schedules to control how often Service Mapping rediscovers services or CIs.

All application services, both manually created and discovered by Service Mapping, are stored in the Application Service [cmdb_ci_service_discovered] table.

1. Navigate to Service Mapping > Home.
   The Home page displays only information on application services that Service Mapping can discover or already discovered. The Home page does not display information on application services that are created manually or using the API.
2. Click Additional options under the Map file.
3. Click Define A Single Service Map.
4. Define the basic application service attributes:
### 5. If you do not know the entry points, request them from the application service owner:

   a) Click the **Request data** link.
   
   The Request for data window opens.

   b) If the **Assigned to** list is blank, select the name of the application service owner.

   c) Enter your questions about this application service in the **Description** field.
   
   For example, you can ask what the entry points are.

   d) Click **Submit**.
   
   The system opens ServiceNow task for the owner and automatically sends an email notification.

   e) Once the owner provides missing information, you receive an email notification. Click the link in the email to open the Questionnaire screen for the relevant application service.

   f) Review information added by the owner on the **Other Entry Points** and **Components** tabs.

   g) Continue with the next step.

### 6. To add an entry point that Service Mapping can discover, perform these steps.

   a) Click **Discoverable by Service Mapping**.
   
   The page offers tiles for applications most commonly used for entry points.

   b) Click the tile matching the application to which the entry point belongs. For example, **Web Application** if you create an application service with a web interface. If tiles do not contain the necessary application, click **See More Types** to choose from a list of all preconfigured entry point types.

   
   
   **Note:**

   If the required entry point type does not appear in the list, you may need to create it as described in [Create entry point types for Service Mapping](#).

   c) Configure attributes for the entry point as described in **Entry point attributes**.
   
   Entry point parameters depend on the type you select.

   d) Click **Add**.
   
   The entry point is added under **Entry Points**.

   e) To add more entry points, click **Add Entry Point** and repeat step 6.

### 7. To add a static entry point that Service Mapping cannot discover, perform these steps.

   a) Click **Manually created**.
b) Define the CI to serve as the entry point.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CI Type</td>
<td>Select the CI type (CI class) for the CI you are adding. Every CI belongs to a CI type which contains a set of attributes configured for this kind of CI, for example, <code>cmdb_ci_appl</code> for applications.</td>
</tr>
<tr>
<td>CI Name</td>
<td>Select the CI from the list of CIs of the selected CI type.</td>
</tr>
</tbody>
</table>

The CI type list includes only allowed CI types. For example, you cannot add an application cluster.

c) Click **Submit**.

8. To save attributes you have defined up until this moment and carry on configuring attributes for this application service, click **Save** or **Update**.
Service Mapping saves the new application service in the application service (`cmdb_ci_service_discovered`) table. It also starts the discovery process in the background.

9. To save definitions, discover this application service, and navigate to the map for this application service, click **Discover**.
Service Mapping starts the discovery process. The map for this application service page opens and displays the mapping in progress. The application service status changes to In Progress.

- If Service Mapping discovers the application service with errors, see [fix errors in individual application service maps](#).
- Send application services discovered without errors to their respective owners for approval. For more information, see [Send application service maps for review](#).

**Entry point attributes**

Check attribute definitions to correctly add entry points to your application services. Service Mapping comes with a wide range of preconfigured entry point types that cover many commonly used applications.

An entry point is how clients access an application service. Entry points are stored as records in the Endpoint (`cmdb_ci_endpoint`) tables.

There are some general attributes shared by almost all entry point types as described in the following table:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host/Hostname/Host Name</td>
<td>The value of the target server on which the service is running. This value can contain a real host name, alias, IP, or VIP.</td>
</tr>
<tr>
<td>Port</td>
<td>The port number of the service that you want to discover.</td>
</tr>
<tr>
<td>Name</td>
<td>The name of the service that you want to discover.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>URL</td>
<td>The URL of the service that you want to discover.</td>
</tr>
</tbody>
</table>

There are some attributes which you configure differently depending on what entry point they relate to, as described in the following table:

**Entry point attributes specific for some entry points**

<table>
<thead>
<tr>
<th>Entry point type</th>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active Directory Domain to Domain Controllers Endpoint</td>
<td>Domain name</td>
<td>The AD domain name.</td>
</tr>
<tr>
<td></td>
<td>Forest name</td>
<td>The AD forest name.</td>
</tr>
<tr>
<td></td>
<td>Domain controller distinguished name</td>
<td>The distinguished name of the AD domain controller. Usually it is a compilation of the domain controller name and the hostname.</td>
</tr>
<tr>
<td></td>
<td>Domain Controller Name</td>
<td>The AD Domain Controller name.</td>
</tr>
<tr>
<td>Active Directory Forest Endpoint</td>
<td>Forest name</td>
<td>The AD Forest name.</td>
</tr>
<tr>
<td>AWS Resource Name Endpoint</td>
<td>ARN</td>
<td>The Amazon Resource name.</td>
</tr>
<tr>
<td>Application to Storage Endpoint</td>
<td>File in use by application</td>
<td>The path to the file used by an application. For example, mssql uses c:\applications\mssql\users.db. Service Mapping populates this attribute using patterns.</td>
</tr>
<tr>
<td></td>
<td>File system name</td>
<td>The file system containing the file used by an application. For example, if a mssql uses c:\applications\mssql\users.db, the value is &quot;c:&quot;.</td>
</tr>
<tr>
<td></td>
<td>Connected array ids</td>
<td>N/A</td>
</tr>
<tr>
<td>Advanced Queue</td>
<td>Scheme</td>
<td>The name of the Oracle DB table where the Queue is defined.</td>
</tr>
<tr>
<td></td>
<td>Instance</td>
<td>The name of the Oracle instance.</td>
</tr>
<tr>
<td></td>
<td>Queue</td>
<td>The name of the queue.</td>
</tr>
<tr>
<td>BizTalk Connection</td>
<td>Adapter address</td>
<td>The connect string to the Biztalk adapter. It can be a path, URL, host, or port.</td>
</tr>
<tr>
<td></td>
<td>Transport Type</td>
<td>The type of the Biztalk adapter. For example a URL, file SOAP, or FTP.</td>
</tr>
<tr>
<td>CRM Component</td>
<td>Role</td>
<td>The role of the CRM. Leave empty if unknown.</td>
</tr>
<tr>
<td>DB2 UDB</td>
<td>Instance</td>
<td>The name of the DB2 instance.</td>
</tr>
<tr>
<td>DCTM Connection to broker</td>
<td>Repository</td>
<td>The name of documentation repository.</td>
</tr>
<tr>
<td>Entry point type</td>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DCTM Index Agent Connection</td>
<td>Instance Name</td>
<td>The name of the instance of Documentation Index Agent.</td>
</tr>
<tr>
<td></td>
<td>Repository</td>
<td>The name of the documentation repository.</td>
</tr>
<tr>
<td>DCTM Job Processor</td>
<td>Repository</td>
<td>The name of documentation repository.</td>
</tr>
<tr>
<td>Citrix Delivery Controller</td>
<td>Farm Type</td>
<td>The Type of the Delivery Controller.</td>
</tr>
<tr>
<td></td>
<td>Controller Name</td>
<td>The name of the Citrix Controller.</td>
</tr>
<tr>
<td>DocBase Connection</td>
<td>Repository</td>
<td>The name of the documentation repository.</td>
</tr>
<tr>
<td>EJB</td>
<td>JNDI Name</td>
<td>The jndi name of target EJB.</td>
</tr>
<tr>
<td>EMS</td>
<td>Queue</td>
<td>The name of Tibco EMS queue.</td>

Provide entry points for mapping an application service

As an application service owner, you may receive a request for information about entry points in an email notification. Provide information about entry points to enable administrators to start discovery of an application service.

Role required: sm_app_owner or sm_admin

If information about application service entry points is missing, an administrator cannot start mapping the application service. In this case, the administrator sends a request for missing data from the application service form, which creates a service process task assigned to you. You receive an email notification with the link to the Questionnaire page where you must enter the missing data. The most important information is about the entry points, however, any additional data about business service components, their connections, or usage is of help for the administrator. When you finish entering data in the Questionnaire and submit it, the system closes the service process task.
1. Click the link in the notification email to access the Questionnaire page.
2. Alternatively, open to the Questionnaire page from the list of tasks assigned to you.
   a) Navigate to Service Mapping > Administration > My Tasks.
   b) Optional: Sort the list of service process tasks as required.
   c) Click the required task.
   d) Click the application service form link.
   e) Click Questionnaire in the left pane.
3. On the Planned Custom Entry Points tab, enter information about application service entry points.

   **Note:**
   If you cannot specify the exact attributes of the entry points, such as the URL or the IP address, add general information which can guide the administrator. For example, the type of the application, like Tomcat server.
4. To add information about any other components comprising this application service, click the Components tab, and enter the relevant data there.
5. When you finished entering the information, click Actions, and then select Submit Questionnaire.
   The data request task assigned to you closes. The application service state changes to In Progress.
6. If there is any other useful information concerning this application service, enter it in the **Notes** field under **Worknotes** and press Enter to post your comment.

**Mapping application services containing Citrix XenApp and Presentation Server**

Service Mapping can discover application services containing Citrix XenApp, Presentation Server, and Citrix Usage Collector.

### Discovered components

<table>
<thead>
<tr>
<th>Name</th>
<th>Platform</th>
<th>Version</th>
<th>Protocol</th>
<th>Discovery type</th>
<th>Pattern (or probe if indicated)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Citrix XenApp Server</td>
<td>Windows</td>
<td>6.x&gt;6.5, 7.x&lt;7.6</td>
<td>WMI/WinRM</td>

</tbody>
</table>

Map application services containing Citrix XenApp and Presentation Server

Map an application service containing Citrix XenApps, Presentation Servers, and Citrix Usage Collectors and verify that Service Mapping discovered all Citrix components correctly.

- Provide a user with permissions to read and query the Citrix repository:
  - For versions 4.5 and later, a PowerShell script from the XenApp server.
  - For versions earlier than 4.5, a Microsoft Visual Basic Script (VBScript) from the Citrix Presentation Server

- On the Now Platform, configure a domain user for accessing the Windows OS as described in **Windows credentials**.

  **Note:** To use this credential later for XenAPP, set the **Credential alias** attribute to `cmdb_ci_appl_citrix_xenapp`. To use this credential later for Citrix, set the **Credential alias** attribute to `cmdb_ci_appl_citrix_collector`.

- (Optional) To discover using the WinRM protocol, see [Configure WinRM trusted hosts on MID Server](#).

- Configure a user with permissions to run PowerShell commands on the Citrix server.

- (For discovery of Citrix Presentation Server only) Find out the icon path for the entry point:
  1. In the Citrix Access Management Console, navigate to **Presentation Server** > **Applications**.
  2. Locate the Icon Path folder in the navigation tree.
  3. Right-click the Icon Path folder and click **Copy path**.

- (For discovery of Citrix XenApp Server only) Find out the icon path for the entry point by checking the Distinguish Name attribute for the Icon Path.
Role required: sm_admin

1. Create an application service:
   a) Navigate to Service Mapping > Application Services.
   b) Click New.
      The Discoverable by Service Mapping option is selected by default.
   c) In the Name field, enter a descriptive name for the application service.

2. Define the entry point for this application service:
   a) Select the Citrix XenApp tile.
   b) Define entry point attributes.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>The URL of the Citrix XenApp or Presentation Server. The URL must contain a VIP IP or a physical host.</td>
</tr>
<tr>
<td>Port</td>
<td>The port that the Citrix XenApp or Presentation Server uses on the host.</td>
</tr>
<tr>
<td>Icon Path</td>
<td>The path to the logical application location as it appears in the Citrix Access Management Console. The path must start with the Applications folder. For example, /Application/Jane/Windows Media Player.</td>
</tr>
<tr>
<td>URL</td>
<td>The URL must contain a VIP IP or a physical host. For example, http://&lt;host&gt;/Citrix/StoreWeb.</td>
</tr>
</tbody>
</table>

c) Click Add.
d) Click Save.

3. Click Additional Info on the left and clear the Traffic based discovery check box.
4. Click Update.
5. Verify that the mapping result is satisfactory:
   a) Click View map and wait until the mapping is complete. It may take a few minutes.
   b) Review the application service map and make sure that it resembles in the following example.
If the mapping result is not as you expected, perform basic troubleshooting.

<table>
<thead>
<tr>
<th>Symptom</th>
<th>Cause</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discovery failed. The discovery log displays the message that starts with the following text: You do not have sufficient permissions.</td>
<td>The indication sections of the pattern fail, because the user does not have permissions for running PowerShell commands.</td>
<td>Make sure that you provided a user with permissions to run PowerShell commands on servers that host Citrix XenApp, Presentation Server, or Citrix Usage Collector.</td>
</tr>
</tbody>
</table>
Mapping application services containing Microsoft Exchange Server

Service Mapping can discover application services containing a Microsoft Exchange Server and the Exchange Server components.

Discovered components

If e-mail services in your organization deploy Microsoft Exchange Server, the discovered application service includes the following components:

<table>
<thead>
<tr>
<th>Name</th>
<th>Platform</th>
<th>Version</th>
<th>Protocol</th>
<th>Discovery type</th>
<th>Pattern (or probe if indicated)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microsoft Active Directory Domain Services</td>
<td>Windows</td>
<td>13, 30, 31, 44, 47, 52, 56, 69</td>
<td>WMI/WinRM</td>
<td>Top-down</td>
<td>Active Directory Service pattern</td>
</tr>
</tbody>
</table>
Typically, you do not want to discover Outlook clients connected to the Exchange Server to avoid noise. If this is the case, disable the traffic-based discovery for this application service.

For information on the discovery flow, refer to pattern-based discovery in Service Mapping. Failure to provide users with required permissions may cause Service Mapping to perform **traffic-based discovery**.

**Limitations**

Discovery and Service Mapping cannot discover the Exchange Server if its configuration does not support public folders, edge transports, and public messaging. Create a pattern or customize the existing pattern to discover the Exchange Server with such configuration.

Map application services containing Microsoft Exchange Servers

Map an application service containing an Microsoft Exchange Server and verify that Service Mapping discovered all Microsoft Exchange Server components correctly.

- On the Now Platform, configure a domain user for accessing the Windows OS as described in [Windows credentials](#). Use the Microsoft Exchange Server administrator's user name and password as Windows credentials. For example, user name: local\administrator and password: Are1300.

  **Note:** If you configure Windows credentials for a user different from the Microsoft Exchange Server administrator, Service Mapping uses traffic-based discovery that results in mapping all Microsoft Exchange clients.

- (For Exchange CAS 2010 and 2013, 2016) On the Now Platform, configure **applicative credentials**, setting the CI type to Microsoft Exchange Mailbox.

  **Warning:** Do not confuse the Exchange Mailbox CI type with the Microsoft Exchange Mailbox server CI type.

Service Mapping uses these applicative credentials to access the of/Servers/Servers.slab folder on the Microsoft Exchange Admin Center (EAC. Service Mapping also uses the applicative credentials to run the following PowerShell commands against the Microsoft Exchange servers:

- Get-ExchangeServer
- Get-ExchangeServer
- Get-MailboxServer
- Get-ClusteredMailboxServerStatus
- Get-ExchangeServer
- Get-StorageGroup
- Get-MailboxDatabase

- (For Microsoft Exchange CAS 2007, 2010) On the Now Platform, upload the rctrIx tool for running PowerShell commands as described in [Upload the rctrIx.exe file to MID Servers](#).
- (For Microsoft Exchange CAS 2007 and 2010) Provide an Exchange Mailbox OS user with the rights to run Exchange services on Windows and has permission to query Exchange repository:

  On the Now Platform, configure **Windows credentials** setting the **Credential alias** attribute to (cmdb_ci_exchange_mailbox). Configuring this attribute allows you later to use the credential for this CI in patterns.
• (Optional) For discovering using the WinRM protocol, see Configure WinRM trusted hosts on MID Server.

• Verify that you know the entry point necessary for discovering the Microsoft Exchange Server. Use the URL for the Outlook web access in the following format:
  http(s)://<hostname>:<port>/owa
  For example, http(s)://myhost:<443>/owa

Role required: sm_admin

1. Create an application service:
   a) Navigate to Service Mapping > Application Services.
   b) Click New.
      The Discoverable by Service Mapping option is selected by default.
   c) In the Name field, enter a descriptive name for the application service.

2. Define the entry point for this application service:
   a) Select the Web Application tile.
      The Discoverable by Service Mapping option is selected by default.
   b) In the URL field, enter the URL of the Outlook web access.
      For example, http(s)://myhost:<443>/owa.
   c) Click Add.
   d) Click Save.

3. Click Additional Info on the left and clear the Traffic based discovery check box.

4. Click Update.

5. Verify that the mapping result is satisfactory:
   a) Click View Map and wait until the mapping is complete. It may take a few minutes.
   b) Review the application service map and make sure that the service layout is as in the examples below.
If the mapping result is not as you expected, perform basic troubleshooting.

<table>
<thead>
<tr>
<th>Symptom</th>
<th>Cause</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discovery failed. The discovery log displays the message that starts</td>
<td>The indication sections of the pattern fail, because the user does</td>
<td>Make sure that you provided a user with permissions to run PowerShell</td>
</tr>
<tr>
<td>with the following text:</td>
<td>not have permissions for running PowerShell commands.</td>
<td>commands on servers that host Microsoft Exchange Server components, for</td>
</tr>
<tr>
<td>You must have the Exchange Common Commands PowerShell Snapin installed</td>
<td></td>
<td>example, CAS.</td>
</tr>
<tr>
<td>to use this script.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Discovery failed. The discovery log displays the error message that starts with the following text: (servername.destination.com) Connecting to remote server failed with the following error message: The WinRM client can not process the request. The authentication mechanism requested by the client is not supported by the server or unencrypted traffic is disabled in the service configuration. Verify the unencrypted traffic setting in the service configuration or specify one of the authentication mechanisms supported by the server.

The application service map is very large, because it includes connections to all Outlook clients. (In deployments using Microsoft Exchange Server 2007, 2010 or 2013), Service Mapping created connections using traffic-based discovery, which traces all open connections, instead of using PowerShell commands. Make sure that you provided a user with permissions to run PowerShell commands on servers that host Microsoft Exchange Server components, for example, CAS.

Mapping application services containing SAP applications
Service Mapping can discover application services containing SAP applications and their components.

Discovered components

<table>
<thead>
<tr>
<th>Name</th>
<th>Platform</th>
<th>Version</th>

</tr>
</tbody>
</table>
Limitations

Service Mapping can map only one instance of ASCS per deployment.

Map application services containing SAP applications
Map an application service containing an SAP applications and verify that Service Mapping discovered all SAP components correctly.

- Provide a user with permissions to run SOAP on RFC read table function.
- (If hosted on a Unix server) On the Now Platform, configure `applicative credentials` and `SSH credentials`. The SSH credentials are used to create connections from SAP Central Instance to other applications and devices. In addition, provide the user elevated rights to be able to run `Service Mapping commands requiring a privileged user`.
- (If hosted on a Windows server) On the Now Platform, configure `Windows credentials` to create connections from SAP Central Instance to other applications and devices.
- (Optional) For discovering using the WinRM protocol, see `Configure WinRM trusted hosts on MID Server`.
- (Optional) If your organization deploys SAP digital business services using web services and you want to map all connected business services, perform the following steps:
  - Configure applicative credentials for a user with permissions to run the following commands: CVERS, DBCONS, and RFCCONS.
  - Ensure that you have the web service URL. For information on how to create web services, see [https://blogs.sap.com/2012/10/24/how-to-create-web-services-abap-based/](https://blogs.sap.com/2012/10/24/how-to-create-web-services-abap-based/).

Role required: `sm_admin`

1. Create an application service:
   a) Navigate to `Service Mapping > Application Services`.
   b) Click `New`.
      - The `Discoverable by Service Mapping` option is selected by default.
   c) In the `Name` field, enter a descriptive name for the application service.

2. Define the entry point for this application service:
   a) Select the `SAP application` tile.
      - The `Discoverable by Service Mapping` option is selected by default.
   b) Define the entry point as follows:
      - A URL to any SAP module
      - A TCP connection to any SAP module
      - To discover environments with connected services, provide the URL to the web service in the following format:

```
http://<hostname>:<port>/sap/bc/srt/scs/sap/z_servicenow_read?sap-client=003
```

c) Click `Add`.

d) Click `Save`.

3. Click `Additional Info` on the left and clear the `Traffic based discovery` check box.
4. Click `Update`.
5. Verify that the mapping result is satisfactory:
a) Click **View Map** and wait until the mapping is complete. It may take a few minutes.
b) Review the application service map and make sure that the service layout is as in the following examples.

If the SAP environment integrates SAP components with Tibco services, you can expect this mapping result:
Troubleshoot application services containing SAP applications

Fix basic discovery issues based on the symptoms and discovery messages.

**Symptom**

On the Now Platform using Jakarta or any later release, the business service or application service map in Service Mapping displays the following message: Failed to discover <SAP component name>.
Cause

The CI failed to identify, and process detection retrieves the process attributes.

Solution

Perform the following steps:

1. Open the failed pattern step in Debug mode:
   a. On the business service or application service map, right-click the error message and select Show discovery log.
      The Discovery Log window opens.
   b. In the right pane, locate the failed identification section and the failed step within this section.
   c. Select this failed identification section and click Debug.
      The Debug Identification Section window opens.
   d. If necessary, fill in the required details and click Connect.
      For information about working in Debug mode, refer to Activate pattern Debug mode.

2. Click the set variables step under Steps.
3. Make sure that the regular expression includes SYS as shown in the following figure.
4. Click the `set install_dir` step under **Steps**.

5. Make sure that the regular expression includes `sap` as shown in the following graphic.
Symptom

Service Mapping fails to discover the web service your organization uses to deploy SAP digital business services.

Cause 1

The pattern fails at the EVAL function for identifying the web service.

Solution 1

1. Verify that the format of the entry point is the URL to the web service as described in the mapping procedure.
2. Verify that you configured the necessary applicative credentials as described in the mapping procedure.
3. Check that the discovery log contains the following message: GROOVE_CODE_FAILURE: No such property: com for class: Script1.
4. Open the failed pattern step in Debug mode:
   a. On the business service or application service map, right-click the error message and select Show discovery log.
      The Discovery Log window opens.
   b. In the right pane, locate the failed identification section and the failed step within this section.
   c. Select this failed identification section and click Debug.
      The Debug Identification Section window opens.
   d. If necessary, fill in the required details and click Connect.
      For information about working in Debug mode, refer to Activate pattern Debug mode.
5. Pattern Designer opens showing the selected identification section.
6. Select the failed step on the right.
7. Verify that the function running on EVAL is com.snc.sw.util.HttpInvokerUtil.post.
8. Try to map the application service again and check the result.

**Cause 2**

The pattern fails at the EVAL function for identifying the web service, because the web service was configured incorrectly.
Solution 2

1. Verify that the format of the entry point is the URL to the web service as described in the mapping procedure.

2. Verify that you configured the necessary applicative credentials as described in the mapping procedure.

3. Check that the discovery log contains the following message: "Debug run railed: Test step failed. GROOVE_CODE_FAILURE: All command implementations (HTTP) failed on host 10.x.x.x. Host must be down or unreachable. ()"

4. Recreate the web service as described in https://blogs.sap.com/2012/10/24/how-to-create-web-services-abap-based/.

5. Try to map the application service again and check the result.

Cause 3

The pattern fails at the EVAL function for identifying the web service, because the URL configured in the entry point is not correct or because the MID Server cannot access this URL.

Solution 3

1. Verify that the format of the entry point is the URL to the web service as described in the mapping procedure.

2. Verify that you configured the necessary applicative credentials as described in the mapping procedure.

3. Check that the discovery log contains the following message: "Debug run railed: Test step failed. GROOVE_CODE_FAILURE: All command implementations (HTTP) failed on host 10.x.x.x. Host must be down or unreachable. ()"

4. Verify that you used the correct URL for the service entry point:
   a. In the TCode SOAMANAGER, navigate to Simplified Web Service Configuration.
   b. On the Configuration tab of the Simplified Service Configuration window, search for the web service that is part of the application service.
   c. Click the check box under User Name/Password (Basic) for this web service.
   d. Click Show Details.
   e. On the Details of the Service Definition window, verify the actual URL of the web service under WSDL URLs.
   f. If necessary, fix the URL you configure for the entry point and try to map the application service again.

Cause 4

MID Server cannot access this URL configured in the entry point of the application service.
Solution 4

1. Verify that the format of the entry point is the URL to the web service as described in the mapping procedure.
2. Verify that you configured the necessary applicative credentials as described in the mapping procedure.
3. Check that the discovery log contains the following message: "Debug run failed: Test step failed. GROOVE_CODE_FAILURE: All command implementations (HTTP) failed on host 10.x.x.x. Host must be down or unreachable. ()"
4. Verify that you used the MID Server that can access the URL you configured in the service entry point:
   a. Log into the MID Server host remotely.
   b. Open a browser.
   c. Paste the URL into the browser address bar and press Enter.
   d. If the page does not open, it means that there is a network issue, for example, there is a firewall that prevents the MID Server from accessing this URL.
5. Resolve the network issue and verify that the MID Server can access the URL as described in step 4.

Cause 5

MID Server cannot access this URL configured in the entry point of the application service.

Solution 5

1. Verify that the format of the entry point is the URL to the web service as described in the mapping procedure.
2. Verify that you configured the necessary applicative credentials as described in the mapping procedure.
3. Check that the discovery log contains the following message: "Debug run railed: Test step failed. GROOVE_CODE_FAILURE: All command implementations (HTTP) failed on host 10.x.x.x. Host must be down or unreachable. ()"
4. Verify that the applicative credentials you configured on the Now Platform for the web service are valid:
   a. Log into the MID Server host remotely.
   b. Open a browser.
   c. Paste the URL into the browser address bar and press Enter.
   d. The browser page displays the credentials pop-up window.
   e. Enter the credentials and check that the page opens.
      The page does not open, it means that the configured applicative credentials are incorrect.
5. Find out the right credentials.
6. Verify the new credentials as described in step 4.

7. If the page opens after you use the new credentials, configure these credentials as applicative credentials on the Now Platform.

**Cause 6**

MID Server cannot access this URL configured in the entry point of the application service.

**Solution 6**

1. Verify that the format of the entry point is the URL to the web service as described in the mapping procedure.

2. Check that the discovery log contains the following message: ‘Debug run railed: Test step failed. GROOVE_CODE_FAILURE: Missing applicative credentials for CI type <name of the CI type>”.

3. Verify that you defined applicative credentials for the relevant CI according as described in Map application services containing SAP applications.

**Mapping application services containing TIBCO BusinessWorks and EMS**

Service Mapping can discover application services containing TIBCO BusinessWorks, Enterprise Message Service (EMS), and their components.

If services in your organization deploy TIBCO applications, the discovered application service includes the following components:

<table>
<thead>
<tr>
<th>Name</th>
<th>Platform</th>
<th>Version</th>
<th>Protocol</th>
<th>Discovery type</th>
<th>Pattern (or probe if indicated)</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIBCO Enterprise Message Service (EMS)</td>
<td>Windows/Unix</td>
<td>5.x, 6.x</td>
<td>WMI/WinRM/SSH</td>
<td>Top-down and horizontal</td>
<td>Enterprise Message Service</td>
</tr>
<tr>
<td>TIBCO Enterprise Message Service (EMS) Queue</td>
<td>Windows/Unix</td>
<td>5.x, 6.x</td>
<td>WMI/WinRM/SSH</td>
<td>Top-down and horizontal</td>
<td>Enterprise Message Service</td>
</tr>
</tbody>
</table>

Map application services containing TIBCO BusinessWorks and EMS

Map an application service containing TIBCO BusinessWorks and Enterprise Message Service (EMS) and verify that Service Mapping discovered all TIBCO components correctly.

- (If hosted on Unix) Configure **applicative credentials** for the TIBCO EMS.
- (If hosted on a Windows server) On the Now Platform, configure **Windows credentials**.
- (If hosted on a Unix server) On the Now Platform, configure **SSH credentials**.
• (Optional) For discovering using the WinRM protocol, see Configure WinRM trusted hosts on MID Server.

Role required: sm_admin

1. Create an application service:
   a) Navigate to Service Mapping > Application Services.
   b) Click New.
      The Discoverable by Service Mapping option is selected by default.
   c) In the Name field, enter a descriptive name for the application service.

2. Define the entry point for this application service:
   a) Select the Other application tile.
      The Discoverable by Service Mapping option is selected by default.
   b) From the Select Entry Point Type list, select HTTP(s) Endpoint, TCP Endpoint, Tibco BW Endpoint.
   c) Define the entry point as follows:
      • The URL to the process that correlates to the TIBCO BusinessWorks Project, for example, http://10.xx.xx.xx:6710/GetMemberActivitiy/Processes/ServiceGetMemberActivitiy.service.
      • (Optional) The hostname on which the BusinessWorks Project runs as a service.
   d) Click Add.
   e) Click Save.

3. Click Additional Info on the left and clear the Traffic based discovery check box.

4. Click Update.

5. Verify that the mapping result is satisfactory:
   a) Click View Map and wait until the mapping is complete. It may take a few minutes.
   b) Review the application service map and make sure that the service layout is as in the following examples.
In addition, verify that the BusinessWorks CIs are inclusions each of which contain a BusinessWorks process. Also, verify that the EMS CIs are inclusions containing EMS Queues.
If the mapping result is not as you expected, perform basic troubleshooting.
### Symptom

<table>
<thead>
<tr>
<th>(Only for deployments hosting BusinessWorks on a Unix server) The application service map shows the BusinessWorks CI without an inclusion of the BusinessWorks process. The discovery log shows the error message stating that the user does not have sufficient credentials.</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Only for deployments hosting BusinessWorks on a Unix server) The application service map shows the BusinessWorks CI without an inclusion of the BusinessWorks process. The discovery log shows the error message stating that the user does not have sufficient credentials.</td>
</tr>
<tr>

Mapping application services containing Oracle Tuxedo platform

Service Mapping can discover application services containing Oracle Tuxedo platform and its components.
Map application services containing Oracle Tuxedo platform

Map an application service containing an Oracle Tuxedo platform and verify that Service Mapping discovered all Tuxedo components correctly.

- On the Now Platform, configure *SSH credentials*.
- (Optional) For discovering using the WinRM protocol, see *Configure WinRM trusted hosts on MID Server*.
- (If hosted on Unix) Provide a user with the elevated rights for running commands described in *Service Mapping commands requiring a privileged user*.

Role required: sm_admin

1. Create an application service:
   a) Navigate to Service Mapping > Application Services.
   b) Click New.
      The Discoverable by Service Mapping option is selected by default.
   c) In the Name field, enter a descriptive name for the application service.

2. Define the entry point for this application service:
   a) Select the Other Application tile.
   b) Select TCP Endpoint from the list.
   c) Define the entry point as follows:
      - A host of the server that hosts the Tuxedo process.
      - A port on this server that the Tuxedo process opens.
   d) Click Add.
   e) Click Save.

3. Click Additional Info on the left and clear the Traffic based discovery check box.
4. Click Update.
5. Verify that the mapping result is satisfactory:
   a) Click View Map and wait until the mapping is complete. It may take a few minutes.
   b) Review the application service map.

If the mapping result is not as you expected, perform basic troubleshooting.

### Fix application service errors in bulk

Service Mapping classifies errors by their root cause, for example, missing credentials or task timeout. For a fast and efficient process, fix errors belonging to the same category in bulk.

**Role required:** sm_admin or admin

You can view errors by category, for example, Configuration, Network, and Credentials. Each category tile also displays the error counter.

As part of the Service Mapping workflow, after you map application services in bulk, you can fix multiple application service errors in bulk (as a group).
After performing initial mapping, Service Mapping rediscovers configuration items (CIs) regularly, constantly updating the list of errors. Discovery schedules define how often Service Mapping runs the discovery process for CIs. Service Mapping discovers only CIs belonging to application services with Operational status.

There may be discovery errors not assigned to any category:

- After upgrading Service Mapping from Jakarta release or earlier.
If there are configuration items (CIs) that have errors associated with them, and that were first removed from application services and then readded to application services.

1. Navigate to **Service Mapping > Home** and then click **Fix Your Services** in the **Fix** box.

   The number in the **Fix** box indicates the number of affected service maps. Click **Update** to update the display.

   **Note:** To fix the errors for a particular service instead, click **Manage Errors by Service**.

2. If there are uncategorized errors, you can categorize them by application service:
   a) Click **View Uncategorized Errors by Service**.
   b) Click the relevant service name.
   c) On the application service map, click **Run Discovery**.

   Service Mapping discovers all CIs discovered with errors and belonging to this application service.

3. If there are uncategorized errors, categorize them by clicking **Rediscover Relevant CIs**, and clicking **Continue** in the confirmation message.

   Service Mapping discovers all CIs discovered with errors and belonging to application services with Operational status.

4. Click an error category box.

   In the example below, configuration errors are selected.

   - The Errors by Category page organizes errors by high, medium, and low impact on the services.
   - For each impact category, errors are grouped into boxes by error code (possibly the root cause).
   - If error tasks have been assigned, the task numbers appear in the box. Click a task to view details. Point to a task to view comments that the assigner might have added. A check mark indicates that a task is completed.
5. To view the list of errors that share an error code, click the box. In the example, All patterns failed is selected.

You can perform one of the Recommended Actions on items that you select or on all items in the list.
6. Click an action in the Action on All section, or select errors and click an action in the Action on Selected section.

**Retry Discovery**
Performs the full Discovery process. You typically perform Discovery after following the fix instructions that appear when you click View instructions.

**View affected services**
Displays a popup list of all services that are affected by the selected error. In the list, click a service to view service details.

**Mark as assigned**
Apply the Mark as assigned action when you plan to perform an out-of-band action to notify a person to fix the error (typically a person who does not use the ServiceNow instance). You can enter a Comment in the Mark as Assigned popup. Click Update to set the Error Status field in the error record as Assigned and associate the Comment with the error. To view the comment, point to the Assigned link.

Note: The Create ServiceNow task action also sets the Error Status field in the error record as Assigned.

**Create a ServiceNow task**
Opens the ServiceNow Error task form in a pop-up window so you can create and assign a task for the selected errors. Sets the Error Status field in the error record as Assigned. For information on creating error tasks, see Task table and Create a task from an incident, problem, or change request.

Note: The Mark as assigned action also sets the Error Status field in the error record as Assigned.
**Retry Discovery**

Performs the full Discovery process. You typically perform Discovery after following the fix instructions that appear when you click **View instructions**.

**View instructions**

Displays a troubleshooting procedure in a pop-up window. Follow the steps to try to resolve the error.

**Ignore Error**

Right-click an error and then select **Ignore Error** to set the **Ignored** value to **true**.

The system performs the action on the items, displays **In progress**, and then displays the result (success or failure) of the action. If the error is resolved, the **Error Status** field in the error record is set to **Resolved**.
Note: If an action (for example, Discovery) is in progress, but taking too long, you can click **Stop** to stop the action.

7. Click **Done** to close the status message.
8. If you performed an action on a selection and the error was resolved, you can click **Resolve All** to apply the same action to all items in the list.

**Fix errors in individual application service maps**

You can address discovery issues in each application service map individually.

Role required: sm_admin

You can fix errors in individual application services at any time. When you perform initial mapping of application services in your organization, you typically fix errors in individual application services after resolving errors in multiple services, in bulk. You may also need to fix errors in an approved and completed application service at a later stage.
1. Alternatively, if Service Mapping is deployed, navigate to **Service Mapping > Services > Application Services**.
2. Click **View Map** next to the relevant application service.
3. Ensure that the map opens in **Edit mode**.
CIs discovered with errors appear with the warning icon (⚠️) on the map. Discovery messages on the **Discovery Messages** tab give short error descriptions.

4. Optional: Group errors by types by clicking **Group Errors**.
   The discovery error messages on the **Discovery Messages** tab appear grouped by predefined types, error codes.

5. To review and fix an error from the list, click **Handle Error** next to the error description.
   Or

6. To review the first error in the largest error group, click **Handle Next Error** at the left top corner of the map.

7. To learn how to resolve the error, click **Open instructions** under **Action on Selected** in the right pane.

   **Note:** Instructions are available only for the most common errors.

   The Instructions window opens.

8. Click the relevant semi-automated resolution option to resolve the error under **Action on Selected** in the right pane.
Error resolution options vary, because they depend on the specific discovery error associated with the selected CI.

<table>
<thead>
<tr>
<th>Use this option</th>
<th>To do this</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add Management IP</td>
<td>Define the management IP for the server hosting the application, which Service Mapping failed to discover.</td>
</tr>
<tr>
<td>Create new WMI credentials</td>
<td>Open the Windows Credentials form and configure missing Windows credentials for the selected CI. See Windows credentials.</td>

<td>Open the SSH private keys form and configure missing credentials for the selected CI. See SSH private key credential type.</td>
</tr>
<tr>
<td>Create new SNMP credentials</td>
<td>Open the SNMP credentials form and configure missing SNMP credentials for the selected CI. See SNMP community credentials.</td>
</tr>
<tr>
<td>Show Discovery Log</td>
<td>See the log to understand at what stage an error occurred and what caused it.</td>
</tr>
<tr>
<td>Skip and resume</td>
<td>Manually add the CI whose discovery failed and configure attributes of the entry point from which Service Mapping continues discovery. For more information, see Skip errors to continue discovering an application service.</td>
</tr>
<tr>
<td>Retry discovery</td>
<td>Run the discovery process for the selected CI after trying to resolve a discovery error associated with it.</td>
</tr>
<tr>
<td>View affected services</td>
<td>Display a list of all services affected by the selected error. In the list, click a service to view service details.</td>
</tr>
</tbody>
</table>

9. If there are no instructions or semi-automated resolution options available, fix errors based on symptoms and discovery messages.

10. To ignore an irrelevant error, right-click its error message on the Discovery Messages tab and select Toggle Ignore State. The ignored error disappears from the map and from the list of discovery error messages.

Note: If necessary, you can still display ignored errors by switching on the Include Ignored Errors option under More Options menu. For more info, see Modify view for an application service map.

11. Click Handle Next Error to review the next error in the largest error group.

12. When finished reviewing and handling errors, click anywhere in the map to close the Resolve Error pane.

If you resolved most errors, send the application service for review.

Fix errors in individual application services using discovery messages

Service Mapping does not offer semi-automated resolution options for errors that require advanced resolution. Fix such errors using symptoms and discovery messages.
Try fixing errors using semi-automated resolution options as described in the *Fix errors in individual application service maps*.

Role required: sm_admin

You can fix errors in individual application services at any time.

1. Navigate to **Service Mapping > Services > Application Services**.
2. Click **View Map** next to the relevant application service.
3. Ensure that the map opens in Edit mode.

CIs discovered with errors appear with the warning icon (⚠️) on the map. Discovery messages on the **Discovery Messages** tab give short error descriptions.

4. Fix errors based on the symptoms and discovery messages.

</tr>
</tbody>
</table>

5. Click **Run Discovery**.

**Skip errors to continue discovering an application service**

If you know what configuration items (CIs) and connections make up your application service, you can enable Service Mapping to continue discovery of the application service even if there are some errors. You can skip errors to troubleshoot later so you can complete mapping most of the application service, even if some CIs are missing.

Familiarize yourself with the structure of the application service to know which CIs make up the next tier after the problematic CI. If necessary, consult the application service owner to collect necessary information.

Role required: sm_admin or admin

Normally, discovery of an application service stops when Service Mapping fails to identify a CI. In this case, the map shows a warning icon instead of the undiscovered CI. There are no CIs or connections going out of the undiscovered CI.
You can overcome the obstacle of the undiscovered CI and restart discovery from the CIs belonging to the next tier after the problematic CI. To do so, add a CI manually if you know what the undiscovered CI is and what the incoming connection of the next tier CI is. Service Mapping uses incoming connections to access a CI for discovery. These connections are referred to as endpoints.

1. Navigate to Service Mapping > Services > Application Services.
2. Click View map next to the application service that you want to view.
3. Ensure that the map opens in Edit mode.
4. Ensure that the map is not in the Host View.
5. Click the arrow next to the undiscovered CI and select **Skip and Resume**.
6. Define attributes of the CI you want to manually place instead of the undiscovered CI.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CI Type</td>
<td>Select the CI type (CI class) for the CI you are adding. Every CI belongs to a CI type which contains a set of attributes configured for this kind of CI, for example, <code>cmdb_ci_appl</code> for applications.</td>
</tr>
<tr>
<td>CI Name</td>
<td>Select the CI from the list of CIs of the selected CI type.</td>
</tr>
</tbody>
</table>

**Note:**
If the CI type does not appear in the list, Service Mapping does not allow adding CIs of this type manually. For example, you cannot add an application cluster or an endpoint manually.
7. Configure attributes of the entry point from which Service Mapping continues discovery by selecting the entry point type and entering relevant fields. If the required entry point type does not appear in the Select Entry Point Type list, create it as described in Create entry point types for Service Mapping.

8. Click Submit.

The map shows the manually added CI instead of the undiscovered CI. Service Mapping starts discovery for CIs of the next tiers. When the discovery process finishes, the map shows all discovered CIs below the manually added CI.

To discover the problematic CI automatically:

1. Perform necessary troubleshooting to enable Service Mapping to discover the problematic CI. For example, you may need to customize the relevant pattern, provide missing credentials or fine-tune traffic-based discovery.

2. Navigate to the relevant application service map.

3. Click Run discovery.

4. After the discovery process finishes, verify that Service Mapping discovered the CI. If Service Mapping discovered the CI, the map shows the actual CI without the Warning icon (⚠).

**Resolve pattern-related mapping errors**

You can troubleshoot mapping errors caused by patterns.
Verify that the mapping error is caused by an inaccurate pattern by checking the discovery message. If the message says “Failed to recognize application”, the error is pattern-related.

You need to be familiar with the Pattern Designer module of Service Mapping.

Role required: admin and sm_admin

If there are configuration items (CIs) that Service Mapping could not map correctly, they appear on your application service map with warning icons. Typically, mapping errors happen when Service Mapping fails to connect to a CI or fails to recognize it due to an inaccurate pattern.

You can identify problematic steps in your pattern and fix them without reviewing all steps and operations contained in the pattern. It allows you to troubleshoot pattern-related errors quickly and effectively.

The following video provides an alternative way of troubleshooting pattern-related errors:

1. Navigate to **Service Mapping > Services > Application Services**.
2. Click **View map** next to the application service that you want to view.
3. Ensure that the map opens in Edit mode displaying discovery messages and errors.

4. Right-click the CI with the warning icon (⚠️) and select **Show discovery log**. The Discovery Log window opens showing mapping patterns and their details.
5. Expand the failed pattern which appears above the result marked red.

6. Expand the failed section and click the failed step.
7. Click **Debug**.
The Pattern Designer window opens showing the pattern with its steps in the left pane.

8. Click the first step and wait for Pattern Designer to run it. Repeat this action for other steps following the order until you reach the faulty step that causes the error.

In the example below the port number is 8081 instead of 8080 which causes the problem.

9. Click **OK**.

10. Fix the pattern attribute that causes the problem.

11. Click **Test**.

12. Verify that Pattern Designer returns a success message.

13. Click **Save**.

14. Click **Activate**.

15. Return to the application service map which contained the mapping error.

16. Right-click the CI for which the pattern was fixed and select **Resume discovery**.

17. Verify that the CI is discovered and mapped correctly.

---

**View status for application services discovered with Service Mapping**

The dashboard provides an up-to-date overview of the mapping status of all application services discovered with Service Mapping, progress on error tasks (tasks that are associated with mapping errors), and counts of error tasks and other tasks associated with services.
Role required: sm_app_owner or sm_admin

Navigate to Service Mapping > Home and click Map Status.

The scorecards count error tasks plus all other tasks. The scorecards and charts are standard ServiceNow widgets that you can modify to suit your needs. Click a data point to view the supporting data.
Review and approval of application service maps

After the Service Mapping administrator maps IT services and fixes errors in them, the administrator and the owner collaborate to review and approve the IT service maps.

You must have Service Mapping enabled to map or review application services.

Users who perform review and approval have the roles of a Service Mapping administrator and an application service owner. The Service Mapping administrator is responsible for mapping, fixing, and maintaining Application services. The application service owner checks that the application service maps are complete and all major components comprising it are correctly represented. If necessary, the owner leaves comments, referred to as reject messages, on application service maps for the Service Mapping administrator to implement.

The review and approval process is performed in the following stages:

1. After the initial mapping of application services, the administrator fixes errors and sends individual application services for review. The system creates a service process task assigned to the application service owner and sends an email notification about it.

2. The application service owner checks that the application service maps are complete and all major components comprising it are correctly represented. If necessary, the owner leaves comments, referred to as reject messages, on application service maps for the Service Mapping administrator to implement. The service process task assigned to the owner closes. The system sends an email notification to the administrator that the owner posted comments.

3. The administrator receives the email notification, views owner requests and implements them.

4. The administrator resends the application service maps for review. The system again creates a service process task assigned to the application service owner and sends an email notification about it.

5. If the revised application service maps are satisfactory, the application service owner approves them. If not, the owner requests further fixes, which the administrator must address.

To see documentation for a review phase, click the relevant box in the diagram.
1. **Send the application service for review**
2. **Review the business service and request fixes**
3. **Review and implement owner’s requests**
4. **Resend the application services for review**
5. **Review and approve the application service**

The process of application service review may take some time as it requires making changes and repeatedly running the mapping process on the application service. Typically, it takes several iterations to arrive at the desired result.

Once the owner approves an application service, the application service status changes to Approved and it appears in the list of completed application services on the **Home** page.

**Send application service maps for review**

After you map an application service, send it to the application service owner for review to make sure that the map is accurate.

Perform initial error fixing as described in [Fix application service errors in bulk](#) and [Fix errors in individual application service maps](#).
Role required: sm_admin

While you can fix errors in bulk, you always send application services for review individually, one by one.

Sending application service maps for review is part of the review and approval process. Typically, you send each application service map for review twice: The first time for the initial owner review and the second time after you implemented owner feedback.

After the initial mapping of application services, you fix errors and send individual application services for review. The system creates a service process task assigned to the application service owner and sends an email notification about it.

To see documentation for another review phase, click the relevant box in the diagram.

1. **Review the application service and request fixes**
2. **Review and implement owner’s requests**
3. **Resend the application services for review**
4. **Review and approve the application service**

1. To send an application service for review from the application service form:
   a) Navigate to Service Mapping > Services > Application Services.
   b) Sort the list of planned application services by status and scroll to see services in **In progress** status, or use the filter to narrow the list.
   c) Click the required application service.
   d) Click **Actions > Send For Review**.

2. Alternatively, send an application service for review from its map:
   a) Navigate to Service Mapping > Home. The Home page displays only information on application services that Service Mapping can discover or already discovered. The Home page does not display information on application services that are created manually or using the API.
   b) Click the **Approve** tile.
   c) Click **Send For Review**.
   d) Click the required application service. The map for this application service opens.
   e) Click **Send For Review** in the upper right corner of the window.

When you receive an email notification that the owner sent comments for this application service, **review and implement the owner's requests**.

**Review application service maps**

As the application service owner for the application service map, you receive an email notification that the application service map is assigned to you for review. Review mapping results for correctness and either provide your feedback or approve the application service map.

Role required: sm_app_owner

Ideally, only the application service owner reviews the planned application service, however, users with the sm_app_owner or sm_admin role can also perform this task.

Reviewing application service maps is part of the **review and approval process**. The process of application service review may take some time as it requires making changes and repeatedly running the mapping process on the application service. Typically, it takes several iterations to arrive at the desired result. Once you are satisfied with the discovery result, you approve the application service.

After you request fixes or approve the application service, the service process task assigned to you closes.

To see documentation for another review phase, click the relevant box in the diagram.
1. **Send the application service for review**
2. **Review and implement owner's requests**
3. **Resend the application services for review**

1. Click the link to the application service map in the email notification. The map of the application service opens in the ServiceNow instance.
2. Alternatively, open to the application service to review from the list of tasks assigned to you.
   a) Navigate to **Service Mapping > Administration > My Tasks**.
   b) Optional: Sort the list of service process tasks as required.
   c) Click the required task.
   d) Click the application service form link.
   e) Click **View map**.
3. On the application service map, check that all essential CIs comprising the application service are discovered and mapped correctly.
### Purpose

**Verify that there are no missing CI connections.**

Pay attention to CIs with no connectors from it to other CIs. For example, in the following figure, the Web Server on win2K12 CI is missing connections.

![Diagram showing missing connections](image)

If connections and CIs to which they lead are missing, the map does not reflect the real state of the application service and its operation. Inaccurate data can also be transferred to Event Management, causing imprecise monitoring.

### Action

**Check that the connections between CIs are correct.**

View CI connection attributes in an application service map.
**Purpose**

Check that clusters are reflected correctly.

**Action**

Click the plus (+) icon next to a CI.

There are two types of clusters:

**Application cluster**

In an application cluster, two or more applications or devices are configured to work together and serve the same purpose. Typically, the clusters provide high availability or load balancing. For example, web servers working behind a load balancer.

This type of cluster appears as a stack of CIs with a label showing the number of CIs in this cluster with the multiplication sign.

Application clusters can have a cluster within a cluster, but never more than two levels:
<table>
<thead>
<tr>
<th>Purpose</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Check that inclusions are reflected correctly.</td>
<td>Click the plus (+) icon next to a CI. In an inclusion, a server hosts applications that are treated as independent objects. For example, IIS Virtual Directory can run on a Windows Service as its host.</td>
</tr>
</tbody>
</table>

4. To notify the service mapping admin of a necessary change or fix, perform the following steps:
   
a) Right-click the CI or connection to which you want to add your comment, and select **Submit Reject Message**. Or
   
   To add a general comment for the application service, click **Actions** on the **Add Reject Message** tab under the map.

   b) In the Add Reject Message window, enter your comment, and click **Add**.
   
   The new comment appears on the **Discovery Messages** tab under the map. If you added the comment to a specific CI or connection, the map shows a warning icon (⚠️) next to them. The application service status changes to Rejected.

   c) If necessary, add more comments.

5. If you are satisfied with the results, approve this application service by clicking **Actions**, and then **Approve service**.

   The application service status changes to Approved and it appears in the list of completed application services on the **Home** page. The operational status changes to Operational. From this point, other applications can use data collected and organized by Service Mapping.

**Fine-tune application services to implement owner requests**

As an administrator, you tweak and fine-tune maps based on comments from the application service owner.

Role required: sm_admin

Reviewing and implementing owner requests is part of the **review and approval process**.

To see documentation for another review phase, click the relevant box in the diagram.
1. **Send the application service for review**

2. **Review the application service and request fixes**

3. **Resend the application services for review**

4. **Review and approve the application service**

1. Navigate to the relevant application service:
   a) Click **Approve** on the **Home** page.
      The Home page displays only information on application services that Service Mapping can discover or already discovered. The Home page does not display information on application services that are created manually or using the API.
   b) Click **Fix Rejected**.
   c) Right-click the required application service and select **Open Service Form**.
      The form for this application service opens.

2. **Click Reject Messages** on the left.
   The owner comments are displayed under the **Service Discovery Messages** tab.
3. Review the reject messages to see comments that the application service owner left.
4. Click **View Map**.
5. Implement changes requested by the application service owner.
6. If necessary, resend the application service for review.

**Manually add CIs to an application service**

Add configuration items (CIs) to manually created application services or to services discovered by Service Mapping.

- Verify that the CI type for the CI that you are planning to add, exists. If necessary, create the CI type as described in *Create CI types for Service Mapping and Discovery*.
- Add CIs to the CMDB for the device or application that you want to add, if necessary. See *Populate the CMDB* for more information.

**Role required:** **app_service_admin** or **sm_admin**

You can populate an application service that was created manually, by manually adding the CIs comprising it. Adding a CI to an application service requires creating a relationship between the new CI and a CI in the application service.

Information about the CI in application service, to which you are connecting a new CI, is updated in the CMDB. This information includes the type of the relationship between the CIs. If other application services use the same applicative flow, the CMDB recognizes it and adds the CI you added manually to these application services by analogy. For example, you manually added an IBM WebSphere Message Broker to an IBM WebSphere HTTP Listener in the Bank Customer Portal service. The system also adds this IBM WebSphere Message Broker to the same HTTP Listener in the Bank Internal Portal, because it uses this HTTP Listener. The same logic applies when you remove a CI you added manually: The system removes it from all application services where you either manually added it or the system added it by analogy.

All connections created between CIs in an application service are of the **Depends on:** : **Used by** relationship type. You can modify this default relationship type by changing the value of the *sa.it_service.manual_ci_rel_type* property.

You can manually connect a CI only to actual CIs existing in the CMDB, not to a visualization of other items on the map such as clusters or boundaries. Also, it is prohibited to add CIs of these CI types to an application service:

- **cmdb_ci_endpoint**
- **cmdb_ci_translation_rule**
- **cmdb_ci_config_file**
- **cmdb_ci_qualifier**
- **cmdb_ci_application_cluster**

If necessary, you can prevent CIs of other CI types from being added to application services by modifying the *sa.mapping.user.manual.citype.blacklist* property.

In environments with domain separation, only CIs belonging to the same domain as the application service are added to the application service. If there is a domain hierarchy, CIs must belong to the same child domain as the application service.

If working with an application service discovered by Service Mapping, manually add a CI:

- To indicate that an application service contains a device or application, which Service Mapping cannot discover. For example, add an A/C unit to the Production Floor service.
- To add a temporary placeholder for a CI, which Service Mapping did not discover. In this case you are planning to perform necessary troubleshooting to ensure that Service Mapping discovers this CI in the future. For example, add an IBM WebSphere Message Broker to the Bank Customer Portal service.
• To create an application service that combines entry points and CIs automatically discovered by Service Mapping with entry points and CIs from the CMDB. After you manually add an entry point, you can update the application service with CIs from the CMDB based on the relationships defined there.

For additional information related to Service Mapping, see Discovery patterns used by ITOM Visibility and Enable traffic-based discovery for CI types or specific CIs.

1. Navigate to Configuration > Application Services > Application Services.
2. Alternatively, if Service Mapping is deployed, navigate to Service Mapping > Services > Application Services.
3. Open the relevant application service map:
   a) Click View map next to the relevant application service.
   b) If needed, click Edit to ensure that the map is in Edit mode.

   If Service Mapping is deployed, then in Edit mode, the Discovery Messages section appears below the map.

4. To connect a CI to another CI on the map, right-click the CI to which you want to connect the new CI, and then select Add a CI.
5. In the Add A CI dialog box, specify the CI to add:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CI Type</td>
<td>Select the CI type (CI class) for the CI you are adding. Every CI belongs to a CI type which contains a set of attributes configured for this kind of CI, for example, cmdb_ci_appl for applications.</td>
</tr>
<tr>
<td>CI Name</td>
<td>Select the CI from the list of CIs of the selected CI type.</td>
</tr>
</tbody>
</table>

   The CI type list includes only allowed CI types. For example, you cannot add an application cluster.

6. Click Submit.

   The manually added CI appears on the map.

   **Note:** When you manually add a CI, which is an application, as a child to a service that already includes its parent application CI, the newly added child application CI is hidden inside the inclusion. Click the plus (+) symbol next to the parent application CI to see the child application CI.

7. Optional: (If Service Mapping is activated) To add a discoverable outgoing connection for the manually added CI:
   a) Right-click the manually added CI.
   b) Select Manually add a connection.

   **Note:** If you do not see the Manually add a connection option in the right-click menu, check that you are logged in with the user that belongs to the same domain as the application service.

   c) Configure attributes for the entry point as described in Entry point attributes.
   d) Click Submit.
Discovery and Service Mapping attempt to discover this CI. If successful, the CI appears on the map. Otherwise, a warning icon (⚠️) appears.

8. Optional: (If Service Mapping is activated) If you want Service Mapping to automatically discover a CI, which you previously added manually:
   a) Customize the relevant pattern or fine-tune traffic-based discovery to enable Service Mapping to discover the CI.
   b) Navigate to the relevant application service map.
   c) Click **Run discovery**.
   d) After the discovery process finishes, verify that Service Mapping discovered the CI by checking the connector leading to the CI. If Service Mapping discovered the CI, then two connectors, a manual and automatically discovered, appear for the CI.

   ![Diagram of service map with manual and automatically discovered connectors]

   e) Right-click the CI you added manually.
      In the example, it is IBM WebSphere Message Broker.
   f) Select **Remove manually added CI**.
The map shows the CI with only one connector leading to it. If this CI had any manually added connections, they are removed together with the manually added CI.

Remove CIs not belonging to application services
If Service Mapping erroneously mapped some CIs as part of an application service, remove these CIs for noise reduction. It is important to remove unnecessary CIs from the map, because they can generate irrelevant alerts in Event Management. For example, when creating an application service for a web portal, Service Mapping may automatically discover a connection to external services, such as PayPal service, that do not belong to the service.

Role required: sm_admin
Removing CIs from the map also removes all their connections. For example, if you remove a CI of the second tier on the map, all CIs of the third tier connected to it through outgoing connections, get removed too.

Depending on why Service Mapping mapped an unwanted CI, you can remove it by the following methods:

- Add mapping boundaries to remove the unnecessary CIs. A boundary makes Service Mapping stop discovery from this point and not follow outgoing connections. Use this method to remove CIs that Service Mapping discovered using patterns or using traffic-based discovery.
- Tweak traffic-based discovery. Service Mapping uses traffic-based connections to collect network statistics and perform traffic-based discovery. This discovery method may clutter an application service with irrelevant CIs. Service Mapping uses an algorithm to reduce the number of erroneously mapped CI. You can further adjust traffic-based discovery to remove unwanted CIs.

1. Navigate to Service Mapping > Services > Application services.
2. Click View map next to the relevant application service.
3. To remove CIs, right-click the connector leading to the CI you want to remove, and select Mark boundary.

The CI is marked as boundary on the map ( ).
4. To remove CIs discovered using traffic-based discovery, perform the following steps:
   a) Right-click the CI on the map.

   Note: You can see traffic-based connections for a CI, even if you disabled the traffic-based discovery for an application service the CI is part of.
   b) Select Show traffic based connections.

   The Traffic Based Connections List opens displaying the following information:

   Traffic Based Connections List

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP</td>
<td>The IP address of the application connected to the selected CI.</td>
</tr>
<tr>
<td>Port</td>
<td>The port on the selected CI that is used to communicate to the other application.</td>
</tr>
<tr>
<td>Process</td>
<td>The ID of the process in the selected CI.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| Already on map      | • Yes — if this connection shows on the map.  
• No — if this connection is not part of the application service and not on the map.   |
| System decision     | The setting defines if Service Mapping keeps the discovered traffic-based connection or removes it. The value comes from the algorithm that Service Mapping uses. |
| User decision       | (Optional) The setting overrides the System decision setting, which defines if Service Mapping keeps the discovered traffic-based connection or removes it. For example, if the System decision setting for a connection is Keep, and you want to remove this connection, select Remove. |

**Note:** There may be a case when you can see traffic-based connections on the map, but the Traffic Based Connections list does not display them. It happens for the connections that have been removed from the TCP Connection (cmdb_tcp) table less than three days.

c) In the **Traffic Based Connections List**, identify the connection used to discover the unwanted CI.
d) Select **Remove** from the **User decision** field for this connection.
e) Click **Close**.

**Transfer a map segment into another application service**

You can remove a branch of a service and place it into another application service, either brand new or existing. The original map shows the link to the other application service instead of the map segment.

**Role required:** sm_admin

Transfer map segments when you need to split large services or when you want to organize services differently from the initial mapping result.

When you transfer a map segment into another application service, you create a link between the original application service and the application service into which you planted the map segment. The connection to the top CI in the segment becomes an entry point when you transfer it into another, existing or new, application service.

When you transfer a map segment into another application service, the information about the connection to the top CI in the transferred segment, is updated in the CMDB. If other application services use the same ingoing connection (endpoint), the CMDB recognizes it and replaces map segments coming out of the same connection with connected service CIs by analogy.

You cannot insert links to multiple application services from the same connection.
If Event Management is activated in your organization, you can monitor impact of the transferred segment in the original application service containing the link.

1. Open the application service map containing the segment that you want to transfer:
   a) Navigate to Service Mapping > Services > Application Services.
   b) Click View map next to the relevant application service.
   c) Optional: Click Edit to be in Edit mode.
   
   ![Application Service Map](image)

   d) If the Host view is on, switch it off by clicking More Options and clicking the Display in Host View toggle.
2. Identify the segment of the map that you want to transfer.
3. Right-click the connection leading to the CI at the top of this segment.

4. To transfer the segment into an existing application service map and connect to it:
   a) Select **Connect to existing service**.
b) In the Add To Existing Discovered Service window, select the application service to which you want to transfer the segment.

c) Click Choose.

The map displays the connected application service icon instead of the transferred segment. The application service map to which you transferred the segment, shows it under the newly added entry point. For example, the Tomcat application service map contains the Trade connected service CI. The Trade application service map shows the segment transferred from the Tomcat application service.

5. To transfer the segment into a new application service map and connect to it:

   a) Select Create new service from here.

   b) In the Create New Discovered Service window, define attributes for the application service that you want to create for this segment:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter the application service name. This name must be unique. Use self-explanatory names such as mailing service or printing service.</td>
</tr>
<tr>
<td>Group</td>
<td>(Optional) Restrict access to an application service by adding it to an application service group. Users must then have the service group role to access the application service.</td>
</tr>
<tr>
<td>Criticality</td>
<td>(Optional) Select the option that reflects how important this application service is to your organization operation. For more information about application service criticality, see Define criticality for application services.</td>
</tr>
</tbody>
</table>
c) Click **Create**.

The map displays the connected application service icon instead of the transferred segment. The new application service appears in the list of application services and contains the transferred segment of the map. For example, the Tomcat application service includes the TP rooms connected service CI. The TP rooms application service map contains the segment transferred from the Tomcat application service.

To revert this operation:

1. On the application service map containing the connected service CI, click the connection leading to it.
2. In the Properties pane, note the URL attribute of the connection.
3. Double-click the connected service CI.
   The application service map for the CI containing the transferred segment opens.

4. Click **Service Map Form**.

5. Under Entry Points on the left, locate the entry point with the same URL you took note of.

6. Click **Delete** on the entry point tab, and click **Remove** to confirm.
   This entry point disappears from this application service form.
   The transferred segment disappears from the map of this application service.

7. Navigate to the map that contained the connected service CI.
   This map displays a boundary instead of the connected service CI.

8. Click the boundary CI and click **Unmark boundary**.
   The map is refreshed and displays the segment of the application service.

Service maps contain no indication of transferred services being linked to their original services.
You may need to know if a service is a part of another, larger service when dealing with changes or incidents.
Use the updateset to add the ability to view the list of all application services that contain a certain service as a link, as described in **KB0748865: Viewing list of application services that contain a certain service as a link**.

**Link application services**
You can manually add to one application service a reference to another application service.
Ensure that you know the name of the application service that you want to add a reference to.
Role required: app_service_admin or sm_admin

An application service can be part of another application service, in which case you can link one to the other. To link, edit an application service, and add a reference to another application service as an outgoing connection of the relevant CI inside the other application service.

When you link an application service to another application service, the information about the CI, to which you linked the service, is updated in the CMDB. The CMDB recognizes other application services that use the same applicative flow, and adds the application service you linked to these application services by analogy. The same logic applies when you remove a linked application service: The system removes it from all application services where you either manually linked this service or the system linked this service by analogy.

When using Service Mapping, you may want to link application services to create:

- A link between two discovered services.
- A placeholder for a map branch that Service Mapping failed to discover. If you modify or add a pattern that can discover the configuration item (CI) serving as an entry point for the linked application service, Service Mapping can discover this linked service.
- An indication that an application service contains a branch, which Service Mapping cannot discover.

You can link application services to one another to create dependencies for impact monitoring in Event Management.

1. Navigate to Configuration > Application Services > Application Services.
2. Alternatively, if Service Mapping is deployed, navigate to Service Mapping > Services > Application Services.
3. Click **View map** next to the application service which you want to link to another application service.

4. Right-click the CI to which you want to link an application service as a reference.

5. Select **Add A CI**.

6. In the Add a CI dialog box, select the application service you want to add as a reference:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CI Type</td>
<td>Select <em>Application service</em> from the list.</td>
</tr>
<tr>
<td>CI Name</td>
<td>Select the name of the application service that you want to link as a reference.</td>
</tr>
</tbody>
</table>

7. Click **Submit**.
   
   The icon for the linked service appears on the map.

Navigate to the linked application service, and double-click its icon on the map. The map window shows the linked application service.

Service maps contain no indication of transferred services being linked to their original services. You may need to know if a service is a part of another, larger service when dealing with changes or incidents. Use the updaterset to add the ability to view the list of all application services that contain a certain service as a link, as described in [KB0748865: Viewing list of application services that contain a certain service as a link](https://servicenow.com/knowledgebase/docs/KB0748865).

**Discover CIs identified as generic applications**

Service Mapping identifies application configuration items (CIs) that it failed to properly discover as generic applications. Correctly identify generic applications by creating a simplified discovery pattern from a business service map, rather than creating a fully functional pattern from scratch using the Pattern Designer.

Make sure that you understand what **discovery process classification** is.

Request information about the CI discovered as generic application from the business service owner.

Role required: pd_admin

ServiceNow applications refer to devices and applications that comprise an application service as configuration items (CIs).

As part of creating a simplified pattern for complete and proper application CI discovery, you create these necessary articles:

**CI type**

All applications and hosts in your organization must have a corresponding configuration item (CI) type, which is necessary for discovering and processing applications and hosts correctly. A CI type (or class) contains several important definitions that apply to all CIs belonging to it. Preconfigured CI types form a hierarchy where child CI types derive attributes from their parents.

Define the CI type name and label for Service Mapping to create a child CI type for the application (cmdb_ci_appl) CI type. For more information about CI types, see [Create CI types for Service Mapping and Discovery](https://servicenow.com/knowledgebase/docs/Create_CI_types_for_Service_Mapping_and_Discovery).

**Process classification**

Service Mapping relies on process information collected and classified by Discovery to run relevant patterns to discover an application CI. During the horizontal discovery process, Discovery checks if the attributes of the processes running by the application match classification criteria you define. When a match is found, Discovery uses the existing Application
Rule identifier to check if the application CI is new or if it already exists in the CMDB. Then Discovery either updates an existing record or creates a new record for this application CI in the CMDB.

Prior to starting the top-down discovery of an application CI, Service Mapping checks its process classification in the CMDB. It then runs only those patterns that are relevant for this application CI.

Create process classification by defining the classification criteria based on preconfigured process attributes. The new process classification is added to the Process Classification (discovery_classy_proc) table. To learn about process classification, refer to Discovery classifiers.

**Pattern**

A pattern is a sequence of steps whose purpose is to detect attributes of a CI and its outbound connections. When you create a simplified pattern for a generic application, Service Mapping assigns the new simplified pattern to the CI type you define as part of this process. The default name for the pattern starts with “ga_”.

**Association of an icon with this CI type**

Each CI type is associated with an icon. When a CI is discovered and classified as belonging to a CI type, the map displays the associated icon to visualize this CI.

You cannot create simplified patterns from generic applications that are based on multiple processes. In this case, you have to either create a fully functional pattern using the Pattern Designer or create a new CI type.

1. Navigate to Service Mapping > Services > Application Services.
2. Click View Map next to the relevant application service.
3. Optional: Click Edit to be in Edit mode.
4. On the map, right-click the relevant generic application CI. The **CI Type** attribute in the **Application** pane is **Generic Application**. In the base system, the map displays generic application CIs with the gear icon.
5. Select **Create pattern for this generic application**.

6. Define the CI type for the application.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Label</strong></td>
<td>CI type name. For example, Citrix Licensing Server.</td>
</tr>
<tr>
<td><strong>Name</strong></td>
<td>The table name containing data for this CI type. For example, cmdb_ci_app_license_server. Use a name that is consistent with existing CI type names. Typically, application CI type names start from &quot;cmdb_ci_app&quot;.</td>
</tr>
<tr>
<td><strong>Icon</strong></td>
<td>Select the name of the existing icon to represent this application on maps.</td>
</tr>
</tbody>
</table>

7. Create the process classification for this CI by defining classification criteria for identifying the process that the generic application is running.

   In the base system, there are two conditions based on the running process name and the running process command. The values are filled in by the latest process discovery.

   a) Select the CI attribute from the list.

      The attributes in the list are from the Running Process (cmdb_running_process) table.

   b) Select an operator from the list.

      If you select **Is Empty**, the second field is rendered irrelevant and disappears.

   c) Specify the value to match.

      The value field displays a dynamically generated suggestion from the latest process discovery.
d) To add a dependent condition, click OR or AND.

**Note:** If the value in the first condition is not unique like Java.exe, use additional conditions to narrow down the results.

For example, to discover a Citrix Licensing server, use the following classification criteria: the process name `Imadmin.exe` with the command `C:\Program Files (x86)\Citrix\Licensing\LS\Imadmin.exe`.

e) To add a top-level condition, click **New Criteria**.

8. **Click Create.**
   
   Once Service Mapping finished creating the CI type, the pattern, and the process classification, it resumes discovery of the CI initially identified as a generic application.

9. Verify that Service Mapping discovered the CI as you expected.
Notice that Service Mapping uses the name of the process for the CI label on the map.

If Service Mapping still has not discovered the CI as you expected, fine-tune the match and classification criteria for the process classifier and configure advanced classification parameters.

If you are familiar with modifying patterns in the Pattern Designer, you can also enrich the simplified pattern by defining operations that discover more attributes for the CI.

You may configure Discovery to use a different identifier. For more information, see Discovery identifiers.

**Application service completion**

After an application service is reviewed and approved, you can define attributes that enhance its discovery, reflect its importance, and control access to it.

There are several configurations you must perform to complete definition of an application service.
Define criticality for application services

For each application service, select a criticality level that reflects how important it is to your organization operations.

Determine how important the application service is to your organization.

Role required: sm_admin
Typically, you might assign high criticality to application services, which impact your customer base or sales revenue, while giving low criticality to internal application services causing minor inconvenience to organization employees. For example, you could set high criticality for an application service that supports sales functionality using the organization web site. An application service that provides internal printing for the organization employees could receive low criticality.

Criticality determines the prominence of an application service on the Event Management dashboard. You can also use a criticality value to define recovery strategies.

Example of an application service criticality on the Event Management dashboard

1. In the classic UI, perform the following steps:
   a) Navigate to **Service Mapping > Home**.
      The Home page displays only information on application services that Service Mapping can discover or already discovered. The Home page does not display information on application services that are created manually or using the API.
   b) Click **View Your Services** on the **Completed** tile.
c) Select the relevant application service.
d) Click **Additional Info**.
e) Select the appropriate option from the **Business criticality** list.
f) Click **Update**.

2. Alternatively, perform the following steps in the Agent Workspace UI:
   a) Navigate to **Agent Workspace > Agent Workspace Home**.
b) Click **Lists** in the left pane.
c) Navigate to **Services > All Services**.
The list of services displays services in Operational status.
d) Select the relevant application service.
e) Click the **Open Preview** icon.

The Details pane opens on the right.
f) Select the appropriate option from the **Business criticality** list.
g) Click **Update**.

---

### Enable traffic-based discovery for an application service

Make Service Mapping use traffic-based connections to discover CIs making up an application service.

Role required: sm_admin
Service Mapping uses traffic-based connections to collect network statistics and perform traffic-based discovery. Not only can Service Mapping discover CIs using patterns, it can also discover them by following traffic connections between CIs. This method is referred to as traffic-based discovery. For more information about how Service Mapping performs traffic-based discovery, see Traffic-based discovery in Service Mapping.

1. In the classic UI, perform the following steps:
   a) Navigate to Service Mapping > Home.
      The Home page displays only information on application services that Service Mapping can discover or already discovered. The Home page does not display information on application services that are created manually or using the API.
   b) Click View Your Services on the Completed tile.
   c) Select the relevant application service.
   d) Click Additional Info.
   e) Click the Traffic based discovery check box.
   f) Click Update.

2. Alternatively, perform the following steps in the Agent Workspace UI:
   a) Navigate to Agent Workspace > Agent Workspace Home.
   b) Click Lists in the left pane.
   c) Navigate to Services > All Services.
      The list of services displays services in Operational status.
   d) Select the relevant application service.
   e) Click the Open Preview icon.
The Details pane opens on the right.

f) Click the Traffic based discovery check box in the Details pane.

g) Click Update.

Group application services

Organize application services by groups to perform actions simultaneously on multiple services, and to control user access to services. You can use Event Management to track service health by service groups.

Role required: sm_admin or app_service_admin

Typically, enterprises have hundreds of services which makes it impractical to manage them individually. Service groups can make service lists much shorter and easier to manage, especially in large organizations or service providers.

How you group application services depends on the user and on service provisioning policies in your enterprise. The relation between application services in groups is purely logical and the same application service can belong to multiple groups. For example, the Mobile service can be part of the following service groups: sales, Beijing, and telephony.

Example of an application service belonging to different groups

You can embed a service group within another service group to create a hierarchy of service groups. If users have access to a parent service group, they automatically have access to all its child groups. By default, all services are assigned to the All service group that lets all users view and manage application services. When you assign a role to a service group, the users with this role can access only application services in this service group. To enable users with this role to access other services, assign this role to the respective service group.
If Service Mapping is activated, service groups can contain a mixture of manually created application services and application services discovered by Service Mapping.

1. Navigate to Configuration > Application Services > Service Groups. Or, if Service Mapping is activated, navigate to Service Mapping > Services > Service Groups.
2. Click New.
3. Enter the name of the new application service group in the Name field.
4. To embed this group in another group, enter the name of the other group in the Parent Group field.
5. Right-click the form header and click Save.
6. Add an application service to the newly created service group.
   a) In the Service Group Members section, click New.
   b) In the Name field, enter the name of the application service. If you are using Event Management, you can also enter an alert group name.
   c) Click Submit.
7. Alternatively, add an application service to a group from the application service form.
   a) Navigate to Configuration > Application Services > Application Services.
   b) Select the application service you want to add to a service group.
   c) In the Service Group Members section, double-click Insert a new row.
   d) Enter the name of the service group to which you want to add the selected application service.
   e) Click the OK icon (✔).
   f) Click Update.

Control user access to application services

Assign user roles to service groups to grant users access to application services in your organization. Your organization may restrict access to some services for security or secrecy reasons.

Make sure that you have performed the user provisioning tasks for the users you want to grant access:

1. Add users to user groups.
2. Create new roles.
3. Assign roles to users or user groups.

Also, make sure that you have created service groups as described in Group application services.

Role required: app_service_admin or sm_admin

In the base system, the following roles provide access to application services:

app_service_admin

Creates and modifies application services, creates service groups, views, and edits application service maps.

app_service_user
Views application service maps. The `itil` role that serves as the basic helpdesk technician role contains the `app_service_user` role.

Service Mapping provides these preconfigured roles:

**sm_admin**
Sets up the Service Mapping application. Maps, fixes, and maintains application services. Also performs advanced configuration and customization of the product. Assign this role to application administrators.

**sm_user**
Views maps for operational application services to plan change or migration, as well as analyze the continuity and availability of services. Assign this role to application users.

**sm_app_owner**
Provides information necessary for successful mapping of an application service. Once a service is mapped, this user reviews the results and either approves it or suggests changes. Assign the `sm_app_owner` role to users who own application services and are familiar with the infrastructure and applications that make up the services.

Event Management provides these preconfigured roles:

**evt_mgmt_admin**
Has read and write access to all Event Management features to configure Event Management.

**evt_mgmt_operator**
In addition to the `evt_mgmt_user` permissions, can also activate operations on alerts such as acknowledge, close, open incident, and run remediations.

**evt_mgmt_user**
Has read access to all Event Management features. Has write access to alerts to manage the alert life. Has the `itil` role to be able to manage incidents that are created from alerts.

**evt_mgmt_integration**
Has create access to the Event (em_event) and Registered Nodes (em_registered_nodes) tables to integrate with external event sources.

Typically, enterprises have hundreds of services which makes it impractical to manage them individually. Service groups can make service lists much shorter and easier to manage, especially in large organizations or service providers. In a hierarchy of service groups, access to a parent service group automatically grants access to all the child service groups.

Users inherit permissions from roles that are assigned to them. You can assign some roles directly to service groups to allow all users with this role to access all application services belonging to this group. However, most enterprises choose to organize their roles as a hierarchy. It helps to manage roles across multiple ServiceNow applications. For example, the Service Mapping administrator (`sm_admin`) can be part of a broader administrator role like administrator (`admin`). You can add users to user groups and then assign roles to the user groups to give permissions of this role simultaneously to all the group users.
Assigning a role to an application service group

By default, all services are assigned to the **All** service group that lets all users view and manage application services. When you assign a role to a service group, the users with this role can access only application services in this service group. To enable users with this role to access other services, assign this role to the respective service group.

**Note:** Some references in the user interface to business services are actually references to application services.

1. Navigate to either of the following:
   - **Configuration > Application Services > Service Group Responsibilities.**
   - If Service Mapping is activated: **Service Mapping > Services > Service Group Responsibilities.**
   - If Event Management is activated: **Event Management > Services > Service Group Responsibilities.**

2. Click **New** and fill out the Business Service Group Responsibilities form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Business Service Group</td>
<td>Service group to which you want to assign a role.</td>
</tr>
<tr>
<td>Role</td>
<td>Role you want to assign to the selected service group. For example, financial_services_admin.</td>
</tr>
</tbody>
</table>
3. Click Submit.

To manage access to services that contain sensitive financial information in your organization:

1. Organize the services into the Financial Services group.
2. Create a new user role, financial services administrator (financial_services_admin) role, that contains the (app_service_it) role.
3. Assign the Financial Services administrator role to the Financial Services group.

As a result, only users with the Financial Services administrator role can access application services belonging to the Financial Services group.

Schedule a top-down discovery by Service Mapping

After Service Mapping discovers configuration items (CIs) belonging to your application service for the first time, it then rediscovers CIs to find changes and updates. Create or modify discovery schedules to control how often Service Mapping rediscovers services or CIs.

Define your application services prior to defining discovery schedules for discovering CIs which are part of these services.

When creating a schedule for CI types or specific CIs, make sure that at least one application service containing the relevant CI is in the operational state.

Role required: sm_admin

When you define a new application service, Service Mapping performs discovery of all CIs that participate in this application service and creates its map. After the initial mapping is complete, Service Mapping regenerates application service maps regularly by rediscovering CIs making up an application service.

By default, Service Mapping is preconfigured with these generic schedules:

**All Applications**

This schedule triggers the top-down discovery of all CIs of the application type (cmdb_ci_appl).

**Load Balancer Service**

This schedule starts the top-down discovery of all CIs of the load balancer service type (cmdb_ci_lb_service)

The generic schedules trigger discovery of all applications and load balancer services in your organization once a day. Typically, these preconfigured schedules are enough to update information for application services. However, if your organization needs to discover specific CIs or services more frequently, you can create the following custom discovery schedules:
Schedule types for top-down discovery

<table>
<thead>
<tr>
<th>Schedule type</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Services</td>
<td>Service Mapping discovers all CIs belonging to certain services that answer filtering criteria.</td>
<td>In your organization, some application services are more critical than others and it is important for you to rediscover such services with high criticality more frequently. Create a custom discovery schedule to discover all services with the business criticality value set to <strong>most critical</strong>. Alternatively, certain services in your organization are undergoing changes more often than once a day. You may want to create custom schedules to rediscover such services more frequently. You can also create a schedule of this type to discover application services in a sub-production instance, where services are not in the <strong>operational</strong> state yet.</td>
</tr>
<tr>
<td>Services belonging to a group</td>
<td>Service Mapping discovers all CIs belonging to services assigned to groups that answer filtering criteria. Service Mapping discovers only services located directly inside the group that answers defined filtering criteria. Service Mapping does not discover services inside embedded groups. Notice that you can define schedules based on service groups, even if your role does not have access to these service groups.</td>
<td>In a distributed organization with offices in several geographic locations, you may want to create a custom discovery schedule to rediscover services in one of these locations. For example, one schedule can trigger rediscovery of all services relevant for the EMEA site at 7am GMT, while another schedule can start rediscovery of services for the US headquarters at 7am PT.</td>
</tr>
<tr>
<td>Schedule type</td>
<td>Description</td>
<td>Example</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------</td>
<td>---------</td>
</tr>
<tr>
<td>For CI types</td>
<td>Service Mapping discovers all application CIs belonging to this application type. Some CI types are prone to more frequent changes and updates than others, so you can manage the load by adjusting the discovery schedule to match the nature of each CI type. When you define discovery schedules based on application CI types, several schedules may apply to the same CI. To avoid discovering the same CIs more than once, the most specific schedule always has precedence. For example, if you create separate discovery schedules for a parent CI type and its child CI type, CIs belonging to the child CI type are discovered using its dedicated schedule. At the same time, if there is no schedule for a child CI type, the parent CI type schedule is used to discover the child CIs. This schedule discovers only CIs belonging to application services in the operational state.</td>
<td>If you modify a certain application more often than the rest of your applications, you may want to discover it more frequently than other CIs. In that case, create a custom discovery schedule for such an application CI type.</td>
</tr>
<tr>
<td>Specific CIs</td>
<td>Service Mapping discovers only one CI that you specified for this schedule. If you define a discovery schedule for a specific CI as well as a schedule for the CI type to which this CI belongs, Service Mapping uses the schedule for this specific CI, and not the generic schedule for its CI type. This schedule discovers only CIs belonging to application services in the operational state.</td>
<td>For rare cases of rediscovering a specific CI that causes discovery errors frequently.</td>
</tr>
</tbody>
</table>

Having customized discovery schedules also allows you to avoid redundant stress on your infrastructure.

Part of discovering an application CI is identifying its host. Service Mapping checks if the device hosting this application CI exists in the CMDB. For a load balancer service, Service Mapping checks if the load balancing device hosting this load balancer service exists in the CMDB. If not, Service Mapping triggers Discovery to perform the horizontal discovery. As a result, Discovery performs host detection and updates the information on hosts in the CMDB. If necessary, you can manage the schedules that trigger horizontal discovery as described in:

- **Schedule a horizontal discovery** — for standard horizontal discovery.
- **Create a schedule for standard serverless Discovery** — for discovering CIs using a protocol such as REST, without using the IP address of any devices or hosts.
- **Create a schedule for host-based serverless Discovery** — for discovering CIs that reside on an already discovered host using this host as a Proxy server.

1. Navigate to Service Mapping > Administration > Discovery Schedules.
2. To create a custom discovery schedule, click New.
Or

To customize the generic schedule for all application CIs, click All Applications or Load Balancer Service.

The Discovery Schedule page opens.

3. In fresh install or reset instances, fill in the fields as follows:

**The Discovery Schedule form in fresh install or reset ServiceNow deployments**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>For a new specific schedule, enter a unique and descriptive name.</td>
</tr>
<tr>
<td>Discover</td>
<td>By default, the value for this field is Service, indicating that you are creating a top-down discovery schedule. You cannot change this value.</td>
</tr>
<tr>
<td>Discover by</td>
<td>For a new specific schedule, select CI Type.</td>
</tr>
<tr>
<td>CI type</td>
<td>This field is available when CI type is selected from Select Discovery. For a new CI type-based schedule, select the relevant CI type from the list.</td>
</tr>
<tr>
<td>CI</td>
<td>This field is available when Specific CI is selected from Select Discovery. For a new schedule for a specific CI, select the relevant CI from the list.</td>
</tr>
</tbody>
</table>
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Filter Services to Discover</td>
<td>This field is available when Service Attributes is selected from Select Discovery. Use the filter to create the filtering criteria for services. Service Mapping discovers only services that answer the defined criteria.</td>
</tr>
<tr>
<td>Filter Groups to Discover</td>
<td>This field is available when Service Group Attributes is selected from Select Discovery. Use the filter to create the filtering criteria for service groups. Service Mapping discovers only services belonging to the groups that answer the defined criteria.</td>
</tr>
<tr>
<td>Active</td>
<td>Select the check box to enable this schedule. If you clear the check box, the schedule is disabled, but you can still run a discovery manually from this form, using the configured values.</td>
</tr>
<tr>
<td>Max run time</td>
<td>Set a time limit for running this schedule. When the configured time elapses, the remaining tasks for the discovery are canceled, even if the scan is not complete. Use this field to limit system load to a desirable time window. If no value is entered in this field, this schedule runs until complete.</td>
</tr>
</tbody>
</table>

4. In upgraded deployments, fill in the fields as follows:

#### The Discovery Schedule form in upgraded ServiceNow deployments

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>For a new specific schedule, enter a unique and descriptive name.</td>
</tr>
<tr>
<td>Discover</td>
<td>By default, the value for this field is Service, indicating that you are creating a top-down discovery schedule. You cannot change this value.</td>
</tr>
<tr>
<td>Service discovery</td>
<td>For a new specific schedule, select a schedule type as described in Schedule types for top-down discovery.</td>
</tr>
<tr>
<td>CI type</td>
<td>This field is available when CI Type is selected from Select Discovery. For a new CI type-based schedule, select the relevant CI type from the list.</td>
</tr>
<tr>
<td>CI</td>
<td>This field is available when Specific CI is selected from Select Discovery. Select the relevant CI from the list to create a discovery schedule for this CI.</td>
</tr>
<tr>
<td>Filter Services to Discover</td>
<td>This field is available when Service Attributes is selected from Select Discovery. Use the filter to create the filtering criteria for services. Service Mapping discovers only services that answer the defined criteria.</td>
</tr>
</tbody>
</table>
5. Optional: For a discovery schedule based on service attributes, click View Selected Services to preview the list of services that answer the filtering criteria you entered. Click Close.

6. Optional: For a discovery schedule based on service group attributes, click View Selected Groups to preview the list of groups that answer the filtering criteria you entered. Click Close.

7. Define the rediscovery frequency by selecting the relevant option from the Run list:

### Discovery schedule run options

<table>
<thead>
<tr>
<th>Run option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>On Demand</td>
<td>Does not run on a schedule. Click Discover now to run Discovery. This is the default option.</td>
</tr>
<tr>
<td>Daily</td>
<td>Runs every day. Use the Time field to specify the time of day.</td>
</tr>
<tr>
<td>Weekly</td>
<td>Runs on one designated day of each week. Use the Time field to specify the time of day.</td>
</tr>
<tr>
<td>Monthly</td>
<td>Runs on one designated day of each month. Use the Day field to select the designated day. Use the Time field to select the time of day. If the designated day does not occur in the month, the schedule does not run in February.</td>
</tr>
<tr>
<td>Periodically</td>
<td>Runs every designated period of time. Use the Repeat Interval field to define the period of time in days, hours, minutes, and seconds. The first Discovery runs at the point in time defined in the Starting field. Repeal Interval period passes.</td>
</tr>
<tr>
<td>Once</td>
<td>Run one time as designated by the date and time defined in the Starting field.</td>
</tr>
<tr>
<td>Weekdays</td>
<td>Runs every Monday, Tuesday, Wednesday, Thursday, and Friday. Use the Time field.</td>
</tr>
<tr>
<td>Weekends</td>
<td>Runs every Saturday and Sunday. Use the Time field to select the time of day.</td>
</tr>
<tr>
<td>Month Last Day</td>
<td>Run the last day of every month. Use the Time field to select the time of day.</td>
</tr>
<tr>
<td>Calendar Quarter End</td>
<td>Runs on March 31, June 30, September 30, and December 31. Use the Time field to select the time of day.</td>
</tr>
</tbody>
</table>

8. Click Submit.

Service definition transfer from one instance to another

Save time and effort by exporting definitions of application services from the source instance and importing these definitions into the target instance. Use this method to copy definitions of discovered application services only, not manually created application services.

Typically, you maintain two ServiceNow instances in your organization: for production and for development. You perform the initial mapping of application services in your organization on the development instance, which you use for testing. The results of initial mapping often require some basic troubleshooting or fine-tuning. Once you finish mapping application services on your source instance, transfer service definitions into the target (production) instance.

Notice that you cannot export the actual application services, only service definitions. Mapping is a dynamic process, and the mapping result reflects the actual infrastructure and its configuration. Therefore, the services you exported from one instance and imported into another may look different.

By default, you export the following service definitions:

- Service name
- Traffic-based discovery usage
- Entry point
- Business criticality
- Group to which the service belongs
  
  If this service group is part of a service group hierarchy, all parent service groups in this hierarchy are exported as well.
- Comments

The system uses the Sys ID (sys_id) attribute to identify services on the source and target instances and implements service definition import according to these rules:

- If a service Sys ID does not exist on the target instance, the system creates a new service on the target instance.
- If a service Sys ID and name already exist on the target instance, the system updates this service by overriding the existing service definitions with the imported definitions.
- If a service Sys ID exists on the target instance, but is associated with a different service name, the system updates the service with this Sys ID. The system overrides service definitions, including the service name.
- If the same name is used for different services on the source and target instances, the system does not import service definitions.
- You cannot export manual services. Likewise, you cannot export manually added entry points. When importing definitions of a service containing manual entry points, the system does not make any changes to the entry points.

When transferring service definitions between instances, imported application services and service groups are assigned to the user's domain.

By default, the system assigns **Non-operational** status to application services whose definitions you imported.

A service definition transfer deploys the standard import set feature available on the Now Platform. When you export service definitions on the source instance, the system creates a JSON file containing exported data. When you copy service definitions into the target instance, you import the data from this JSON file, which becomes an import set.
Export service definitions
Create an import set containing definitions of services. You use this import set to import service definitions into another instance.

- Decide which service definitions you want to export.
- Verify that the source and the target instances are on the same ServiceNow release.
- Open the source instance from which you want to copy service definitions.
- If necessary, fine-tune the import set creation by modifying relevant properties under Service Mapping > Administration > Properties. For more information, see Components installed with Service Mapping.

Role required: sm_admin

1. If the instance uses domain separation and you have access to the global domain, select the domain to which the application service belongs from the domain picker.
3. Select the application services that you want to export.
4. Click Actions on selected rows at the bottom of the page and select Export Services.
   The import set appears in the Downloads folder. The file name follows this convention: export_service_<datetime>.json.
5. If necessary, copy the import set to a different location on the computer.

Import service definitions from one instance to another
Import definitions of application services from the source instance.

- Verify that the source and the target instances are on the same ServiceNow release.
- Open the target instance into which you want to import service definitions.

Role required: import_admin

1. If the instance uses domain separation and you have access to the global domain, select the domain to which the application service belongs from the domain picker.
3. In the Import Service Definitions window, click Choose File, navigate to the JSON file that contains service definitions, and click OK.
4. Optional: Click Show Preview and check the definitions in the chosen JSON file.
5. Click Import.
6. Click Yes to confirm that you are ready to import service definitions.

Attention: During import, the system irreversibly overrides the current service definitions.

The Progress window displays the success message.
Service Mapping automatically starts the discovery of services containing imported entry points.
7. Review imported or updated services after Service Mapping finishes the mapping process. If the transfer result is not as you expected, perform basic troubleshooting as described in the following table.

<table>
<thead>
<tr>
<th>Symptom</th>
<th>Cause</th>
<th>Solution</th>
</tr>
</thead>
</table>
| Changes you have recently made to an application service disappear. | Definitions of existing application services are always overridden during transfer. | 1. Make necessary changes to the definitions of this application service again.  
2. Run the top-down discovery of this application service by clicking Run Discovery in the service map. |
| An imported service group does not appear.         | The import of an application service assigned to this group failed and the system did not create the group because it appears to be empty. | 1. Resolve the issue that prevented the system from importing the application service belonging to this group.  
2. Import the import set again.  
3. Check that the service group appears. |
<table>
<thead>
<tr>
<th>Symptom</th>
<th>Cause</th>
<th>Solution</th>
</tr>
</thead>
</table>
| An imported service group appears to have wrong application services assigned to it. | This is a different service group with the same name, not the service group you imported. The system failed to import the service group, because the source instance already has a service group with the same name or with the same name and Sys ID. | 1. Check the import log.                                                                                                                                  
2. If an error states that a record creation failed while running the Check Name Uniqueness business rule, perform the following steps:
   a. Rename the service group on the source instance.
   b. Re-export the application services assigned to this group.
   c. Import the latest import set on the target instance.
3. If an error states that a record creation failed because the Sys ID already exists, perform the following steps:
   a. Recreate the service group on the source instance, ensuring you provide a different group name and Sys ID to it.
   b. Re-export the application services assigned to this group.
   c. Import the latest import set on the target instance.
4. Verify that the service group appears correctly on the source instance. |

**Application service analysis and maintenance using maps**

Service Mapping creates maps to help you see the architecture and organization of application services. These maps are useful for planning change or migration, as well as analyzing the continuity and availability of services.

The maps are useful in the following cases:

**Planning the migration of an entire application service or its segments**

Use the map to see which configuration items (CIs) need relocating or which CIs become redundant.

**Planning the upgrade or replacement of a CI**
Check the map to see what other CIs are affected when the CI is non-operational during maintenance. You can assess and plan the downtime or make provisions to avoid the downtime.

Because the same CI may be used for multiple application services, check the CI using the Dependency Views application. With this application, you can see all application services that a CI belongs to.

**Analyzing a application service for high availability and continuity**

Use the map to identify CIs crucial for the service performance. Decide if you want to fortify these CIs by creating clusters.

**Troubleshooting application services**

Use the map to understand the impact of an issue and determine which CI is causing the problem.

**Application service maps**

Maps offer you a visualization of data on configuration items (CIs) comprising application services, and relations and connections between these CIs.

A new map is created every time you manually create an application service or map an application service using Service Mapping. The system updates the map every time you add CIs to the application service or when Service Mapping runs discovery for CIs belonging to this application service.

**Note:**

The following user interface screens refer to application services as business services: Business Service Group Responsibilities, Approve, Service Mapping Properties, and Service Map Planner.

Information and actions available on a map depend on your role:

- As a Service user (app_service_user) or Service Mapping user (sm_user), you can view the map in the View mode.
- As a Service administrator (app_service_admin) or Service Mapping administrator (sm_admin), you can view application services in View mode and modify services in Edit mode.
- As a Service Mapping administrator (sm_admin), you can view discovery messages and errors generated by Service Mapping and modify services in the Edit mode. You can also reload the map to ensure the map reflects the latest information.
- As a Service owner (sm_app_owner) role, you can review, provide feedback, and approve services discovered using Service Mapping in the View mode.

Also, actions and information related to automatic discovery using Service Mapping are not available for CIs that Service Mapping cannot discover. For example, you do not see the tab for Discovery Messages for a manually created application service that Service Mapping does not discover.

**Map window**

Aside from the map itself, the map window also displays the Properties pane and tabs with additional information.
You can navigate to a different application service map directly from this window by selecting it from the list:
By default, the entire map is shown in the center of the visible map area of the window. You can zoom in and out as well as position the map depending on which segment of the map you must see using these controls:

You can also click anywhere in the map area and drag the required segment of the map into the visible area.
You can view changes made to an application service as a whole and to individual CIs belonging to a service by choosing a time range. For more information, see View the change history of application services.

**Map elements and their appearance**

Every map consists of icons representing CIs and arrows that represent the connections between them.

Some map elements can contain other elements such as in the case of application clusters. On the map, application clusters appear as a stack of CIs with the plus (+) symbol next to it. The cluster label shows the number of CIs in this cluster with the multiplication sign.

When the CI has inclusions, the CI icon has the plus (+) symbol next to it and shows the contained application when you expand it.
An OS cluster appears as a CI with the plus (+) symbol and the number of CIs in this cluster.

**CI attributes and CI-related messages**

When a map is loaded and no elements are selected, the Properties pane shows the details of this application service.

A selected device, application, or connector appears in blue and is highlighted. Information about the selected map element is displayed in the Properties pane on the right of the map. The Properties pane contains the links to the Detailed Properties page.
The attributes for the server hosting applications and applications themselves are shown separately inside the Properties pane.
If there is any information related to the selected CI or connection, it is highlighted on the tab at the bottom of the window.
When you select information on a tab at the bottom of the map window, the related CI displays in yellow.
Map indicators

You can show additional information for a CI or application service itself by displaying its related records such as alerts, outages, incidents, and problems. If you enable this feature, record indicators appear next to relevant CIs and next to the application service name. Records themselves are displayed on the tabs at the bottom of the map window.
Map views

Customize a map view to exclude irrelevant information and increase clarity, as described in Modify view for an application service map.

To open this application service in Event Management and view alerts on CIs that are part of the application service, click **Monitor Service** at the top of the window.

View CI attributes in an application service map

An application service map displays attributes for each configuration item (CI) that is part of the application service, as well as for the application service itself. The attributes come from the CMDB.

Role required: sm_admin or sm_user

You can view the following information for each CI:

**Name label**
The CI name. This attribute is either preconfigured on the CI or configured during CI installation.

**Basic attributes**
A summary of the most important CI attributes.

**Detailed attributes**
A complete list of all attributes collected for the CI.

Each CI type (CI class) has different attributes. For example, the Linux Server type has different attributes than the SQL Instance type.

If Service Mapping is deployed, the way CIs appear on the map depends on the **view you select for the map**. Attributes available for viewing also depend on the Service Mapping setup. For more information see description of **components installed with Service Mapping**.

The following user interface screens refer to application services as business services: Business Service Group Responsibilities, Approve, Service Mapping Properties, and Service Map Planner.

1. Navigate to **Configuration > Application Services > Application Services**.
2. Alternatively, if Service Mapping is deployed, navigate to **Service Mapping > Services > Application Services**.
3. Click **View Map** next to the relevant application service.
4. To see the full name of a CI whose name has been shortened on the map, point to the CI. A tooltip displays the full CI name.
5. Click a CI to see its details in the **Properties** pane. The attributes of applications and the servers that host them appear separately.
6. To view more detailed attributes for the CI, click **Detailed properties** at the bottom of the Properties pane.

7. Optional: (If Service Mapping or Discovery are enabled, and if tracking changes to configuration files is enabled for a CI) To view configuration files associated with a CI:
   - Review the list of files under **Tracked Files** in the Properties pane. Click the file name to open the actual file.
   - Click the **Affected CIs** tab and view the list of configuration files. Click the file name to open the actual file.

**View CI connection attributes in an application service map**

You can view attributes of connections between configuration items (CIs).

Role required: sm_admin or sm_user
You can view the following information for each connection:

- The source and target CIs of this connection displayed in the Context (right-click) menu.
- A complete list of all attributes collected about the connection in the Properties pane.

By default, Service Mapping merges connection lines for the same CI to declutter an application service map. It helps to make the map more readable.

Each connection type has different attributes. For a merged connection line, all underlying connections are listed.

The way an application service map displays connection attributes depends on the following factors:

- **Views you configure for CIs** define which connection attributes appear in the Properties pane of the map.
- Connection lines on the map depend on the **view you select for the map**.
- Attributes available for viewing also depend on the Service Mapping setup, for more information see description of **components installed with Service Mapping**.
The following user interface screens refer to application services as business services: Business Service Group Responsibilities, Approve, Service Mapping Properties, and Service Map Planner.

1. Navigate to **Configuration > Application Services > Application Services**.
2. Alternatively, if Service Mapping is deployed, navigate to **Service Mapping > Services > Application Services**.
3. Click **View map** next to the application service including the connections you want to view.
4. View connection attributes as follows:

<table>
<thead>
<tr>
<th>To view</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td>The source and target CIs of a regular connection</td>
<td>Right-click the connection.</td>
</tr>
</tbody>
</table>

![Diagram of connection attributes](image)
<table>
<thead>
<tr>
<th>To view</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Available for application services discovered with Service Mapping) The source and target CIs for a merged connection</td>
<td>Right-click the merged connection line with a number and select the relevant connection.</td>
</tr>
</tbody>
</table>

- Right-click the merged connection line with a number and select the relevant connection.

Or

- If a segment of a connection line is shared by more than one merged connections, there is no indication that it is a merged line.

Right-click the connection line coming out or going into a CI, and select the relevant connection.
<table>
<thead>
<tr>
<th>To view</th>
<th>Do this</th>
</tr>
</thead>
</table>
| The source and target CIs for a connection if the spanning tree view is enabled. The spanning tree view simplifies an application service map concealing most of the connection lines. | 1. Click the CI whose connections you want to view. All concealed connections for this CI appear on the map.  
2. Right-click the relevant connection line. |
| Detailed attributes of a regular connection in the Properties pane      | Click the connection line.                                                                                                               |
To view

(Available for application services discovered with Service Mapping)
Detailed attributes of a merged connection in the Properties pane.

Do this

Click the merged connection line indicated by a number.
All underlying connections are displayed separately in the Properties pane.
<table>
<thead>
<tr>
<th>To view</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td>Detailed attributes of a connection segment shared by more than one merged connection in the <strong>Properties</strong> pane.</td>
<td>Right-click the connection line coming out or going into a CI, select the relevant connection, and then choose <strong>Select edge</strong>.</td>
</tr>
</tbody>
</table>

The detailed attributes are displayed in the **Properties** pane.

**Note:** Shared segments do not have an indication that it is a merged line.
<table>
<thead>
<tr>
<th>To view</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Available for application services discovered with Service Mapping) Detailed properties of a connection in the <strong>Properties</strong> pane, when the spanning tree view is enabled. The spanning tree view simplifies an application service map concealing most of the connection lines.</td>
<td>1. Click the CI whose connections you want to see. All concealed connections for this CI appear on the map. 2. Click the required connection line.</td>
</tr>
</tbody>
</table>
To view Traffic-based connections for a CI.

1. Right-click the CI whose traffic-based connections you want to check.
2. Select Show traffic based connections.
   The Traffic Based Connections List opens displaying the information in Traffic Based Connections List table.
3. Click Close when finished viewing this list.

Note: You can see traffic-based connections for a CI, even if you disabled the traffic-based discovery for an application service the CI is part of.

Manually added connection.
You can either add a connection or a CI manually. In both cases, the connection you manually add an entry point to the next tier of the application flow.

Click the manually added connection.
The Properties pane shows Manual Endpoint under Endpoint Type.

Traffic Based Connections List

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP</td>
<td>The IP address of the application connected to the selected CI.</td>
</tr>
<tr>
<td>Port</td>
<td>The port on the selected CI that is used to communicate to the other application.</td>
</tr>
</tbody>
</table>
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Process</td>
<td>The ID of the process in the selected CI.</td>
</tr>
</tbody>
</table>
| Already on map         | - **Yes** — if this connection shows on the map.  
- **No** — if this connection is not part of the application service and not on the map.                                                   |
| System decision        | The setting defines if Service Mapping keeps the discovered traffic-based connection or removes it. The value comes from the algorithm that Service Mapping uses. |
| User decision          | (Optional) The setting overrides the System decision setting, which defines if Service Mapping keeps the discovered traffic-based connection or removes it. For example, if the System decision setting for a connection is Keep, and you want to remove this connection, select **Remove**. |

### View the change history of application services

You can view changes made to an application service as a whole and to the individual configuration items (CIs) comprising the service. Change history is useful for maintenance, planning, or troubleshooting procedures.

Role required: admin, sm_admin, sm_user, app_service_admin, or app_service_user

Details about changes to an application service and to its CIs is stored in the CMDB. Typically, these changes reflect adding or removing CIs from an application service, upgrading or updating CIs, or modifying CI configuration files. The system gathers this data by querying CMDB tables and then creating the change history view. In deployments where Service Mapping is activated, the type of change information Service Mapping queries depends on discovery patterns that Service Mapping uses to discover CIs.

Changes to configuration files are associated with CIs to which these files belong. Maps show configuration file changes as changes to related CIs.

While you can see change records for a specific CI in the context of application services, you can also see detailed history of a specific CI separate from its application service as described in [History Timeline](#).

If the Now Platform is configured to validate changes, all changes are evaluated and rendered as valid or not. If a change is valid, its change record on the application service map is marked as approved. For more information about configuring the platform for change validation, see [Managing proposed changes](#).

Changes to the application service appear on the history timeline.
The type of change mark depends on the nature of changes that it represents:

- **Light gray balloon**
  Unapproved change that does not influence the application service behavior. For example, a change in a network path or adding a node to a cluster.

- **Dark gray balloon**
  Unapproved change that changes the application service behavior.

- **Green balloon**
  An approved change in deployments where the Now Platform is configured to validate changes.

- **Double balloon**
  Multiple separate changes that happened a short time from each other.

You can mark times on the history scale by creating baselines to quickly return to the marked view.

The following user interface screens refer to application services as business services: Business Service Group Responsibilities, Approve, Service Mapping Properties, and Service Map Planner.

1. Navigate to **Configuration > Application Services > Application Services**.
2. Alternatively, if Service Mapping is deployed, navigate to **Service Mapping > Services > Application Services**.
3. Click **View map** for the application service for which you want to see change history. Actions or map elements which are relevant only for application services discovered by Service Mapping, do not appear on maps for manually created application services.
4. On the history timeline, set the time range of changes that you want to view.

<table>
<thead>
<tr>
<th>Option</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>To set the time range of the history timeline</td>
<td>Click the hour, day, week, or month icons.</td>
</tr>
<tr>
<td>Option</td>
<td>Action</td>
</tr>
<tr>
<td>---------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>To increase or decrease the time range</strong></td>
<td>Click the zoom in and zoom out icons.</td>
</tr>
<tr>
<td><img src="image" alt="Zoom in and zoom out icons" /></td>
<td><img src="image" alt="Zoom in and zoom out icons" /></td>
</tr>
<tr>
<td><strong>To change the upper limit on your history range</strong></td>
<td>Click the history scale.</td>
</tr>
<tr>
<td><img src="image" alt="History scale" /></td>
<td><img src="image" alt="History scale" /></td>
</tr>
</tbody>
</table>

The time that serves as the upper limit appears above the history timeline.

**Note:**
You cannot set the lower limit on your history range to a time before this application service was created. This time is marked with the IT Service Created event on the history timeline.

The map shows the history view of the application service for the time you selected.

**Note:** The Change tab shows all change records, even the ones which are filtered out of the history view.

5. To mark a time on the time scale, set a baseline:
   a) Click the Compare icon.
   b) Navigate to the time you want to mark as a baseline on the history scale.
   c) Click Set baseline.
d) Enter the name of the baseline and click **OK**.
The new baseline appears as a button above the history scale and as a blue flag on the history scale.

6. View the change history:
Option | Action
--- | ---
To see the CI responsible for a change record | Select a change record on the Changes tab. The related CI is marked yellow in the map.
<table>
<thead>
<tr>
<th>Option</th>
<th>Action</th>
</tr>
</thead>
</table>
| **To see only change records related to a CI** | Select the required CI or the connection on the map.  

The Changes tab displays only change records related to the selected CI or connection. |

| **To see the configuration file at the selected moment in the past** | 1. Set the time on the history scale.  
2. In the Properties pane, scroll to Tracked Configuration Files, and click the file name.  

The new tab opens displaying the content of the tracked configuration file at the selected time. |
To see network at the selected moment in the past

1. Set the time on the history scale.
2. Right-click the connection and select Show network path.

The new tab opens displaying the network or storage path map for the time you selected.

Note: You cannot view the network path for connections marked as boundaries to this application service.

7. To exit the history view and see the current status of the application service, click the current icon.

**Compare two versions of an application service**

You can see a summary of application service changes at a glance by comparing two versions of an application service. This feature is useful for checking the application service status before and after a certain change or problem.

Role required: admin, app_service_admin, app_service_user, sm_admin, or sm_user

Specify two points in time for which to compare the two versions of an application service. You can use the change indicators on the timeline to specify one point in time that is before and another that is after a change for which to see the details. For example, if you know that the application service started to fail at a certain time, you can compare two versions of the application service, one before and one after the problem started. This comparison lets you see the summary of changes that possibly led to the problems.

Service Mapping, if deployed, tracks and shows all changes to a CI including configuration files associated with a CI. When you compare two versions of an application service, you can see changes made to configuration files as changes to CIs. You can also compare two versions of a configuration file to see the actual changes in the files, during the time range specified for the comparison.

The following user interface screens refer to application services as business services: Business Service Group Responsibilities, Approve, Service Mapping Properties, and Service Map Planner.

1. Navigate to Configuration > Application Services > Application Services.
2. Alternatively, if Service Mapping is deployed, navigate to Service Mapping > Services > Application Services.
3. Click View Map next to an application service.
4. On the history timeline, set the time range of changes that you want to view.

<table>
<thead>
<tr>
<th>Option</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>To set the time range of the history timeline</td>
<td>Click the hour, day, week, or month icons.</td>
</tr>
<tr>
<td>Option</td>
<td>Action</td>
</tr>
<tr>
<td>---------------------------------------------</td>
<td>--------</td>
</tr>
<tr>
<td>To increase or decrease the time range</td>
<td>Click the zoom in and zoom out icons.</td>
</tr>
<tr>
<td>To change the upper limit on your history range</td>
<td>Click the history scale.</td>
</tr>
</tbody>
</table>

The time that serves as the upper limit appears above the history timeline.

**Note:**
You cannot set the lower limit on your history range to a time before this application service was created. This time is marked with the IT Service Created event on the history timeline.

The map shows the history view of the application service for the time you selected.

**Note:** The Change tab shows all change records, even the ones which are filtered out of the history view.

5. Click the Compare icon.

6. Set **Compare point 1** and **Compare point 2** as the two points in time for the comparison.

You can drag the pointers on the history scale to set corresponding time points.
If the history scale does not include the time set for comparison, then its corresponding pointer appears next to the compare point in yellow:

![Image of history scale with yellow pointer]

**Note:** If there are no changes to the service during the time interval specified by **Compare point 1** and **Compare point 2**, then no change details are displayed.

7. **Click Compare.**  
   The comparison view opens in a separate tab.
8. **Select a marked CI to see the relevant change record on the Changes tab.**
9. Optional: If Service Mapping is deployed, you can compare two versions of a configuration file that appears on the map as Updated:
   a) Select the CI that is associated with the updated configuration file.
   b) In the Properties pane, click the link to the updated file.
The **Tracked Configuration Files Version Compare** tab opens showing two versions of the configuration file side by side.

c) **Review actual changes.**

Highlight colors indicate the type of change:
- Purple — Updated line
- Pink — New line
- Gray — Deleted line

d) **Navigate between the changes using the arrows in the upper right corner.**

e) **Close the Tracked Configuration Files Version Compare** tab when finished.

10. Close the comparison view when finished.
Check CI dependencies

You can see if a particular configuration item (CI) is part of other application services and check if it depends on other CIs.

Role required: admin, app_service_admin, app_service_user

While Service Mapping shows position of a CI in a particular application service, your organization may also use the same CI in other application services. If you are planning to perform changes to this CI, make sure that the changes do not affect other application services.

The following user interface screens refer to application services as business services: Business Service Group Responsibilities, Approve, Service Mapping Properties, and Service Map Planner.

1. In the map, right-click the relevant CI and select **Open dependency views**.
   The Dependency Views page opens in the new tab showing the selected CI in the center.

2. Click **Details**.

3. Click the **Related Services** tab.
   The list of links to application services containing this CI appear on the **Related Services** tab.

4. To view the map of another business service containing this CI, click the relevant link.

View network or storage path

You can drill down to see objects behind a connection on a map for troubleshooting service performance or maintaining your network. This feature is not available for manually created services or for services on instances using Edge Encryption.

Role required: admin, sm_admin or sm_user

Displaying a network or storage path allows you to see routers, switches, and host ports which are part of the connection. The following connection types exist:

**Network path**

The infrastructure route between two CIs of the host type.

**Storage path**

The infrastructure route between a CI of the host type and a CI of the storage type.

Service Mapping discovers and displays network devices located on your organization local network, not on WAN or the public cloud. When Service Mapping encounters a connection between two applications, it uses traceroute on the source host to figure out the path to the target host. Then Service Mapping use SNMP credentials to discover the devices it found on the path.

Service Mapping can show devices for storage paths using the following protocols:

- Fiber Channel: Storage Area Network (SAN)
- IP Ethernet: Internet Small Computer Systems Interface (iSCSI) or Network Attached Storage (NAS)

**Note:** For storage paths using Fiber Channel, Service Mapping does not display Fiber Channel switches.
Between a host CI and a storage CI there may be two separate storage paths using different protocols: Fiber Channel and IP Ethernet. If so, the application service map displays one connection line for both protocols.

You can see the change history for network and storage paths for application services. Checking path history for manual or technical services is not supported.

1. Navigate to **Service Mapping > Services > Application Services** and click **View map** next to the relevant application service.
2. Alternatively, navigate to **Event Management > Dashboard** and double-click an application service.
3. On the map, right-click the connection for the network or storage path you want to see.
4. Select **Show network path** or **Show storage path**.
5. If necessary, select the type of protocol and click **Choose** in the Choose Protocol Type dialog box.
   The view showing the network or storage path opens in a new tab.

If Service Mapping cannot discover all objects in a connection, the connector line on the network or storage path appears dotted as shown above.

6. For storage paths, use the Storage Mapping tab at the bottom of the screen to view correlation between file systems on the host and the storage volume or the shared folder on the storage device.
7. To view the change history for network paths, perform steps in **View the change history of application services**.
8. If you access the network or storage path map from Event Management, you can see the list of alerts related to this path appear at the bottom of the screen.
Convert application service maps into PDFs

You may want to create a PDF for a map to share information about the service content with other people. PDFs are especially useful during the review and approve process for application services discovered by Service Mapping.

Role required: app_service_admin, app_service_user

The PDF of an application service map shows the name of the application service and the exact time when this PDF was created.

1. Navigate to Configuration > Application Services > Application Services.
2. Alternatively, if Service Mapping is deployed, navigate to Service Mapping > Services > Application Services.
3. Click View map next to the relevant application service.
4. Click the Additional actions menu.

5. Click the button next to the Export to PDF option.
6. When the PDF is ready, click the **Download PDF** button in the Export Map into PDF Format dialog box.
   The PDF appears in the downloads folder on your computer.

**Modify view for an application service map**

Customize a map view to exclude irrelevant information and increase clarity.

Role required: app_service_admin, app_service_user, sm_admin, or sm_user

By default, service maps are concise and contain every detail about all CIs that you added manually or Service Mapping mapped. While it provides a complete picture, using such a map might be difficult.

Customizing maps allows you to:
- make it easier to navigate the map.
- hide irrelevant information.
- show essential information.
Attributes you show or hide when you customize maps are not removed permanently and can be displayed or hidden again as you need. The system saves the changes to the map view and displays the last map view when you reopen an application service.

The following user interface screens refer to application services as business services: Business Service Group Responsibilities, Approve, Service Mapping Properties, and Service Map Planner.

1. Navigate to Configuration > Application Services > Application Services.
2. Alternatively, if Service Mapping is deployed, navigate to Service Mapping > Services > Application Services.
3. Click View map next to the relevant application service.
4. Click the Additional actions menu.

5. Select the relevant option:
<table>
<thead>
<tr>
<th>Option</th>
<th>When Enabled</th>

Map indicators
This option is available only for users with these roles: Service user ([app_service_user]) and Service Mapping user ([sm_user]).

Display additional information for a CI or application service itself by displaying related records such as alerts, outages, incidents, and problems.

The base system provides map indicators for the following record types:

- Affected CIs
- Open alerts
- Current, planned, or recent change requests
- Open incidents
- Current, planned, or recent outages
- Open problems

For more information, see [Event Management Map Indicators (Video)](https://www.servicenow.com/servicenow).

**Advanced Service Mapping configuration**

Fine-tune Service Mapping collaboration with other components and modules as well as customize data display in application service maps.

In addition to the basic setup described in [Service Mapping setup](#), you can perform optional configurations to meet the needs of your organization.

**Enable traffic-based discovery for CI types or specific CIs**

Service Mapping can discover and map CIs by detecting the inbound and outbound traffic that the CIs generate. Create a traffic-based discovery rule to determine which configuration items are available for traffic-based mapping.

If your ServiceNow instance uses domain separation and you have access to the global domain, select the domain to which the application service belongs from the domain picker. The selected domain must be a domain without any child domains.

Role required: sm_admin

- Ensure that the traffic-based discovery is enabled at the Service Mapping product level: navigate to **Service Mapping > Administration > Properties** and verify that the **Traffic based discovery** check box is selected.
- Enable traffic-based discovery for a specific application service as described in **Map a single application service**.

You may choose to use traffic-based discovery and mapping in addition to the pattern-based mapping.

You can create rules to configure Service Mapping to use traffic-based discovery for certain CIs. You can configure traffic-based discovery rules to monitor specific CIs or types of CIs.

Rules for specific CIs take precedence over rules for CI types. For example, if you do not want to use traffic-based discovery on any Tomcat servers, you can define a **CI type** rule disabling the traffic-based discovery on the Tomcat table. At the same time, you can create a discovery rule enabling the traffic-based discovery for a specific Tomcat server. In that case, Service Mapping uses the traffic-based discovery only for this specific Tomcat server out of all Tomcat servers.
If you used both pattern-based and traffic-based mapping for an application service, its map displays CIs and hosts that Service Mapping discovered using both methods. While detecting CI inbound and outbound traffic creates a very inclusive map, it may also result in mapping many redundant CIs that do not influence the application service operation.

If your instance uses domain separation, you can create traffic-based rules for specific domains. Rules in the base system are assigned to the global domain and apply to all domains of all levels.

When you create a rule for a specific domain, the new rule is used only for this domain and does not exist in any other domains. If you customize an existing rule in the global domain and assign it to a specific domain, you create a copy of the global rule, which is still used in all other domains except the domain that has the customized version of this rule. Likewise, if you customize a rule in the global domain, the change affects all domains except the one that uses a customized copy of this rule.

1. Navigate to **Service Mapping > Administration > Traffic Based Discovery**.
2. Click **New**.
3. Define the rule parameters as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Action</strong></td>
<td>Select <strong>Enable</strong> to add traffic-based connections to the specific CI or CI Type.</td>
</tr>
<tr>
<td><strong>Rule Scope</strong></td>
<td>Select <strong>Specific CI</strong> to detect traffic for one configuration item, or select <strong>CI Type</strong> to detect traffic for all configuration items in one of the CI-based table.</td>
</tr>
<tr>
<td><strong>CI/CI Type</strong></td>
<td>Select a specific CI, or select the table that contains the CIs for which you want to detect traffic.</td>
</tr>
<tr>
<td><strong>Domain</strong></td>
<td>Select the domain to which the rule belongs.</td>
</tr>
</tbody>
</table>

4. Click **Submit**.
5. To fine-tune traffic-based discovery, define advanced parameters as follows:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| **sa.traffic_based_discovery.conn_aging_time** | Time period in hours for a Traffic Based Connection to remain active since last discovered.  
  - **Type**: integer  
  - **Default value**: 72  
  - **Other possible values**: any number higher than 24  
  - **Location**: Service Mapping > Administration > Properties. |
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sa.traffic_based_discovery.ignored_ports</td>
<td>Ports to ignore when found by traffic-based discovery. This property is available in the System Property (sys_properties) table. Change this property to define ports that Service Mapping ignores while performing traffic-based discovery. It makes discovery more efficient since resources are not wasted on discovering irrelevant connections.</td>
</tr>
</tbody>
</table>
| | · **Type**: string  
| | · **Default value**: 445, 139, 111, 2049, 860, 3260, 135, 53  
| | · **Other possible values**: any relevant port numbers  
| | · **Location**: System Property (sys_properties) table |
| sa.traffic_based_discovery.max_connections | Maximum number of traffic-based connections from a single CI. This property is available in the System Property (sys_properties) table. This property helps to keep the map size reasonable by limiting the number of possible CI connections. |
| | · **Type**: integer  
| | · **Default value**: 30  
| | · **Other possible values**: any number higher than 1  
| | · **Location**: System Property (sys_properties) table |

### Configuration file tracking

The horizontal discovery process can find configuration files that belong to certain applications and add those configuration files to the CMDB. You can track the changes to these files by comparing them to previous versions.

**Warning**: Configuration files contain sensitive system information. To prevent unauthorized access, ensure that access control lists (ACL) are placed on the Tracked Configuration file table (cmdb_ci_config_file_tracked). Only allow authorized users to view this table or uncheck the **Save Content** setting.

### Components for configuration file tracking

#### CI type

All applications and hosts in your organization must have a corresponding configuration item (CI) type, which is necessary for discovering and processing applications and hosts correctly. In a base system, many CI types have configuration file paths defined for them. You can add
new or modify existing definitions for tracking configuration files. See Modify tracking changes in configuration files for instructions.

**Patterns**

Configuration file tracking is available for patterns that discover applications. On the pattern, you can create tracked file definitions that specify the CI type to which the application CI belongs and the path of the configuration file. Specify as many tracked file definitions as needed. You can also specify whether you want to save the contents of configuration files so you can view and compare the contents of different versions.

**Note:**

Configuration file tracking is not available for discoveries performed by traditional probes and sensors. The classifier that triggers the pattern must specify the Horizontal Pattern probe, which in turn, must specify the pattern. If you upgrade your instance to the current version, not all classifiers are configured to use patterns for discovery by default.

**CMDB**

All configuration files are saved as a CI in the Tracked Configuration file (cmdb_ci_config_file_tracked) table. If you enable the content to be saved, these CI records provide the contents of the configuration files, including previous versions. From the configuration file CI record, you can compare different versions.

**Dependency maps and application service maps**

Both dependency maps and application service maps display tracked configuration files. The relationship between a configuration file and its host is a contains relationship. The application contains the configuration file.

For example, this IIS web server contains three tracked configuration files:

![Dependency map diagram]

Sometimes you organize CI types as a main CI type and its related CI types. On an application service map, Service Mapping shows changes to configuration files of related CIs for the main CIs in inclusions. In inclusions, the system treats applications hosted on a server as independent objects. For example, the Tomcat WAR CI appears separate from its host, the Tomcat CIs. In this case, Service Mapping shows changes to configuration files of Tomcat WAR when you select
Tomcat. In addition, Service Mapping displays changes to configuration files of the hardware server hosting inclusions. In this example, it is a Linux server:

**Deletion strategy**

You can specify what you want to do with tracked configuration file CI records when discovery can no longer find them. You can keep the configuration file CI record, automatically delete it, delete only the CI relationships to it, or mark it absent.

**Discovery patterns that support configuration file tracking by default**

These patterns provide tracked file definitions by default:

<table>
<thead>
<tr>
<th>Classifier</th>
<th>Pattern</th>
<th>CI Type</th>
<th>File path of tracked file</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Apache Server</strong></td>
<td>Apache On Unix Pattern</td>

</table>

## What to do

1. **Enable configuration file tracking by setting the glide.discovery.enable_file_tracking Discovery property to true.**

   You can also configure other properties to control the size and number of tracked configuration files, the time window during which changes to configuration files are tracked for a given version, and the number of changes allowed on a configuration file during that time window. See [Discovery properties](https://servicenow.com) for details.

2. **To prevent unauthorized access to the sensitive information from configuration files, perform the following steps:**

   a. Ensure that access control rules (ACL) are placed on the Tracked Configuration file table (cmdb_ci_config_file_tracked). Only allow authorized users to view this table or uncheck the Save Content setting.

   b. Ensuring that the tracked_file_reader role that controls access to configuration file data is assigned to correct users and user groups. By default, the itil role contains the
tracked_file_reader role giving all users with the itil role access to the configuration file information.

3. Verify that the Horizontal Discovery probe is active on the classifier for the software that you want to discovery. If not, you can enable it, specify the pattern, and then disable the other probes. See Add the Horizontal Pattern probe to a classifier for instructions.

4. Add or modify tracked file definitions to change the CI type or file path.

5. Set the tracked files deletion strategy to specify what you want to do with tracked configuration file CI records when pattern discovery can no longer find them.

6. Run horizontal discovery on the hosts that are running the applications you want to discover with patterns, open the application CI record, and check the Tracked Configuration Files related list.

7. Compare two versions of tracked CI configuration files to see the actual changes made to them.

Modify tracking changes in configuration files

Configure the system to collect information about changes in configuration files belonging to a configuration item (CI). Service Mapping uses this information to notify users that CI configuration files changed and to view actual changes to configuration files directly in the application service maps.

Role required: cloud_admin, sm_admin or admin

To enable tracking configuration files for a CI for which the system does track files, configure classification for the CI type to which this CI belongs:

- For CI types representing applications, create a Discovery process classification for the relevant pattern. Add the Horizontal Pattern probe in the Probe column, and then specify your pattern in the Pattern column.
- For CI types representing SNMP devices, perform configuration as described in Create a Discovery CI classification.

Note: There is no need to create CI classifications for hosts because these classifications are included in the base system.

The system tracks configuration files as part of horizontal discovery process of a CI to which these files belong. Configuration files contain CI settings and parameters. Service Mapping uses this information to notify users that CI configuration files changed and to view actual changes to configuration files directly in the application service maps. To learn about how the system tracks configuration files, stores and updates information about these files, see Configuration file tracking.

The system tracks configuration files for CI types with process classifiers that trigger patterns. The patterns contain tracked file definitions, which specify the CI type that the application belongs to and the path of the configuration file. Several patterns, such as the IIS pattern, provide tracked file definitions by default. You can use these default definitions or create your own for any pattern a process classifier triggers.

1. Navigate to Pattern Designer > Discovery Patterns.
2. Click the pattern for the relevant CI.

Attention: Enabling configuration file tracking does not modify the contents of a pattern.

3. Click the Tracked Files tab.
One or more tracked file definitions appear by default for Discovery patterns that support configuration file tracking.

If you do not see the Tracked Files tab, verify that the pattern is specified process classier. See Add the Horizontal Pattern probe to a classifier for instructions.

4. Click Edit to modify an existing definition or click New to create a new one.
5. Fill out or modify the form fields (see table):
Tracked File Definition

Define the file path for the selected CI type. File path consists of CI attributes in variable or wildcard format. For example, $install_directory+/conf/*.xml

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CI Type</td>
<td>Select either the primary or related CI type to which the configuration file belongs.</td>
</tr>
<tr>
<td>File Path</td>
<td>Define the path of the configuration file to track. You can use pattern variables and wildcards. For example, for the following path: &lt;the folder with the &quot;install_directory&quot; parameter&gt;/conf/&lt;any xml file&gt;, enter $install_directory+/conf/*.xml</td>
</tr>
<tr>
<td>Save Content</td>
<td>Select this check box to make this file available for viewing and comparing directly the ServiceNow instance.</td>
</tr>
<tr>
<td>Active</td>
<td>Select this check box to enable tracking of this configuration file.</td>
</tr>
</tbody>
</table>

Example tracked file definition for IIS Server discovery

6. Click Done.
7. If necessary, set the tracked files deletion strategy as described in Set the deletion strategy for tracked configuration files

Run discovery on the hosts that are running the applications you want to discover with patterns, open the application CI record, and check the Tracked Configuration Files related list.
If you are using Service Mapping, verify that it started collecting information about changes to configuration files:

1. Navigate to the application service map containing the CIs.
2. On the Changes tab, check that the list includes a record of the change you made. For example, that the configuration file was added, modified or deleted.
Data collection and discovery using Netflow

Service Mapping can perform discovery based on data collected using the Netflow protocol. Netflow is a protocol that Service Mapping can use to collect data about CIs and their connections along with Netstat and lsof commands.

Using the Netflow protocol for collecting data is one of the traffic-based discovery methods. Other methods deployed by Service Mapping are using netstat and lsof commands and the VPC Flow Logs. For more information, refer to Traffic-based discovery in Service Mapping.

In base systems, traffic-based discovery uses only TCP-related data collected with the help of the netstat and lsof commands. Discovery based on Netflow and VPC logs requires additional configuration. You can enrich your traffic-based discovery by configuring Service Mapping to use the Netflow protocol.

The component, which receives data in the Netflow format is the Netflow Collector. Its location depends on whether you configure data collection for testing purposes or standard operation:

For the test purposes

This setup results in half automated data collection flow, where Service Mapping imports data only if you manually copy it from the Netflow Collector. You place the Netflow Collector on a server inside your organization network. This must be a server different from the server hosting the MID Server. You configure and test this setup as described in Configure onetime data import using Netflow for testing purposes.

For standard operation

This setup results in fully automated data collection flow, where all involved components send, collect and analyze data automatically. You place the Netflow Collector on the same server as the MID Server inside your organization network. For instructions, see Configure data collection using Netflow.

Netflow-based discovery has the following flow:

1. The Netflow daemon runs and receives data from switches communicating with servers in the organization. The Netflow Collector writes received data from the Netflow daemon.

2. The server, hosting the Netflow collector, uses the Netflow nfdump utility to write the data into the nfdump output file. This file summarizes the raw data on all switches used for server communication.
3. In testing setups, where the Netflow Collector is located not on the same server as the MID Server, you may need to convert the nfdump into the gzip format. Then you must manually copy the raw data in the nfdump output file onto the MID Server.
4. The MID Server processes the raw data in the nfdump output file and places the processed information onto the ECC queue.
5. A sensor retrieves the processes data from the ECC queue and writes it into the Flow Connection (sa_flow_connection) table.

6. Whenever Service Mapping checks the ECC queue and receives information on a discovered CI, it checks these tables for any data on outbound connections related to the CI: the cmdb_tcp and sa_flow_connection tables. If these two tables contain unique data that patterns did not discover, Service Mapping enriches the information about the CI connections and adds them to the map.
Configure onetime data import using Netflow for testing purposes

Configure and test Service Mapping discovery process based on data collected using the Netflow protocol.

Learn about Traffic-based discovery in Service Mapping.

Role required: admin or sm_admin

In base systems, traffic-based discovery uses only TCP-related data collected with the help of the netstat and lsot commands. Discovery based on Netflow and VPC logs requires additional configuration. You can enrich your traffic-based discovery by configuring Service Mapping to use the Netflow protocol. For more information about the way Service Mapping to collect Netflow data, see Data collection and discovery using Netflow.

For testing purposes, install the Netflow Collector (nfdump) on a Unix server inside your organization. In this case, this Unix server should be different from the server hosting the MID Server server.

Configure the ServiceNow connector to trigger MID Server to collect the data from the flow log and processes it.

1. Download and install the Netflow collector (nfdump) on a Unix or Ubuntu server inside your organization.
   - For a Linux server, download, compile, and install the nfdump package. You can download the nfdump package from https://sourceforge.net/projects/nfdump/.
   - For an Ubuntu server, install the nfdump package without predownloading or compiling it. Open the command-line window and run the following command:
sudo apt-get install nfdump

For an Ubuntu server, if the `apt-get` command fails, predownload the nfdump package, save it locally and then install it. Open the command-line window and run the following commands:

```
sudo dpkg -i nfdump_1.6.15-3_i386.deb
sudo apt-get -f install
```

**Note:** The file name for the nfdump package has the following format: `nfdump_<version number> .deb`. In this example it is `nfdump_1.6.15-3_i386.deb`.

2. Configure the Netflow collector to save data for one day:
   a) Open the command-line window on the server hosting the Netflow collector.
   b) Create a cron job by using the following command:
      ```
crontab -e
      ```
   c) Enter the following command using the correct paths:
      ```
      */10 * * * * /usr/local/bin/nfexpire -e /data/nfdump -t 1d
      ```

3. Create a file with the nfdump data. For example, use the following command:
   ```
nfdump -q -m -R /data/nfdump/ -o extended -t 2016/07/06.07:00:00-2016/07/06.07:10:00 ©inet and proto tcp© >> /tmp/my_file
   ```

4. If the file is very large, you can compress it using the gzip format. Use the following command:
   ```
gzip /tmp/my_file
   ```

5. Copy the nfdump data file to the MID Server.

6. Configure Service Mapping to receive data collected by the Netflow collector:
   a) Navigate to Service Mapping > Administration > Flow Connectors.
   b) Click New.
   c) Click ndfdump file.
   d) On the ndfdump file page, configure parameters as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A descriptive name for the connector.</td>
</tr>
<tr>
<td>nfdump data path</td>
<td>The path to a location on the MID Server to which you saved the nfdump data</td>
</tr>
<tr>
<td>MID Server</td>
<td>The MID Server, onto which you copied the nfdump file.</td>
</tr>
<tr>
<td>Gzipped file</td>
<td>If you converted the nfdump file into the gzip format before saving it on</td>
</tr>
<tr>
<td></td>
<td>the MID Server, set this parameter to true to unzip it.</td>
</tr>
</tbody>
</table>

   e) Click Submit.

7. Verify that Service Mapping collects data using Netflow:
   a) On the nfdump file form, select the newly configured connector and click Run now to start the data collection flow and populate the Flow Connection (sa_flow_connection) table.
b) Navigate to **System Definitions > Tables**.

c) Click the Flow Connection (sa_flow_connection) table.

d) Under **Related Links**, click **Show List**.

e) Verify that the table contains data.

If you are satisfied with the results of the test, configure Netflow-based data collection as described in [Configure data collection using Netflow](#).

**Configure data collection using Netflow**

Enable Service Mapping to perform discovery based on data collected using the Netflow protocol. This setup results in fully automated data collection flow, where all involved components send, collect, and analyze data automatically.

Learn about [Traffic-based discovery in Service Mapping](#).

**Role required:** admin or sm_admin

In base systems, traffic-based discovery uses only TCP-related data collected with the help of the netstat and lsof commands. Discovery based on Netflow and VPC logs requires additional configuration. You can enrich your traffic-based discovery by configuring Service Mapping to use the Netflow protocol. For more information about the way Service Mapping uses Netflow, see [Data collection and discovery using Netflow](#).

Configure the ServiceNow Netflow connector to trigger the MID Server to collect the data from the Netflow flows and process them.

1. Install the nfdump package on a server hosting the MID Server in your organization:
   - For a Linux server, download, compile, and install the nfdump package. You can download the nfdump package from [https://sourceforge.net/projects/nfdump/](https://sourceforge.net/projects/nfdump/).
   - For an Ubuntu server, install the nfdump package without predownloading or compiling it.
     
     Open the command-line window and run the following command:
     
     ```
     sudo apt-get install nfdump
     ```
     
   - For an Ubuntu server, if the `apt-get` command fails, predownload the nfdump package, save it locally and then install it. Open the command-line window and run the following commands:
     
     ```
     sudo dpkg -i nfdump_1.6.15-3_i386.deb
     sudo apt-get -f install
     ```

   **Note:** The file name for the nfdump package has the following format: `nfdump_<version number>`. deb. In this example it is `nfdump_1.6.15-3_i386.deb`.

2. Configure the Netflow collector to save the nfdump file in the required directory.
   
   a) Open the `/etc/init.d/nfdump` file.
   
   b) Modify the parameter responsible for saving this file in the required location.
     
     For example, on an Ubuntu server, specify the location using the `DEAMON_ARGS` parameter:
     
     ```
     DATA_BASE_DIR="/var/cache/nfdump"
     DAEMON_ARGS="-D -l $DATA_BASE_DIR -P $PIDFILE"
     ```

     For operational information, refer to [https://sourceforge.net/projects/nfdump/](https://sourceforge.net/projects/nfdump/).
3. Configure the switches to forward their nfdump files to the MID Server. The default value for the MID Server is port 9995.

4. Configure the Netflow collector to save data for one day:
   a) Open the command-line window on the server hosting the Netflow collector.
   b) Create a cron job by using the following command:
      ```
      crontab -e
      ```
   c) Enter the following command using the correct paths:
      ```
      */10 * * * * /usr/local/bin/nfexpire -e /data/nfdump -t 1d
      ```

5. Verify that the Netflow collector is configured correctly and receives the correct data from the network resources.
   a) Run the following command:
      ```
      nfdump -q -O tstart -R /data/nfdump/ -o extended
      ```
   b) In the command output, verify that marked fields contain real data:

6. Configure Service Mapping to receive data collected by the Netflow collector:
   a) Navigate to Service Mapping > Administration > Flow Connectors.
   b) Click New.
   c) Click nfdump install.
   d) On the nfdump install page, configure parameters as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A descriptive name for the connector.</td>
</tr>
<tr>
<td>MID Server</td>
<td>The MID Server on which you installed the Netflow collector.</td>
</tr>
<tr>
<td>nfdump data directory</td>
<td>The data directory where you configured the Netflow collector to save the nfdump files.</td>
</tr>
</tbody>
</table>

   e) Click Submit.

7. Verify that Service Mapping collects data using Netflow:
   a) On the nfdump install form, select the newly configured connector and click Run now to start the data collection flow and populate the Flow Connection (sa_flow_connection) table.
   b) Navigate to System Definitions > Tables.
   c) Click the Flow Connection (sa_flow_connection) table.
   d) Under Related Links, click Show List.
e) Verify that the table contains data.

**Data collection and discovery using VPC Flow Logs**

Service Mapping can perform discovery based on data collected using VPC Flow Logs. Amazon VPC hosts Amazon Elastic Compute Cloud (EC2) instances that provide Amazon Web Services. VPC Flow Logs collect data on IP traffic going to and from network interfaces in the VPC.

In base systems, traffic-based discovery uses only TCP-related data collected with the help of the `netstat` and `lsof` commands. Discovery based on Netflow and VPC logs requires additional configuration. You can enrich your traffic-based discovery by configuring Service Mapping to use VPC Flow Logs.

Service Mapping discovery based on VPC Flow Logs has the following flow:

1. Amazon EC2 instances collect their individual logs into log streams and forward them to the central flow log group.

2. The ServiceNow connector triggers MID Server to collect the data from the flow log and processes it.

3. The MID Server places the processed information onto the ECC queue.
4. A sensor retrieves the processes data from the ECC queue and writes it into the Flow Connection (sa_flow_connection) table.

5. Whenever Service Mapping checks the ECC queue and receives information on a discovered CI, it checks these tables for any data on outbound connections related to the CI: the cmdb_tcp and sa_flow_connection tables. If these two tables contain unique data that patterns did not discover, Service Mapping enriches the information about the CI connections and adds them to the map.
In deployments with multiple flow log groups, configure a dedicated connector that works with one MID Server for every flow log group. Multiple flow log groups may use the same AWS credentials.

**Configure data collection using VPC Flow Logs**
Enable Service Mapping to perform discovery based on data collected using Virtual Private Cloud (VPC) logs. This method is relevant for organizations using Amazon Web Services (AWS).

Verify that credentials for the AWS account are configured in the Credentials module of the platform by navigating to **Service Mapping > Credentials > AWS Credentials**. For more information about AWS credentials, see [Cloud credentials](#).

Role required: admin or sm_admin

In base systems, traffic-based discovery uses only TCP-related data collected with the help of the `netstat` and `lsof` commands. Discovery based on Netflow and VPC logs requires additional configuration. You can enrich your traffic-based discovery by configuring Service Mapping to use VPC Flow Logs. For more information about the Service Mapping discovery flow based on VPC Flow logs, see [Data collection and discovery using VPC Flow Logs](#).

Amazon VPC hosts Amazon Elastic Compute Cloud (EC2) instances that provide Amazon Web Services. VPC flow logs collect data on IP traffic going to and from network interfaces in the VPC.

Configure the ServiceNow connector to trigger MID Server to collect the data from the flow log and processes it. In deployments with multiple flow log groups, configure a dedicated connector that works with one MID Server for every flow log group. Multiple flow log groups may use the same AWS credentials.

2. Configure Service Mapping to work with VPC Flow Logs:
   a) Navigate to **Service Mapping > Administration > Flow Connectors**.
b) Click New.

c) Click AWS VPC flow logs.

d) On the AWS VPC flow logs page, configure the connector parameters as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A descriptive name for the connector.</td>
</tr>
<tr>
<td>Group name</td>
<td>The name of the central flow log group to which Amazon EC2 instances forward their log streams.</td>
</tr>
<tr>
<td>MID Server</td>
<td>The MID Server that Service Mapping uses to collect the data from the flow log group on AWS.</td>
</tr>
<tr>
<td>AWS Credentials</td>
<td>Select AWS credentials relevant for the account for which you want to collect flow logs.</td>
</tr>
</tbody>
</table>

e) Click Submit.

3. Verify that Service Mapping collects data using VPC Flow Logs:

a) On the AWS VPC flow logs form, select the newly configured connector and click Run now to start the data collection flow and populate the Flow Connection (sa_flow_connection) table.

b) Navigate to System Definitions > Tables.

c) Click the Flow Connection (sa_flow_connection) table.

d) Under Related Links, click Show List.

e) Verify that the table contains data.

Configure Search Assistant for Windows

The Search Assistant feature of Pattern Designer allows you to search within files or registries. Upload grep files on to your instance to enable this feature to search on Windows servers.

Role required: admin or sm_admin

Grep is a utility that the Search Assistant feature uses to search files for matches. Grep is native to Unix-based systems, therefore you must upload it only for Windows-based configuration items (CI). Once you upload grep files onto the instance, it transfers them onto all MID Server which distribute the files onto all Windows-based CIs in your organization.

1. Download the following files onto the computer from the Internet.

   - egrep.exe
   - libiconv2.dll
   - libintl3.dll
   - pcre3.dll
   - regex2.dll

   Note: Make sure to unzip folders if necessary.

For example, you can download the zip files for the Dependencies and Binaries folders at the following location: [http://gnuwin32.sourceforge.net/packages/grep.htm](http://gnuwin32.sourceforge.net/packages/grep.htm)
After you unzip the downloaded folders, the files are located as follows:

- grep-2.5.4-bin/bin/egrep.exe
- grep-2.5.4-dep/bin/libiconv2.dll
- grep-2.5.4-dep/bin/libintl3.dll
- grep-2.5.4-dep/bin/pcre3.dll
- grep-2.5.4-dep/bin/regex2.dll

2. Navigate to Pattern Designer > Uploaded Files.
3. Click New.
4. Enter the original file name in the Name field on the Logical Name tab, for example egrep.exe.
5. Click OS Types and select Windows.
6. Click **OS Architectures** and select both 32-bit and 64-bit option.
7. Click the **Manage Attachments** icon.
8. Click **Choose Files**.
9. In the **Downloads** folder on your computer, navigate to the file which name you entered before, for example **egrep.exe**.
10. Click **Choose**.
11. Close the Attachments window.
12. Repeat **Step 3 to Step 11** to upload the rest of the files:
   - **libiconv2.dll**
Modify display for CI attributes

You can control what configuration item (CI) attributes the system displays in the Properties pane of application service maps.

Get familiar with the notion of views. For more information on views, see View management.

Decide for which CI classes you need to modify display.

Decide whether you want to modify display for parent CI classes to see the view change in all their child CI classes. To check the parent CI class of a CI class, perform the steps below:

Note: Service Mapping user interface refers to CI classes as CI types.

1. Navigate to System Definition > Tables.
2. Set the search field to Name, and enter the relevant CI class.
   The list of all CI class that match the name is displayed.
3. Check the Extends table column to see the parent CI class.

Role required: sm_admin or app_service_admin

When working with application service maps, the Properties pane displays attributes for CIs and connections you select in a map. Since there is a large number of attributes to display, you may want to choose which attributes are displayed, and in what order.

The attributes and their order of display is determined by a combination of the CI type definition and the view for this CI type.

CMDB stores CI class in the form of a hierarchy where some CI classes are parents to other CI classes, who automatically derive their parent's attributes in addition to attributes you configure specifically for child CI classes. CI class hierarchy is used widely for configuring CI behavior, relationships, and display.
The view that controls the attribute display in application service maps is called **sa_map_properties**. You can assign this view to new CI classes or modify the view for CI classes which already use it. Use the CI type hierarchy to configure the **sa_map_properties view**:

- The parent CI class at the top of the hierarchy is **cmdb**.
- If you do not define the view for a child CI class, the system displays attributes derived from the parent with the addition to all the attributes of this child CI class.
If you define a view for a child CI class, it includes only the attributes that you specifically added to the child CI class. The system does not display any of its parent attributes automatically.
• If you do not add a parent CI class or its child CI class to the view, the system uses the ascendant CI class that was added to the view in addition to all attributes of all parent CI classes in the hierarchy between this child CI classes and the parent CI class that is added to the view.
For example, if you define the `sa_map_properties` view for the CI class for Windows Servers, the Properties pane displays the same attributes for all Windows Servers: CI type (class), Class, Model ID, and name.
You can modify the view at any time.

1. Navigate to **Configuration > Application Services > Application Services**.
2. Alternatively, if Service Mapping is deployed, navigate to **Service Mapping > Services > Application Services**.
3. Click **View map** next to the application service that contains the required CIs.
4. In the application service map, select the CI whose attributes you want to change.
5. In the **Properties** pane, click **Detailed Properties**.
6. In the CI Detailed Properties page, click the **Additional actions** icon and select **Configure > Form Layout**.

7. In the **View name** list under **For view and section**, define which view you want to modify:

   - Select **sa_map_properties** if it appears in the list, or
   - If **sa_map_properties** does not appear in the list:
     1. Select **New**.
     2. In the **View name** field, enter **sa_map_properties**.
     3. Click **OK**.

8. Use the slushbucket to add or remove attributes from the view.

9. Click **Save**.

10. Return to the application service map and reselect the CI for which you changed the view.
The Properties pane displays the attributes that you configured for the view.

11. If necessary, repeat the procedure for other CI classes.

Configure support for Windows servers with non-English OS

You can configure your Now Platform to support Windows servers that use non-English Windows operating system (OS).

You can perform this procedure only on the MID Servers that serve locations using non-English operating system. Alternatively, you can perform this configuration on all MID Servers in one go, even MID Servers that are used for locations using English operating systems.

Role required: mid_server

If your organization does not deploy Service Mapping, this configuration is not necessary.

Sometimes organizations choose to use operating systems in local languages. While having a localized operating system (OS) may be user-friendly, it poses a problem when it comes to automatically discovering Windows servers running the localized OS. During the discovery and mapping process Service Mapping sends discovery commands to Windows servers on your infrastructure via a MID Server. If a Windows server returns a message in a language other than English, Service Mapping does not recognize it as a valid response and the interaction fails.

If your organization uses non-English operating system for some of the Windows servers, you must perform this procedure to make sure that Service Mapping can access all Windows servers, not exclusively Windows servers using the English operating system. This configuration allows the MID Server, that is located between Service Mapping and Windows servers, to recognize a non-English response from a Windows server and to change the language of the CI operating system into English.

This configuration affects only the user for which you perform this procedure.

1. Navigate to MID Servers > Properties in the Modules pane.
2. Click New.
3. In the Name field, enter mid.servicewatch.wmi.mui.
4. In the Value field, enter true.
5. In the MID server field, select the server to which you want to apply this change:

<table>
<thead>
<tr>
<th>Option</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>To apply the change to all MID Servers in your organization</td>
<td>Leave the MID Server field blank.</td>
</tr>
<tr>
<td>To apply the change to a specific MID Server</td>
<td>Select the relevant MID Server from the list.</td>
</tr>
</tbody>
</table>

6. Click Submit.

Upload the rctrlx.exe file to MID Servers

Role required: admin or sm_admin

During the discovery process, the MID Server runs Service Mapping and Discovery patterns on applications and devices located inside the organization network. A pattern is a sequence of steps whose purpose is to detect attributes of a CI and its outbound connections. To execute commands over PowerShell correctly, MID Server runs patterns as services using the rctrlx.exe file. The rctrlx.exe file is part of the open source ManagePC utility and is available for downloading from the Internet.
Upload an `rctrlx.exe` file for every MID Server in your deployment.

1. Download the `rctrlx.exe` file onto your computer from the Internet.
   For example, [https://github.com/leonsodhi/rctrlx/releases](https://github.com/leonsodhi/rctrlx/releases) offers the latest versions of the `rctrlx.exe` file:

2. Place the `rctrlx.exe` file into the folder for Windows 32-bit servers:
   `<MID Server installation directory>\agent\bin\sw_wmi\bin\32`
   For example, `C:\SN_MID\SN_MID_Dev\agent\bin\sw_wmi\bin\32`.

3. Place the `rctrlx.exe` file into the folder for Windows 64-bit servers:
   `<MID Server installation directory>\agent\bin\sw_wmi\bin\64`
   For example, `C:\SN_MID\SN_MID_Dev\agent\bin\sw_wmi\bin\64`.

**Plan application services**

You can centrally manage the process of planning, creating, and reviewing numerous application services using the Service Map Planner.

Fresh install deployments do not have the Service Map Planner module. The improved planning functionality is provided as an integral part of the new Service Mapping user interface. For more information, see [KB0689681: Features replacing deprecated Service Planner in Service Mapping](https://support.servicenow.com/index.html). Service Map Planner module refers to application services as application services.

Typically, the process of creating an application service is intensive. It includes collecting information and performing multiple tests until you get a satisfying result. Most organizations have hundreds or thousands of services which makes this process even harder to manage. Service Mapping allows you to gather and test all the information related to application services in one central location.

You can create reports based on planning phases to monitor progress you made in planning and creating application services.

The process of planning and creating application services using Service Map Planner consists of several stages:

1. Decide how you want to manage your application service planning by splitting application services into groups. These groups are referred to as phases. You are free to organize application services into phases whichever way you find effective: by location, by type of service, by priority, and so on. For example, if you decided to start your planning project from application services in the EMEA office, you create a phase with that name and populate it with all application services belonging to this office.

   You do not have to accomplish planning phases in Service Mapping in any particular order. On the contrary, you can simultaneously make progress on testing and reviewing application services belonging to different phases.

2. To begin the actual work on creating application services, you must add planned application services to phases. It creates an association between application services and their phases, which helps to manage creating application services. In our example, you add all application services used by the EMEA office to the EMEA phase.

3. **Creation of actual application services during planning**

   You create each application service individually even if you simultaneously added multiple application services to the phase. During this stage, an administrator responsible for planning application services collects data and runs the mapping process. Then a staff member who is familiar with the infrastructure and applications reviews mapping results for correctness and approves the newly created application service.
Going through these actions may take a long time. As a rule, a phase contains planned application services at different stages depending on how much progress you were able to make.

**Planning flow for application services**

1. **Decide on planning strategy and create phases**
2. **Populate phases**
3. **Create individual services**:
   - Collect data
   - Test connectivity
   - Create and map service
   - Review and approve service

**Create empty phases**

Service Mapping allows you to split planned application services into groups which are referred to as phases.

Role required: sm_admin or sm_app_owner

Set up Service Mapping as described in [Service Mapping setup](#).

Fresh install deployments do not have the Service Map Planner module. The improved planning functionality is provided as an integral part of the new Service Mapping user interface. For more information, see [KB0689681: Features replacing deprecated Service Planner in Service Mapping](#).

Decide how you want to manage your application service planning by splitting application services into groups. These groups are referred to as phases. Then populate phases with application services. You are free to organize application services into phases whichever way you find effective: by location, by type of service, by priority, and so on. For example, if you decided to start your planning project from application services in the EMEA office, you create a phase with that name and populate it with all application services belonging to this office.
You do not have to accomplish planning phases in Service Mapping in any particular order. On the contrary, you can simultaneously make progress on testing and reviewing application services belonging to different phases.

1. Navigate to Service Mapping > Service Map Planner > Phases.
2. Click New.
3. Define phase attributes as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Provide a descriptive, but short name for the phase.</td>
</tr>
<tr>
<td>Description</td>
<td>Provide a short description of the phase.</td>
</tr>
<tr>
<td>Status</td>
<td>Verify that the status is set to Active.</td>
</tr>
</tbody>
</table>

4. Click Submit.
   The new phase appears in the list of phases.

**Phase population**

You associate planned application services to phases.

Fresh install deployments do not have the Service Map Planner module. The improved planning functionality is provided as an integral part of the new Service Mapping user interface. For more information, see [KB0689681: Features replacing deprecated Service Planner in Service Mapping](#).

To begin the actual work on creating application services, you must add planned application services to phases. It creates an association between application services and their phases, which helps to manage creating application services. In our example, you add all application services used by the EMEA office to the EMEA phase.

You can associate an application service using different methods depending on how you have been managing your application services up until now and what information about them you gathered.

### Methods of associating planned application services to phases

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
<th>Advantages</th>
<th>Disadvantages</th>
</tr>
</thead>
<tbody>
<tr>
<td>Import from the CSV file</td>
<td>This method suits you if your organization has performed cross-organization mapping and analysis and collected some information about planned application services. If so, you can organize the collected information in a specific order and save it as a CSV file. Service Mapping extracts information from this file and creates potential application services referred to as service candidates.</td>
<td>You associate multiple application services at a time. There is a relatively low chance of mistakes.</td>
<td>You must prepare all the necessary information in a very specific format before you can perform the import.</td>
</tr>
<tr>
<td>Method</td>
<td>Description</td>
<td>Advantages</td>
<td>Disadvantages</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>-------------------------------------------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Import from a load balancer</td>
<td>To enable you to map your application services in bulk, Service Mapping extracts entries directly from load balancers and convert them into application service candidates.</td>
<td>You associate multiple application services at a time. There is no preparation.</td>
<td>The result of the import is not precise. There may be many false or duplicate application services created by mistake because the data from the load balancer is raw.</td>
</tr>
<tr>
<td>Add application services manually</td>
<td>Use this method if you do not have any organized data on your application services or you do not want to use other methods.</td>
<td>There is no preparation. There is a relatively low chance of mistakes.</td>
<td>If you have many application services for a phase, the process may take a long time.</td>
</tr>
</tbody>
</table>

**Import planned application services from the CSV file**

Associate multiple application services to a phase in a single step by importing them from the CSV file containing necessary information.

Fresh install deployments do not have the Service Map Planner module. The improved planning functionality is provided as an integral part of the new Service Mapping user interface. For more information, see KB0689681: Features replacing deprecated Service Planner in Service Mapping.

Prepare the information necessary for the import in the CSV file:

1. Copy the following template in the .xlsx format: importCSVexample.xlsx.
2. Populate the fields in the .xlsx file:

   **Warning:** Do not modify column labels in the .xlsx file.

   **Warning:** If information on application services is not formatted in the .xlsx file according to the template, Service Mapping fails to create planned services or creates them with errors.

   **Warning:** This .xlsx format is correct only for importing business services using the Service Map Planner module. When you map business services from a CSV file from the new Home page, follow the procedure in Prepare a CSV file for mapping your candidates.

<table>
<thead>
<tr>
<th>Column label</th>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name of the planned application service.</td>
</tr>
<tr>
<td>ServiceDeploymentOwner</td>
<td>Enter the service deployment owner name as it is displayed in the platform: <code>&lt;firstname.lastname&gt;</code>. The service deployment owner is responsible for creating and fixing application services during planning. The service deployment owner must have the sm_admin role.</td>
</tr>
<tr>
<td>Column label</td>
<td>Information</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ApplicationOwners</td>
<td>Enter the application owner owner. The application service owner is a user who is familiar with the infrastructure and applications making up the service. This user is the application service SME who provides information necessary for a successful creation of an application service. Use the following syntax: <code>&lt;firstname.lastname&gt;</code>. To enter more than one name, use semicolon (:) to separate names.</td>
</tr>
<tr>
<td>PlannedEntryPoints</td>
<td>Enter the HTTPS entry points that Service Mapping uses to discover this application service. To enter more than one entry point, use semicolon (:) to separate them. An entry point is how clients access an application service. Usually, it is either a URL or a combination of the IP address and port. Service Mapping starts the mapping process from this point. For example, to map your electronic mailing application service, define an IP address or host name of the email server as an entry point.</td>
</tr>
<tr>
<td>OtherEntryPoints</td>
<td>Enter information about entry points that either a service deployment owner or application owner manually defines for this application service. Enter this information as free text.</td>
</tr>
<tr>
<td>ComponentsDetails</td>
<td>Enter information about components you expect to discover as part of this application service. Enter this information as free text.</td>
</tr>
</tbody>
</table>

3. Save the file in a drive that you can access during the import with the `.csv` extension.

**Role required: sm_admin**

This method suits you if your organization has performed cross-organization mapping and analysis and collected some information about planned application services. If so, you can organize the collected information in a specific order and save it as a CSV file. Service Mapping extracts information from this file and creates potential application services referred to as service candidates.

1. Navigate to **Service Mapping > Service Map Planner > Phases**.
2. Click the relevant phase.
3. On the Phase page, click **Import from CSV**.
4. In the Select CSV file to import window, click **Choose file**.
5. Navigate to the CSV file to use for the import and click **Choose**.
6. Click **Import**.
   The newly associated application services appear under Business Service Planning.
7. If necessary, troubleshoot import-related errors.
   a) Click the **Import Errors** tab.
   b) Review information on application services that Service Mapping failed to import.
   c) Create a separate CSV file to these application services.
**Note:** Make sure that the information and its format are correct.

d) Import application services from the second CSV file by repeating 3-6.

*Import planned application services from load-balancers*

Associate multiple application services to a phase in one go by importing them from load balancers.

Role required: sm_admin

Fresh install deployments do not have the Service Map Planner module. The improved planning functionality is provided as an integral part of the new Service Mapping user interface. For more information, see KB0689681: Features replacing deprecated Service Planner in Service Mapping.

To enable you to map your application services in bulk, Service Mapping extracts entries directly from load balancers and convert them into application service candidates.

1. Navigate to **Service Mapping > Service Map Planner > Phases**.
2. Click the relevant phase.
3. On the Phase page, click **Import from load balancer**.
   The Load Balancer Services page shows the list of entries in all load balancers configured in the instance.
4. Mark the entries that you want Service Mapping to import as a application service by clicking check boxes next to them.
5. Click **Import**.
   The newly associated application services appear under Business Service Planning.

   By default, Service Mapping assigns the following parameters for every application service:
   - **Name** - based on the following rule: <load balancer name>+<VIP name>. You can change names at a later stage.
   - **Entry point type** - inferred from the port value as follows:

<table>
<thead>
<tr>
<th>Port number</th>
<th>Entry point type</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>HTTPS</td>
</tr>
<tr>
<td>80</td>
<td>HTTP</td>
</tr>
<tr>
<td>Any number except 443 and 80</td>
<td>TCP</td>
</tr>
</tbody>
</table>

6. If necessary, troubleshoot import-related errors.
   a) Click the **Import Errors** tab.
   b) Review error messages and fix issues that caused errors.

*Add planned application services to phases manually*

If you cannot associate an application service to a phase by importing it, add it manually.

You can add an application service only to an existing phase.

Role required: sm_admin

Fresh install deployments do not have the Service Map Planner module. The improved planning functionality is provided as an integral part of the new Service Mapping user interface. For more information, see KB0689681: Features replacing deprecated Service Planner in Service Mapping.
Use this method if you do not have any organized data on your application services or you do not want to use other methods.

1. Navigate to **Service Mapping > Service Map Planner > Phases**.
2. Click the relevant phase.
3. On the Phase page, click **New**.
4. Define attributes for the business service you want to add:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a descriptive and short name for this application service.</td>
</tr>
<tr>
<td>Application Owner</td>
<td>The application service owner is a user who is familiar with the infrastructure and applications making up the service. This user is the application service SME who provides information necessary for a successful creation of an application service. Once a service is mapped, this user reviews the results and either approves it or suggests changes. The owner cannot create or modify application services. Click the <strong>Add me</strong> or <strong>Edit Application Owner</strong> icons to define this parameter.</td>
</tr>
<tr>
<td>Service Deployment Owner</td>
<td>The application service owner is a user who is familiar with the infrastructure and applications making up the service. This user is the application service SME who provides information necessary for a successful creation of an application service. Once a service is mapped, this user reviews the results and either approves it or suggests changes. The owner cannot create or modify application services. Select the name from the list. If you add more than one name, separate them with a semicolon (;).</td>
</tr>
</tbody>
</table>

5. Click **Submit**.

**Creation of actual application services during planning**

You create each application service individually even if you simultaneously added multiple application services to the phase.

Fresh install deployments do not have the Service Map Planner module. The improved planning functionality is provided as an integral part of the new Service Mapping user interface. For more information, see **KB0689681: Features replacing deprecated Service Planner in Service Mapping**.

After you created phases and populated them with application services, you are ready to look at individual application service in a phase. Application services in phases are only planned services, they are drafts. You are going to create actual application services based on them. The actual application service inherits all information defined for the planned service. This new actual application service appears in the list of all application services and has the Non-Operational state.

The following users collaborate to create actual application services:
• Service deployment owner

Ideally, only the service deployment owner should create the actual application service, however, any user with the sm_admin role can perform this task.

• Application owner

The application service owner is a user who is familiar with the infrastructure and applications making up the service. This user is the application service SME who provides information necessary for a successful creation of an application service. Once a service is mapped, this user reviews the results and either approves it or suggests changes. The owner cannot create or modify application services.

Notice that although service deployment owner fixes the actual application service, the application owner provides feedback and approves the draft version of it - the planned application service. It allows you to have all the information related to planning and creation of the application service in one central place.

Creating an actual application service during planning has the following flow:

Collect data
A service deployment owner or an application owner collects data for the planned application service.

Role required: sm_admin or sm_app_owner

Fresh install deployments do not have the Service Map Planner module. The improved planning functionality is provided as an integral part of the new Service Mapping user interface. For more information, see KB0689681: Features replacing deprecated Service Planner in Service Mapping.

At this stage you are planning your application service and collect information that Service Mapping uses later to create, review, and approve this application service.

You provide information on people responsible for creating and reviewing your application service.

Make sure that your planned application service has some entry points assigned to it. An entry point is how clients access an application service. Service Mapping starts the mapping process from this point. You cannot create an actual application service, review, and approve the planned application service unless it has at least one entry point. Even if this planned application service has some entry points assigned to it during import, you can add additional entry points if necessary.

Some information, such as information about components, is not used to create an application service, but to review it at a later stage.

1. Navigate to Service Mapping > Service Map Planner > Phases.
2. Select the phase which contains the application service.
3. Click the name of the application service.
4. Define the application owner for this application service.

The application service owner is a user who is familiar with the infrastructure and applications making up the service. This user is the application service SME who provides information necessary for a successful creation of an application service. Once a service is mapped, this user reviews the results and either approves it or suggests changes. The owner cannot create or modify application services.

a) Click the Add me icon next to Application Owner to define yourself as the application owner.

Or
b) Click **Edit Application Owner** (Padlock) icon next to **Application Owner** and enter a single or multiple names. If necessary, enter an email.

5. Define the service deployment owner for this application service in the **Service Deployment Owner** field.

The application service owner is a user who is familiar with the infrastructure and applications making up the service. This user is the application service SME who provides information necessary for a successful creation of an application service. Once a service is mapped, this user reviews the results and either approves it or suggests changes. The owner cannot create or modify application services.

Select the name from the list. Separate multiple names with a semicolon (;).

6. If there is no entry point, add it.

An entry point is how clients access an application service. Usually, it is either a URL or a combination of the IP address and port. Service Mapping starts the mapping process from this point. For example, to map your electronic mailing application service, define an IP address or host name of the email server as an entry point.

   a) Click **New** on the **Planned Entry Points** tab.

   b) Select the relevant type for the entry point from **Entry point type**.

      If there is no entry point type you need, enter its description on the **Other Entry Points** tab.

   c) Define other entry point attributes that vary depending on the type you selected.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host/Hostname/Host Name</td>
<td>The value of the target server on which the service is running. This value can contain a real host name, alias, IP, or VIP.</td>
</tr>
<tr>
<td>Port</td>
<td>The port number of the service that you want to discover.</td>
</tr>
<tr>
<td>Name</td>
<td>The name of the service that you want to discover.</td>
</tr>
<tr>
<td>URL</td>
<td>The URL of the service that you want to discover.</td>
</tr>
</tbody>
</table>

   d) Click **Submit**.

7. Provide information for components that are part of this application service, and that you know of.

   a) Click the **Components** tab.

   b) Click **New**.

   c) Enter description of the application service component.

   d) Click **OK**.

---

**Check entry point connectivity**

A service deployment owner or an application owner tests that Service Mapping can connect to the devices that are expected to make up this application service. This feature is not available on instances using Edge Encryption.

Run either horizontal or top-down discovery on the host for which you want to check connectivity.

Role required: sm_admin or sm_app_owner
Fresh install deployments do not have the Service Map Planner module. The improved planning functionality is provided as an integral part of the new Service Mapping user interface. For more information, see KB0689681: Features replacing deprecated Service Planner in Service Mapping.

You can check if Service Mapping can connect to hosts to identify any connectivity-related issues. You can investigate the problem source, fix it, and run the connectivity check again to verify that you are ready to create an actual application service. The most common causes of connectivity problems are missing or wrong credentials for a host.

You can check connectivity of entry points you defined for a planned application service. An entry point is how clients access an application service. Service Mapping starts the mapping process from this point. You can also check connectivity of hosts connected to specified entry points.

As part of defining entry points for an application service, you enter their IP addresses. When you run this test, Service Mapping checks the corresponding record in the CMDB (cmdb_ci) for information on credentials for IP addresses you defined. By default, Service Mapping checks the IP address that you defined for the entry point, but you can add additional IP addresses during the procedure.

To check connectivity of hosts connected to entry point IP addresses, you must specify the number of levels to check as Hop Count. Service Mapping uses information on TCP and Netflow connections stored in the CMDB tables, to find hosts connected to the IP address.

### Tables containing data collected using traffic-based methods

<table>
<thead>
<tr>
<th>Table</th>
<th>Source</th>
<th>Used by Service Mapping to</th>
</tr>
</thead>
<tbody>
<tr>

<td>netstat and lsof commands</td>
<td>Discover connections during top-down discovery.</td>
</tr>
</tbody>
</table>

1. Navigate to Service Mapping > Service Map Planner > Phases.
2. Select the phase which contains the planned application service.
3. Click the name of the planned application service.
4. On the Planned Entry Points tab, click the check boxes next to the entry points whose credentials you want to check.
5. Click Check Connectivity.

The Check IP Address Connectivity window opens displaying the IP address you defined for the entry points.
6. If necessary, modify or add IP addresses in the IP Address(es) field.

   Use comma without whitespace to separate multiple IP addresses.
7. Select the number of levels to check in the Hop Count list.
   The number of hops performed by the actual test depends on the ability of Service Mapping to connect to hosts in the next level. If you use Netflow to collect data, you can see CIs on all levels even if Service Mapping cannot connect to them.
8. Click OK.

   The Connectivity Test page opens.
9. Verify that the status of the test is Completed.
10. Review the result of the test:
    - If the status and the message state that the IP address is found, Service Mapping can connect to this host.
If the status is Info, there is a possibility that there is a connectivity problem or that this host is not in the CMDB.

If the status is Not found, either there is a connectivity problem or this host is not in the CMDB.

11. Click the IP address to read the full message. Use this information to troubleshoot connectivity issues.

To troubleshoot, you may need to:
- Run discovery on a problematic CI either from Discovery or Service Mapping.
- Define missing or wrong credentials for this CI.

12. Perform this procedure on the same entry points to verify that Service Mapping does not experience the same connectivity issues.

Create actual application services during planning

The service deployment owner creates an actual application service based on the planned one.

Role required: sm_admin

Fresh install deployments do not have the Service Map Planner module. The improved planning functionality is provided as an integral part of the new Service Mapping user interface. For more information, see KB0689681: Features replacing deprecated Service Planner in Service Mapping.

The actual application service inherits all information defined for the planned service. This new actual application service appears in the list of all application services and has the Non-Operational state.

Ideally, only the service deployment owner should create the actual application service, however, any user with the sm_admin role can perform this task.
When Service Mapping creates an actual application service during planning, it performs the following validation:

- Checks that the entry point is not used for another application service.
- Checks that the application service name is unique and does not exist in the CMDB.

1. Navigate to **Service Mapping > Service Map Planner > Phases**.
2. Select the phase which contains the planned application service.
3. Click the name of the planned application service.
4. Make sure that the name and the service deployment owner are defined.
5. Click **Create and Discover**.

   Service Mapping creates the actual application service and starts the process of discovery and mapping.

   When the discovery process completes, the **View map** link appears on the page.

6. If necessary, troubleshoot validation errors:

   a) Click the **Validation Errors** tab.
   b) Review error messages and fix the issues that caused them.

7. Enter the name of the application owner. The application service owner is a user who is familiar with the infrastructure and applications making up the service. This user is the application service SME who provides information necessary for a successful creation of an application service.

8. Click **Send for Review**.

   At this stage, you let the application owner review mapping results and provide feedback in the form of notes on the planned application service page.

---

**Review application services**

An application owner reviews mapping results for correctness and provides feedback for the application service.

Role required: sm_app_owner

Fresh install deployments do not have the Service Map Planner module. The improved planning functionality is provided as an integral part of the new Service Mapping user interface. For more information, see [KB0689681: Features replacing deprecated Service Planner in Service Mapping](https://service-now.com/kb).  

As a staff member that is familiar with the infrastructure and applications, review mapping results of the actual application service and provide your feedback in the form of notes. After that, a service deployment owner reviews and implements your feedback, and possibly, leaves some notes for you. The process of application service review may take some time as it requires making changes and running the mapping process on the application service. Typically, it takes several iterations to arrive at the desired result. Once the service deployment owner fixes all issues, you can approve it.

Ideally, only the application owner reviews the planned application service, however, any user with the sm_app_owner role can perform this task. As the application owner for the planned application service, you receive an email notification that the application service is assigned to you for review.

1. Navigate to the planned application service:
   a) Navigate to **Service Mapping > Service Map Planner > Business Service Planning**.
   b) Sort the list of planned application services by status and scroll to see services in In Review status.

   Or
Use the filter to narrow the list.

c) Click the required application service.

2. Review the actual application service:
   a) On the Planned Business Service page, check entries on the Components tab to see which devices and applications are expected to be part of this application service.
   b) Click View Map and review the map.
   c) Return to the planned application service, enter your comments for the service deployment owner in the Notes field and click Post.
      At this stage, let the service deployment owner read your comments and make the necessary changes.

3. Approve the planned application service:
   a) Navigate to the same application service.
   b) Review the notes from the service deployment owner.
   c) Click View Map and check that the changes you required are implemented.
   d) If the mapping results are satisfactory, click Approve.

Fix actual application services during planning
The service deployment owner checks the feedback and updates the actual application service as necessary.

Role required: sm_admin

Fresh install deployments do not have the Service Map Planner module. The improved planning functionality is provided as an integral part of the new Service Mapping user interface. For more information, see KB0689681: Features replacing deprecated Service Planner in Service Mapping.

The process of application service review may take some time as it requires making changes and running the mapping process on the application service. Typically, it takes several iterations to arrive at the desired result.

Ideally, only the service deployment owner should fix the actual application service, however, any user with the sm_admin role can perform this task.

1. Navigate to Service Mapping > Best Practice > Planned Business Services.
2. Sort the list by status.
   Business services reviewed by the application owner are in In Review status.
3. Click one of the application services in In Review status.
4. Review the notes made by the application owner.
5. Click View map.
   The map of the actual application service opens.
6. Make necessary changes on the actual application service page.
7. Check the map for correctness.
8. Enter your comments for the application owner in the Notes field and click Post.
   At this stage, let the application owner read your comments and review the changes you made.

Approve application services during planning
The application owner reviews the fixed application service and approves it if the result is satisfactory.
Role required: sm_app_owner

Fresh install deployments do not have the Service Map Planner module. The improved planning functionality is provided as an integral part of the new Service Mapping user interface. For more information, see [KB0689681: Features replacing deprecated Service Planner in Service Mapping](#).

As a staff member that is familiar with the infrastructure and applications, review the mapping results of the actual application service and provide your feedback in the form of notes. Then, a service deployment owner reviews and implements your feedback, and possibly, leaves some notes for you. The process of application service review may take some time as it requires making changes and running the mapping process on the application service. Typically, it takes several iterations to arrive at the desired result. Once the service deployment owner fixes all issues, you can approve the application services.

Ideally, only the application owner should approve the planned application service, however, any user with the sm_app_owner role can perform this task.

1. Navigate to the planned application service:
   a) Navigate to Service Mapping > Best Practice > Planned Business Services.
   b) Sort the list of planned application services by status and scroll to see services in In Review status.
      Or
      Use the filter to narrow the list. For example, filter by your name if you are the application owner.
   c) Click the required application service.

2. Review notes made by the service deployment owner.
3. Click View Map and check that the changes you required are implemented.
4. If the mapping results are satisfactory, click Approve.

### Discovery

ServiceNow® Discovery finds applications and devices on your network, and then updates the CMDB with the information it finds.

Discovery is available as a separate subscription from the rest of the Now Platform. See [Request Discovery](#) for details.

**Explore**
- Upgrade to New York
- Discovery basics
- Data collected by Discovery
- Domain Separation and Discovery

**Set up**
- Request Discovery
- Installing the MID Server
- Create and test your credentials
- Discovery setup

**Administer**
- Discovery properties
- Create a Discovery behavior
- Create a Discovery CI classification
- Create a Discovery process classification

**Use**
- Schedule a horizontal discovery
- Run a Quick Discovery
- Discovery status
- Validate discovery results

**Integrate and develop**
- Activate SCCM Asset Intelligence scheduled imports
- Discovery APIs on the developer portal

**Troubleshoot and get help**
- Discovery monitoring and issue resolution
- Search the HI knowledge base for known error articles
- Ask or answer questions in the ITOM forum

Discovery basics

Discovery finds computers, servers, printers, a variety of IP-enabled devices, and the applications that run on them. It can then update the CIs in your CMDB with the data it collects.

Horizontal discovery and top-down discovery

There are two types of discovery:

Horizontal discovery

Horizontal discovery is a technique that Discovery uses to scan your network, find computers and devices, and then populate the CMDB with the CIs it finds. Horizontal discovery does create direct relationships between CIs, such as a runs on relationship between an application CI and the actual computer CI that it runs on. Horizontal discovery is not aware of business services and does not create relationships between CIs based on the business service they are in.

Top-down discovery

Top-down discovery is a technique that Service Mapping uses to find and maps CIs that are part of business services, such as an email service. For example, top-down discovery can map a website business service by showing the relationships between an Apache Tomcat web server service, a Windows server, and the MSSQL database that stores the data for the business service.

Typically, Service Mapping and Discovery work together to run horizontal discovery first to find CIs, and then top-down discovery to establish the relationships between business services that you need to know.

Watch this video to see an overview of horizontal discovery and top-down discovery.

Note: For this tutorial, the term discovery means horizontal discovery.

Probes, sensors, and patterns

Discovery uses these components to find CIs:

Probes and sensors

Basically, probes and sensors are scripts that collect and process data on a host and then update the CMDB. More specifically, probes explore or investigate CIs on your network, and sensors parse the data returned from the probes. Several probes and sensors are provided by default, but you can customize them to find different information, or you can create ones. You can also configure several parameters to control the behavior of a particular probe every time it is triggered.

Patterns

Patterns, like probes and sensors, are a series of operations that also collect data on a host, process it, and update the CMDB. Patterns differ from probes and sensors in that they are written in Neebula Discovery Language (NDL) rather than JavaScript, and they are called into action in
Horizontal discovery phases

The phases of horizontal discovery are:

Discovery follows these phases:

- **Scanning**
  Discovery sends a probed called Shazzam to the network to see if commonly used ports are open and if these ports can respond to queries. For example, if Shazzam finds a device that responds on port 135, Discovery knows that it is a Windows server.

- **Classification**
  If Discovery finds devices or computers, it sends additional probes to find the type of device or the operating system on the device. For example, Discovery sends the WMI probe to a Windows machine to detect the Windows 2012 operating system. Then Discovery uses records called classifiers, which specify the trigger probe or probes that run during the next two phases. If you are using patterns, the classifier specifies a trigger probe that in turn launches a pattern.

- **Identification**
  Discovery tries to gather more information about the device and then tries to determine if a CI for the device exists in the CMDB. Discovery then uses additional probes, sensors, and identifiers to update existing CIs in the CMDB or create new ones. Identifiers, also known as identification rules, specify the attributes that the probes look at when reconciling data with the CIs in the CMDB. If you are using patterns, Discovery uses the appropriate identification rule for the CI type specified in the pattern.

- **Exploration**
  The identifier launches additional probes configured in the classifier. These probes are especially designed as exploration probes to gather additional information about the device, like the applications running it, and additional attributes, such as memory, network cards, and drivers. Discovery then creates relationships between applications and devices and between applications. If you are using patterns, the operations in the pattern perform the exploration of the CI.

Discovery communication through MID Servers

A MID Server, which constantly queries the instance for probes to run, executes the instructions in the probe or in the pattern that the probe specifies. The MID Server then returns the results to the instance, where sensors process it. The MID Server does not retain any discovery information.

The MID Server starts all communications, using SOAP on HTTPS, which means that all communications are secure, and all communications are initiated inside the enterprise's firewall. No special firewall rules or VPNs are required.

Because Discovery is agentless, meaning that it does not require any permanent software to be installed on any computer or device to be discovered, the MID Server uses several techniques to probe devices without using agents. For example, the MID Server uses SSH to connect to a Unix or Linux computer, and then it can run a standard command, as specified in the probe, to gather information. Similarly, it uses the Simple Network Management Protocol (SNMP) to gather information from a network switch or a printer.
Types of discovery

The types of horizontal discovery that the Discovery application can perform are explained in the following table:

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Network discovery</td>
<td>Run this type of discovery to find the internal IP networks within your organization. If you already know the IP address ranges in your network, it is not necessary to run network discovery.</td>
</tr>
<tr>
<td>CI discovery</td>
<td>Run this type of discovery to find the devices, computers, and applications on your network. This is essentially the standard type of discovery that you run most often.</td>
</tr>
<tr>
<td>Cloud discovery</td>
<td>Run this type of discovery to find AWS and Azure resources in your organization’s cloud.</td>
</tr>
<tr>
<td>Serverless discovery</td>
<td>Run this type of discovery to find applications on host machines without the need to discover the host first. Serverless discovery relies on patterns to explore CIs on a host.</td>
</tr>
</tbody>
</table>

IP service affinity

IP Service affinity saves the IP service information that is used to successfully find a device and associates it with the IP address of the device. Using this information, Discovery can target the device in subsequent runs with the accurate protocol. Discovery records the IP Service along with the IP address. Discovery can store the successful IP service information in the IP Service Affinity table (ip_service_affinity).

For example: A network device has both an SSH port and an SNMP port open. By its agentless design, Discovery tries SSH first. However, network devices should be discovered through SNMP. Discovery tries the SSH probe and it fails. This triggers the SNMP probe, which succeeds. With the association between the IP address and the IP service, subsequent discovery runs that target this IP address use SNMP first, because that is the probe that succeeded.

Help the help desk

Help the Help Desk is a standard feature available through the self-service Help the Help Desk application. It gathers information, much as Discovery does, about a single Windows computer by running a script on that computer. Discovery does many things that Help the Help Desk cannot do.
<table>
<thead>

* When Discovery is installed.

**Horizontal discovery process flow with probes and sensors**

The horizontal discovery process passes through the four phases of discovery using probes, which gather information on the target machine, and then sensors, which help Discovery determine what to do with that information.

**Kicking off Discovery**

A user triggers horizontal discovery by configuring a discovery schedule or by launching an on-demand discovery with Discover now or Quick Discovery. The schedule specifies one or more IP addresses or range of IP addresses.

**Scanning phase**

1. Discovery first takes the Shazzam probe (and then port probes) and places it in a request in the External Communication Channel (ECC) queue.
2. The MID Server checks the ECC queue, retrieves the discovery request, and runs the probes against the host and discovers open ports.
3. The port probes scan common ports using several protocols, such as WMI, HTTP, SSH, and SNMP.
4. If one or more ports respond, the Shazzam probe sends information about the port back to the ECC queue through the MID Server.
5. Discovery checks the ECC queue to find out which ports responded, which identifies the type of machine. For example, if Shazzam detects that the machine is listening on port 22, Discovery treats the machine as a UNIX or Linux machine.

Classification phase

1. The Discovery application determines which classification probe to send to the newly discovered device by using information in the record of the port probe that successfully responded.
2. Discovery puts the classification probe into the ECC queue.
3. The MID Server checks the ECC queue, retrieves the discovery request, and runs the classification probe.
4. The classification probe retrieves additional information, such as which version of the operating system is running on a machine. This information determines the class of the CI that Discovery found. There is only one classification probe per discovered device.
5. The classification probe sends information back to the instance ECC queue through the MID Server.

The Identification phase

1. Discovery determines which classifier to use based on the class of the CI and the criteria specified in all CI classifier records. The classifier specifies which probes to use for the next two phases.
2. Discovery puts the identification trigger probe for the CI classifier into the ECC queue. For example, a Unix machine running HP-UX would require the HP-UX classifier, which specifies that the Multi Probe-HP-UX Identity identification trigger probe. These probes use identification rules to determine whether or not to insert or update a CI in the CMDB.

Note: The trigger probe could also be the Horizontal Pattern probe, which tells Discovery to follow the operations in the specified pattern, rather than sending out additional probes. The operations in the pattern cover both the identification and exploration phases. Discovery knows which identification rules to use based on the CI type, and Discovery makes inserts or updates to the CMDB based on these rules. Probes and sensors are not used.

3. The MID Server checks the ECC queue, retrieves the discovery request, and runs the identification trigger probe.
4. The identification probe accumulates identification data for each device and sends that data back to the instance via the MID Server.
5. Discovery uses sensors for the identifier probe to process the information.
6. Discovery performs the analysis on the CMDB using CI identifiers. Discovery can update existing CIs in the CMDB or create new ones.
The Exploration phase

1. Discovery looks at the Triggers Probes related list in the classifier to find exploration probes to run.
2. Discovery puts the exploration trigger probe into the ECC queue.
3. The MID Server checks the ECC queue, retrieves the discovery request, and runs the exploration trigger probes.
4. The probes send data back to the instance via the MID Server and sensors make updates to the CMDB, just as in the identification phase.

Horizontal discovery process flow with patterns

Horizontal discovery with patterns has four phases, just as horizontal discovery with probes does. However, for the last two phases, Discovery triggers operations from a pattern, rather than additional sets of probes.

Scanning phase

1. Discovery first takes the Shazzam probe (and then port probes) and places it in a request in the External Communication Channel (ECC) queue.
2. The MID Server checks the ECC queue, retrieves the discovery request, and runs the probes against the host and discovers open ports.
3. The port probes scan common ports using several protocols, such as WMI, HTTP, SSH, and SNMP.
4. If one or more ports respond, the Shazzam probe sends information about the port back to the ECC queue through the MID Server.
5. Discovery checks the ECC queue to find out which ports responded, which identifies the type of machine. For example, if Shazzam detects that the machine is listening on port 22, Discovery treats the machine as a UNIX or Linux machine.

Classification phase

1. The Discovery application determines which classification probe to send to the newly discovered device by using information in the record of the port probe that successfully responded.
2. Discovery puts the classification probe into the ECC queue.
3. The MID Server checks the ECC queue, retrieves the discovery request, and runs the classification probe.
4. The classification probe retrieves additional information, such as which version of the operating system is running on a machine. This information determines the class of the CI that Discovery found. There is only one classification probe per discovered device.
5. The classification probe sends information back to the instance ECC queue through the MID Server.
The Identification and Exploration phases

Patterns unify the Identification and Exploration phases of discovery.

1. Discovery determines which classifier to use based on the class of the CI and the criteria specified in all CI classifier records. The classifier specifies the Horizontal Pattern probe, which in turn specifies which pattern to launch. The Horizontal pattern probe also contains a sensor which does the actual work of updating the CMDB.

   **Note:** Patterns need applicative credentials to find applications running on host machines. Make sure you have applicative credentials configured along with the credentials required to access the host machine itself.

2. The operations in the pattern specify the actions that Discovery needs to take for both the identification and exploration phases. Discovery knows which identification rules to use based on the CI type in the pattern, and Discovery makes inserts or updates to the CMDB based on these rules. Only the Horizontal Discovery Sensor is used. Other probes and sensors are not used.

Devices and applications that Discovery can discover

In the base instance, Discovery can find and classify these devices and applications.

This list shows all device types and applications for Discovery only. For a detailed list of all supported applications for both Discovery and Service Mapping, including the protocol and the patterns or probes used for discovery, see Applications supported by Discovery and Service Mapping.

**Windows classifications**

Discovery uses patterns to find CIs noted with an asterisk *.

Applications supported by Discovery and Service Mapping
Discovery and Service Mapping can discover a wide range of operating systems and applications.

Discovery finds computers, servers, printers, a variety of IP-enabled devices, and the applications that run on them. It can then update the CIs in your CMDB with the data it collects. This discovery method is referred to as horizontal discovery. Service Mapping maps dependencies, based on a connection between devices and applications. This method is referred to as top-down mapping. The top-down mapping helps you immediately see the impact of a problematic object on the rest of the application service operation.

On top of hosts and applications supported by default, you can discover additional hosts and applications by deploying patterns available on Store.
If your organization uses devices or applications, which are not supported by default or using patterns available at Store, you can configure Discovery and Service Mapping to discover them as described in *Discovery patterns used by ITOM Visibility*.

**Request Discovery**

Discovery is available as a separate subscription from the rest of the Now Platform and requires the Discovery (com.snc.discovery) plugin.

Role required: admin
To purchase a Discovery subscription, contact your ServiceNow account manager or sales representative. When the Discovery plugin is activated, the following plugins are also activated:

- The Cloud Management Core (com.snc.cloud.core) plugin is also activated to provide functionality for Azure and AWS discovery
- The ITOM Licensing (com.snc.itom.license) plugin

1. From your instance, navigate to System Definition > Plugins.
2. On the All Applications page, click Request Plugin to open the request form on HI.
3. On HI, select to be redirected to the HI Service Portal Service Catalog.
4. On the Activate Plugin request form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target Instance</td>
<td>Instance on which to activate the plugin.</td>
</tr>
<tr>
<td>Plugin Name</td>
<td>Name of the plugin to activate.</td>
</tr>
<tr>
<td>Specify the date and time you would like this plugin to be enabled</td>
<td>Date and time must be at least two business days from the current time.</td>
</tr>
<tr>
<td>Reason/Comments</td>
<td>Information that would be helpful for the ServiceNow personnel who are activating the plugin. For example, if you need the plugin activated at a specific time instead of during one of the default activation windows, specify it in the comments.</td>
</tr>
</tbody>
</table>

5. Click Submit.

Pattern updates for the New York release

Several new patterns are available for horizontal discovery.

Patterns for newly discovered CIs

These patterns are new for the New York release:

<table>
<thead>
<tr>
<th>Pattern</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>UNIX Cluster - ORACLE Clusterware</strong></td>
<td>This pattern finds Oracle cluster software that runs Real Application Clusters (RAC) for Oracle databases. This pattern supports the discovery of High-availability Service Management that includes the cluster, nodes, resource information, and status.</td>
</tr>
<tr>
<td><strong>UNIX Cluster - Linux Red hat cluster and Linux - Red Hat Cluster</strong></td>
<td>These patterns find Linux Red Hat clusters that offer high availability and load balancing.</td>
</tr>
<tr>
<td><strong>F5 LB REST</strong></td>
<td>This pattern finds F5 BigIP load balancers via HTTP/HTTP classification, which is prioritized after SNMP and SSH. This pattern requires a GET request from the HTTP - Classify port probe.</td>
</tr>
</tbody>
</table>
Pattern changes

These patterns were modified in this release:

<table>
<thead>
<tr>
<th>Pattern name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Netscaler Load Balancer</td>
<td>Populates DNS names and aliases.</td>
</tr>
<tr>
<td>F5 Load Balancer</td>
<td>Includes a new section to find F5 clusters via SNMP.</td>
</tr>
<tr>
<td>Router and switch discovery</td>
<td>Added support for router stacks. Discovery creates a Master of::Stack Member of relationship between two switches.</td>
</tr>
</tbody>
</table>

Discovery setup

After you activate the Discovery application, you have several ways to get started.

Select your method of setup:

<table>
<thead>
<tr>
<th>Setup method</th>
<th>Description</th>

<td>Discovery Quick Start</td>
<td>Use this wizard to configure everything you need to perform subnet and CI Discovery in your environment. Before you can use Quick Start, you must first install and validate your MID Servers and create the necessary credentials.</td>
</tr>
</tbody>
</table>

Set up Discovery without Guided Setup

If you are not using Guided Setup, you must perform several configuration steps manually to activate the application, set up the MID Server, and then set up Discovery.
Grant Discovery role: Verify that users who are expected to configure and execute Discovery in your network have the discovery_admin role. This role grants access to the tables in the Discovery application.

Designate a computer to host the MID Server.

Gather the login credentials that the MID server must use to access the devices it is expected to discover.

Determine which IP addresses Discovery must scan. In a highly complex network, group IP ranges into a range sets, which are reusable for different schedules. Discovery does not scan anything outside of these ranges.

Role required: discovery_admin

1. Install one or more MID Servers on physical or virtual servers that meet the minimum requirements and configure them to communicate with the appropriate ServiceNow instance.
   Install at least two MID Servers at first and assign them to different schedules and IP ranges to help complete discoveries quicker. Starting with the Istanbul release, you must make sure that the MID Server is assigned the Discovery application or the ALL application.

2. Ensure MID Server connectivity by navigating to Discovery > MID Servers.
   If the MID Servers are configured properly, they appear in the list of MID Servers.

3. If a MID Server does not appear as a choice in the instance, perform the following checks:
   - Ensure that the URL in the Configuration Parameters related list provided is correct.
   - If the MID Server is installed on Windows, make sure the ServiceNow MID Server service is configured properly with the correct logon credentials and is running.
   - Check the MID Server log for errors.
     - On the instance, navigate to Discovery > MID Servers > (MID Server) > Logs.
     - On the MID Server host, navigate to the agent\logs\agent0.log0 directory.
   - If Basic Authentication is enabled, a user name and password must be provided.
   - The MID Server might not have outbound access on port 443 (SSL) or a proxy server might be preventing TCP communication to the instance.
   - Make sure that no firewalls are blocking communication between the MID Server and the instance.

4. Set the credentials on the instance for all the computers, printers, and network gear in your environment.
   Credentials for Windows devices (using the WMI protocol) are provided by the logon configured for the MID Server service on the Windows server host. Credentials for UNIX, vCenter, and SNMP must be configured on the instance. Discovery automatically determines which credentials work for a particular computer or device.

5. Define and run Discovery schedules.
   The Discovery Schedule is the control point for running discoveries. The schedule controls when Discovery runs, defines the MID Server to use, the type of Discovery that should run, and the IP addresses to query. Create as many schedules as necessary, using different types of discoveries, and configure them to run at any time. Let Discovery run on its configured schedule or manually execute Discovery at any time. You can set up a single schedule for the entire network or separate schedules for each location or VLAN. If you do not know the IP address to scan in your network, run a Network Discovery first to discover the IP networks. Once discovered, you can convert these networks into IP address range sets that you use in a Discovery Schedule.
6. Validate the Discovery results.
   Open the ECC queue and analyze the XML payload, then check the Discovery log. For more information, refer to the section for validating results in Schedule a horizontal discovery.

Discovery Quick Start

Discovery Quick Start is a wizard that helps you get up and running with Discovery quickly. Use Discovery Quick Start tasks to discover IP ranges, or subnets, in your environment and then to identify the configuration items (CI) in those subnets.

Before using Discovery Quick Start, install and validate MID Servers. See MID Server Installation for details.

Configure and schedule subnet discovery
Subnet discovery finds all the subnets in your environment to determine available IP ranges and to ensure that there are MID Servers available to access these ranges.

Role required: discovery_admin

The goal of this phase is to discover all the subnets in your network. To do this, Discovery must have the correct SNMP credentials to identify the routers it encounters. Using the credentials you provide, Discovery begins by reading the router tables of the router connected to the MID Server to identify connected routers. Discovery then moves outward through the network from router to router until it has discovered all the local subnets.

After Discovery identifies the subnets, it automatically assigns the IP ranges of these subnets to qualified MID Servers in preparation for the CI discovery phase.

1. Navigate to Discovery > Home.
   The first time you access Discovery Home, a welcome screen appears. After you have configured subnet discovery and run the schedule, Quick Start shows the subnet results information.

2. Click Discovery Quick Start to begin configuration.
3. In the **Select MID Servers** tab, select qualified MID Servers for subnet discovery.
   a) Move the MID Servers you want to use for subnet discovery from the **Available** column to the **Selected** column.

   Available MID Servers must meet these requirements:
   
   - Be configured and in an **Up** state.
   - Be validated.
   - Have the Discovery application attached or **ALL** applications configured.
b) If you want Discovery to use all new MID Servers that meet the setup criteria, select the **Automatically include new MID Servers** option.

c) Click **Next**.

4. In the **Add Credentials** tab, add credentials for the routers you are going to discover. This tab shows any SNMP credentials that are already configured. Routers that appear in the **Targeted Routers** list are default gateway routers to which the MID Server host is connected.

**Note:** You can return to this phase after creating a schedule to add credentials.
a) Click **New** to add SNMP community or SNMP V3 credentials, if necessary.

b) If the list of targeted routers does not include all the routers you expect to use, click the plus icon and add the router by IP address.
c) After you configure all necessary credentials, click **Test Router Access** to verify that Discovery can use your credentials to access routers.

The gateway routers appear in the **Routers** column, regardless of whether the credentials can access the router. Those routers that the credentials can successfully access appear with a **Success** indicator. The routers that cannot be reached, appear with a **Failed** indicator.

You can filter the list using the **Search by IP** field or by using the **Reached Routers** or **Unreached Routers** options from the **View** choice list.

d) Click **Next**.

5. In the **Create Schedule** tab, create a schedule to run subnet discovery regularly.

Execution of this schedule performs subnet discovery and triggers IP subnet auto-assignment, in which the discovered subnets are assigned to qualified MID Servers.

a) Complete the schedule using the fields from the list.
• **Active**: Enables or disables this schedule.

• **Frequency**: Select how often the schedule should run:
  
  • **Daily**: Run Discovery at a specified time each day.
  
  • **Weekly**: Run Discovery on one designated day of each week.
  
  • **Monthly**: Run Discovery on one designated day of the month. If the designated day does not occur in the month, the schedule does not run that month. For example, if you designate day 30, the schedule does not run in February.
  
  • **Once**: Run Discovery once on the designated date and time.
  
  • **Periodically**: Run Discovery every designated period of time. Use the **Repeat Interval** field to define the period of time in days, hours, minutes and seconds. The first discovery runs at the point in time defined in the **Starting** field. The subsequent discoveries run after each **Repeat Interval** period passes.

• **Cancel Discovery if longer than**: Terminate the Discovery process if it exceeds the specified duration. Discovery might run for an excessive amount of time based on multiple factors, including the size of your network.

  **Note**: Any MID Server processing taking place when Discovery is canceled is allowed to complete. However, all output records that MID Servers have not picked up are canceled.

b) Click one of these:

  • **Finish and Run** saves the schedule and runs discovery immediately.
  
  • **Finish** saves the schedule. Discovery then runs at the interval specified in the schedule.

6. View subnet discovery results.
a) Click each tile for details. If subnet Discovery did not yet run, each of these tiles shows 0.

- **Reached Routers**: The number of routers that Discovery was able to access and discover.
- **Unreached Routers**: The number of routers that Discovery was not able to access.
- **Found Subnets**: The number of subnets that Discovery found.
- **Assigned Subnets**: IP subnets that were assigned to at least one MID Server.
- **Unassignable Subnets**: IP subnets that were not assigned to any MID Servers.

b) Click **Edit Schedule** to return to the **Select MID Servers** tab.

c) Resolve any issues with subnet discovery by returning to the Router Access page and making sure each credential is configured correctly. Also test router access for each credential.

d) Click **Advanced View** to see the Automation Status Set form. This form displays detailed results for both subnet discovery and the automatic assignment of IP ranges.

Configure and schedule CI discovery

Using the credentials you provide, the Quick Start wizard finds all the configuration items (CI) for the IP ranges identified during subnet discovery.

Role required: discovery_admin

You should perform this procedure after you complete Configure and schedule subnet discovery in the Discovery Quick Start.

The goal of this phase is to create the schedules necessary to discover the CIs on each subnet. Discovery Quick Start does that automatically, and then runs these schedules using the credentials you provide. You can add additional credentials at any time. Optionally, you can
define locations for each of the subnet routers, and Discovery creates separate schedules for each location.

You must be familiar with the types of credentials that you need for the CIs in your network. Each CI type requires different credentials. For example, if Discovery uses patterns instead of probes, the patterns might require **applicative credentials**.

Review the requirements for the CI types you intend to discover. See *Data collected by Discovery*, and then locate the specific type of device, computer, or application.

1. In the **Add Credentials** tab in the Discovery Quick Start, create the credentials necessary to discover CIs in your network.
   a) Select the credential type you want to manage from the **Type** field.

   All the credentials currently configured for that CI type appear in rows of tiles.
   
   b) To add a credential, click **New**.

   The Add Credential form appears, allowing you to specify your new credential.

   c) Click **Next** to go to the **Router Location** phase.
2. **Optional:** In the **Assign Router Location** tab, assign a location to each router that subnet discovery found.

When you configure router locations, you have the option of creating a schedule for each location. If you do not assign locations, a single Discovery schedule is created for all your subnets. If you assign a timezone to a location, Discovery creates a schedule that runs in that location’s timezone. If you do not assign a timezone to a location, the schedule for that location runs in the user’s local timezone.

**Note:** A subnet can belong to multiple routers. If schedules are created by location, Discovery finds subnets managed by multiple routers using multiple schedules.

The list of gateway routers shows those devices not currently assigned to a location.

![Image of Assign Routers to Locations](image-url)

<table>
<thead>
<tr>
<th>Unassigned Routers (4/4)</th>
<th>for next</th>
<th>search</th>
<th>Select All</th>

<td>6.7.80.1</td>
</tr>
</tbody>
</table>

- a) Select the check boxes for the routers you want to assign a location.
  
  Use the **System Location** column in the table to help you assign a location to the router.

- b) Select the location in the **Assign to** choice list.

- c) If the location is not already in the list, click **Add New Location** and add the location.

- d) Ensure that the location has a timezone defined.
  
  Timezones allow you to create a schedule for each location based on the timezone.

- e) Click **Assign**.
f) Click **Next**.

3. Create a CI Discovery schedule.
   a) Complete the schedule using the fields in the list.

- **Active**: Enables or disables this schedule.
- **Frequency**: Select how often the schedule should run:
  - **Daily**: Run Discovery at a specified time each day.
  - **Weekly**: Run Discovery on one designated day of each week.
  - **Monthly**: Run Discovery on one designated day of the month. If the designated day does not occur in the month, the schedule does not run that month. For example, if you designate day 30, the schedule does not run in February.
  - **Once**: Run Discovery once on the designated date and time.
  - **Periodically**: Run Discovery every designated period of time. Use the **Repeat Interval** field to define the period of time in days, hours, minutes and seconds. The first discovery runs at the point in time defined in the **Starting** field. The subsequent discoveries run after each **Repeat Interval** period passes.

- **Create a separate schedule for each location**: Automatically create schedules for any router locations you have configured. These schedules run on the day and time...
you specify, but in their own local timezone. Clear this check box to create a single schedule for all your locations that runs in the user's local timezone. This option is only available if you have configured router locations.

- **Cancel Discovery if longer than**: Terminate the Discovery process if it exceeds the specified duration. Discovery might run for an excessive amount of time based on multiple factors, including the size of your network.

  Note: Any MID Server processing taking place when Discovery is canceled is allowed to complete. However, all output records that MID Servers have not picked up are canceled.

b) Click one of these options to finish the Quick Start:

- **Finish and Run** saves the schedule and runs a discovery immediately.
- **Finish** saves the schedule. Discovery runs at the interval you specified in the schedule.

### Running discoveries in your network

You can run discoveries from schedules or scripts to create configuration items, define subnets, or to find resources in AWS and Azure clouds.

### MID Server configuration prerequisites

Ensure that your MID Servers are properly configured prior to creating a Discovery schedule.

- **Supported applications**: Select the applications that are allowed to use the MID Server. You can use the **ALL** application option to allow any application to use the MID Server.
- **IP ranges**: Define the ranges of IP address the MID Server can scan. To find a MID Server match, the IP range you configure on the Discovery schedule must fall into the ranges that one or more MID Servers can support.
- **Capabilities**: Create the capabilities that the MID Server supports. You can use the **ALL** capability option to allow any application to use the MID Server.

### Discovery configuration prerequisites

Ensure that your MID Servers can authenticate on the devices they find and classify configuration items (CI) properly.

- **Credentials**: Configure the MID Servers with the login credentials they need to query the devices in the network.
- **Classifications**: The device and process classifications provided in the base platform are normally sufficient. Create classifications as needed for the devices, processes, and applications in the network not covered by the default classifiers.

### Get started running a discovery

1. Use the Discovery Configuration Console to get started with Discovery. The console provides configuration options which let you choose the types of devices, applications, software files, and software CIs you want Discovery to find. If you select a CI to exclude from scanning, the
instance disables the related probe or classifier that Discovery uses to identify the CI. See *Discovery Configuration Console* to get started.

2. Determine what type of discovery to run:

- **Run a Configuration item (CI) discovery** to find the devices, computers, and applications on your network. This is the most common type of discovery. Run CI discovery from the Discovery Schedule, where you set up a recurring schedule or run a discovery on demand. The Discovery Schedule also provides configuration options for MID Servers and the Shazzam port probe.

- **Run a Network Discovery** to find the internal IP networks within your organization. If you already know the IP address ranges in your network, it is not necessary to run Network Discovery. It is intended for organizations that do not have complete knowledge of the IP addresses available for Discovery in their networks.

- **Run a Serverless Discovery** to find applications on host machines without the need to discover the host first. Serverless Discovery relies on infrastructure patterns to explore CIs on a host. This kind of discovery skips the scanning and classification phases of discovery. You need an advanced knowledge of patterns to use this type of discovery. Refer to *Patterns and horizontal discovery* to get started with patterns.

3. After you run a discovery, monitor the results of the discovery and resolve errors if they occurred:

- **Use the Discovery status** to see a summary of a Discovery and to access the ECC queue, which shows probe and sensor activity, as well as the actual XML payload that is sent to or from an instance.

- **Use the Discovery dashboard** to monitor ongoing Discovery operations.

- Use the **Discovery Home page** to access details for all schedules, cloud resources (virtual machines), discovered devices, and related errors that might have occurred. Error details include possible remediation steps.

**Discovery Configuration Console**

Use the Discovery Configuration Console to manage what kind of CIs and CI information you want to discover.

By default, Discovery finds all the information on your network that is specified in probes and patterns. Use the controls in this console to select the data Discovery adds to the CMDB that your organization needs. You can control these aspects of Discovery:

- The discovery of entire CI types, such as Windows servers.
- The discovery of specific CI details, such as OS information on Windows servers.
- The discovery of software packages containing keyword terms that you add, such as Hotfix or Security Update.
- File-based Discovery of software on UNIX and Windows by particular extension or folder, such as .cert or .ext.

**Note:** Discovery returns all data from the target to the instance before applying console settings. The instance ignores any excluded data when it updates the CMDB.

**Requirements and accessibility**

If you use Internet Explorer, you must use version 8 or later. The configuration console supports keyboard navigation and screen readers.
Console overview

To open the configuration console, navigate to Discovery Definition > Configuration Console.

The console is divided into these sections. Use the toggle buttons to enable various options (right to enable, left to disable).

- **Devices**: network devices such as printers, storage devices such as storage switches, and Unix and Windows computers
- **Applications**: automation applications such as Puppet, databases such as MSSQL, and web servers such as Tomcat
- **Software Filter**: Unix and Windows applications that include or exclude keywords that you enter
- **File-based Discovery**: software files by path, folder, and extensions to scan or ignore
Disabling the discovery of device data at the top level disables the related port probes and pattern libraries. For example, blocking Network Devices disables the SNMP port probe. Blocking devices at the second level of the hierarchy has the following effects:

- Device class categories disable classifiers.
- Device info categories disable probes and pattern libraries.

Device Discovery
Application Discovery

Disabling the discovery of application data affects all host devices on which the application runs. For example, if you configure Discovery to ignore databases, no information is gathered for either Linux or Windows databases. Conversely, if you configure the system to ignore a device type, such as a Windows server, no databases running on that server are explored, even if they are configured to be discovered. The instance cannot identify the applications running on a server until it first discovers that server.

When you exclude an item from the Applications section, the system disables the relevant process classifier. The probes that belong to this classifier, including the Horizontal Pattern probe that launches patterns, never launch.

Software Discovery

You can filter the discovery of software packages based on the keywords they contain for Windows and UNIX computers. A keyword can be any term that is present in a software package name. Keywords for filtering software are stored in the Software Filter Keys (discovery_spkg_keys) table. The system does not provide default filtering keywords for UNIX software.
**Attention:** Keyword software filtering occurs after the probe returns its payload to the instance and not on the target host.

The following default keywords are provided for Windows and are filtered out by default:

- Hotfix
- Language Pack
- Security Update

**File-based Discovery**

You can configure Discovery to either scan or ignore paths, folders, and extensions for File-based Discovery. Discovery then scans a Windows or UNIX file system with these settings to identify file fingerprints. Installed software products detected with these attributes are matched to products in a comprehensive software normalization library.

**Effects on Discovery tables**

This table shows you what is disabled in Discovery tables when you use the Discovery Configuration Console.

<table>
<thead>
<tr>
<th>When you disable</th>
<th>Field disabled</th>
</tr>
</thead>
<tbody>
<tr>
<td>Top-level device categories, such as:</td>
<td>The <code>Cls</code> field is disabled on the Port probes (discovery_port_probe) table.</td>
</tr>

<td>The Process Classifiers (discovery_classy_proc) table is referred to from the Application Category (discovery_category_appl) table.</td>
</tr>
</tbody>
</table>

**Note:** If you use patterns for discovery, and you disable the discovery of device classes or device information, the system disables the pattern libraries that collect the device information. For example, if you have a Windows pattern in which you create a shared...
Exclude CIs from discovery
Use the Discovery Configuration Console to determine which devices and applications to exclude from discovery.

Role required: discovery_admin, admin

1. Navigate to **Discovery > Discovery Definition > Configuration Console**.
2. If you want to exclude specific devices and device information, expand the category for the device types.
3. To see what applications can be disabled, hover your cursor over the application type.
4. Click the toggle button to turn off the CIs you do not want to discover.

The instance creates an update set record for any change you make to the console.

Customize Applications and Devices to Discover
You can toggle on and off Applications and Devices using the Discovery Configuration Console. Some are listed out-of-the-box, but you may also customize which specific Applications and Devices you want to Discover according to your specific requirements.

Role required: admin

1. Customize Applications.
   a) Navigate to **Discovery Definition > Application Categories**.
   b) Click Automation, Databases, or Web & Application Servers.
   c) Unlock the Process classifier list.
   d) To delete from the list, select an application then click the X to remove.
   e) To add to the list, type in the box and click Enter.
   f) Click the lock icon.
   g) Click Update. The next time Discovery runs, it will process those types of specific applications that you configured.

2. Customize Devices.
   a) Navigate to **Discovery Definition > Device Info Categories**.
   b) To create a new record, click New.
   c) Enter the details and click Submit.
   d) To update an existing device, click on a device listed.
   e) Make any changes and click Update or Delete.

Filter software to discover
Use the Discovery configuration console to filter the software you add to the CMDB.

Role required: discovery_admin, admin

The instance creates an update set record for any change you make to the console.

1. Navigate to **Discovery > Discovery Definition > Configuration Console**.
2. In the Software Filter panel, select the tab for the operating system you want, either Unix or Windows.
3. Add or delete keywords for filtering software packages.
To add a keyword, enter it in the field provided and click **New Key**.

To delete a keyword, click the red **x** icon to the right of the keyword.

Discovery looks for software packages containing these terms in the selected operating system and either includes or excludes them from the CMDB. The system does not provide default keywords for filtering UNIX software packages, but provides these default keywords for Windows:

- Hotfix
- Language Pack
- Security Update

4. Select whether to **Include** or **Exclude** software packages with the keywords in their names.
   - **Include**: Only add software packages that match the keywords.
   - **Exclude**: Add all software packages except those matching the keywords.

5. Disable software filtering for either **UNIX** or **Windows**.

   When the filter is disabled for an operating system, all discovered software packages for that operating system are added to the CMDB, with no filtering applied.

   The instance creates an update set record for any change you make to the console.

**Configure File-based Discovery**

Use the Discovery configuration console to configure several settings to find and manage all of your installed software.

Role required: discovery_admin, admin

1. Navigate to **Discovery > Discovery Definition > Configuration Console**.
2. Enable **File-based Discovery**.
   - This is disabled by default.
3. Select customizable options specifically for Windows and UNIX machines as well as options common to both types.
   - Some options have default values and others, such as folders to ignore or extensions, are blank until you add in values.
4. For Windows and/or UNIX, click the arrow to expand the target path options.
5. Configure basic selections.

**Folders to Scan**

Indicates which folders to scan for Windows and/or UNIX. Default values are listed. You can also add additional paths to scan.
Folders to Ignore

Indicates which folders and child folders/files to ignore from within the list of Window or UNIX folders that you want to scan. For example, if you have specified “C:\Program Files” as a folder to scan, you could additionally specify “C:\Program Files\Temp” as an ignore folder. When File-based Discovery scans a Windows server, it will scan all files and sub folders under C:\Program Files, excluding C:\Program Files\Temp.

Extensions Blacklist

Indicate extensions (.txt, .war, .exe, etc.) that you want to ignore for Windows.

Extensions Wildcards

Indicate extensions (.cert, .crt, etc.) that you always want to scan for Windows. This allows you to scan for extensions such as *.cert where the file name itself might not be known ahead of time. You should be able to find certificates (.cert or .crt) and java keystore files (.jks) in this way.

**Advanced**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep Time</td>
<td>10000</td>
</tr>
<tr>
<td>File Throttle</td>
<td>500</td>
</tr>
<tr>
<td>Skip Hidden Folders</td>
<td></td>
</tr>
<tr>
<td>Scan Running Process Paths</td>
<td></td>
</tr>
<tr>
<td>Scan SWID Tags</td>
<td></td>
</tr>
</tbody>
</table>

**Sleep Time**

Sets the length of time in milliseconds to sleep during each throttling interval while scanning for Windows files. The default value is 10000. Do not change this value unless you are an advanced user. If you are an advanced user and need to make a change, make sure to set to a non-zero value.

**File Throttle**

Sets the number of files to scan on Windows before sleeping. The default value is 500. Do not change this value unless you are an advanced user. If you are an advanced user and need to make a change, make sure to set to a non-zero value.

**Skip Hidden Folders**

Skips hidden folders on target computers when scanning for file signatures. For Windows devices, the visibility of a folder is based on a hidden attribute that can be set for each folder.

**Scan Running Process Paths**

Enables the use of running process paths in the list of targeted paths to scan. This automatically adds paths that we know contain running processes and therefore most likely contain files of interest for use in determining software installations.
Scan SWID Tags

Scans for and analyzes the software identification (SWID) tags. This option is only visible if SAMP is enabled. When Scan SWID Tags is enabled, this returns the software product, publisher, and version in the payload to be directly inserted into software installs table, bypassing the software match API. This is disabled by default.

7. Configure **Advanced UNIX** settings.

![Advanced settings](image1)

Skip Hidden Folders

Skips hidden folders when scanning for file signatures. For Unix-based devices these are folders prefixed by a “.” in their name.

Scan Running Process Paths

Enables the use of running process paths in the list of targeted paths to scan. This automatically adds paths that we know contain running processes and therefore most likely contain files of interest for use in determining software installations.

8. Configure **Common** settings for either Windows or UNIX.

![Common settings](image2)

Maximum Files

Sets the maximum number of files that you want to discover. This is the number of files scanned per CI/IP.

**Frequency**

Sets the frequency that File-based Discovery runs on the CI.

File-based Discovery is now enabled, configured, and ready for you to run. See [Run File-based Discovery](#) for more information.

**Schedule a horizontal discovery**

A discovery schedule determines what horizontal discovery searches for, when it runs, and which MID Servers are used. Create a Discovery schedule for your local environment or a schedule for discovering the resources in your cloud service account.
Roles required: admin, discovery_admin

You can use a Discovery schedule to launch horizontal discovery, which uses probes, sensors, and pattern operations to scan your network for CIs. Use this procedure to create a schedule manually from the Discovery Schedule form.

Service Mapping also provides a Discovery schedule for top-down discovery. See Schedule a top-down discovery by Service Mapping for more information.

Use the Discovery Schedule module in the Discovery application to:

- Configure a schedule to discover resources in your cloud service account.
- Configure device identification by IP address or other identifiers.
- Determine if credentials are used in device probes.
- Name the MID Server to use for a particular type of discovery.
- Create or disable a schedule that controls when the discovery runs in your network.
- Configure the use of multiple Shazzam probes for load balancing.
- Configure the use of multiple MID Servers for load balancing.
- Run a Discovery schedule manually.
- Run Discovery on a single IP address.

**Note:** To view the run-results of your schedules for both IP-based and Cloud Discovery, use the summaries on the Discovery Home page. The Home page publishes the details of any errors that might have occurred and displays possible actions to take to remediate problems.

1. Navigate to Discovery > Discovery Schedules to create a new record.
2. Select the type of schedule to open:
   - **New:** Creates a new horizontal schedule for discovering components in your network.
   - **Quick Discovery:** Runs an horizontal discovery on a single IP address without requiring a schedule.
   - **Create a Cloud Discovery schedule:** Creates a schedule, using the Discovery Manager wizard, for discovering resources in a cloud service account.
3. Complete the Discovery Schedule form, using the fields in the table.
4. Right-click in the header of the record and select Save from the context menu.
5. To create a range of IP addresses to discover, click Quick Ranges under Related Links.
## Discovery Schedule

**Name:** My Discovery Schedule

**Discover:** Configuration Items

**NIS Server selection method:** Auto-Select NIS Server

**Max run time:**
- Days: 0
- Hours: 10
- Minutes: 00

**Run:** Weekly

**Day (run, day/week):** Monday

**Time:**
- Hours: 02
- Minutes: 00

### Advanced

- **Include alive:** Yes
- **Hashcheck size:** 5000
- **Log state changes:** Yes
- **Hashcheck cluster support:** Yes

Discovery Schedule Form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a unique, descriptive name for your schedule.</td>
</tr>
<tr>
<td>Discover</td>
<td>Select one of the following scan types:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Configuration items</strong>: Uses Discovery identifiers to match devices with CIs in the CMDB and update the CMDB appropriately. Perform a simple discovery by selecting a specific MID Server to scan for all protocols (SSH, WMI, and SNMP). Or, perform advanced discoveries with discovery behaviors. When you select a behavior, the MID Server field is not available.</td>
</tr>
<tr>
<td></td>
<td>• <strong>IP addresses</strong>: Scans devices without the use of credentials. These scans discover all the active IP addresses in the specified range and create device history records, but do not update the CMDB. IP address scans also show multiple IP addresses that are running on a single device. Identify devices by class and by type, such as Windows computers and Cisco network gear. The Max range size Shazzam probe property determines the maximum number of IP addresses Shazzam scans. See <a href="#">Configure Shazzam probe</a> for details.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Networks</strong>: Discovers IP networks (routers and switches). Results from this search are used to populate the IP Network (cmdb_ci_ip_network) table in Discovery &gt; IP Networks with a list of IP addresses and network masks. Network scans update routers and layer 3 switches in the CMDB.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Service</strong>: Discovers services for the Service Mapping application. See <a href="#">Schedule a top-down discovery by Service Mapping</a> for instructions.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Serverless</strong>: Finds CIs without needing to run discovery on a host, or CIs on a proxy host that is already in the CMDB. See <a href="#">Serverless Discovery</a> for more information.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Cloud application</strong>: Discovers only the cloud resources for the patterns that you specify. See <a href="#">Cloud Discovery</a> for instructions.</td>
</tr>
</tbody>
</table>
|           | • **Cloud resources**: Discovers resources on AWS and Azure clouds. This option only appears when you run Discovery on a [cloud service account](#). You cannot select it from a new Discovery schedule.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MID Server selection method</td>
<td>Select the method that Discovery uses to select a MID Server:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Auto-Select MID Server</strong>: Allow Discovery to select the MID Server automatically based on the Discovery IP Ranges you configure. To find a matching MID Server, you must configure MID Servers to use:</td>
</tr>
<tr>
<td></td>
<td>• The Discovery application, or ALL applications. This setting authorizes the MID Server access from Discovery.</td>
</tr>
<tr>
<td></td>
<td>• The IP Range that includes the ranges you configure on the Discovery Schedule.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Specific MID Cluster</strong>: Use a preconfigured cluster of MID Servers. Select the cluster. You are not required to specify one member of the cluster. The MID Server cannot be part of multiple clusters, such as one that supports load balancing and one that supports failover. You can add any cluster regardless of the application that the MID Servers are assigned to. When you select the cluster, the <strong>Discovery</strong> application is automatically added when it does not exist for the MID Servers in the cluster.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Specific MID Server</strong>: Use only one MID Server. If that MID Server is part of a cluster, only that MID Server is used. The cluster is not used. You can add any MID Server regardless of the application it is assigned to. The <strong>Discovery</strong> application is automatically added when it is not already assigned for the MID Server you select. You can assign a specific MID Server for all types of Discover scans except <strong>Service</strong>.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Use Behavior</strong>: Use a behavior when a single schedule requires the use of multiple MID Servers to perform any of the following activities:</td>
</tr>
<tr>
<td></td>
<td>• Scans requiring multiple Windows credentials.</td>
</tr>
<tr>
<td></td>
<td>• A schedule that must execute two or more particular protocols (SNMP, SSH, or WMI) using more than one MID Server.</td>
</tr>
<tr>
<td></td>
<td>• Load balancing for large discoveries where a single MID Server would be inadequate.</td>
</tr>
<tr>
<td></td>
<td>• Scanning multiple domains.</td>
</tr>
</tbody>
</table>

**Note**: The Discovery schedule enforces domain separation. The MID Servers that are available for selection are limited to the same domain of the user who is configured.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| MID Server          | Select the MID Server to use for this schedule. This field is available if MID Server selection method is set to Specific MID Server, or if you discover IP addresses, networks, or web services.  
To verify that the MID Server you selected is up and validated, look at the [MID Server dashboard](#). |
| MID Server Cluster  | Select the MID Server cluster to use for this schedule. This field is available if MID Server selection method is set to Specific MID Cluster.                                                                   |
| Behavior            | Select a behavior configured for the MID Servers in your network.  
This field is available only if MID Server selection method is set to Use Behavior.                                                                                                           |
| Active              | Select the check box to enable this schedule. If you clear the check box, the schedule is disabled, but you can still run a discovery manually from this form, using the configured values.                               |
| Location            | Choose a location to assign to the CIs that the schedule discovers. If this field is blank, then no location is assigned.                                                                                       |
| Max run time        | Set a time limit for running this schedule. When the configured time elapses, the remaining tasks for the discovery are canceled, even if the scan is not complete.  
Use this field to limit system load to a desirable time window. If no value is entered in this field, this schedule runs until complete.                |
| Run and related fields | Determines the run schedule of the discovery. Configure the frequency in the Run field and the other fields that appear to specify an exact time.  
**Note:** The run time always uses the system time zone. If you add the optional Run as tz field, it has no effect on the actual runtime.            |
| Include alive       | Select this check box to include alive devices, which are devices that have at least one port that responds to the scan, but no open ports. Discovery knows that there is a device there, but has no information about it.  
If this check box is cleared, Discovery returns all active devices, which are devices that have at least one open port. |
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Log state changes</td>
<td>Select this check box to create a log entry every time the state changes during a discovery, such as a device going from Active to Classifying. View the discovery states from the Discovery Devices related list on the Discovery Status form. The Completed activity and Current activity fields display the states.</td>
</tr>
<tr>
<td>Shazzam batch size</td>
<td>Enter the number of IP addresses that each Shazzam probe can scan. Dividing the IP addresses into batches improves performance by allowing classification for each batch to begin after the batch completes, rather than after all IP addresses have been scanned. The probes run sequentially. For example, the value is set to 1000 and a discovery scans 10,000 IP addresses using a single MID Server. It creates 10 Shazzam probes with each probe scanning 1000 IP addresses. By default, the batch size is 5000. A UI policy enforces a minimum batch size of 256 because batch sizes below 256 IP addresses do not benefit from clustering. The policy converts any value below 256 to a value of zero. The value for this field cannot exceed the value defined in the maximum range size property for the Shazzam probe.</td>
</tr>
<tr>
<td>Shazzam cluster support</td>
<td>Select the check box to distribute Shazzam processing among multiple MID Servers in a cluster and improve performance. This setting works with the Shazzam batch size. For example, a schedule is created to scan 100,000 IP addresses, with 10 MID Servers assigned to do the work. Each MID Server is assigned to scan 10,000 IP addresses. If the Shazzam batch size is set to 5,000 IP addresses per probe, the schedule runs two Shazzam probes per MID Server (10,000 IP addresses/5,000 per batch). These probes are run in sequence and not concurrently.</td>
</tr>
<tr>
<td>Use SNMP Version</td>
<td>Use this field to designate the SNMP version to use for this discovery. Valid options are v1, v2c, v3, or All.</td>
</tr>
<tr>
<td>Quick ranges</td>
<td>Define IP addresses and address ranges to scan by entering IP addresses in multiple formats (network, range, or list) in a single, comma-delimited string. For more information, see Create a Quick IP range for a Discovery schedule.</td>
</tr>
<tr>
<td>Discover now</td>
<td>Use this link to immediately start this Discovery.</td>

### Discovery schedule run options

<table>
<thead>
<tr>
<th>Run option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>On Demand</td>
<td>Does not run on a schedule. Click <strong>Discover now</strong> to run Discovery. This is the default option.</td>
</tr>
<tr>
<td>Daily</td>
<td>Runs every day. Use the <strong>Time</strong> field to specify the time of day.</td>
</tr>
<tr>
<td>Weekly</td>
<td>Runs on one designated day of each week. Use the <strong>Time</strong> field to specify the time of day.</td>
</tr>
<tr>
<td>Monthly</td>
<td>Runs on one designated day of each month. Use the <strong>Day</strong> field to select the designated day and the <strong>Time</strong> field to specify the time of day. If the designated day does not occur in the month, the schedule does not run. For example, if you designate day 30, the schedule does not run in February.</td>
</tr>
<tr>
<td>Periodically</td>
<td>Runs every designated period of time. Use the <strong>Repeat Interval</strong> field to define the period in days, hours, minutes, and seconds. The first Discovery runs at the point in time defined in the <strong>Starting</strong> field. Discovery runs after each <strong>Repeat Interval</strong> period passes.</td>
</tr>
<tr>
<td>Once</td>
<td>Run one time as designated by the date and time defined in the <strong>Starting</strong> field.</td>
</tr>
<tr>
<td>Weekdays</td>
<td>Runs every Monday, Tuesday, Wednesday, Thursday, and Friday. Use the <strong>Time</strong> field to select the time of day.</td>
</tr>
<tr>
<td>Weekends</td>
<td>Runs every Saturday and Sunday. Use the <strong>Time</strong> field to select the time of day.</td>
</tr>
<tr>
<td>Month Last Day</td>
<td>Run the last day of every month. Use the <strong>Time</strong> field to select the time of day.</td>
</tr>
<tr>
<td>Calendar Quarter End</td>
<td>Runs on March 31, June 30, September 30, and December 31. Use the <strong>Time</strong> field to select the time of day. To change the dates, modify the DiscoveryScheduleRunType script included.</td>
</tr>
<tr>
<td>After Discovery</td>
<td>Allows you to sequentially stagger the schedule. Use this option to run this schedule after the <strong>Run after</strong> Discovery finishes. Select the <strong>Even if canceled</strong> check box to designate the Discovery is canceled before it finishes.</td>
</tr>
<tr>
<td></td>
<td>- This option is not valid when the Discovery is started via DiscoverNow, or if you cannot designate an inactive Discovery schedule.</td>
</tr>
<tr>
<td></td>
<td>- You cannot create a loop by designating the run after Discovery to be the same Discovery.</td>
</tr>
<tr>
<td></td>
<td>- This Discovery does not run if the <strong>Run after</strong> Discovery does not finish, with the exception that the <strong>Even if canceled</strong> check box is selected and the Discovery is canceled.</td>
</tr>
</tbody>
</table>

---

**Run a Quick Discovery**

Quick Discovery, or DiscoverNow, allows an administrator to run a CI Configuration discovery on a single IP address without requiring a schedule.

The platform automatically selects the correct MID Server to use for the discovery if one is associated with the IP address selected. If no MID Server is configured for the network in which that address appears, you can select a MID Server. Use this feature to discover new devices in the network as soon as they are connected to the network, rather than waiting for a regularly scheduled discovery.
To configure the system to automatically determine which MID Server to use, set up the IP range capabilities for each MID Server in your system.

You can run DiscoverNow from a Discovery schedule form or from a script.

1. Open Quick Discovery from one of these locations:
   - Navigate to Discovery > Discovery Schedules and click Quick Discovery in the header bar.
   - Navigate to Discovery > Home and click Discovery Quick Start under the Schedules tile.

   A dialog box appears asking for an IP address and the name of the MID Server to use. Only Up and Validated MID Servers are available.

2. Enter the target IP address for a discovery in the Target IP field.

   \[\textbf{Note:}\] DiscoverNow does not currently support IP network discovery. Make sure that you enter a single IP address only and not an entire network, such as 10.105.37.0/24.

   When a MID Server is assigned to the subnet containing the target IP address and currently in an operational status of Up, the name appears automatically in the MID Server field. If multiple MID servers are found, the system selects one for you. The value in the MID Server field can be overwritten if you want to select a different MID Server.

   \[\textbf{Attention:}\] If the selected MID Server is part of a load balanced cluster and becomes unavailable for any reason, the instance does not assign another MID Server from that cluster to the quick Discovery. You must select another MID Server from the list of appropriate MID Servers.

3. If no MID Server is defined for that network, select one from the list of available MID Servers.

   \[\textbf{Quick Discovery Dialog}\]

4. Click OK to run discovery.

   The status record for that discovery appears. The Schedule column is empty because no schedule is associated with this discovery.
Quick Discovery Status List

Run DiscoverNow from a script
You can run DiscoverNow from a script, such as a background job, a business rule, or web services.
Role required: admin

1. Create the following script:

   ```javascript
   var d = new Discovery();
   var statusID = d.discoveryFromIP(TARGET_IP, TARGET_MIDSERVER);
   ```

   The `discoveryFromIP` method takes two arguments: IP and MID Server. The IP argument is mandatory, but the MID Server argument is optional.

2. To choose the MID Server, supply either the `sys_id` or name of the MID Server as the argument. If you do not name a MID Server, the system attempts to find a valid one automatically. A valid MID Server has a status of Up and can discover the given IP address. If the system finds a valid MID Server and runs a Discovery, the `discoveryFromIP` method returns the `sys_id` of the Discovery status record. If no MID Server can discover this IP address, the method returns the value `undefined`.

   If you manually specify the `TARGET_MIDSERVER`, the system validates the given value and ensures that the MID Server table contains the specified MID Server record. If the validation passes, the `discoveryFromIP` method returns the `sys_id` of the discovery status record. If the validation fails, the method return the value `undefined`.

Validate discovery results
Validate the results of your discovery by accessing the ECC queue, analyzing the XML payload, and checking the Discovery log.
Role required: discovery_admin

Initial discoveries often reveal unexpected results, such as previously unknown devices and processes or failed authentication. Results should also accurately identify known devices and update the CMDB appropriately. Become familiar with the network that is being discovered and the types of data returned for the different types of discoveries. Use the Discovery Log and the ECC Queue to monitor the Discovery process as data is returned from probes or pattern operations.

1. To view the actual payload of a probe, click the XML icon in a record in the ECC Queue.
This XML file does not appear to have any style information associated with it. The document tree is shown below.

```xml
<parameters>
  <parameter name="port" value="5988"/>
  <parameter name="source" value="10.1.134.226"/>
  <parameter name="device_instance" value=" Hitachi StorageVolume [Name: AN20100.03043211, CreationClassName: Hitachi_StorageSystem, Device ID: 8D04321120022, CreationClassName: Hitachi_StorageVolume, SystemName: AN20100.03043211] " />
  <parameter name="probe" value="CIM - SNIA - Storage Controllers" />
  <parameter name="queries" value="(Device[Name: AN20100.03043211, CreationClassName: Hitachi_StorageSystem, Device ID: 8D04321120022, CreationClassName: Hitachi_StorageVolume, SystemName: AN20100.03043211])" />
  <parameter name="credential_id" value="79fe74a9373110004d0fe5d12" />
</parameters>
```
2. To view the actual payload of a probe, click the XML icon in a record in the ECC Queue.

3. Use the Discovery Log form for a quick look at how the probes are doing. To display the Discovery Log, navigate to Discovery > Discovery Log.

### Discovery Log

The Discovery Log provides this information:

<table>
<thead>
<tr>
<th>Column</th>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created</td>
<td>Displays the timestamp for the probe launched. Click this link to view the record for the probe launched in this list.</td>
</tr>
<tr>
<td>Level</td>
<td>Displays the type of data returned by this probe. The possible levels are:</td>
</tr>
<tr>
<td></td>
<td>- Debug</td>
</tr>
<tr>
<td></td>
<td>- Error</td>
</tr>
<tr>
<td></td>
<td>- Information</td>
</tr>
<tr>
<td></td>
<td>- Warning</td>
</tr>
<tr>
<td>Message</td>
<td>Message describing the action taken on the information returned by the probe.</td>
</tr>
<tr>
<td>ECC queue input</td>
<td>Displays the ECC queue name associated with the log message.</td>
</tr>
<tr>
<td>CI</td>
<td>The CI discovered. Click this link to display the record from the CMDB for this CI.</td>
</tr>
<tr>
<td>Source</td>
<td>Displays the probe name that generated the log message.</td>
</tr>
</tbody>
</table>
### Column Information

| Device | Displays the IP address explored by the probe. Click this link to examine all the log entries for the action taken on this IP address by this Discovery. |

**Note:** If you cancel an active discovery, note the following information:
- Existing sensor jobs that have started processing are immediately terminated.
- The existing sensor jobs that are in a Ready state, but have not started processing, are deleted from the system.

4. View the [Discovery Home page](#) for details about all schedules, cloud resources (virtual machines), discovered devices, and related errors that might have occurred. **Error details** include possible remediation steps.

### MID Server selection sequence for Discovery schedules

The Discovery application follows this sequence to find a MID Server.

#### MID Server auto-selection

Discovery follows this sequence when you select **Auto-Select MID Server** for the **MID Server selection method** on the Discovery Schedule form.

1. Discovery looks for a MID Server that also has an appropriate IP range configured.
2. If no MID Servers meet these criteria, it looks for a MID Server that has the **ALL** application that also has an appropriate IP range configured.
3. If more than one MID Servers meet the criteria, Discovery chooses the first MID Server with the status of **Up**. If more than one MID Servers are up, it randomly picks one.
4. If none are up, it uses the default MID Server specified for the Discovery application, assuming it is up.
5. If no default MID Server is specified, it uses the default MID Server specified for the **ALL** application, assuming it is up.
6. If no default MID Server is specified, Discovery cycles through the previous steps and looks for MID Servers with the status of **Paused** or **Upgrading**.

**Note:** When a MID Server is paused or upgrading, it does not actually process commands until it returns to the status of **Up**.

### MID Server clusters

These steps are followed when you select **Specific MID Cluster** for the **MID Server selection method** on the **Discovery** form, and the cluster is a load balancing cluster:

1. **Discovery** uses the first MID Server in the cluster that it finds with the status of **Up**.
2. If more than one MID Servers are up, it randomly picks one. If it cannot find any MID Servers, it looks for MID Servers in the cluster with the status of **Paused** or **Upgrading**.

These steps are followed when the cluster is a failover cluster:

1. **Discovery** uses the MID Server with the lowest **Order** value that also has the status of **Up**.
2. If no MID Servers are found, it looks for MID Servers in the cluster with the status of **Paused** or **Upgrading**, choosing the one with the lowest **Order** value.

**Note:** **Discovery** ignores the default MID Server for it and **ALL** applications when selecting a MID Server from the cluster.

**Port scan (Shazzam) phase**

During the port scan phase, **Discovery** collects all the target IP addresses. It splits them equally between MID Servers matching the criteria (MID Servers are qualified to do the port scan). The Shazzam batch size, which you configured on the **Discovery** schedule, determines the number of IP addresses that each Shazzam probe can scan. This phase helps determine how much work each MID Server does during the port scan phase.

For example, you have 16,000 IP addresses to scan among three qualified MID Servers, and you use the default Shazzam batch size of 5000. Two of the MID Servers handle 5000 IP address scans (one Shazzam probe each). The other MID Server handles 6000 IP address scans by launching two Shazzam probes.

**File-based Discovery**

File-based Discovery helps you identify what software is running on your Windows and UNIX servers and devices, even if there is no registration information available. You can then manage and maintain records of your software licenses, check for unlicensed files, detect forbidden or damaged files, and help evaluate any threats from unwanted files.

**Required plugins**

The File-based Discovery (com.snc.discovery.file_based_discovery) plugin is required for file signature filtering. Your Discovery subscription includes this plugin, but you must request activation. Once the File-based Discovery plugin is active, the Software Asset Management - File Signature Normalization (com.snc.file_signature_normalization) plugin will also be activated. For more information on the File Signature Normalization plugin, see [File Signature Normalization](#).

**How File-based Discovery works**

File-based Discovery enhances the pre-existing discovery of installed software. It scans target servers for a known list of file signatures and processes those files with an established set of rules. The resulting data enhances the identification of installed software and identifies unregistered software products.

File-based Discovery is triggered in the exploration phase of normal Discovery. File-based Discovery probes execute a scan searching for specific file extensions or file names in paths that you configure. The resulting file information is returned in the probe payload. The sensor attempts to match the discovered files with installed software, using the file name, size, and version returned by the probe. File-based Discovery uses file signatures to detect software that might not have
been registered. This information is then stored in the File Information (cmdb_file_information) table with a reference to the CI of the server. You can view the files found from each CI in a related list on this table. For more information, see Related Lists of CI components.

When Software Asset Management Professional (SAMP) is active, if any file matches a software product, Discovery populates the Product and Publisher information for that file. Use this information to understand what software is running on your server and to help evaluate any threats from unwanted files. Discovery uses lists of known file signatures for Windows and UNIX to constrain the scope of the search. The filtering process for Windows and UNIX hosts is executed differently because their signature lists differ greatly in size. The much smaller UNIX signature list is included with the Unix - File Discovery probe and processed directly on the target. The Windows signature list is much larger and cannot be processed on the target. The Windows - File Discovery probe scans the target for specific file extensions and paths and returns these results to the MID Server. The MID Server performs file signature filtering using the entire Windows list. The MID Server then sends all file information back to the instance for normalization and matching.

If SAMP is active on the instance, File-based Discovery creates or updates identified software products in the Software Installation (cmdb_sam_sw_install) table and updates the licenses of matched software packages. Without SAMP, no software records are created and only the file information goes into the File Information (cmdb_file_information) table.

File-based Discovery filtering flow

File-based Discovery inserts any file not matched by the normalization API into the Unidentified File Set (cmdb_unidentified_file_set) table. You can update the records in this table and provide additional details for previously unidentified files. If you provide values for the Product and Publisher fields for a file, settings in SAMP can enable File-based Discovery to use that file for installed software matching in future discoveries.
**Note:** You can disable File-based Discovery at any time by changing the setting in the Discovery Configuration Console. If you disable File-based Discovery before scan results are returned, the file data is ignored.

File-based Discovery table schema

**Note:** File-based Discovery supports Windows and UNIX devices. The UNIX probe is POSIX-compliant and should run on any Linux/Solaris server. We support Windows versions 2008, 2008R2, 2012R2, 2016, 2019, and above with PowerShell 3.0 and above. We also support AIX versions 5.3, 6.1, and 7.1 and HP/UX 8.11.
1. **File-based Discovery reference information**

*Run File-based Discovery*
Run File-based Discovery to find all of your installed software whether it is registered or not. You can enable and configure File-based Discovery at any time using the Discovery Configuration Console.

Role required: admin

1. Set up the PowerShell script.
   
   By default, the `filebaseddiscovery.ps1` script has a ServiceNow signature. Its certificate chain resolves up to the VeriSign Universal Root Certification Authority which is trusted by Windows by default. Since PowerShell scripts are signed by ServiceNow publisher, add ServiceNow publisher to your trusted publisher repository.

   ![](image)

   If your Execution Policy requires you to use your own certificate or if you need to make any changes to the script, re-sign the script.
1. Navigate to the probe “Windows - File discovery.”
2. Open the filebaseddiscovery.ps1 probe parameter.
3. Copy the contents of the value field into a file.
4. Make the necessary changes to the file and then remove the (old) signature block at the end of the file.
   After re-signing, the file should have a new signature block at the end of it.
6. Copy the entire file contents and replace the old value in the filebaseddiscovery.ps1 probe parameter from step b.
   Windows File-based Discovery should now run using the updated signed script.

If you are using anti-virus software, make sure to whitelist all of the ServiceNow Windows PowerShell scripts so the anti-virus software does not see it as a threat.
2. Activate the File-based Discovery plugin.
3. Enable and configure File-based Discovery.
   Using the Discovery Configuration Console, you can enable File-based Discovery as well as configure several components to find and manage all of your installed software.
   To avoid impacting performance for existing customers, File-based Discovery is disabled by default.
4. Configure File-based Discovery scans.
   After Discovery runs and returns file information for a CI, it will not execute File-based Discovery again on that target until the interval has expired. Since there is a performance cost when File-based Discovery performs scans, it is important to determine how frequently to scan. However, choosing a more frequent interval than Monthly is not recommended due to performance considerations.
   a) Using the Discovery Configuration Console, expand Common and then enter the maximum number of files that you want to discover. NOTE: Increasing this value can impact performance.
   b) Select the Frequency that File-based Discovery runs on the CI. The default is set to Monthly.

   Note: File-based Discovery does not trigger until initial Content Data Service (CDS) synchronization occurs. CDS synchronization could take approximately 24 hours for the initial set of data to be synchronized from CDS. For more information see, File Signature Normalization.

Your File-based Discovery should run based on the configurations set. You can then monitor the results using the Discovery Dashboard.

1. File-based Discovery reference information

File-based Discovery issue resolution
If you have any issues while setting up or running File-based Discovery, follow the actions listed here to help resolve them.
<table>
<thead>
<tr>
<th>Issue</th>
<th>Cause/Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error message: File Discovery data not yet synced...</td>
<td>• Allow CDS time to sync the samp_file_* tables.</td>
</tr>
<tr>

1. **File-based Discovery reference information**

**File-based Discovery references**

Review this reference material for further details on File-based Discovery.
How File-based Discovery minimizes performance impact

Scanning large networks, particularly for Windows computers, can extend scan time considerably. Moreover, file scanning can create heavy CPU demands on target machines and produce large payloads that greatly increase processing time. To avoid performance issues, File-based Discovery allows you to optimize processing with many of the settings configured using the Discovery Configuration Console.

- **Multi-phase scan**: Probes are triggered in multiple phases to reduce long scan times. The first probe creates the scanning process on the target, which runs in the background. Subsequent probes check the progress of this scan each time Discovery runs and return the results when the scan is complete. For example, if a file scan is initiated via Quick Discovery or from a Discovery schedule, no information is returned if a background scan is still running. If the scan is finished the next time the server is discovered, the probe returns the data.

  **Attention**: The multi-phase scan that File-based Discovery uses does not return results immediately. Do not expect any results from a file-based scan until Discovery runs again on those targets and fetches the list of files discovered by the previous scan.

- **Scan folders**: You can limit the scope of the scan to particular folders as well as scan hidden folders.
- **Scan extensions**: You can retrieve all files for a given list of extensions as well as ignore specific file extensions when scanning.
- **Scan UNIX file names**: Because the number of unique file names used to identify installed software on UNIX is relatively small, the complete list of file names is included in the UNIX probe. This enables the probe to filter the files it discovers against the signature list on the target. No additional filtering is required until the results are returned to the instance.
- **Scan Windows file names**: For Windows File-based Discovery, the probe does not initiate a scan on target for full signature list. Instead, Discovery generates a list of file extensions that the probe attempts to match on the target. This reduced list is then filtered on the MID Server against the entire Windows signature list.
- **Reduced payloads**: By filtering the scan results with the file signature list before the results get to the instance, Discovery reduces the size of the payload from target servers. Only those files from the targets that match the files specified in this list are returned to the instance.
- **Scan throttling**: To reduce the impact on Windows CPU and I/O performance on remote targets, Windows File-based Discovery is configured to sleep occasionally during scans. You can fine-tune this behavior with Discovery properties. Throttling Windows scans can make those scans take longer.

File-based Discovery tables

Descriptions of the tables provided by the File-based Discovery (com.snc.discovery.file_based_discovery) plugin for storing data:

### File Information (cmdb_file_information)

This table stores all the files, matched or unmatched, that were discovered on a particular CI. The files are available in a related list on CI computer records. The following columns are provided in the default view:

- **Path**: Path in which the file was found on the target.
- **Product**: Software product name. This field is populated when SAMP is activated and a match exists.
• **Publisher**: Name of the publisher of the file, such as Oracle or Microsoft. This is a reference to the Company (core_company) table. This field is populated when SAMP is activated and a match exists.

• **Size**: Size of the file.

• **Software installation**: Name of the installed software associated with this file, from the Software Installation (cmdb_sam_sw_install) table. This field is populated when SAMP is activated and a match exists.

• **Version**: Version of the file.

**Unidentified File Set (cmdb_unidentified_file_set)**

This table stores all the files returned by Discovery that cannot be matched to a software product, with or without SAMP. Discovery populates the name, size, and version of each unmatched file in the record. These optional fields can be used to further identify the file and make it available for future file matching:

- Publisher
- Product
- Version
- Edition
- Platform
- Language

**Note**: A feature in Software Asset Management Professional (SAMP) allows signature data in this table to be shared with Content Data Services (CDS). When you enable data sharing, the system automatically uploads records from the Unidentified File Set (cmdb_unidentified_file_set) table to CDS when you provide the missing information. Uploading the identified files makes them available to improve future file matching. For details, see *Add a custom software product*.

**File-based Discovery troubleshooting**

If you are experiencing any issues when setting up or running File-based Discovery, see *File-based Discovery issue resolution*.

**Network discovery**

Network Discovery discovers the internal IP networks and subnets within your organization.

**Note**: If you already know the IP address ranges in your network, it is not necessary to run Network Discovery. It is intended for organizations that do not have complete knowledge of the IP addresses available for Discovery in their networks.

**How network discovery works**

Discovery uses the information it gathers to update routers and Layer 3 switches in the CMDB. A single MID Server that begins its scan on a configurable list of starting (or seed) routers performs network Discovery. Typically, the starting routers are the default routers used by all the MID Server host machines in the network, but can be any designated routers. The MID Server uses the router tables on the starting routers to discover other routers in the network. The MID Server then spreads
out through the network, using router tables it finds to discover other routers. It continues until all the routers and switches have been explored.

After running Network Discovery, convert the IP networks it finds into IP address Range Sets that you use in Discovery schedules to discover configuration items (CI).

Configure **SNMP credentials** or (optionally) **SSH credentials**. Port 161 must be open for SNMP access and port 22 for SSH access.

**Network Discovery properties**

The default values are correct for most discoveries. Navigate to **Discovery Definitions > Properties** to edit the properties.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.discovery.bgp_router_disable</td>
<td>BGP router exploration disable: Disables running the <strong>SNMP – Routing</strong> probe or pattern when discovering a router running the BGP protocol. Normally such exploration IS disabled because of the huge size of BGP routing tables, and because generally such routers are only operating at the edge of large networks where further network discovery would be irrelevant. This value could be set to false if your organization only uses BGP routers as edge routers between relatively small networks (such as between buildings on a single campus).</td>
</tr>
</tbody>
</table>
| | **Type**: true | false

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.discovery.discoverable.network.max.netmask.bits</td>
<td>Maximum netmask size for discoverable networks (bits): The maximum number of bits in a regular netmask for networks that are discovered by Network Discovery. A regular netmask is a netmask that can be expressed in binary as a string of ones followed by a string of zeroes. For example, 255.255.255.0 is regular and 255.255.255.64 is irregular. Regular networks are commonly expressed like: 10.0.0.0/24, which means a network address of 10.0.0.0 with a netmask of 255.255.255.0. Larger bit numbers mean networks with smaller numbers of addresses in them. For example, the network 10.128.0.128/30 has four addresses in it: one network address (10.128.0.128), one broadcast address (10.128.0.131), and two usable addresses (10.128.0.129 and 10.128.0.130). Small networks are commonly configured in network gear to provide loopback addresses or networks used strictly by point-to-point connections. Since these sorts of networks generally don't need to be discovered by Network Discovery, it would be useful to filter them out. By setting this property to a value of 1 through 32, you can limit the sizes of regular networks that are discovered. Setting it to any other value causes all networks to be discovered. Irregular networks are always discovered. The default value is 28, which means that regular networks with 8 or fewer addresses cannot be discovered.</td>
</tr>
<tr>
<td>Type</td>
<td>integer</td>
</tr>
<tr>

</tbody>
</table>
| glide.discovery.physical_interface_types  | Physical interface types: A comma-separated list of interface types that are considered physical for the purposes of network discovery. If a router (or device capable of routing) has an interface of this type, the networks connected to that interface are considered locally connected to that device. The default interface types include Ethernet, 802.11, and Token Ring types. Interface type numbers are defined in the SNMP MIB-2, specifically in OID 1.3.6.1.2.1.2.1.3.  
   - **Type**: string  
   - **Default value**: 6,117,9,71,209  

| glide.discovery.switch_interface_types     | Switch interface types: A comma-separated list of interface types that are considered. Interface type numbers are defined in the SNMP MIB-2, specifically in OID 1.3.6.1.2.1.2.1.3. Devices with any interface types that do not appear in this list are classified as routers, when they have routing. A complete list of the interface type numbers may be found on the IANA web site, in the section 'ifType definitions'.  
   - **Type**: string  
   - **Default value**: 7,8,9,26,53,62,69,71,78,115,117,209  

---

**Run network Discovery**  
Configure network Discovery from a Discovery schedule.  

Configure **SNMP credentials** or (optionally) **SSH credentials**. Port 161 must be open for SNMP access and port 22 for SSH access.  

1. Navigate to **Discovery > Discovery Schedules**.  
2. Click **New** and select **Networks** from the list in the Discover field.  
3. Select a MID Server.  
   - This field is mandatory.  
4. Complete the form, including the scheduling fields.  
5. Right-click in the header bar and select **Save** from the pop-up menu.  
   - The **Related Links** and related lists appear.  
6. Click **Network Discovery Private IPs** in Related Links to view the list of default private IP networks in the Discovery IP Ranges Related List.  
   - The default IP networks in this list are available to every Network Discovery you conduct and are sufficient for most discoveries.  
7. If your organization has additional private IP addresses, click **New** to add them.
8. Add starting routers to the schedule in the Discovery Range Sets list.
   a) Click the **Network Discovery Auto Starting Routers** link to populate the list with the starting router for each MID Server in your network.
b) Click **Edit** to add or delete routers from the list.
### Discovery Schedule - Enterprise Networks

**Actions or selected rows...**
9. Run Discovery manually, or through the scheduler.

_Convert IP networks into Discovery range sets_

After you conduct a network Discovery, you must convert the IP networks that were found into range sets for use in discovering other devices.

Role required: agent_admin or admin

1. Navigate to **Discovery > Output and Artifacts > IP Networks**.
2. Click **New** to add an IP network.
3. Ensure that the following field values are provided:
   - **State**: Ready
   - **Discover**: selected (true)
   - **Router**: Select a router from the list. This field must not be empty.

   If your IP Networks were created through network Discovery, then these fields are populated automatically in the IP Networks related list. However, if you entered the IP Networks manually, and you want to convert your IP Networks into range sets manually, you must edit these fields accordingly.
4. Click **Update** to return to the list of IP Networks.

5. In **Related Links**, click **Create Range Sets**.

   Use this feature to convert all the IP networks in the list into range sets.
### IP network list

The **Discovery Status** page appears, displaying the progress of the conversion. The system increments the **Started** and **Completed** count of IP networks, until all the networks are converted.

Add discovery range sets to **Discovery schedules**.  
**Add a Discovery range set to a Discovery schedule**  
After creating discovery range sets from a network discovery, add the sets to a discovery schedule. This process narrows down the range of IP addresses that Shazzam probes can scan. You can also add a behavior.

**Role required:** agent_admin or admin

1. Open a **Discovery schedule**.
2. In the **Discovery Range Sets** related list, click **Edit** to add an existing range set and use the slushbucket to add the range set.
3. On the **Discovery schedule** form, click the name of the range set under the **Range** column in the **Discovery Range Sets** related list.
4. On the **Discovery Range Set** form, add a **Discovery behavior** if necessary. You can also activate or deactivate the range set for this schedule.
5. Right-click the header, and then click **Save**.

### Cloud Discovery

Cloud Discovery provides a wizard that allows you to create and run cloud schedules in a single interface. When you create a schedule with the Discovery Manager, you select the accounts to discover, the credentials for accessing these accounts, and the MID Servers to scan the resources. You can then view the results in the Discovery Home page and track any errors that might have occurred.
How Cloud Discovery works

You can select an existing service account to discover or create one with the wizard. Select the appropriate credentials for the account and test the connection. If the connection is successful, Discovery returns the logical datacenters associated with the account, as well as any sub-accounts for selection. The cloud schedule creation process launches the necessary patterns to discover the sub-accounts and datacenters you select.

The Discovery Manager offers you the option to discover your cloud resources (virtual machines). Cloud Discovery by IP ranges finds all the VMs in a cloud service account. Just select a MID Server configured for Cloud Discovery and create the schedule. Discovery determines the IP addresses to scan, based on the IP ranges in your cloud service account. Make sure you have one or more MID Servers up and running that can access those addresses.

Note: You do not need the Cloud Management plugin to use Cloud Discovery. The Discovery plugin includes the necessary components from Cloud Management to perform Cloud Discovery.

Managing your cloud resources

The instance displays all results from a Cloud Discovery in the Discovery Home page. You can drill down into specific schedules, discovered devices, cloud resources, and errors. Sort these results for a closer look and view Discovery trends for the devices you find. Error results give you specific suggestions for fixing any problems you encounter.

Your instance can detect notifications and alerts from AWS and Azure clouds. You can configure these events to make the necessary updates to your CMDB without additional scanning. AWS or Azure event processing requires the Cloud Management plugin and is configured in the application. For more information, see Configure the Amazon AWS Config service to auto-update the CMDB and Configure the Azure Alert service to auto-update the CMDB.

AWS master accounts for AWS Organizations

An AWS organization is a collection of AWS accounts under a single account. Cloud discovery refers to AWS Organizations in the wizard as master accounts. The member accounts that belong to a master account are called sub-accounts.

Note: Cloud discovery on AWS Organizations is not fully supported in a GovCloud isolated region.

The advantages of using master accounts are:

**Easy population of sub-accounts**

After you configure the master account and supply the necessary credentials, you can test the connection to it. Discovery then detects the member accounts in that master account and displays them for selection. You can choose one or more sub-accounts to include in the Discovery of the master account.

**Discovery of sub-account resources using dynamically acquired credentials**

When you run Discovery on your cloud resources, you do not need separate credentials for each sub-account. The Cloud Discovery process handles credentials automatically by acquiring a temporary credential for each sub-account via an AWS API. You can elect to use the default
configuration or customize the MID Server to assume other roles for additional controls and security.

Cloud Discovery process

1. Install and validate a MID Server using the procedure in MID Server installation. If you do not have a MID Server running in your environment, you can use Guided Setup to quickly install and validate a MID Server. Make sure you configure Cloud Discovery MID Servers with the Cloud Management capability.

2. Open the Discovery Manager and configure the following:

   **Service account**
   You can provide the information for an existing account or add an account. If you have an AWS organization with several member accounts that belong to it, you can designate a service account as a master account, and then select any sub-accounts to discover.

   **Cloud credentials**
   Select and test your cloud credentials or add new credentials. If you are using AWS, you can configure IAM roles in an AWS instance profile that will grant temporary credentials to your master account without requiring credentials in the instance. To receive temporary AWS credentials for one or more member accounts, you can assume an AWS member role.

   **Datacenters**
   Select specific datacenters in your account to discover or configure Discovery to automatically include all current and future datacenters.

   **Virtual machine (VM) resources**
   Optionally, configure the schedule to discover VM resources by IP address. Discovery returns additional information about the VMs, including installed software and running applications.

   **Note:** For the Cloud Insights application, Cloud Discovery does not display the Discover Virtual Machines (optional) phase in the Discovery Manager tab bar.

   **Schedule**
   Create a Cloud Discovery schedule. You can run your schedule immediately from the Discovery Manager or exit the configuration and let Discovery run as scheduled.

3. View Discovery results on the Discovery Home page. You can view details for:
   - Schedules
   - Discovered Devices (VMs)
   - Cloud Resources
   - Errors

Using a MID Server through a proxy

If your MID Server must go through an unauthenticated proxy server to access cloud resources, you must modify the `agent\conf\wrapper-override.conf` file, as follows:

```
wrapper.java.additional.1=-Dhttp.proxySet=true
wrapper.java.additional.2=-Dhttp.proxyHost=<proxyHost>
```
As with any changes to the MID Server files, restart the MID Server and then test Discovery.

**Using the Discovery Manager**

Use the Discovery Manager wizard to quickly create a schedule for discovering elements of your cloud service account. Specify your provider account, the MID Servers to use, and the datacenters you want to discover. Optionally, you can schedule a deep discovery of the running applications on the virtual machines that are discovered for a selected cloud service account.

**Accessing the Discovery Manager**

To access the Discovery Manager, navigate to **Discovery > Home**. Click **Discover Cloud Resources** in the Welcome screen to begin configuring a schedule to discover your cloud resources.

**Note:** The Welcome screen contains a link to the **Discovery Quick Start**. This wizard is designed to get you up and running with a basic Discovery quickly. Use the Quick Start to evaluate Discovery or to explore new network devices. It is not intended for discovering your cloud resources.

If the system cannot detect a MID Server, you are prompted to install and configure one, using **MID Server Guided Setup**. This notice also displays if an existing MID Server is not available because it is upgrading.
Discovery Manager interface

Use the Discovery Manager to input the information you need to access your service accounts and sub-accounts, including credentials and MID Servers. Test the connections to your accounts and then create schedules to execute Discovery on the cloud resources in the datacenters you have selected.

Progress indicator

As you complete each configuration phase, tabs at the top of the Discovery Manager track your progress. A check mark indicates a completed phase. A dark underline marks the current phase. The tabs are interactive, so you can move to a phase by clicking on that tab.

Select a service account and test your credentials

The Cloud Discovery wizard begins with the account selection and testing phase. Specify your cloud provider and select the service account to discover. Discovery allows you to include one or all available sub-accounts (AWS only) on the schedule. Provide the credentials for the cloud service account and test the connection.

Before you attempt to configure Cloud Discovery, you must have at least one validated MID Server, with a status of Up, that is capable of reaching the IP ranges you intend to discover. You can install the MID Server using Guided Setup or by manually downloading and running the installer. For details, see the MID Server installation instructions for Linux and Windows. Make sure you configure MID Servers used for Cloud Discovery with the Cloud Management capability.

Role required: discovery_admin, admin

The cdud.record.watcher.timeout system property defines the maximum waiting period for these Cloud Discovery configuration processes to run:

- Service account validation
- Member account Discovery
• Discovery of logical datacenters

The default timeout value is 120,000 milliseconds, or 2 minutes.

1. In the Basic Info pane of the Discovery Manager, select the name of your cloud provider, such as AWS.
2. In the Schedule Name field, enter a unique and descriptive name for this schedule.
   The wizard displays the count of the validated and available MID Servers.
3. If no MID Servers have the Cloud Management capability, click Configure MID Servers and configure a MID Server appropriately.
   a) Navigate to MID Servers > Capabilities.
   b) Select the Cloud Management capability.
      You can also select the ALL capability, which includes Cloud Management by default.
   c) Click Edit in the MID Servers related list, and then add your MID Servers to the capability.
   d) Click Save.
      Your MID Servers are ready to communicate with your cloud service accounts.

4. In the Service Accounts pane, select the existing account for the newly named schedule.
   If you select an existing account, the system auto-completes the form with the available information. If you add an account, you must provide the account ID, credentials, and URL, if applicable. For VMware, the URL is mandatory.
   • The AWS account ID is the 12-digit account number.
   • The Azure account ID is the Subscription ID.
   • The IBM account ID is also called the Account ID.
The **GCP account ID** is the Project ID.

The **VMware account ID** is the virtual machine instance UUID.

**Note:** VMware discovery can run without a service account. To discover VMware resources, configure the schedule to run on the [IP address of the vCenter server](https://example.com).

5. Select the credentials for this cloud service account or add new credentials.
   a) To add a credential, click the plus icon (+).
   b) Select the appropriate [cloud credential type](https://example.com) from the list.
   c) Complete the form and click **Save**.

**Note:** AWS users can configure AWS to generate temporary credentials for service accounts. This capability eliminates the need to define some credentials on the instance and can be used to increase security on your sub-accounts. For details, see [Assume an AWS role for temporary cloud Discovery credentials](https://example.com).
6. Click **Test Account** to validate the account with the details provided.

Messages in the header bar notify you of the validation results. If you specified a master account and the connection test was successful, the wizard displays a selection screen for any sub-accounts associated with the master account. By default, all current sub-accounts are selected for the schedule and cannot be moved to the **Available** list.

**Note:** If the validation process does not return any sub-accounts or sub-accounts that you added recently, click **Refresh Members** or re-run the validation process. If validation times-out repeatedly, increase the timeout interval in the `cdu.record.watcher.timeout` MID Server property.
7. To select specific sub-accounts for the schedule, deactivate the auto-select feature. By default, all sub-accounts are selected. To disable the feature and to permit the selection of specific datacenters to discover, slide the toggle switch to the left.
8. Drag and drop the sub-accounts you want to exclude from the schedule from the **Selected** list to the **Available** list.

Select a cloud provider datacenter to discover

Discovery displays the list of available datacenters when you validate the service account. Specify which datacenters you want to discover with this schedule.

Role required: discovery_admin, admin

1. To select the datacenters to discover, click the **Select Datacenters** phase in the Discovery Manager tab bar.

   By default, all datacenters associated with your service account are selected for the schedule.

   **Note:** If no datacenters appear, click **Refresh Datacenters** or re-run the account validation. If validation times-out repeatedly, increase the timeout interval in the `cdu.record.watcher.timeout` MID Server property.
2. To select specific datacenters for the schedule, deactivate the auto-select feature by moving the toggle switch to the left.
3. Drag and drop the datacenters you want to discover from the **Available** list to the **Selected** list.
4. Click the next phase in the tab bar.
   Optionally, you can configure IP ranges to discover virtual machines (VM), or move to the schedule phase and complete Cloud Discovery setup.

Enable virtual machine Discovery in your cloud environment

Virtual machine (VM) Discovery is an optional configuration that performs a deep discovery of the virtual machines identified by the cloud schedule, using the IP addresses of the VMs. VM Discovery is enabled by default in the Discovery Manager wizard.
All MID Servers you intend to use for Cloud Discovery must be validated, have a status of **Up**, and be able to access the IP ranges in your cloud provider account.

**Attention:** The upgrade process from Madrid to New York deactivates existing schedules for the discovery of cloud resources. Make sure to re-activate any schedules in the Discovery Manager that might have been deactivated during an upgrade from Madrid. These schedules have a Run status of **undefined** in the list view of the Discovery Schedule (discovery_schedule) table.

Role required: admin

You do not need to configure IP ranges for the MID Servers used with Cloud Discovery. Discovery automatically selects the IP addresses of the virtual machines in the datacenters you selected in the wizard.

1. To discover the VMs that are part of the current schedule, click the **Discover Virtual Machines (optional)** phase in the Discovery Manager tab bar.
   By default, VM discovery is active.
2. Select the MD Server to use.
   The available MID Server selection types are:
   - **Auto-Select MID Server:** Discovery selects an appropriate MID Server automatically.
   - **Specific MID Cluster:** Discovery uses the named MID Server cluster.
   - **Specific MID Server:** Discovery uses the named MID Server.

3. To prevent VM Discovery from running, toggle the activation switch to the left.
   The **MID Selection Type** field disappears.
4. When you have completed this configuration, click the **Create Schedule** phase in the tab bar.

Create a Cloud Discovery schedule
The final phase in the Discovery Manager wizard creates the schedule that triggers Cloud Discovery.

Role required: admin, discovery_admin
You can also access the schedule phase of the Discovery Manager from the Discovery Schedule form. Navigate to **Discovery > Discovery Schedules** and click **Cloud Discovery** in the schedules list.

1. To configure the Cloud Discovery schedule, click **Create Schedule** in the Discovery Manager tab bar.
   
   By default, the schedule is active.

2. Configure when and how often the schedule should run and define a timeout threshold if you want to restrict Cloud Discovery to a specific duration.

3. To deactivate the schedule, toggle the switch to the left.
   
   This prevents Cloud Discovery from running.

4. Complete the Cloud Discovery configuration process by selecting one of these options:
   
   - **Finish and Run**: Runs Discovery immediately, using the current configuration. All subsequent cloud discoveries run on the schedule you provided.
   
   - **Finish**: Exits the wizard and runs Cloud Discovery on the schedule you provided.

5. Open the **Discovery Home page** and view the results of your cloud Discovery.

**Cloud Discovery account credentials**

Provide the credentials needed to access your cloud service accounts or create new credentials.

The ServiceNow® platform provides these cloud credential types:

- AWS Credentials
- Google API Credentials
- IBM Credentials
- VMware Credentials
- Azure Service Principal
**AWS Credentials**

You do not need to configure credentials for accounts that are member accounts of an AWS Organization or if IAM Instance Profiles are used. If a service account is a member account, the Discovery process automatically generates a temporary credential for the account through AWS.

**AWS Credentials form fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Input value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a unique and descriptive name for the AWS credentials.</td>
</tr>
<tr>
<td>Active</td>
<td>Select the check box to use the credential.</td>
</tr>
<tr>
<td>Access Key ID</td>
<td>Enter the Access key ID that you generated on the AWS Management Console, such as: APIAIOSFODNN7EXAMPLE.</td>
</tr>
<tr>
<td>Secret Access Key</td>
<td>Enter the Secret access key that you generated on the AWS Management Console, such as: wPaliXUtnFEMI/K7MDENG/bPxrffYEXAMPLEKEY.</td>
</tr>
</tbody>
</table>

**Google API Credentials**

If your cloud resources are in Google Cloud Platform (GCP), create credentials that can access your GCP account.

**Google API credentials form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Unique name of the GCP credentials to register with the instance. Ensure that this credential is easy to identify as belonging to GCP, so that it can be selected for a cloud schedule in the Discovery Manager.</td>
</tr>
<tr>
<td>Active</td>
<td>Select the check box to use the credential.</td>
</tr>
<tr>
<td>Applies to</td>
<td>Determines whether this credential is available to specific MID Servers or all MID Servers.</td>
</tr>
<tr>
<td>Order</td>
<td>Order (sequence) in which the Discovery tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), the instance tries the credentials in a random order.</td>
</tr>
<tr>
<td>Email</td>
<td>Email ID used to create your service account (or “profile”) in GCP.</td>
</tr>
<tr>
<td>Secret Key</td>
<td>Key provided by Google. This key must include any leading and trailing characters and must not be altered in any way.</td>
</tr>
</tbody>
</table>
IBM Credentials

If your cloud resources are in an IBM cloud, create credentials that can access your IBM account.

### IBM credentials form

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Credential alias</td>
<td>Specifies the credentials that a Discovery schedule can use. Use credential aliases to prevent the creation of credential affinities that use inappropriate or sensitive credentials.</td>
</tr>
</tbody>
</table>

### IBM Credentials

If your cloud resources are in an IBM cloud, create credentials that can access your IBM account.

#### IBM credentials form

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Unique name of the IBM credentials to register with the instance.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Order</td>
<td>Order (sequence) in which Discovery tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), the instance tries the credentials in a random order.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Softlayer API User</th>
<th>Softlayer cloud user name.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Softlayer API Key</td>
<td>Softlayer API key.</td>
</tr>
<tr>
<td>Bluemix API Key</td>
<td>Bluemix API key.</td>
</tr>
</tbody>
</table>

VMware Credentials

Applications that access VMware cloud resources need access to VMware credentials. For example, the VMware credential type allows Discovery to explore VMware's vCenter running on a Windows machine to discover ESX machines, virtual machines, and resource pools. The VMware Discovery and automation API (vCenter API) now provides the globally unique serial number for computer CIs. CIM credentials are not needed to allow access to each VMware host.

**Note:** Windows credentials are not necessary for vCenter Discovery, when valid VMware credentials are used.

#### VMware credentials form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a unique and descriptive name for the VMware credentials.</td>
</tr>
<tr>
<td>Active</td>
<td>Enable or disable these credentials for use.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>User name</td>
<td>Enter the user name you use for your VMware account. Avoid leading or trailing spaces in user names. A warning appears if the platform detects leading or trailing spaces in the user name. The VMware credentials must have the read-only role in vCenter.</td>
</tr>
<tr>
<td>Password</td>
<td>Enter the password for the VMware account.</td>
</tr>
<tr>
<td>Applies to</td>
<td>Select one or more MID Servers from the list of available MID Servers. The credentials configured in this record are available to the MID Servers in this list. This field is available only when you select Specific MID servers from the Applies to field.</td>
</tr>
<tr>
<td>Order</td>
<td>Order (sequence) in which Discovery tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), the instance tries the credentials in a random order.</td>
</tr>
</tbody>
</table>

Create credentials for Azure Cloud Discovery

If your cloud resources are in an Azure cloud, create credentials that can access the Azure account. This procedure requires configuration in your Azure account.

Role required: discovery_admin, sm_admin, sn_cmp.cloud_admin

Note: On the Azure portal, the Active Directory administrator or Azure administrator role is required.

A service principal for Azure cloud services is similar to a Microsoft Windows service account that enables Windows processes to communicate with each other within an Active Directory domain.

While you create the Azure service principal, you copy service principal credential values from the Azure portal into a text editor. The text file that you generate during this procedure might look something like this:
This table shows you the location in Azure where you can find the values you need for the credentials.

<table>
<thead>
<tr>
<th>Cloud Management setting</th>
<th>Location of the Azure value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tenant ID</td>
<td>Azure Active Directory &gt; Properties &gt; Directory ID</td>
</tr>
<tr>
<td>Client ID</td>
<td>Azure Active Directory &gt; App registrations &gt; Registered App.Application ID</td>
</tr>
<tr>
<td>Secret Key</td>
<td>Azure Active Directory &gt; App registrations &gt; Registered App &gt; Settings &gt; Keys (hidden)</td>
</tr>
<tr>
<td>Account ID</td>
<td>Azure Active Directory &gt; Subscriptions &gt; Subscription ID</td>
</tr>
</tbody>
</table>

1. Log in to the Azure portal and navigate to **Azure Active Directory**.
2. In the **Properties** section, click the **copy to clipboard** shortcut for the **Directory ID** field.
3. Paste the **Directory ID** value (the UUID) into the text editor and label the value **Directory ID**.
4. In the Azure portal, navigate to the **App registrations** section and click **New application registration**.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Unique name for the application and its integration credentials. For example, ServiceNow Integration.</td>
</tr>
<tr>
<td>Application type</td>
<td>Web app / API</td>
</tr>
<tr>
<td>Sign-on URL</td>
<td>URL that will access Azure. Typically the URL of the ServiceNow instance.</td>
</tr>
</tbody>
</table>

5. Click **Save** and then select the application in the list.
6. Hover over the **Application ID** and click **Copy to clipboard**.
7. Paste the Application ID into the text editor and label it **Application ID**.
8. In the Azure portal, navigate to the **Keys** section and then specify the following values:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key description</td>
<td>Description for the key.</td>
</tr>
<tr>
<td>Duration</td>
<td>The default is <strong>Never Expires</strong>.</td>
</tr>
</tbody>
</table>

**Note:** Your organization may apply policies to restrict key durability. Select the appropriate duration.

9. Click **Save**.
10. Paste the key value into the text editor and label the value **Application key**.
11. To enable the service principal to work with various Azure subscriptions, navigate to **Subscriptions**. To manage multiple subscriptions, you must perform the following procedure for each subscription:
    a) Paste the subscription ID into the text editor and label it **Subscription ID**.
    b) Navigate to the subscription and select **Access Control (IAM)** from the menu.
    c) Click **+ Add** at the top of the screen.
    d) Select the value **reader** from the **Role** field. Let the default value **Azure AD user, group, or application** remain as is in the **Assign access to** field.

**Note:** The **contributor** role is only required for provisioning.

    e) Select the name you created in step 4 in the **Select** field and click **Save**.
12. In the Discovery Manager, click the plus icon (⁺) and then select **Azure Service Principal** from the list.

13. Specify the following values on the Azure Service Principal form:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the service principal to register with the instance. For example, Azure service principal credentials.</td>
</tr>
<tr>
<td>Authentication Method</td>
<td>Select <strong>Client secret</strong>. The <strong>Secret key</strong> field appears when you select <strong>Client secret</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> <strong>Client assertion</strong> is not supported.</td>
</tr>
</tbody>
</table>

14. Copy and paste values from the temporary text file into the remaining fields.
15. Click **Save** to create the Azure service principal.

16. Click the **Discover Subscriptions** related link to find all subscriptions for the Azure service principal. The instance creates a service account for each discovered subscription. The **Azure Subscriptions** related list displays all subscriptions for the Azure service principal.

17. Click a subscription to view the service account created for the subscription.

18. Click a Discovery status entry in the **Credential Discovery Status** list to view the Discovery log. Each time you click **Discover Subscription**, the instance generates a new Discovery status and displays it in the **Credential Discovery Status** list.

### Assume an AWS role for temporary cloud Discovery credentials

You can configure the MID Server to assume an AWS role that provides temporary cloud service account credentials. Using AWS credentials eliminates the need to manage account credentials on your instance.

AWS offers temporary credentials for the following types of service accounts:

- **Discrete account**: Standalone account, with no parent account. The `is_master_account` check box in the Discovery Manager is cleared (false).
- **Master account**: Master account that may or may not contain member accounts (sub-accounts). The `is_master_account` check box in the Discovery Manager is selected (true).
- **Member account**: Account that has a parent account. The `is_master_account` check box in the Discovery Manager is cleared (false).

Use these features to receive temporary credentials for your accounts:

- **Identity and Access Management (IAM) roles**: Provides temporary credentials granted by an AWS role for the discovery of discrete accounts and master accounts. IAM roles are defined in EC2 instance profiles. MID Servers installed on an EC2 instance can use the temporary credentials available to these roles to discover cloud resources.

- **AWS Security Token Service API**: Provides temporary credentials for any member account in a master account that does not have a permanent credential specified in the instance. The MID Server assumes a role that provides temporary credentials for a given member account, when discovering cloud resources in that member account. The ServiceNow instance includes a default configuration that provides credentials automatically for all member accounts that belong to an organization controlled by a master account. Advanced configuration allows you to customize the roles and other parameters that a MID Server can assume. You can use this capability to restrict access to certain member accounts, which enhances security.

**AWS IAM roles in EC2 instance profiles**

Amazon EC2 uses an AWS instance profile to create temporary security credentials for discovering cloud resources. These credentials are provided and managed by Identity and Access Management (IAM) roles in the profile and rotate automatically.

**Delegating permissions for a MID Server**

Use IAM roles for a MID Server installed on Amazon EC2 within the AWS cloud that is configured to discover cloud resources in "discrete" accounts. A "discrete" account is one that is not an organization - an account with no member accounts. This method of delegating permissions within the cloud eliminates the need to manage AWS account credentials on your instance. Discovery uses the credentials from AWS if an instance profile is configured in AWS for the EC2 instance.

The MID Server retrieves the security credentials from AWS that are provided by the role. The MID Server is then granted the permissions for the actions and resources defined for that role through those security credentials. These security credentials are temporary and rotate automatically. AWS generates new credentials at least five minutes before the expiration of the old credentials.

For instructions on configuring roles for an AWS instance profile, see Amazon Web Services documentation on IAM Roles for Amazon EC2.
EC2 Instance Configuration with IAM role

Configuring member accounts to use temporary credentials

To ensure that Cloud Discovery can discover member accounts with temporary credentials, configure the AWS member accounts with:

- A role named `OrganizationAccountAccessRole`.
- A trusted relationship between the `OrganizationAccountAccessRole` role and the AWS master account.
- An attached policy called `AdministratorAccess` which allows all (*) actions on all (*) AWS resources, as in this example:

```json
{
```

Configure the MID Server for AWS IAM roles

If you configure an IAM role for an AWS instance profile, configure the MID Server to retrieve the temporary security credentials from AWS that are provided by the role.

Role required: admin

1. Navigate to Discovery > MID Servers.
2. Select a MID Server to use for AWS Cloud Discovery. This MID Server must be installed on an EC2 server within the AWS cloud.
3. Open the Configuration Parameters related list.
4. Click New.
5. In the configuration parameter form, select mid.aws.instance_profile_name in the Parameter name field.
6. Enter the IAM role name from the EC2 Instance Configuration record in the Value field.
7. Click Submit.

The new parameter is listed in the MID Server record.
Assuming member roles with an AWS API

The MID Server can call an AWS API and use the permanent credentials of an AWS master account (organization) to assume the role of one or more member accounts. By assuming the role, the MID Server receives temporary credentials for the member accounts generated by AWS for that role.

Assuming member account roles in a large AWS organization is more convenient and offers better security than using large numbers of permanent credentials for all member accounts. Temporary credentials are only acquired on behalf of a member account when there is no permanent credential specified for that member account in the Service Accounts [cmdb_ci_cloud_service_account] table.

The MID Server uses the `AssumeRole` action in the `AWS Security Token Service API` to assume a member account role. Parameters passed to this API determine what additional security restrictions are applied to the role when it accesses AWS resources.

**Default member role configuration**

By default, the MID Server is configured to assume the `OrganizationAccountAccessRole`, which grants temporary credentials to all the members of a master account. This action occurs automatically if no permanent credentials exist for the member accounts. This configuration does not apply any additional security or restrict access to any resources in member accounts.
Advanced member role configuration

You can improve security by defining additional roles that a MID Server can assume. These roles can have access to certain member accounts and determine the actions that Discovery is allowed to take on the resources in those accounts.

Create records in the Cloud Management AWS Org Assume Role Parameters module that specify the roles and restrictions that apply. Records in the Cloud Service Account AWS Org Assume Role Params (cloud_service_account_aws_org_assume_role_params) table pass their parameters to the AWS Security Token Service API, which then provides the appropriate credentials and permissions to the MID Server.

How Discovery determines which credentials to use

Cloud Discovery uses the following logic to determine which credentials to use to discover AWS cloud resources in member accounts:

1. If permanent credentials are defined for the member account in the Cloud Service Account (cmdb_ci_cloud_service_account) table, Discovery uses those credentials.
2. If no permanent credentials are defined for the member account, Discovery checks the Cloud Service Account AWS Org Assume Role Params (cloud_service_account_aws_org_assume_role_params) table for any special parameters associated with the member account. If parameters exist in that table, Discovery uses the temporary credentials acquired from specifying a role and its parameters in the AWS Security Token Service API AssumeRole action.
3. If no special parameters are associated with the member account in the (cloud_service_account_aws_org_assume_role_params) table, Discovery checks that table for parameters associated with the master account. If parameters exist that define a role for the master account, Discovery uses the temporary credentials provided by that role.
4. If no special parameters are present in the (cloud_service_account_aws_org_assume_role_params) table for either master or member accounts, Discovery uses the defaults defined for the OrganizationAccountAccessRole role.

Caching of temporary credentials

By default, temporary credentials for member accounts are cached for 60 minutes. This interval allows the horizontal Discovery process to run multiple times without generating new credentials during each Discovery.

These MID Server properties control credential caching:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| mid.aws.sts.assume_role.disable_credential_caching | Set this property to true to prevent the caching of the temporary AWS credentials.  
- Type: true | false  
- Default: false |
### Configure a custom AWS member role

Customize the AWS roles that a MID Server can assume to receive temporary credentials for member accounts. You can configure additional parameters to improve security and customize the way that the member account’s role is assumed when discovering cloud resources. To configure custom AWS member roles with the procedure, see Configure a custom AWS member role.

**Data collected for AWS and Azure Cloud Discovery**

Discovery collects information about cloud resources in AWS and Azure datacenters.

**How Discovery finds AWS and Azure resources**

Discovery uses the Cloud Management API and patterns to find cloud resources.

#### Default patterns

<table>
<thead>
<tr>
<th>Pattern</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon AWS Elastic Load Balancer Service</td>
<td>Retrieves AWS load balancers and populates the Load Balancer Services (cmdb_ci_lb_service) table. Application load balancers, network load balancers, and classic load balancers are supported.</td>
</tr>
<tr>
<td>Amazon AWS Relational Database Service</td>
<td>Retrieves RDS instances and populates the Cloud Database (cmdb_ci_cloud_database) table.</td>
</tr>
<tr>
<td>Amazon AWS Route53 HD</td>
<td>Resolves DNS names and aliases for the AWS cloud.</td>
</tr>
<tr>
<td>Azure Database</td>
<td>Retrieves Azure databases, including MSSQL, MySQL, Redis, and Documentum, and populates the (cmdb_ci_cloud_database) table.</td>
</tr>
<tr>
<td>Azure LoadBalancer TD</td>
<td>Retrieves Azure load balancers and populates the cmdb_ci_lb_service table. This pattern is only used by Service Mapping for top-down discovery, not by the Discovery application for horizontal discovery. <strong>Note:</strong> When using Service Mapping to find AWS cloud resources, this pattern is not used.</td>
</tr>
<tr>
<td>Azure WebSite</td>
<td>Retrieves Azure web servers and populates the Cloud WebServers (cmdb_ci_cloud_webserver) and IP address (cmdb_ci_ip_address) tables.</td>
</tr>
</tbody>
</table>

**Note:** Amazon Route 53 is supported.

**AWS Config and Azure Alerts services**

If you configured the *AWS Config* or *Azure Alert* services, the instance can receive notifications when changes to cloud resources occur. Discovery can then take action and make updates.

**AWS config**

The instance can detect an AWS config notification with message type `ConfigurationItemChangeNotification` for these resource types:

- AWS::EC2::Instance
- AWS::EC2::VPC
- AWS::EC2::Subnet
- AWS::EC2::Volume

Discovery can then make updates to records in the Response Mappings (sn_cmp_response_mapping) table that have Cloud Event in the *Datasource* field.

**Azure alerts**

The instance can detect alerts for the following resource types:

- Microsoft.Compute/virtualMachines
- Microsoft.Network/networkSecurityGroups
- Microsoft.Resources/deployments
- Microsoft.Storage/storageAccounts
- Microsoft.Compute/availabilitySets
- Microsoft.Network/networkInterfaces
- Microsoft.Network/publicIPAddresses
- Microsoft.Network/loadBalancers
- Microsoft.Network/virtualNetworks

Discovery can then run on the specific cloud resource to retrieve the changes and update the CMDB.

*Data collected for GCP Cloud Discovery*

Discovery collects information about cloud resources in Google Cloud Platform (GCP).

### Data collected for IBM Cloud Discovery
Discovery collects information about cloud resources in the IBM Cloud and creates relationships between the CIs it finds.

### Load balancers

#### Data collected for load balancers

<table>
<thead>
<tr>
<th>Table</th>
<th>Field Name / Description</th>
</tr>
</thead>
</table>
| Cloud Load Balancer (cmdb_ci_cloud_load_balancer) | **object_id**: The load balancer’s unique identifier.  
**name**: Name of the load balancer.  
**fqdn**: Address (Host name) of the load balancer. This is the fully qualified domain name of the load balancer.  
**dns_name**: Address (Host name) of the load balancer.  
**short_description**: Description of the load balancer.  
**operational_status**: The operational status of the load balancer, either ONLINE or OFFLINE.  
**location**: References the load balancer’s location with type.  
**state**: Provisioning status of the load balancer, either Available or Terminated. |
| Load Balancer Service (cmdb_ci_lb_service) | **object_id**: Unique identifier of the load balancer service.  
**name**: Name created by the pattern that contains the following:  
- Load balancer name  
- Protocol  
- Port  
- Resource type: -listener  
**port**: Listener’s protocol port number.  
**front_end_port**: Listener’s protocol port number.  
**listener_protocol**: Listener’s protocol, either TCP, HTTP, or HTTPS.  
**operational_status**: The provisioning status of the listener. |
<p>| Load Balancer Pool (cmdb_ci_lb_pool) | <strong>object_id</strong>: Unique identifier of the load balancer pool. |</p>
<table>
<thead>
<tr>
<th>Table</th>
<th>Field Name / Description</th>

Data collected for VMware Cloud Discovery
Discovery collects information about VMware resources in your cloud service accounts.

Distributed Resource Scheduler (DRS) discovery

VMware Discovery collects these DRS settings and saves them to the DRS VM Config (cmdb_ci_drs_vm_config) table:

- DRS settings of vCenter clusters.
- DRS settings of VMs configured to override cluster behavior.

<table>
<thead>
<tr>
<th>Field label</th>

Serverless Discovery

Discovery can find applications on host machines without the need to discover the host first. This type of Discovery is referred to as serverless Discovery.

Serverless Discovery relies on infrastructure patterns to explore CIs on a host. This kind of Discovery skips the scanning and classification phases of Discovery. There are two types of serverless Discovery: standard and host-based. Both types require an infrastructure pattern.

Standard serverless Discovery

Standard serverless Discovery finds remote application CIs that reside on an unknown host. This type of serverless Discovery uses protocols, such as REST or HTTP, to find the CIs. The IP address of the host machine is not required. You define input parameters in an infrastructure pattern to connect to a remote resource. Use this type of Discovery when you want to discover web-based applications.

Host-based serverless Discovery

Host-based serverless Discovery finds CIs that reside on a host machine that you already discovered. The host acts as a proxy through which you find other CIs. You do not actually run Discovery on the host. Use this type of Discovery when:

- You do not know the IP address of the CIs you want to discover, or the CIs do not actually have IP addresses.
- The CIs reside on an already discovered host CI.

For this type of Discovery, you also need an infrastructure pattern, but you do not need to define input parameters like you do for standard serverless Discovery. The pattern can specify operations, such as a WMI Query, which executes queries on a host. After Discovery connects to the host, it uses the credentials of the host to perform the Discovery of CIs you are exploring in the pattern. You do not need to specify additional credentials. When you run debug mode on the pattern, you can see the details under Temporary Variables on the pattern. You can then create pattern operations that make API calls from the host to the CIs you are trying to discover.

Serverless Discovery schedules

The infrastructure patterns that serverless Discovery uses are triggered from a Discovery schedule, rather than from a classifier. Serverless Discovery ignores classifiers. Use a serverless schedule type for both types of serverless Discovery. The serverless schedule allows you to specify:

- Values for input parameters in the pattern if you are using standard serverless Discovery. See Create a schedule for standard serverless Discovery for instructions.
- A host CI if you are using proxy-host based Discovery. See Create a schedule for host-based serverless Discovery for more information.

Create a pattern and a schedule for standard serverless Discovery

To find application CIs that reside on an unknown host, create an infrastructure pattern for standard serverless discovery. After creating the pattern, create a Discovery schedule that triggers the pattern.

Role required: cloud_admin, sm_admin, or admin
In the pattern, you must specify input parameters to explore the CI.

1. Navigate to Pattern Designer > Discovery Patterns.
2. Click New.
3. Specify an Infrastructure type pattern with the correct CI type that applies to the CIs you want to discover. See Create or modify patterns for an explanation of all form fields.
4. Create an identification section and save the pattern.
5. Click the Input Parameters tab, and then click New.
6. Enter the parameters that are required to reach the serverless CIs. For example, you could enter url to reach a remote resource via an HTTP request.

Note: You specify the actual URL in a serverless discovery schedule.

7. Save the pattern.
8. Click the Basic tab, and then click the identification section name to open the pattern designer.
9. Create the steps you need to explore serverless CIs. For example, create an Http Get Call operation to reach a remote resource through a URL. In this case, you would specify the $url parameter in the URL field.
10. To test the pattern, click Debug Mode and fill in values for the input parameters. You do not need to enter a value for Proxy Host.

In this example, we are connecting to a website that serves up an XML file. The XML file parsing method is already defined in the Http Get Call operation. To test the pattern operation, click Debug Mode, enter the URL, and click Connect.

Example debugging of an HTTP Get Call

11. After you connect and run the operation, the Output field displays the content.
After you create a pattern for standard serverless discovery, create a Discovery schedule and specify the pattern. Discovery triggers the pattern from the schedule rather than from a classifier.

Ensure you have basic authentication credentials for HTTP calls in the pattern.

Role required: cloud_admin, sm_admin, or admin

You can reuse this schedule to run the same pattern using different parameters.

1. Navigate to Discovery > Schedules.
2. Click New.
3. Select Serverless in the Discovery field. See Schedule a horizontal discovery for explanation of other fields.
4. Right-click the form header and select Save.
5. In the Serverless Execution Pattern related list, click New.
6. Fill out the form fields (see table):

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Provide a descriptive name.</td>
</tr>
<tr>
<td>Pattern</td>
<td>Select the pattern you created for standard serverless discovery or for proxy host-based discovery.</td>
</tr>
<tr>
<td>Proxy Host</td>
<td>Leave this field empty. This field applies to the host proxy-based scenario.</td>
</tr>
<tr>
<td>Active</td>
<td>Keep this check box selected to use the pattern execution definition.</td>
</tr>
</tbody>
</table>

7. Right-click the form header and select Save.
8. In the Discovery Pattern Launcher Parameters related list, add the parameters required by the pattern and provide a value for each one in the Volume column.
9. Click Submit.
10. Define as many serverless execution pattern records as needed. You can launch the same pattern, but they should have different parameters.
11. Execute discovery by clicking Discover Now or wait until the schedule triggers the discovery.

Check the Discovery status to see the Discovery log, the devices list, which holds the discovered CIs, and the ECC queue records. Note that the Shazzam probe did not launch and Discovery did not trigger any classification probes.

Create a pattern and a schedule for host-based serverless Discovery
To find application CIs that reside on a known host in your CMDB, create an infrastructure pattern for host-based serverless discovery. After creating the pattern, create a Discovery schedule that triggers the pattern.

Role required: cloud_admin, sm_admin, or admin

1. Navigate to Pattern Designer > Discovery Patterns.
2. Click New.
3. Specify an Infrastructure type pattern with the correct CI type that applies to the CIs you want to discover. See Create or modify patterns for an explanation of all form fields.
4. Create an identification section and save the pattern.
5. Add operations to the pattern to discover the CI that you can access via the host.
6. To test the pattern, click Debug Mode and enter the IP address of the host.

Create a schedule for host-based serverless Discovery
Discovery triggers the pattern for host-based, serverless Discovery from the schedule rather than from a classifier.

Ensure you have credentials for the host device that acts as the proxy.

Role required: cloud_admin, sm_admin, or admin

1. Navigate to **Discovery > Schedules**.
2. Click **New**.
3. Select the **Serverless** in the Discovery field. See *Schedule a horizontal discovery* for explanation of other fields.
4. Right-click the form header and select **Save**.
5. In the **Serverless Execution Pattern** related list, click **New**.
6. Fill out the form fields (see table):

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Provide a descriptive name.</td>
</tr>
<tr>
<td>Pattern</td>
<td>Select the pattern you created for host-based discovery.</td>
</tr>
<tr>
<td>Proxy Host</td>
<td>If you are using host-based discovery, specify an existing CMDB CI. Discovery uses the credentials of this CI when exploring the CIs on the host.</td>
</tr>
<tr>
<td>Active</td>
<td>Keep this check box selected to use the pattern execution definition.</td>
</tr>
</tbody>
</table>

7. Right-click the form header and select **Save**.
8. Define as many serverless execution pattern records as needed. You can launch the same pattern, but they should have different parameters.

**Note**: You do not need to create entries in the **Discovery Pattern Launcher Parameters** related list.

9. Execute discovery by clicking **Discover Now** or wait until the schedule triggers the discovery.

Check the Discovery status to see the Discovery log, the devices list, which holds the discovered CIs, and the ECC queue records. Note that the Shazzam probe did not launch and Discovery did not trigger any classification probes.

**Discovery configuration**

Configure the elements that Discovery requires to investigate your network, such as credentials, schedules, and IP addresses.

**Configuration overview**

Discovery can run on a regular, configurable schedule, or can be launched manually. The IP address ranges you provide tell Discovery which specific devices to investigate. To retrieve useful information, Discovery needs credentials for devices within a particular range, so that Discovery can connect to and run various probes on the devices it finds. Discovery compares the devices it finds with configuration items (CI) in the CMDB and updates any matching devices. If Discovery does not find a matching CI in the CMDB, it creates a CI.
Discovery configuration procedures

Use the following links to configure Discovery for your environment. You do not need to perform all these procedures to run a Discovery. The platform provides many defaults you can use to explore your network that are suitable for most discoveries. To get started quickly with Discovery, you can use Guided Setup, which expedites the setup of a basic Discovery.

</tr>
<tr>
<td>-------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| glide.discovery.bgp_router_disable | BGP router exploration disable: Disables running the SNMP – Routing probe or pattern when discovering a router running the BGP protocol. Normally such exploration IS disabled because of the huge size of BGP routing tables, and because generally such routers are only operating at the edge of large networks where further network discovery would be irrelevant. This value could be set to false if your organization only uses BGP routers as edge routers between relatively small networks (such as between buildings on a single campus).  
  - **Type**: true | false  
  - **Default value**: true |
| glide.discovery.debug.network_discovery | Network discovery debugging: Enables extensive logging of all Network Discovery activities on the instance.  
  - **Type**: true | false  
  - **Default value**: true  
  - **Learn More**: Discovery monitoring and issue resolution |
| glide.discovery.discoverable.network.max.netmask.bits | Maximum netmask size for discoverable networks (bits): The maximum number of bits in a regular netmask for networks that are discovered by Network Discovery. A regular netmask is a netmask that can be expressed in binary as a string of ones followed by a string of zeroes. For example, 255.255.255.0 is regular and 255.255.255.64 is irregular. Regular networks are commonly expressed like: 10.0.0.0/24, which means a network address of 10.0.0.0 with a netmask of 255.255.255.0. Larger bit numbers mean networks with smaller numbers of addresses in them. For example, the network 10.128.0.128/30 has four addresses in it: one network address (10.128.0.128), one broadcast address (10.128.0.131), and two usable addresses (10.128.0.129 and 10.128.0.130). Small networks are commonly configured in network gear to provide loopback addresses or networks used strictly by point-to-point connections. Since these sorts of networks generally don’t need to be discovered by Network Discovery, it would be useful to filter them out. By setting this property to a value of 1 through 32, you can limit the sizes of regular networks that are discovered. Setting it to any other value causes all networks to be discovered. Irregular networks are always discovered. The default value is 28, which means that regular networks with 8 or fewer addresses cannot be discovered.  
  - **Type**: integer  
  - **Default value**: 28 |

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| glide.discovery.file_tracking.change_limit_count | File Tracking: Number of changes allowed on a tracked configuration file in the defined time window.  
  - **Type**: integer  
  - **Default value**: 4 |
| glide.discovery.file_tracking.change_limit_days | File Tracking: Time window (in days) that limits the number of changes on a tracked configuration file.  
  - **Type**: integer  
  - **Default value**: 7 |
| glide.discovery.fqdn.regex | DNS Host Name And Domain Name Regex: The default parsing of FQDN (Fully Qualified Domain Name) is to pick the first name separated by dots as the host name and the rest of the names as the domain name. For example, “machine1.testlab.service-now.com” has host name of “machine1” and domain name of “testlab.service-now.com”. The property allows regex with two capturing groups with the first group representing the host name and the second group the domain name.  
  - **Type**: string  
  - **Default value**: `^(([^.]+)\.(?:[^.]+)+[^.]+$` |
| glide.discovery.hostname.always_update | Always update host name. If set to **true**, discovery always updates the host name with the most recently discovered value contingent upon the source being trusted. Note that this may result in hand-entered values being overwritten.  
  - **Type**: true | false  
  - **Default value**: true |
| glide.discovery.hostname.case | Host name case. If **Lower case** is selected, always translate the host name into lower case; if **Upper case** is selected, always translate the host name to upper case; if **No change** is selected, leave the host name intact. This primarily affects host names discovered with NETBIOS, though some non-standard DNS systems may also return some or all of the name in upper case.  
  - **Type**: choice list  
  - **Default value**: Lower case  
  - **Additional options**: Upper case, No change |
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| glide.discovery.hostname.dns_nbt_trusted | DNS or NetBIOS is trusted host name source: If set to **true**, trust the device name discovered via DNS or NetBIOS. If checked, CI's host name found via DNS or NBT is used.  
  - **Type**: true | false  
  - **Default value**: true |
| glide.discovery.hostname.include_domain | Includes domain name in host name: If set to **true**, include the domain name as part of the host name. For example, "bosco.service-now.com" instead of "bosco".  
  - **Type**: true | false  
  - **Default value**: false |
| glide.discovery.hostname.snmp_trusted | SNMP is trusted host name source: If set to **true**, trust the device name discovered via SNMP. If checked, any device name found via SNMP is used instead of the name found by a reverse DNS lookup.  
  - **Type**: true | false  
  - **Default value**: false |
| glide.discovery.hostname.ssh_trusted | SSH is trusted host name source: If set to **true**, trust the device name discovered via SSH. If checked, any device name found via SSH is used instead of the name found by a reverse DNS lookup.  
  - **Type**: true | false  
  - **Default value**: false |
| glide.discovery.hostname.wmi_trusted | WMI is trusted host name source: If set to **true**, trust the device name discovered via WMI. If checked, any device name found via WMI is used instead of the name found by a reverse DNS lookup.  
  - **Type**: true | false  
  - **Default value**: false |
| glide.discovery.ip_service_affinity | IP service affinity: If set to **true**, IP service affinity is enabled. IP service affinity allows Discovery to remember the last port of the IP address that was discovered.  
  - **Type**: true | false  
  - **Default value**: false  
  - **Learn More**: [Check IP service affinity for Discovery and Orchestration](#)
<table>
<thead>
<tr>

*Note:* In previous releases, this property was **true** by default. The value in this property is not changed during an upgrade to Kingston.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| glide.discovery.virtual_interface_types | Virtual interface types: List of interface types (comma-separated) that can be considered "virtual" for the purposes of network discovery. In other words, if a router (or device capable of routing) has an interface of this type, the networks connected to that interface are considered virtually connected to that device. The default interface types include the propVirtual type. Interface type numbers are defined in the SNMP MIB-2, specifically in OID 1.3.6.1.2.1.2.2.1.3.  
  - **Type**: integer  
  - **Default value**: 53 |
| glide.discovery.warn_minor_version | Warn on Minor Version Mismatch: If set to true, warnings are logged when minor_version mismatches are detected during Discovery sensor processing.  
  - **Type**: true | false  
  - **Default value**: false |
| glide.ecc_agent.validated.override | An override for the ecc_agent validated field: If set to true, ecc_agent records will always be treated as valid.  
  - **Type**: true | false  
  - **Default value**: false  
Navigate to System Properties > All Properties to find this property. |
| glide.eccprobe.awsrestprobe.max_retries | Set the maximum number of times the AWS request will be retried if a rate limit exceeded error occurs. Maximum value is 10. Note that retries use exponential backoff (2^x). Setting negative values is equivalent to setting the maximum value.  
  - **Type**: integer  
  - **Default value**: 4 |
| glide.eccprobe.awsrestprobe.max_wait | Set the maximum total amount of time (seconds) the AWS request attempts to retry. Maximum value: 2046 seconds. Setting negative values is equivalent to setting the maximum value.  
  - **Type**: integer  
  - **Default value**: 30 |
| glide.eccprobe.max_queued_probes_per_run | Set the maximum number of probes a node can pick up during a run.  
  - **Type**: integer  
  - **Default value**: 20 |

</tr>
</tbody>
</table>

### Discovery IP address configuration

Use one or more of these methods in any combination to define the network or network segment for Discovery to query. You can include or exclude specific IP ranges from your query.

**Note**: If you do not know the IP addresses in the network, run Network discovery first to determine the IP networks. Then, convert the IP networks into IP address range sets.

There are three types of IP collections:

<table>
<thead>
<tr>
<th>IP collection type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP address list</td>
<td>Use IP address lists to add individual addresses to query. These addresses are not included in any existing IP range or IP network. You can enter the IP address of the device or a host name (DNS name). If you enter a host name, it must be mapped to an IP address.</td>
</tr>
<tr>
<td>IP address range</td>
<td>You can define arbitrary ranges of IP addresses to query. This process is a good way to include selected segments of a network or subnet. However, Discovery has no way of knowing if the IP range includes addresses for private networks or broadcast addresses, and scans all the addresses in the range. If the network and broadcast addresses are included, then the results are inaccurate. Discoveries configured to detect IP networks are more accurate than discoveries configured for IP address ranges. Only those IP addresses in your range that are reserved for manageable devices on the public network should be included.</td>
</tr>
</tbody>
</table>

**Note**: To avoid any possible performance issues, limit Discovery schedules to a maximum range of /16 or no more than 65,000 IPs. You can also split the Discovery schedules into even smaller ranges of IP addresses.
### IP collection type

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP network</td>
</tr>
</tbody>
</table>

You can also scan an entire IP network. An IP network includes the range of available IP addresses in that network. The scan also includes the network address (the lowest address in the range) and the broadcast address (the highest address in the range). After you run network discovery, convert the IP networks that were found into range sets for use in discovering other devices.

An example of a class C network range is 192.168.0.0 to 192.168.0.255. In the Range Set form, this network can be entered with either of the following notations:

- 192.168.0.0/24
- 192.168.0.1/255.255.255.0

This notation indicates that Discovery is scanning an IP network, and does not scan the highest and lowest numbers in the range. Significant errors are prevented and introduced into the Discovery data by the broadcast address. All devices are returned in the network, and the network address, which can add an arbitrary number of redundant devices. This built-in control makes IP networks the best method of defining which IP address ranges to query.

### IP address selection properties

You can use system properties to control the selection of IP address for specified CI classes.

Use these properties to determine if the system should replace the IP address returned by Discovery in a device’s CI record if the address does not match that of a network interface (NIC) on the device. This is important for the discovery of devices with management IP addresses that differ from IP addresses associated with one or more NICs on the device. Because a device’s management IP is used in the Discovery schedule for that device, this is the address that Discovery returns. Use these properties to determine which IP address to use for CIs of any class.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.discovery.enforce_ip_sync</td>
<td>Enforce syncing of IP addresses: This sets the first IP address. Each time a computer with multiple NICs is discovered, one of the IP addresses associated with the NICs is chosen as the IP Address field of the CI. A value of false collects all NIC IP addresses.</td>
</tr>
<tr>
<td></td>
<td>Type : true</td>
</tr>
<tr>
<td></td>
<td>Default value: true</td>
</tr>
</tbody>
</table>
### Field: glide.discovery.exclude_ip_sync_classes

**Description:** Defines CI classes whose IP addresses should not be substituted if the address returned by Discovery does not match one of the devices’ NICs. Use a comma separated list to define multiple classes. By default, the system uses the management IP of a load balancer returned by Discovery in the CI record, rather than substituting it for the IP address of one of the load balancer’s NICs.

- **Type:** string
- **Default value:** cmdb_ci_lb

---

**Create a Quick IP range for a Discovery schedule**

Quick ranges allow administrators to define IP addresses to scan in a single comma-delimited string without creating separate records.

Only MID Servers that are up and validated are used with quick ranges. The MID Servers must specify the Discovery application (or ALL applications) and have IP ranges configured if you use the auto-select feature on the Discovery schedule.

You can enter IP addresses in one of the following formats:

- An IP range defined by a slash and the number of bits in the subnetwork. For example, the string 10.10.10.0/24 scans 24 bits of IP addresses from 10.10.10.0 to 10.10.10.254.
- An IP range defined by a dash. For example, the string 10.10.11.0-10.10.11.165 scans the IP addresses from 10.10.11.0 to 10.10.11.165.
- A comma-separated list of specific IP addresses. For example, the string 10.10.11.200,10.10.11.235 scans the IP addresses 10.10.11.200 and 10.10.11.235.

1. Click the **Quick Ranges** related link on the Discovery Schedule form.
2. Enter the IP ranges and specific IP addresses to scan.
3. Click **Make Ranges**.

**Note:** The Quick Range interface is for entering IP addresses only and cannot be used to edit IP addresses that have already been submitted.
Entering a quick range from a Discovery schedule

Advanced

- Include alive
- Log state changes
- Use SNMP version v1/v2

Quick Ranges

Enter comma-separated IP address ranges, IP networks, or individual IPs describing the range to add. For example:

```
10.0.1.0/24,10.0.2.1-10.0.2.15,10.0.3.176,10.0.3.222
```

Specifies an IP network with valid IP addresses between 10.0.1.1 and 10.0.1.254 inclusive, and an IP range from 10.0.2.1 to 10.0.2.15 inclusive, and the two individual IP addresses 10.0.3.176 and 10.0.3.222 you make that cannot be interpreted will simply be ignored.

```
10.0.1.0/24,10.0.2.1-10.0.2.15,10.0.3.176,10.0.3.222
```

Quick ranges
Discover now
The instance automatically displays the entries in the proper format.

4. For changes to IP address ranges, select the IP address records in the **Discovery Range Sets** related list.

**Import IP ranges into Discovery schedules with import sets**

The most efficient method of entering large numbers of IP networks into Discovery schedules is by using import sets.

Common groups of IP addresses, known as **ranges** can be used in Advanced Discovery schedules.

Use a data source that can be mapped. Include these fields:

- Start IP: the first IP address in the range (inclusive).
- End IP: the last IP address in the range (inclusive).

1. Navigate to **System Import Sets > Load Data**.
2. Identify the file or data source that contains the desired information.
3. Create a table name, such as `ipnetworks`.
4. Select **Upload an Excel file** and browse to the source file.
5. Click **Go** to import the file.

![Image of System Import Sets](image)

**Data Source**

6. Navigate to **System Import Sets > Create Transform Map** and map the items in the Excel spreadsheet to the fields of the CMDB in the target table IP Range `[ip_address_range]` table.
7. Give the Transform Map a unique and descriptive name.
8. Submit the form, and then click **New** in the **Field Maps** Related List.
9. Map the fields from the Excel spreadsheet to the fields in the IP Range `[ip_address_range]` table. The fields you need values for are the Start IP and End IP addresses.
10. Click the **Mapping Assist** Related Link and use the lists that appear to resolve the fields between the table and the data source (the Excel spreadsheet in this example).
11. Click **Save**.

The view returns to the Table Transform Map form.
12. Click **Transform** in the Related Links to move the data into the proper fields in the IP Range `[ip_address_range]` table.
The imported IP ranges are available now for use in any advanced Discovery schedule.

**Exclude IP ranges from a Discovery range set**
You can specify a range of IP addresses that you want to exclude from your Discovery query.

1. Navigate to **Discovery > Discovery Range Sets**.
2. Select one of the range sets.
3. Select one of the types from the **Discovery IP ranges** related list.
4. Click **New** from the **Discovery Range Item Excludes** related list.
5. Enter a starting IP and ending IP address to create the range to exclude.
6. Click **Submit**.

**Domain Separation and Discovery**
This is an overview of domain separation and Discovery. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can then control several aspects of this separation, including which users can see and access data.

**Overview**

**Support: Level 2**
ServiceNow applications are defined by incremental support levels. The Discovery application includes all of the features of lower support levels.

Domain separation is supported in this application. Not all ServiceNow applications support domain separation; some include limitations on the data and administrative settings that can be domain separated. To learn more, see Application support for domain separation. Application support for domain separation.

Service Providers (SPs) use domain separation to segregate data for each customer. Users in a given domain have visibility only to the data in their own domains or in child domains. SPs typically control the top-level domain, which gives them visibility to data associated with all domains. Given that Discovery domain separation support is considered Level 2, there is no delegated administration to the child domains. The SPs must retain administrative control.

**How domain separation works in Discovery**

Multiple domains can be supported by a single MID Server. In releases prior to Kingston, each MID Server could support only a single domain. In newer releases, segregating domains by MID Server is useful when the domain is large, or when the domain's resources are held in a customer's data center rather than the SP's. For Discovery on MID Servers supporting a single domain, the discovered CIs are assigned to the domain of the MID user used to authenticated against the ServiceNow instance. In multi-domain MID Servers, the discovered CIs are assigned to the domain of the user that created the Discovery schedule.

Discovery implements data domain separation through the MID Server by impersonating the MID Server user during sensor processing. Discovery uses the domain that the MID Server user is in to determine which domain the discovered data should be put into. Discovery configuration information, including classifiers, identifiers, probes, and sensors, is not domain-separated.

SPs generally use IP-based Discovery. In cases where the SP controls the network addressing, they divide the address space among their customers to ensure that each domain has a distinct IP address space. The SP assigns one or more subnets to a customer or domain and creates Discovery schedules for those subnets.
If the SP is remotely managing their customer's data center, there will often be some overlap between address spaces different customers use. In these cases, the SP can use network address translation (NAT) on the IP range and run a Discovery schedule.

Once the CIs are assigned to the correct domain, the visibility and read/write access control are provided by the platform through the domain hierarchy. Schedules are visible to users in their respective domains. Cross-domain schedule visibility is not possible, except for the SP who controls the parent domain and has visibility to all domains.

**Domain separation for MID Server files**

You can create versions of these specific MID Server policy records that only a MID Server from the same domain can use. This process separation is supported for records in tables that extend MID Server Synchronized Files (`ecc_agent_sync_file`):

- MID Server MIB File (`ecc_agent_mib`)
- MID Server JAR File (`ecc_agent_jar`)
- MID Server Script File (`ecc_agent_script_files`)

By default, all records in these tables are members of the global domain. A user can override the default global domain and create a version of these policies for use in the user's own domain.

**Note:** Attachments on MIB or JAR file records might not appear as they did in a non-domain separated environment. The attachments do not appear because the Attachments (sys_attachment) table is data separated. When data is separated between domains, a record in a child domain cannot access records in a parent domain.

See [MID Server domain separation](#) for instructions on setting up domain separation through the MID Server.

**Domain-separated tables**

Records in all tables that extend the Base Configuration Item (cmdb) table can be domain separated. In addition, records in these tables can also be domain separated:

- Serial Number (`cmdb_serial_number`)
- TCP Connection (`cmdb_tcp`)
- Fibre Channel Initiator (`cmdb_fc_initiator`)
- Fibre Channel Targets (`cmdb_fc_target`)
- IP Address to DNS Name (`cmdb_ip_address_dns_name`)
- Service (`cmdb_ip_service_ci`)
- KVM Virtual Device (`cmdb_kvm_device`)
- Load Balancer Service VLAN (`cmdb_lb_service_vlan`)
- Load Balancer VLAN Interface (`cmdb_lb_vlan_interface`)
- Switch Port (`cmdb_switch_port`)

**SNMP support for Discovery**

Discovery supports SNMP versions 1, 2c, and 3. Discovery uses version 1 and 2c by default. You must enable support for version 3.

MID Servers support all SNMP protocol versions by default. You can set a MID Server to support only specific versions of SNMP.
Add an SNMPv3 user credential in Discovery
Set up your credentials so Discovery can access SNMPv3 targets.

Role required: admin

A MID Server parameter is also available to control SNMP versions. See MID Server parameters.

1. Navigate to Discovery > Credentials.
2. Click New.
3. Click SNMPv3 Credentials.
4. Use the following table to fill in the form.
   This form creates an entry in the SNMPv3 credentials table. The SNMPv3 credentials table stores the credentials.

<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Unique and descriptive name for this credential.</td>
</tr>
<tr>
<td>Field</td>
<td>Input Value</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Active</td>
<td>If the credential can be used. Select this box to activate the credential.</td>
</tr>
<tr>
<td>User name</td>
<td>The user name to authenticate to the target devices. This selection must match the name that is set on the devices to be discovered. If a domain account is used to execute PowerShell commands in Discovery, the user name must include the domain. Avoid leading or trailing spaces in user names. A warning appears if the platform detects leading or trailing spaces in the user name. This is the only required field.</td>
</tr>
</tbody>
</table>
| Authentication protocol | The encryption protocol. This selection must match the encryption protocol that is set on the devices to be discovered. Valid options are:  
  - **None**: No encryption is used.  
  - **MD5** *(Message Digest version 5)*  
  - **SHA** *(Secure Hash Algorithm)*  
  See the SNMPv3 security options table below to configure the type of security.                                                                                           |
| Authentication key    | The authentication key that is set on the target devices.                                                                                                                                                     |
| Privacy protocol     | The encryption standard. This selection must match the encryption standard that is set on the devices to be discovered. Valid options are None, AES128 *(standard AES)*, AES192, AES256, DES, or 3DES.                                                |
| Privacy Key          | The privacy key that is set on the target devices.                                                                                                                                                           |
| Tag                  | The name of a credential tag.                                                                                                                                                                                   |
| Applies to           | The MID servers that use this credential. You can choose **All MID servers**, or you can create a list of **Specific MID servers**.                                                                           |
| Order                | The order in which the credentials are tried, if there is more than one credential for a given type.                                                                                                             |

          - Privacy Key: Set

Set SNMP version on the Discovery schedule
You must also add an SNMPv3 credential if you set the SNMP version to v3 or All.

Role required: admin
A MID Server parameter is also available to control SNMP versions. See MID Server parameters.

1. Navigate to Discovery > Discovery schedules > your Discovery schedule.
2. In the Use SNMP Version field, select the appropriate version.
   Valid options are v1/v2c, v3, or All.

Discovery and SCCM together
Use these guidelines to avoid common issues when you use Discovery and System Center Configuration Manager (SCCM) together.

You must decide if you will use Asset Intelligence (AI) or non-AI software data sources. Because the software correlation data is tracked differently for each of these data sources, you should avoid switching back and forth between the two. If you must switch between data sources, remove all the software installation records imported by SCCM before the switch occurs.

When Software Asset Management is not enabled, software installation records are stored in the Software Instance (cmdb_software_instance) table. When Software Asset Management is enabled, software installation records are stored in the Software Installation (cmdb_sarn_sw_install) table.

Note: If records are not removed before the switch, duplicate records may exist. In the event that AI and non-AI data becomes mixed, clear the Software Installation table.

Overview of SCCM plugins
These are the plugins for the currently supported SCCM versions, all of which support Asset Intelligence and Incremental Software Reconciliation:
- Microsoft SCCM 2007
- Microsoft SCCM 2012 v2
- Microsoft SCCM 2016
Upgrading to a new version

The ServiceNow SCCM integrations are self-contained and can exist independently. They each use their own import set tables, data sources and transform maps. However, all SCCM integrations will transform data into the same tables within the ServiceNow CMDB. To avoid the data being overwritten by another source:

- Use one SCCM integration and disable all other SCCM scheduled imports.
- Perform a full import to clear the cmdb_software_instance table, the cmdb_sam_sw_install table, and other tables of old SCCM data.

To change the SCCM integration:

- Disable the current integration by deactivating the SCCM import schedule.
- Activate the new SCCM plugin.
- Reimport all the software records when you are switching to an integration that supports incremental imports of removed software.

For instructions on disabling the current SCCM import schedule, see Upgrade the SCCM integration version

Collect software data with either SCCM or Discovery

When Discovery and SCCM are both enabled on a system, the software records found through both tools could overwrite each other.

Role required: admin

Determine how software data is collected.

1. Navigate to Discovery Definition > Properties.
2. Set the Windows software is SCCM managed property (glide.discovery.software_sccm_managed) appropriately.
   - If this property is set to Yes, software for computer CIs is populated in the CMDB by SCCM. An internal process determines that the computer is managed by SCCM, and Discovery does not populate the software records for Windows software data. The following information level message is written to the Discovery log file.
     Skipping software population because the CI is managed by SCCM
   - If the check box is cleared, the property is set to No, and the system manages software data with Windows.
3. Click Save.

Important: If SCCM Integration is active before Discovery is enabled and the property is enabled, Discovery ignores the population of software for any CIs that are also
imported through SCCM. If Discovery is enabled before the SCCM Integration, it is possible for software installation data from both sources to be mixed.

Discovery classifiers

A classifier tells Discovery which probes to trigger for the identification and exploration phases of discovery. Classifiers can also trigger the Horizontal Pattern probe, which launches a pattern, rather than additional probes, for identification and exploration.

The classifier essentially starts the identification stage. Discovery uses it after the classification probe returns important parameters to the instance that tell Discovery what to do next. In most cases, you do not need to create a classifier or modify a classifier. But if you are having trouble with horizontal discovery, you might want to check the conditions that determine when a classifier runs based on the parameters the classification probe returns to the instance. Or if you want to discover a new type of CI that Discovery does not already find, you can create your own classifier.

Device, process, and IP address classification

Discovery classification can be broken down into three types: device classification, process classification, and IP address (or IP scan) classification:

Device classification

The classification of actual device types, such as a computer running Windows, a computer running a flavor of UNIX or LINUX, a router, a switch, or a load balancer, and so on.

When Discovery identifies a computer CI, it triggers an active processes probe to explore the computer CI further. Discovery compares the results of the active processes probe to the process classification conditions to determine if there is a match.
Starting with the Madrid release, the horizontal discovery process can classify devices using HTTP. Of all protocols that Discovery uses (including WMI, SSH, and SNMP), HTTP is the lowest priority by default. Discovery uses HTTP classification only if:

- Shazzam determines that the ports for HTTP (80) and HTTPS (443) traffic are open.
- The horizontal discovery process fails for the higher priority port probes (WMI, SSH, and SNMP) if the ports for those protocols are not open, or if discovery for those protocols fail. The horizontal
discovery process can fail, for example, if SSH and SNMP credentials are not configured or are incorrect.

**Note:** See [Port Probes](#) for more details on how port scanning works and to see the priorities of the different protocols.

HTTP classification launches the [HTTP Classify](#) probe to classify the device. The [HTTP - Classify](#) probe runs a GET request for each device for each HTTP classification. The URL of the request is built as follows: `PROTOCOL://IP:PORT/PATH`, where:

- `PROTOCOL` is port 80 for HTTP or port 443 for HTTPS.
- `IP:PORT` is the IP address and port number of the device.
- `PATH` is the path that you specify in the HTTP classifier.

For more information on port probes, see [Port probes](#). For instructions on creating an HTTP classifier, see [Create an HTTP classification](#).

### Process classification

The classification of applications based on the processes that are running.

Discovery classifies processes during the last phase of discovery: the exploration phase, after identifying devices in the Computer (cmdb_ci_computer) table and its extensions. Just like device classification, process classification has its own classification criteria and also has the ability to launch probes. Unlike device classification, process classification creates child configuration items (CI) with Runs on::Runs relationships. By default, Discovery includes classifications for most common processes.

If a process matches the classification criteria, Discovery determines whether to run the process handler script. The process handler script modifies the parameter data to help Discovery identify whether the process represents an existing or new application CI. Discovery process handlers prevent the creation of duplicate CIs by filtering out parameters known to have inconsistent values before process classification occurs. Every time Discovery adds or updates an application CI, it also determines the application dependency mapping of the application CI to other CIs in the CMDB.
Process classification workflow

**IP address (IP scan) classification**

IP address discovery is credential-less, meaning that it attempts to identify devices and software based on just the open ports and banners it finds without requiring you to create credentials.
If the classification criteria are met for a device in the IP Scan mode, Discovery automatically updates the CI in the CMDB. After a device is properly classified, Discovery launches the exploration probes configured for that class of device and begins gathering detailed information about the CI.

In the default Discovery system, the Linux classifier triggers eleven exploration probes that return information such as disk size, memory, and the number of current connections. The data from these probes returns at different times and is stored in the ECC Queue until processing is complete.

This diagram shows the processing flow for classifying and probing devices with an IP scan (no identifiers):
See Classification for IP address discovery for more details about the parameters available to classifiers for this type of discovery.

**Classifier criteria**

Classifiers also provide criteria that you can use to specify when Discovery should use the classifier under the conditions that you define. The criteria is based on the parameters that a classify probe returns to Discovery. Criteria is constructed with the parameter, an operator, and a value.

**Note:** Condition filters in process classifiers are case-sensitive.

**Classifiers and patterns**

Discovery can use patterns, rather than probes, to identify and explore CIs. Discovery triggers patterns from the Horizontal Discovery probe, which can be specified on a classifier. You can create your own patterns and add them, via the Horizontal Discovery probe, to a classifier. See Add the Horizontal Pattern probe to a classifier for instructions. You might already be using one of the out-of-box patterns that are provided with Discovery. You can verify this by looking at the classifier to see if the Horizontal Pattern Probe is specified.

**Logging classification debugging information**

To log debugging information about classifications, add the following system property. The resulting log entries list the name of each classifier that runs, along with all the names and values that are available to the criteria in the classifier.

<table>
<thead>
<tr>
<th>System property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.discovery.debug.classification</td>
<td>Enables debugging information for process classification.</td>
</tr>
<tr>
<td></td>
<td>Type: true</td>
</tr>
<tr>
<td></td>
<td>Default Value: false</td>
</tr>
<tr>
<td></td>
<td>Location: Add to the System Properties (sys_properties) table</td>
</tr>
</tbody>
</table>

What you can do with Discovery classification

- Create or modify a discovery classifier if you want to classify CIs that Discovery does not already classify, or trigger other probes that are not already on a classifier. You can modify classifiers that Discovery uses in standard CI discovery, process classifiers for applications, and classifiers based on IP address scans.

Before you modify any classifiers, review the parameters that are available for each type of classifier.

- If Windows machines are on your network, you can use the WinRM protocol, rather than WMI, for more efficient lightweight data transfer and remote command execution. By default, Discovery uses WMI. For instructions on the classifier modifications you can make to use WinRM, see Use Windows Remote Management for classification.

- If you have Windows computers that are acting as servers and you want them to be classified by their function rather than by the operating system, you can make changes to the criteria
of the Windows classifier. See *Reclassify a Windows Workstation machine as a server* for instructions.

Create a Discovery CI classification

A CI classification allows Discovery to discover most common operating systems, network devices, and processes.

Role required: admin

**Caution:** Adding SNMP OID classifications with a Net-SNMP module OID starting with 1.3.6.1.4.1.8072.3.2 can result in misclassification of devices and incorrect model names. These are template system OIDs that can remain on a device if the manufacturer fails to replace them with OIDs specific to their own model. For example, a Check Point Smart-1 3050 Firewall, which uses Linux as its OS, might have the OID for a Linux server, 1.3.6.1.4.1.8072.3.2.10. This results in the firewall being classified incorrectly. If you know you only have one device with a specific template system OID, it is safe to add it. Discovery will always choose the classification matched to that OID. If two or more devices have the same OID, configure classification criteria that differentiate the devices from one another. For details, see KB0751287.

1. Navigate to **Discovery Definition > CI Classification**.
2. Select the type of classification to create.
3. Click **New** in the list of classifications for the type you selected.
4. Complete the form using the fields in the table.

**Classification form fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the configuration item (CI).</td>
</tr>
<tr>
<td>OID</td>
<td>SNMP system OID for matching this device. When the OID value matches that of an SNMP device, Discovery uses the information to populate the CMDB with the specified manufacturer, model, and classifier.</td>
</tr>
<tr>
<td>Operator</td>
<td>Operator for determining how to match and SNMP OID. The choices are <em>Is</em> and <em>Starts with</em>. This field is available only for SNMP System OIDs classifiers.</td>
</tr>
<tr>
<td>Active</td>
<td>Enables or disables this classifier. When a classifier is disabled, the system stops classification at this level and does not launch classifiers of a lower order. For example, when the classifier for Windows 2008 Server is disabled, the system stops Discovery at this point and does not launch the Windows 2012 Server classifier.</td>
</tr>
<tr>
<td>Order</td>
<td>Order (sequence) in which the platform runs this classifier.</td>
</tr>
<tr>
<td>Table</td>
<td>Table for this classification. For example, if this record classifies a Linux server, select the Linux Server (cmdb_ci_linux_server) table.</td>

MultiProbe-SNMP - F5 BIG-IP - Identity
SNMP - F5 BIG-IP - Identity
Create a Discovery process classification

A process classification allows Discovery to create a particular CI type from information gathered during the identification and exploration phases.

When a process matches the classification criteria, Discovery uses the process classification record to create a CI. You can also have Discovery update existing CIs or ignore certain processes by creating a process handler.

1. Navigate to Discovery Definition > CI Classification > Processes.
2. Click New.
3. Enter the classification fields (see table).

### Classification fields

</thead>
<tbody>
<tr>
<td>Table</td>
<td>Select the table where this classification generates CI records. This table must be an extension of the Applications (cmdb_ci_appl) table.</td>
</tr>
</tbody>
</table>
| Relation type | Select the CI relationship type for this classification. The relationship field is only available for Process and Scan Application classifications. Discovery process classifications typically use one of these relationship types:
  - Runs on::Runs: Defines the relationship of an application to the host on which it runs. This relationship is expressed from the perspective of the host and the application. For example: My database application runs on server001::server001 runs my database application.
  - Depends on::Used by: Defines the relationship of an application that communicates with another application. This relationship is expressed from the perspective of each application. For example: The Tomcat application depends on the MySQL database:: The MySQL database is used by Tomcat.
  - Virtualized by::Virtualizes: Defines the relationship of a virtual machine to its host. This relationship is expressed from the perspective of the virtual machine and of the host. For example: server001 is virtualized by Server ESX::Server ESX virtualizes server001. |
<p>| Active        | Select this option to enable the process classification record. Only active process classifications can create application CI records. |
| Order         | Enter the order in which Discovery should run this process classification when there are multiple classifications available for a table. Discovery runs process classifications from the lowest to highest order. |</p>
<table>
<thead>
<tr>

<tbody>
<tr>
<td>Test with</td>
<td>Lists the host CI where an automatically generated process classification conditions were met. Use this field to test changes to the process classification to ensure that the updated classification behaves as expected.</td>
</tr>
<tr>
<td>Condition</td>
<td>Use the condition builder to create the match and classification criteria for the process classification. This field replaces both the Match criteria field and Classification Criteria related list. The upgrade process converts all existing classification criteria into conditions.</td>
</tr>
<tr>
<td>Note:</td>
<td>Condition filters in process classifiers are case-sensitive.</td>
</tr>
</tbody>
</table>
| On classification script     | Enter a script to run when the condition and classification criteria are met. Use this script to perform any special tasks after a device is classified. It is possible to use the g_probe_parameters hashmap from within a classification script to set probe parameters for any configured, triggered probes. For example, this code sets a 'node_port' parameter to 16001 for all triggered probes.  
  
  ```javascript
  g_probe_parameters['node_port'] = 16001;
  ```
  
  See On classification script objects for Discovery for more examples and for a list of the objects you can use in this kind of script. |
<p>| Triggers probes              | Select the exploration probes you want Discovery to launch. These probes gather detailed information about a classified CI. Discovery will not launch these probes when it is configured to stop after classification. If you want to use patterns for horizontal discovery, add the Horizontal Pattern probe in the Probe column, and then specify your pattern in the Pattern column. |
| Warning:                     | Do not specify your pattern in Probe column. You must chose the Horizontal Pattern probe, which launches the specified pattern.                                                                              |
| Applications                 | Use this related list to view the application CIs that match this process classification.                                                                                                                      |
| Test results                 | Use this related list to view the how Discovery classifies processes on the Test with host and build better classification conditions.                                                                          |</p>

### Process Classification

**New York SQL Temp**

<table>
<thead>
<tr>
<th>Name</th>
<th>MYCustomSQLServer2014</th>
</tr>
</thead>
</table>

**Active:** True

**Order:** 100

**Condition:**
- **Add Filter Condition:** MYCustomSQLServer2014
- **Operator:** And
- **Value:**

```
// This script gets run when something gets classified
```

**Related Links**

Create a "new class" process handler.

**Triggers probes**

<table>
<thead>
<tr>
<th>Name</th>
<th>MYCustomSQLServer2014</th>
</tr>
</thead>
</table>

No records to display
Run a discovery through the **Discovery Schedule** to search for applications. You can also **create or modify process handlers** that prevent the creation of duplicate CIs based on process classifiers if that is an issue for your environment.  

**On classification script objects for Discovery**  
Use an **On classification** script in a process classifier to customize an application record. This kind of script is used in a process classifiers.

---

**Renaming the default application name**

By default, application names are in this format: `<name of the process classifier>@<the name of the computer CI where the process resides>`;

For example, for a MySQL server running on a computer called `machineA`, the application is named `mysql@machineA`.

You can use the **On classification script** field in the **process classifier record** to change the default application name to match your business needs. For example, the following script changes the default application name to include a suffix after the process classifier:

```javascript
var computerName = g_sensor.deviceGR.name;
var processClassifierName = g_classification.name;
current.name = processClassifierName + "999" + "@" + computerName;
```

In this example, the name of the application record becomes `mysql999@machineA`.

Another common technique is to set the application name based on the name, command, and parameter variables. For example, an Eclipse process might have the following values in these variables:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>&quot;eclipse&quot;</td>
</tr>
<tr>
<td>command</td>
<td>&quot;/glide/eclipse/Eclipse.app/Contents/MacOS/eclipse&quot;</td>
</tr>
<tr>
<td>parameter</td>
<td>&quot;-psn_0_1884620&quot;</td>
</tr>
</tbody>
</table>

If an Eclipse application runs on a computer called `machineA`, ServiceNow names the application `eclipse@machineA`. The following script appends the parameter value as part of the application name.

```javascript
var computerName = g_sensor.deviceGR.name;
var processClassifierName = g_classification.name;
current.name = processClassifierName + parameters + "@" + computerName;
```

In this example, the name of the application record becomes `eclipse-psn_0_1884620@machineA`.

Sometimes it is useful to pass values to the triggered probes in the process classification. You can do this by creating a custom script that defines a name/value pair for the `g_probe_parameters` object. For example:

```javascript
g_probe_parameters['processCommand'] = command;
```

In this example, when a classification record triggers a probe, the script passes the probe a parameter called `processCommand` with the value of the `command` variable.
### Script objects

Use these objects in the script:

<table>
<thead>
<tr>
<th>Script object</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>current</td>
<td>Points to a JavaScript object with its (property:value) pair to update the application record. (It is not an actual GlideRecord object of the application.)</td>
</tr>
<tr>
<td>g_sensor</td>
<td>Points to the running process sensor class. This object contains a deviceGR object, which points to the computer CI record on which the process resides.</td>
</tr>
<tr>
<td>g_classification</td>
<td>Points to the process classifier record itself.</td>
</tr>
<tr>
<td>name</td>
<td>Points to the process name.</td>
</tr>
<tr>
<td>command</td>
<td>Points to the process command.</td>
</tr>
<tr>
<td>parameters</td>
<td>Points to the process parameters.</td>
</tr>
<tr>
<td>g_probe_parameters</td>
<td>A JavaScript object that will allow parameter passing to the triggered probes.</td>
</tr>
</tbody>
</table>

Create a Discovery process handler

Process handlers prevent the creation of duplicate CIs by filtering out parameters known to have inconsistent values before process classification occurs. You can create new classifiers or edit existing ones.

1. Navigate to **Discovery Definition > CI Classification > Process Handlers.**
2. Click **New.**
3. Complete the fields on the Process Handler form.

#### Process Handler form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a unique name for the process handler record.</td>
</tr>
<tr>
<td>Active</td>
<td>Select the check box to run the process handler.</td>
</tr>
<tr>
<td>Classify</td>
<td>• Select the check box to enable classification of any Running Process (cmdb_running_process) record that matches this Process Handler's conditions.</td>
</tr>
<tr>
<td></td>
<td>• Clear the checkbox to disable classification of any Running Process (cmdb_running_process) record that matches this Process Handler's conditions.</td>
</tr>
<tr>
<td>Condition</td>
<td>Select the conditions that trigger the process handler to run the script. In most cases, this condition contains either specific executable names or the presence of certain parameters.</td>
</tr>
</tbody>
</table>
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Script</td>
<td>Enter the JavaScript you want to run on the current record in the Running Process (cmdb_running_process) table when the Condition is met. The current variable is a reference to a Running Process GlideRecord. The script should examine current.parameters for certain values, perform string replacement to manipulate these values, and save the result to current.key_parameters. ServiceNow uses the key_parameters field, together with the process name, to determine whether the process is unique on a specific machine. See On classification script objects for Discovery for additional options.</td>
</tr>
</tbody>
</table>

4. Click **Submit**.

Run a discovery through the Discovery Schedule to search for applications and then verify the results in the CMDB for the applications that are found.

**Create an HTTP classification**

An HTTP classifier enables the horizontal discovery process to find devices via the HTTP protocol.

**Role required:** discovery_admin

You can create additional HTTP classifications if you want to classify devices via HTTP/REST, rather than by another protocol. Use HTTP classification for device discovery only, not for application discovery.

**Note:** By default, the **F5 HTTP classifier** is provided to classify F5 load balancers using REST. The **F5 LB REST** pattern is also provided to explore the device. You do not need to create a new HTTP classifier for F5 load balancers.

Of all protocols that Discovery uses (including WMI, SSH, and SNMP), HTTP is the lowest priority by default. Discovery uses HTTP classification only if:

- Shazzam determines that the ports for HTTP (80) and HTTPS (443) traffic are open.
- The horizontal discovery process fails for the higher priority port probes (WMI, SSH, and SNMP) if the ports for those protocols are not open, or if discovery for those protocols fail. The horizontal discovery process can fail, for example, if SSH and SNMP credentials are not configured or are incorrect.

**Note:** See **Port Probes** for more details on how port scanning works and to see the priorities of the different protocols.

HTTP classification launches the **HTTP Classify** probe to classify the device. The **HTTP - Classify** probe runs a GET request for each device for each HTTP classification. The URL of the request is built as follows: `PROTOCOL://IP:PORT/PATH`, where:

- **PROTOCOL** is port 80 for HTTP or port 443 for HTTPS.
- **IP:PORT** is the IP address and port number of the device.
- **PATH** is the path that you specify in the HTTP classifier.

1. Navigate to **Discovery Definition > CI Classification > HTTP**.
2. Click New.
3. Fill out the form fields (see table):

The F5 HTTP classification

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a name for the classifier.</td>
</tr>
<tr>
<td>Path</td>
<td>Enter the path for the HTTP GET request.</td>
</tr>
<tr>
<td>Headers</td>
<td>Add an option header with a value. You can use a variable in the format <code>${variable}</code> instead of a static value. Supported headers depend on the REST web service provider you want to connect to. See the documentation for your web service provider to identify which headers are valid or required.</td>
</tr>
</tbody>
</table>
### Field | Description
--- | ---
Port (IP Service) | If you want this classifier to use a custom port that is not already a default value in the IP Service (cmdb_ip_service) table, do the following:
1. Click the lookup icon to see the list of IP Services.
2. Click New and create a new port-to-protocol mapping.
3. Select that port-to-protocol mapping for this Port field.
Many commonly used protocols are already mapped to ports by default, such as http to port 80 and https to port 443. If you want to use one of these default port-to-protocol mappings, do not enter any values in the Port field. The HTTP port probe uses the correct one by default.

Order | Enter a number that represents the priority of this classifier. If Discovery finds more than one classifier that applies, it uses the classifier with lower Order number.

Protocol (optional) | If you configure a unique port-to-protocol mapping for the Port field, enter an optional protocol override that Discovery uses with this classifier. For example, if you want to use port 5000 and the HTTP protocol, add the 5000/HTTP port-to-protocol mapping to the Port field, and then choose http in the Protocol field.
This field is not visible by default. You must configure the form to add it.

4. Right-click the header and select **Save**.
A record is created in the HTTP Classifications (discovery_classy_http) table.
The HTTP Classification Match related list appears. This related list shows criteria that you can configure to match against the body of the response to the GET Request that Discovery sends.

5. In the HTTP Classification Match related list, define the criteria and specify the pattern to launch for this classifier. The criteria must be met for Discovery to use this HTTP classifier.
a) Click **New**.
b) On the HTTP Classification Match form, fill in the form fields (see table).
c) Click Submit.

d) If there are different patterns for different versions of the device you are trying to discover, define as many HTTP Classification Matches as necessary.

**Classification for IP address discovery**

Discovery provides a way to classify devices it finds through IP address discovery, even when no credentials are available.

When you run a discovery for IP addresses, as opposed to a CI discovery, the Discovery application makes certain assumptions about devices and the applications running on those devices from the ports that it finds open. Classification parameters for this type of Discovery are generated differently from scans in which credentials are available.
The syntax for creating parameters is derived from the fields returned by the Shazzam probe when conducting a Discovery for IP addresses. Parameters for CIs and applications are formed in the same way. The Shazzam probe creates an XML file containing the following fields:

- name
- port
- portprobe
- protocol
- result
- service

**Note:** Optional fields that can be used to form parameters appear as child tags beneath the default fields. Example of these are the `sysDescr` and `banner_text` fields.

Parameters are expressed in the form of `<portprobe.service.field>`. The value for field can come from any of the fields or child tags in the XML file. For example, the following parameters classify a device as a UNIX server and detect an installation of MySQL:

- ssh.ssh.result
- mysql.mysql.result

These parameters were derived from the values in the following XML file generated by a Shazzam probe conducting an IP Scan. The result field returned a value of open for ports 22 and 3306 on the target device. The service field indicates the services that normally communicate over those ports.

The `sysDescr` field can provide additional information about devices, depending upon the manufacturer. This XML file from the Shazzam probe reveals the following about port 161 on the device at IP 10.10.11.149:
In the classification criteria, we can construct the following parameter with `sysDescr` that returns an Apple AirPort wireless router:

```
<sysDescr>
Apple AirPort
<sysDescr>
```

Modify classifiers for IP address discovery

When you run an IP address type of discovery, port probes scan devices without the use of credentials, and then Discovery can determine which classifiers to use. You can add port probes and additional classifiers for IP address discovery.

Role required: admin

Although no credentials are required to scan for Windows or UNIX devices with this type of scan, credentials are still required for SNMP devices. By determining which ports are open on the devices that it scans, IP address classification can discover such things as the type of device (computer, UPS, etc.), operating system, running applications, and version numbers.

**Note:** IP address classification attempts to classify devices when no credentials are available; however, Discovery will use credentials when they are available, even when IP address classification is configured.

To use IP address classification, follow these steps:

1. Determine what ports to use for classification. Run a scan program such as Nmap on specific IP addresses to decide which ports reveal the desired information about a device or application.

   The scan can reveal several pieces of data that are useful for configuring classification parameters. An Nmap scan displays port numbers, their state (open or closed), their service names, and any version information it can find. From the port information returned in the example below, we can construct criteria to classify UNIX servers (port 22), MySQL (port 3306), and Apache Tomcat (port 16000).
2. Add an IP Service and port probe.

The out-of-box system supplies probes for some of the most common ports, but additional port probes will be needed for effective IP address scanning.

1. Navigate to Discovery Definition > IP Services and click New.

2. Create a new IP Service record using the port number and service from the Nmap scan. In this example, we associate the mysql service with port 3306 and add the CI (sanops02) on which the service runs to the Available on Related List.
3. To use Basic Discovery, navigate to **Discovery Definition > Functionality Definition** and select the record for **All**.

4. Add the new port probes to the list. This tells Discovery which port probes to run for IP address scans.
5. Save the record and navigate to Discovery Definition > Port Probes and click New.
6. Create a port probe using the new IP Service you just defined.
3. Create a new classification and add the parameter for IP address scanning.

In this example, we have created an application classifier that will discover Apache Tomcat, based on the port information we received from the Nmap scan. See the following section for details about forming parameters for IP address scans.
4. Optional: In the Classification Criteria related list, create a criteria filter that determines when this classifier applies to the discovered devices. See the IP address classification parameters for a list of the parameters you can use.

Run a IP address discovery through the Discovery Schedule to search for devices.

Use Windows Remote Management for classification
You can configure the discovery of Windows hosts using the Windows Remote Management (WinRM) protocol.

- Install and configuration a Windows MID Server on the local network.
- WinRM service must be enabled on all discoverable Windows hosts.

Roles required: discovery_admin, agent_admin, admin

By default, the system uses the WMI protocol for device classification of Windows hosts. Administrators can instead use the WinRM protocol for more efficient lightweight data transfer and remote command execution.

1. Enable the WinRM service on all Windows hosts you want to discover.
2. Navigate to Discovery > MID Servers.
3. Select the MID Server you will use for discovery of Windows hosts.
   The system displays the MID Server record.
4. From the Configuration Parameters related list click New.
   The system displays a MID Server Configuration Parameter record.
5. In the Parameter name field, select the mid.windows.management_protocol parameter from the choice list.
6. Enter a value of WinRM.

7. Click Submit.
   The system displays the MID Server record.
8. Optional: Add other Windows Remote Management protocol parameters as needed.
### Additional WinRM parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default</th>
<th>Requires MID Server restart</th>
</tr>
</thead>
<tbody>
<tr>
<td>mid.powershell_api.winrm.remote_port</td>
<td>Specifies the communications port the MID Server uses to communicate with the WinRM protocol.</td>
<td>5985</td>
<td>No</td>
</tr>
<tr>
<td>mid.powershell_api.session_pool.target.max_size</td>
<td>Specifies the maximum number of sessions allowed in the pool per target host.</td>
<td></td>
<td>Yes</td>
</tr>
<tr>
<td>mid.powershell_api.session_pool.max_size</td>
<td>Specifies the maximum number of sessions allowed in the session pool.</td>
<td>100</td>
<td>Yes</td>
</tr>
<tr>
<td>mid.powershell_api.idle_session_timeout</td>
<td>Specifies the timeout value of idle Powershell sessions in seconds.</td>
<td>60</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Run a discovery from the [Discovery schedule](#) to find Windows machines on your network.  

**Reclassify a Windows Workstation machine as a server**

By default, Discovery automatically classifies computers using certain Windows operating systems as workstations. However, you might want specific computers in your network that are acting as servers to be classified by their function and not their operating system.

Use the following variables, preceded by `cidata`, to construct a reclassification condition. For example, to reclassify based on a machine's IP address, use `cidata.ip_address`.

- name
- dsn_domain
- os_domain
- ip_address
- serial_number

The following procedure reclassifies any Windows workstation operating system (Windows Vista, XP, or Windows 7) that is acting as a server.

1. Navigate to **Discovery Definition > CI Classification > Windows**.
2. Create a new classification record, such as Windows XP Server.
4. Right-click in the header bar and select **Save** from the context menu.  
   The **Classification Criteria** and **Triggers Probes** Related Lists appear.
5. Configure the following **Classification Criteria**:
Select a variable to use as the classification criteria from the list above. For example, to reclassify a machine by name, enter `cidata.name`. This works for servers that have a uniform naming convention, such as SRV001, SRV002, etc., regardless of operating system.

Select an operator for the classification condition. In networks containing servers named with a specific convention, you might select `starts with` or `contains`.

Enter the value for the condition. In our example of a network with a server naming convention, this value would be the root of that convention, such as `SRV`. This condition will classify all computers as servers if their machine name is SRVXXX.

6. Select the **Triggers Probe** related list and add the appropriate probes.

   a) Copy the list of probes from another Windows server classification, including the **Condition scripts**.

   b) Ensure that the **Windows - Identity** probe has a phase of **Identification** (the default is **Exploration**).

   The completed form looks like this:
Run a discovery from the Discovery schedule to find Windows machines on your network, and then check the cmdb_ci_win_server table and related tables to see how data is populated in the CMDB.
Discovery classification parameters
These parameters are available for Discovery classifiers.

Note: Condition filters in process classifiers are case-sensitive.

Unix parameters

The UNIX parameters define the characteristics of several types of computers, such as Linux, Solaris, and HP-UX, communicating with SSH protocol, version 2.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>output</td>
<td>The raw output of the classifier probe (uname -a).</td>
</tr>
<tr>
<td>type</td>
<td>Returns the classification UNIX.</td>
</tr>
<tr>
<td>IP address</td>
<td>Returns the IP address of the device being discovered.</td>
</tr>
<tr>
<td>name</td>
<td>Name of the operating system for this UNIX CI. For example, Linux or HP-UX.</td>
</tr>
</tbody>
</table>

Windows parameters

Windows parameters identify Windows computers communicating with the WMI protocol.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>isNode</td>
<td>Indicates if this instance is a node.</td>
</tr>
<tr>
<td>type</td>
<td>Returns the classification windows.</td>
</tr>
<tr>
<td>isVIP</td>
<td>Indicates if this CI is a virtual machine, with a virtual IP address.</td>
</tr>
<tr>
<td>ip_address</td>
<td>Returns the IP address of the device being discovered.</td>
</tr>
<tr>
<td>name</td>
<td>Name of the Windows version.</td>
</tr>
</tbody>
</table>

SNMP parameters

The SNMP parameters can define the characteristics of several types of devices, such as routers, switches, and printers.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>powering</td>
<td>A value of true indicates that this device is an uninterruptible power supply (UPS).</td>
</tr>
<tr>
<td>hosting</td>
<td>A value of true indicates that this device can host programs. Hosts are general purpose computers such as servers.</td>
</tr>
<tr>
<td>netware</td>
<td>A value of true indicates that this device is running the Netware operating system.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>routing</td>
<td>A value of true indicates that this device has network routing capabilities.</td>
</tr>
<tr>
<td>ip_address</td>
<td>Returns the IP address through which the device is being discovered. A device can have multiple IP addresses.</td>
</tr>
<tr>
<td>sysdescr</td>
<td>Required descriptive field on any SNMP device that can contain useful classification data, such as the operating system and its version.</td>
</tr>
<tr>
<td>vlans</td>
<td>A value of true indicates that this device can host a virtual local area network.</td>
</tr>
<tr>
<td>hint_router</td>
<td>A value of true indicates that Discovery has determined that this device is a router. This field only applies to devices that can be used as both a router and a switch.</td>
</tr>
<tr>
<td>block_router_exploration</td>
<td>If this parameter is true, Discovery will not launch exploration probes for routers it detects. This parameter is used for network Discovery only.</td>
</tr>
<tr>
<td>switching</td>
<td>A value of true indicates that this device has network switching capabilities.</td>
</tr>
<tr>
<td>mfr_apc</td>
<td>A value of true indicates that this device is an uninterruptible power supply (UPS) manufactured by American Power Conversion (APC).</td>
</tr>
<tr>
<td>printing</td>
<td>A value of true indicates that this device has printing capabilities.</td>
</tr>
<tr>
<td>block_switch_exploration</td>
<td>If this parameter is true, Discovery will not launch exploration probes for switches it detects. This parameter is used for network Discovery only.</td>
</tr>
</tbody>
</table>

**Process parameters**

Process parameters identify processes such as those used by LDAP, Apache Server, and JBoss Server.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>parameter</td>
<td>The parameters used to run the process.</td>
</tr>
<tr>
<td>command</td>
<td>The command used to run the process.</td>
</tr>
<tr>
<td>output</td>
<td>The complete output of the current line of the process probe.</td>
</tr>
<tr>
<td>type</td>
<td>Indicates the process type (e.g. unix or windows).</td>
</tr>
<tr>
<td>PID</td>
<td>The process ID generated by the operating system of a device to identify a running process. Generally, this parameter is not a practical classification criteria, because the value does not remain static, except in the case of processes running on an appliance that is never restarted.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>name</td>
<td>Name of the process being discovered. In some cases, this parameter is not reliable, since several processes might be given the same name. In Windows, for example several processes return scvhost.exe for this parameter.</td>
</tr>
</tbody>
</table>

**Check IP service affinity for Discovery and Orchestration**

You can check the IP Services table for a list of IP addresses that are associated with a protocol.

**Role required:** admin

The IP Services table maps a port to a protocol. Several mappings are provided by default for commonly used port-protocol combinations, such as port 80 for HTTP, port 22 for SSH, and port 161 for SNMP.

A system property called `glide.discovery.ip_service_affinity` allows Discovery to remember the last port of the IP address that was discovered. This property is set to `false` by default.

**Caution:** You should not modify IP services unless your organization uses custom ports.

1. Navigate to **Discovery Definition > IP Services**.
2. Filter the list to find the appropriate IP service.
3. Click the name of the service to go to that IP service page.
4. Click the **IP Service Affinities** tab for the list of IP addresses associated with that service.
Discovery identifiers

After Discovery classifies a CI, it uses identifiers to determine if the device already exists in the CMDB.

Discovery launches special identity probes that accumulate identification data for each device and feed that data into the identifiers, which determine the action that Discovery must take for each device. Identifiers accurately determine the identity of the device to prevent the creation of duplicate CIs. This identification step only takes place for the Configuration item type of discovery, not for the other types of discovery.

The identity probe in the base Discovery system can be configured to ask the device for information such as its serial numbers, name, and network identification. The results of this scan are processed by an identity sensor, which then passes the results to the identifier. The identifier then attempts to find a matching device in the CMDB. If the identifier finds a matching CI, the identifier either updates that CI or does nothing. If the identifier cannot find a matching CI, it either creates a new CI or does nothing. If Discovery is configured to continue, the identifier launches the exploration probes configured in the classification record to gather additional information about the device. Exploration probes can be multiprobes or simple probes.

**Important:** Serial numbers are necessary for accurate asset tracking. If you modified baseline probes, sensors, or patterns, verify that they still discover serial numbers. In addition, do not configure sensors or patterns to modify the serial number syntax, such as adding a custom prefix. Non-standard serial numbers can lead to inaccurate asset tracking.

This diagram shows the processing flow for classifying and probing devices with identifiers configured.
CMDB identifier tables

<table>
<thead>
<tr>
<th>Table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identifier (cmdb_identifier)</td>

</tbody>
</table>
## Identifier rules

The default Discovery system contains these identifier rules, each of which is associated with a specific CI type (the `sys_class_name` field on the CI record) or the table in the **Applies to** field and contains the appropriate attributes for discovering CIs from the specified table. Where necessary to discover all possible occurrences of an attribute, tables from related lists (Search on tables) are included in the rule. For more information, see [Create or edit a CI identification rule](#).

### Matching strategy for the hardware rule

The `sys_class_name` cannot be an attribute for independent rules, such as `cmdb_ci_hardware`. If your Discovery identification strategy depends on matching a CI with a specific class, you must create a new rule for each class you want to use for matching and specify that class in the **Applies to** field of the Identifier form.
For example, you can create an identifier for a Linux server with different attributes than the Hardware Rule. You might want to use the machine name, IP address, and MAC address for identification. This is a solution for networks that use NIC bonding or teaming to increase available bandwidth. Bonded interfaces appear to be the same physical device and share the same IP and MAC addresses. The use of the name attribute allows Discovery to differentiate between the individual interfaces in the bonded channel.

**Caution:** If you create an identifier with the name attribute, avoid changing adapter names. Discovery will be unable to resolve existing CIs for renamed adapters. Discovery labels the Install Status of that CI as “Absent” and creates another CI.

Your new rule would look like this:
### Linux identifier rule

**Name:** Linux Rule  
**Active:** ✓  
**Applies to:** Linux Server (cmdb_ci_linux_server)  
**Description:** Identifier for Linux servers  
**Independent:** ✓

<table>

</tr>
</tbody>
</table>

Actions on selected rows...
Evaluation order for Discovery identifiers

Custom identifiers must have different Order values than those of the default identifiers. Discovery parses identifiers and attributes in sequence from low order numbers to high. You can create identifiers to run before or after the default identifiers, or mixed in with the identifiers from the base system. To prevent any identifier or rule from running, disable it by clearing the Active check box. The evaluation order for CMDB identifiers is established within each rule and only controls the parsing order of the attributes in that rule.

Properties for processing duplicate CIs

You can control how Discovery handles duplicate CIs with properties installed with Identification and Reconciliation. Use the glide.identification_engine.skip_duplicates and glide.identification_engine.skip_duplicates.threshold properties. For more information, see Properties for Identification and Reconciliation.

Properties that control identifier versions

All instances use identifiers from the CMDB Identification and Reconciliation framework. Upgrades from pre-Geneva versions still preserve the legacy identifiers, but you can switch to the new identifiers using a property: glide.discovery.use_cmdb_identifiers. If you upgraded from a pre-Geneva version, you must manually add this property and set it to true to use the new identifiers. If you upgraded from Geneva or later releases, this property is available in the System Properties (sys_properties) table. To preserve functionality in custom legacy identifiers, convert them to the new CMDB identifier rules format before enabling this property. The system does not reconfigure your custom identifiers to the new framework automatically.

Note: When Service Mapping is active, the new identifiers from the CMDB Identification and Reconciliation framework are always used regardless of the property value.

How Discovery identifiers work

When Discovery has determined the device’s class, it launches an identity probe that is configured to run one or more commands with a single authentication.

The identity probe in the base Discovery system can be configured to ask the device for information such as its serial numbers, name, and network identification. The results of this scan are processed by an identity sensor, which then passes the results to the identifier. The identifier then attempts to find a matching device in the CMDB. If the identifier finds a matching CI, the identifier either updates that CI or does nothing. If the identifier cannot find a matching CI, it either creates a new CI or does nothing. If Discovery is configured to continue, the identifier launches the exploration probes configured in the classification record to gather additional information about the device. Exploration probes can be multiprobes or simple probes.

Note: When you use patterns for Discovery, the identity probe is not used. Discovery uses the appropriate identifier rules based on the CI type that you are trying to discover as specified in the pattern operations. The operations in the pattern along with these identifier rules perform the identification and exploration phases of discovery.

This diagram shows the processing flow for classifying and probing devices with identifiers configured.
Configure Discovery identity probes

Identity probes are multi-probes, which contain one or more simple probes configured to extract specific information from manageable devices. You can create your own identity multi-probe to identify CIs that Discovery does not already identify.

Role required: discovery_admin, admin
Identity probes return such information as device serial numbers (there can be several per device), the computer name, and network identification (MAC address). For example, the Linux - Identity multiprobe provided in the system, contains two simple SSH probes configured to return hardware and network information about the device. After the probe has discovered this information, it passes the data to a multisensor configured to process identity information.

**Note:** A multiprobe cannot contain another multiprobe.

1. Navigate to **Discovery Definition > Probes**.
2. Select a probe from the list whose **Class** is Multiprobe.
3. Make sure the scope is set to **Global**.
4. In the **Includes Probes** Related List, click **Edit** to select simple probes to include in this multiprobe.
5. Click **New** to create a new simple probe.
Configure Discovery identity sensors that are part of the identify probes.

If you customize an identify multi-probe, you can also configure a multi-sensor for it.

Role required: discovery_admin, admin

These multi-sensors pass the data returned by the identity probes to the Discovery identifiers. The identifiers then search the CMDB for matching CIs. When the identity of a device is resolved, the identifiers pass the result state for the device to the multi-sensors, which react accordingly, either by launching exploration probes or stopping Discovery for that device.

1. Navigate to Discovery Definition > Sensors.
2. Select an existing identity multi-sensors from the list.

   **Note:** To avoid confusion, the multi-sensors provided in the instance must have the same names as their matching multi-probes.

The Responds to Probes related list shows the simple probes which pass their data to this multi-sensors. These are the same simple probes that appear in the Includes Probes list in the matching multi-probes record.

3. Click the Script link for each probe in the list to see the script that the multi-sensors runs to process the data from the probe.
Run a discovery through the Discovery Schedule to search for CIs and verify that they are identified correctly in the CMDB.

**Serial number types for identification**

As Discovery finds CIs, their serial numbers are listed in the Serial Number (cmdb_serial_number) table so they are easy to identify. Serial number types vary depending on the CI, as described in the following examples.

**Important:** Serial numbers are necessary for accurate asset tracking. If you modified baseline probes, sensors, or patterns, verify that they still discover serial numbers. In addition, do not configure sensors or patterns to modify the serial number syntax, such as adding a custom prefix. Non-standard serial numbers can lead to inaccurate asset tracking.

**Linux**

In the result of dmidecode | cat, the value on the left side is what Discovery looks for. The value on the right side is how it is stored in the Serial Number (cmdb_serial_number) table.

<table>
<thead>
<tr>
<th>Serial Number</th>
<th>Expected Storage</th>
</tr>
</thead>
<tbody>
<tr>
<td>system_serial_number</td>
<td>Serial Number : system_serial_number</td>
</tr>
<tr>
<td>uuid_serial</td>
<td>UUID : uuid_serial</td>
</tr>
<tr>
<td>baseboard_serial</td>
<td>Serial Number : baseboard_serial</td>
</tr>
<tr>
<td>chassis_serial</td>
<td>Serial Number : chassis_serial</td>
</tr>
</tbody>
</table>

**Windows**

For Win32 WMI classes, the value on the left is the name by which it is stored in the Serial Number (cmdb_serial_number) table. The value on the right is the WMI value.

```python
{'system' : Win32_ComputerSystemProduct.IdentifyingNumber};
{'uuid' : Win32_ComputerSystemProduct.UUID};
{'chassis' : Win32_SystemEnclosure.SerialNumber};
{'bios' : Win32_BIOS.SerialNumber};
{'baseboard' : Win32_BaseBoard.SerialNumber};
```

**SNMP**

For SNMP, the mapping below is based on the code. Physical types of serial numbers are from all instances of iso.org.dod.internet.mgmt.mib-2.entityMIB.

```python
'cisco_stack' :
    'iso.org.dod.internet.private.enterprises.cisco.workgroup.ciscoStackMIB.chassisGrp.chassisSerialNumberString'
'cisco_chassis' :
    'iso.org.dod.internet.private.enterprises.cisco.temporary.chassis.chassisId'
'foundry' :
    'iso.org.dod.internet.private.enterprises.foundry.products.switch.snChassis.snChasGen.snChasSerNum'
```
Discovery status

The Discovery status provides a summary of a Discovery launched from a schedule. You can also cancel a Discovery that is in progress from the status form.

To access the Discovery Status form, navigate to **Discovery > Status** and open the status record for a Discovery.

Each record in the Status list represents the execution of a Discovery by a schedule and displays such high level information as the date of the Discovery, the mode, the number of probe messages sent to devices, and the number of sensor records that were processed. A status record contains data that can help you troubleshoot a failed discovery. Use this data to troubleshoot the behavior of individual probes and sensors or even run those elements separately. Use the status controls to enter probe/sensor threads at any point for a specific Discovery, and then follow the process in either direction.

- **Refresh**: Refreshes the related tabs, including the **Discovery Log** and **ECC Queue** for discoveries still in progress.
- **Discovery timeline**: The Discovery timeline is a graphical display of a discovery, including information about each probe and sensor that was used.
- **Discovery log entries**: The Discovery Log shows information such as classification failures, CMDB updates, and authentication failures. A Discovery Log record is created for each action associated with a discovery status.
- **ECC queue entries**: Entries in the ECC queue provide you with a connected flow of probe and sensor activity, as well as the actual XML payload that is sent to or from an instance.
- **Device history**: The device history provides a summary of all the devices scanned during discovery, and what action sensors took on the CMDB.

**Note**: By default, only 30 days of Discovery records are displayed in the status list at a time.

The following Discovery status record shows the discovery of a load balancer using a pattern.
The Discovery Status contains the details of a Discovery that has been launched from a Discovery Schedule. The Status displays the status of the Discovery and the ECC queue. Read more about the Discovery Status or find assistance with Discovery troubleshooting.

<td>Indicates that this Discovery includes devices on which one port responded to the scan, but no ports are open. Such a device is considered to be alive. If this check box is not selected, only active devices with one or more open ports that Discovery can query are displayed.</td>
</tr>
<tr>
<td>Log state changes</td>
<td>Indicates that state changes were logged during this Discovery. These states can be seen in the Last and Current fields in the Discovery Devices list in this form.</td>
</tr>
</tbody>
</table>

**Cancel a Discovery from a Discovery Status**
You can manually cancel a discovery while it is in progress from the Discovery Status record.
Role required: discovery_admin

1. Navigate to **Discovery > Status**.
2. Click a **Number** to open the status record.
3. Click **Cancel Discovery** in the **Related Links**.
   This action is only available for an active Discovery.

When a Discovery status cancels, any associated sensor transactions are immediately terminated and any scheduled sensor jobs are deleted from the system. After cancellation, the cleanup Status shows the **Completed count** and the cancellation is logged in the Discovery log. In the
Queue (ecc_queue) table, any records belonging to sensors exceeding the Transaction Quota Rule are set to the **Error** state.

**Discovery timelines**

A Discovery timeline generates a graphical display of a Discovery Status record, including information about each probe and sensor that was used in the discovery.

Use Discovery Timelines to display the following:

- The flow of **probes and sensors**, including those that are used with **patterns** through a discovery.
- The duration of each probe and sensor that ran during a discovery, and the proportion of time required for queuing and processing.
- Tooltips containing additional data about a probe and sensor.
- Records from the ECC Queue.

**Size of discoveries in the timeline**

View timelines for an entire discovery or for individual devices in a discovery. In the out-of-box system, the maximum size discovery that can be displayed in a timeline is 300 entries in the ECC Queue (150 probes and 150 sensors). To display larger discoveries, change the default setting in the `glide.discovery.timeline.max.entries` property.

**Example Discovery Timelines**

This example shows the Discovery timeline for the first two phases of Discovery (Port scan and Classification):

**Discovery DIS0010002 Timeline**

In this example, the Shazzam probe and sensor run, followed by the Unix classifier probe and sensor. The classifier calls the Horizontal Pattern probe, which runs a specific pattern.

**Discovery (early phases) on the timeline**

In this example, the Shazzam probe and sensor run, followed by the Unix classifier probe and sensor. The classifier calls the Horizontal Pattern probe, which runs a specific pattern.

View the Discovery timeline

A Discovery Timeline generates a graphical display of a Discovery Status record, including information about each probe, sensor, and pattern running.

Role required: admin, discovery_admin
1. Navigate to **Discovery > Status**.
2. Select a Discovery from the record list.
3. Click the **Show Discovery Timeline** Related Link.
4. Clear the warning, and then select the **Devices** Related List.
5. Click the IP address of a device.
6. In the Device record, click the **Show Discovery Timeline** Related Link.

   The Discovery timeline for that device appears.

   ![Discovery Timeline Diagram](image)

   **Discovery Timeline**

7. Use the pink slider at the bottom of the timeline to change the perspective.
   a) Move the slider from right to left to view all the tasks on a long timeline.
   b) Adjust the end points of the slider to change the magnification. A narrow slider zooms in on the spans and provides a more detailed view of complex timelines. A wide slider pulls the view out and makes more of the timeline visible on the screen.

8. Use the selector range at the top of the screen to adjust the visible time frame. To limit the timeline to the length of the Discovery, click **Max**.

   The time scale adjusts automatically to the length of the Discovery. The available time scale range is from one day to 1 year.

   **Tooltips**

   Discovery timelines display probe and sensor performance data and CI information in tooltips. Hover the cursor over a span to view this data. Probes are displayed by black spans. The queue time for a probe is shown as a silver bar within the span, and the processing time is represented by the remaining space. Sensor spans are red, and the queue time is shown as a green bar. Selected spans of any type display in yellow.
Discovery Timeline Shazzam Sensor

ECC Queue
Double-click a span to open the ECC Queue record for that probe or sensor.

Discovery Timeline ECC Queue
The ECC queue for Discovery
The External Communication Channel (ECC) Queue is a connection point between an instance and other systems that integrate with it, most commonly a MID Server.

Contents of the ECC Queue
The ECC queue contains records that are created during all stages of discovery. Each record is essentially a message from the instance and another system, classified as output, or a message from the external system to the instance, classified as input. ECC queue records provide you with a connected flow of probe and sensor activity, as well as the actual XML payload that is sent to or from an instance.

Automatic deletion of ECC queue records
If Discovery is running on an instance, the size of this table can grow to several gigabytes. Most of the accumulated data is unnecessary, but some entries might be important for troubleshooting any problems with Discovery. For example, if Discovery is not properly capturing the disk drives on a particular Windows server, look in the ECC Queue at the data returned by the Windows - System Information probe. You should retain ECC Queue data from Discovery for at least a month.

By default, records in the ECC Queue older than 7 days are deleted automatically. You can set the deletion schedule by updating the table rotation schedule for the ECC queue. The table rotation names are:

- ecc_queue_event
- ecc_queue

Accessing the ECC queue
You can access the ECC queue from either of these locations:

- Discovery > Output and Artifacts > ECC Queue
- ECC > Queue

The following image is an example of a record in the ECC queue. This record shows that a WMI classifier probe was instructed to run and has been processed. See MID Server ECC Queue for a description of each field.
An example ECC queue record

**ECC queue states**

Input and output messages keep processing in turn until the discovery is finished or terminated. You can monitor the ECC queue to see records populate during discovery, and see the states of each record change. The process is as follows:
1. When new probe instructions are available for the MID Server, the system creates an output record with the state of ready.

2. The MID Server then starts processing the probe instructions and the state changes to processing before it finally changes to processed.

3. When a result returns to the MID Server and is ready to be sent to the instance, the system creates an input record with the state of ready.

4. While the system processes the payload, the state changes to processing before it finally changes to processed.

   If any errors are encountered, the state changes to error. You can look for errors to troubleshoot failed discovery.

**Properties and parameters that affect the ECC queue**

These properties are available to control aspects of the ECC queue:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Save ECC queue attachments</td>
<td>The normal behavior for discovery sensors is to delete attachments to ECC queue entries upon successful sensor processing. Enabling this property overrides this behavior, and forces attachments to be preserved. This would normally only be useful for debugging purposes. Location: Navigate to Discovery Definition &gt; Properties to enable the property.</td>
</tr>
</tbody>
</table>

**Discovery device history**

The Devices related list in the Discovery Status form provides a summary list of all the devices scanned.

During a Discovery, the list tracks current and completed activity and displays an incremental scan counter. When Discovery is finished for a device, the final disposition is displayed in the Completed activity column. Successful Discoveries that result in updated or created CIs are highlighted in green. To view the log entries for errors (such as connection failure) on a specific device, click the Details link in the Issues column.
Discovery device list

Click the IP address of a device in this list for details about that device. The log results for that device are displayed in the list at the bottom of the form.
The following fields are available in this form:

<table>
<thead>
<tr>
<th>Field</th>
<th>Input value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source</td>
<td>The IP address of the device discovered.</td>
</tr>
<tr>
<td>Completed activity</td>
<td>Indicates the outcome of Discovery for this device or the last completed activity for a Discovery in progress, such as Identified CI. Successful outcomes are indicated in green.</td>
</tr>
<tr>
<td>Current activity</td>
<td>The current scanning activity for this device for a Discovery in progress, such as Updating CI.</td>
</tr>
<tr>
<td>CMDB CI</td>
<td>The name of this device as it appears in the CMDB.</td>
</tr>
<tr>
<td>Started</td>
<td>The number of device-specific probes run. This number does not include the universal probes, Shazzam and Ping, that run initially.</td>
</tr>
<tr>
<td>Completed</td>
<td>The number of sensor records created from the device-specific probes that were run.</td>
</tr>
<tr>
<td>Scan status</td>
<td>Shows the final scan count of a completed Discovery or an incremental scan counter for a Discovery in progress. For example, Scan 17 of 19.</td>
</tr>
<tr>
<td>Issues</td>
<td>Displays the number of issues encountered during Discovery of this device. Select the Discovery Log Related List to view these issues.</td>
</tr>
<tr>
<td>Fields that can be added by configuring the form:</td>
<td></td>
</tr>
<tr>
<td>DNS Names</td>
<td>Displays DNS names for each discovered device.</td>
</tr>
</tbody>
</table>

If there were issues, or if Discovery failed to complete, click the Details link to view the log records for the issue. The failure of any probe is considered an issue, even if the device was eventually classified properly and updated in the CMDB.
Discovery details about a device

Address scan data

When Discovery scans for IP addresses only (without credentials or identifiers), no updates are made to the CMDB. All IP addresses discovered appear on this list, including multiple IPs on the same device. The results of IP address scans include slightly different information than the results of a CI scan. Since there is no CMDB activity associated with the IP address scan, the Completed activity column displays only the classification status.

Possible statuses are:
- Classified
- Unclassified
- Alive, not classified

For Classified devices, Discovery might identify the type of device in the Current activity column. For example, Network Gear might be classified as Cisco Network Gear, and a Computer might be classified as a Windows Computer.

Logs for Discovery
The Discovery log and Pattern Discovery/Horizontal Discovery log display the activity that takes place during a discovery. Use the logs to debug failed discoveries.

Discovery Log
The Discovery Log shows information such as classification failures, CMDB updates, and authentication failures. A Discovery Log record is created for each action associated with a discovery status.
Discovery Log Records

Pattern Discovery and Horizontal Discovery log

The Pattern Discovery log includes Horizontal Discovery log records, which display information about discoveries that were performed with patterns. A horizontal discovery log record is created for an entire horizontal discovery run, which includes the results of all the operations specified in the pattern.
View the Discovery Log
Open the Discovery Log to troubleshoot a discovery.

Role required: discovery_admin

1. Navigate to Discovery > Status.
2. Open a Discovery Status record.

Log entries appear in the Discovery Log related list.
### Discovery Log records

The Discovery Log provides the following information:

<table>
<thead>
<tr>
<th>Field</th>
<th>Input value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created</td>
<td>Timestamp of the Discovery activity. Each timestamp defines the approximate time of the activity. Several Discovery events may occur in random order within a second.</td>
</tr>
<tr>
<td>Level</td>
<td>Classifies the activity into one of the following levels for general sorting:</td>
</tr>
<tr>
<td></td>
<td>- Error</td>
</tr>
<tr>
<td></td>
<td>- Information</td>
</tr>
<tr>
<td></td>
<td>- Warning</td>
</tr>
<tr>
<td>Short Message</td>
<td>Informative message detailing the outcome of the activity or the Discovery progress. Look here for the result of a classify probe or for authentication failure.</td>
</tr>
<tr>
<td>ECC queue input</td>
<td>The related input record from the ECC queue for this discovery. You can also view these records from the ECC Queue related list.</td>
</tr>
<tr>
<td>CI</td>
<td>Names a device for which a matching CI was found in the CMDB. Click the link to view the CI record for the device.</td>
</tr>
<tr>
<td>Source</td>
<td>Names the particular activity, such as the Shazzam probe or a UNIX classify probe.</td>
</tr>
</tbody>
</table>
**Field** | **Input value**
---|---
Device | Lists the IP address of the CI discovered. All devices identified by IP address appear in the log, even if they refused all invitations to communicate. Any port activity from a device places it into the log, even if all subsequent efforts to identify it fail. Click the IP address of the device to view the events associated with discovering that device.

3. Do any of the following:
- Click a link in the **CI column** to open the record for that CI.
- Click the link in the **Created** column to view the log record.
- Click the IP address link in the **Device** column to view the log records for a particular device.

**Note:** The Discovery log also displays errors that occur during identification by taking log entries from the Identification Engine log. See [Examine identification engine run logs](#) for more information about the identification engine and possible errors.

Open the Pattern Discovery Log
Open the Pattern Discovery Log to troubleshoot a discovery with patterns.

Role required: discovery_admin

1. Navigate to **Pattern Designer > Discovery Pattern Log**.
2. Sort the list of pattern log entries by any column, such as **Pattern** or **Status**.
3. Click the **View Log** link in the **Log message** column for the desired log record.
   The Horizontal Discovery Log window opens.
### The Horizontal Discovery Log

**Discovery Log Item** | **Description**
--- | ---
Pre Pattern Execution | The actions that were run before the pattern was launched.
Selecting Pattern for Execution | The pattern that was run for discovery.
{Identification Section name} | Displays the results of the operations in the pattern. Expand the name to see each operation.
Pre Payload Processing Scripts | The results of scripts that were run before the payload was received.
### Discovery Log Item

<table>
<thead>
<tr>
<th>Discovery Log Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Payload Processing</td>
<td>Details about the payload and how it was processed. Look in this section to find errors that might have been encountered during various activities, such as the running of identification rules, updates to the CMDB, and so on.</td>
</tr>
<tr>
<td>Post Payload Processing Scripts</td>
<td>The results of scripts that were run after the payload was received.</td>
</tr>
</tbody>
</table>

4. Click an item in the left-hand column to see more information about it in the right-hand column.

5. To debug the pattern, click the name of the Identification Section, and then click the **Debug** button in the upper-right.

6. To return to the log record, click the **X** in the upper-right.

### Change Discovery log retention time

You can configure the amount of time that Discovery retains log entries.

**Role required:** admin

By default, the Discovery log retains information for 30 days, or 2,592,000 seconds.

1. Open the Auto Flushing table by typing `sys_auto_flush.list` in the navigation filter.
2. Open the **discovery_status** record.
3. Change the value in the **Age in seconds** field.
4. For the change to take effect immediately, run the Table Cleaner Job in the Schedule (`sys_trigger`) table.
5. Click **Update**.

### Patterns and horizontal discovery

A pattern is a series of operations that tell Discovery which CIs to find on your network, what credentials to use, and what tables to populate in the CMDB.

This topic assumes you understand the phases of horizontal discovery. If you need to review the horizontal discovery process for probes and for patterns, see the following:

- Horizontal discovery process flow with probes and sensors
- Horizontal discovery process flow with patterns

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article KB0694477 for more information.

### How Discovery uses patterns

A pattern performs the same function as a probe: it identifies and explores a target CI. Discovery uses patterns only during the last two phases of discovery: Identification and Exploration.

When you kick off horizontal discovery with patterns, the Scanning and Classification phases run as they would if you were not using patterns (only using probes and sensors). After the Classification stage completes, Discovery looks at the trigger probes on the classifier to see which probe to launch. When the **Horizontal Pattern** probe is specified as a trigger probe, Discovery launches both the **Horizontal Pattern** probe and the pattern that it specifies.
Differences between probes and patterns

The main differences between using patterns for horizontal discovery and using only probes for horizontal discovery are outlined in this table:

<table>
<thead>
<tr>
<th>Topic</th>
<th>Horizontal discovery with probes</th>
<th>Horizontal discovery with patterns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discovery phases</td>
<td>Probes run during all four discovery phases.</td>
<td>Patterns run only during the identification and exploration phases. Discovery still uses the Shazzam probe and port probes to kick off discovery.</td>
</tr>
<tr>
<td>Finding new CIs</td>
<td>Discovery offers several out-of-box probes and sensors. However, if you want to find new CIs or change the data that Discovery populates in the CMDB, you must create new probes and sensors or customize the existing ones. To do this, you need knowledge of Java and JavaScript, and you need to understand how probes work together with other probes and with sensors.</td>
<td>Discovery is offering more patterns in every major release and on the ServiceNow App Store. If you want to create a new pattern or customize an existing one, you can use the pattern designer, which is a user-friendly interface that helps you construct steps and enter values.</td>
</tr>
<tr>
<td>Feature support</td>
<td>Supports all standard network, and CI discovery. Certain applications are not supported without the use of patterns. See Applications supported by Discovery and Service Mapping for a full list.</td>
<td>In addition to supporting all standard discovery, patterns support:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Cloud discovery</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• configuration file tracking</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• CI deletion strategies</td>
</tr>
<tr>
<td>The ECC queue and troubleshooting</td>
<td>Discovery creates Multiple ECC Queue records depending on how many probes are launched.</td>
<td>Discovery creates only one additional ECC queue record for the pattern. To troubleshoot any issues with horizontal discovery during identification and exploration, you only have to analyze one ECC queue record for the pattern.</td>
</tr>
<tr>
<td></td>
<td>To troubleshoot any issues with horizontal discovery, you must analyze several ECC queue records to see the data that Discovery retrieved.</td>
<td></td>
</tr>
<tr>
<td>Performance</td>
<td>Depending on what type of target CI you are trying to identify and explore, Discovery might trigger multiple probes during the identification phase, and then trigger additional probes during the discovery phase. It is possible that horizontal discovery with probes can take longer because of the extra overhead in triggering and processing many probes.</td>
<td>Discovery triggers one pattern during the identification an exploration phases. All operations that Discovery needs to run are in the pattern and Discovery can execute them in order until the pattern is finished. Therefore, pattern discovery can lead to faster performance.</td>
</tr>
</tbody>
</table>

Patterns for top-down and for horizontal discovery

Both Discovery and Service Mapping can use the same pattern for horizontal and top-down discovery. But they are edited differently. See Create or modify patterns for all steps. If you take a pattern that was exclusively used for top-down discovery and you want to use it for horizontal discovery, you have to make a few modifications. See Use a pattern for horizontal discovery for instructions.
Add the Horizontal Pattern probe to a classifier

To use a pattern for the identification and exploration phases of horizontal discovery, you must add the Horizontal Pattern probe to the classifiers for the CIs you are trying to discover.

Role required: discovery_admin

**Warning:** This procedure is only intended for custom classifier records or those that do not include a pattern by default. However, if you have already populated your CMDB with data using probes from this classifier and then switch to use patterns, Discovery may create duplicate CIs. Therefore, only follow this procedure if you have never run Discovery with probes for this classifier type.

1. Navigate to Discovery Definition > CI Classification > {classifier type}.
2. Open the classifier record.
3. Click the Triggers probe related list.
4. Deactivate the existing identification and exploration probes.
5. Click Edit, and add the Horizontal Pattern probe. The probe appears in the related list.
6. From the related list view, double click the field under the Pattern column and add the pattern you want to associate with the classification.
7. Remove or deactivate the other probes from the Triggers probe related list.

**Note:** If you delete a pattern, the Horizontal Pattern probe is not automatically removed from the classifier. You must select another pattern for the Horizontal Probe, or you can switch back to using identification and exploration probes specific to the classifier. If you use the Horizontal Probe without a pattern specified, discovery stops after the classification stage.

Use a pattern for horizontal discovery

If you want to use a new pattern, or if you already have a pattern that you were using for top-down discovery, you can use the pattern for horizontal discovery with a few modifications to the relevant classifier.

Role required: discovery_admin

**Warning:** This procedure is only intended for custom classifier records or those that do not include a pattern by default. However, if you have already populated your CMDB with data using probes from this classifier and then switch to use patterns, Discovery may create...
duplicate CIs. Therefore, only follow this procedure if you have never run Discovery with probes for this classifier type.

1. Verify that Discovery can use the pattern:
   a) Navigate to **Pattern Designer > Discovery Patterns**.
   b) Open the pattern. Application patterns that Service Mapping uses are indicated as type **1-Application**.
   c) In the **Identification Sections** on the **Basic** tab, verify that there is at least one section that allows for an entry point type of **TCP** or **All**. If not, create one. See the Identification steps for creating a new pattern.
   d) Save the pattern.

2. On the instance, create or modify the classification for the CI type you want to discover. Configure the classifier as follows:
   a) Navigate to **Discovery Definition > CI Classification > {classification type}**.
   b) Open the relevant classifier.
   c) Configure the classifier as follows:
      * **Relationship type**: Select **Runs on::Runs** (for process classifiers only)
      * **Condition**: Configure the same condition you defined in the pattern.
      * **Triggers probes** Related list: Add the Horizontal Pattern probe, and then add the pattern you are using to the **Pattern** column.

See [Create a Discovery CI classification](#) for a description of the other fields on the classifier.

Run the pattern in **Debug mode** to test it. When you are sure the pattern works, you can run discovery by setting up a discovery schedule or running an on-demand discovery. See [Schedule a horizontal discovery](#) for more information.

### Discovery probes and sensors

Discovery probes and sensors perform data collection and update the CMDB.

**Note:** With each release, patterns are replacing many probes and sensors for Discovery. Consider creating new patterns or editing existing ones if you want to customize what Discovery can find. The information on probes and sensors is intended for customers who are not using patterns yet and for customers who already have customized probes that are retained upon upgrade. See [Patterns and horizontal discovery](#) for more information on patterns.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

### Discovery phases

Discovery always uses probes and sensors during the first two phases of discovery: **scanning** and **classification**. For the last two phases, **identification** and **exploration**, Discovery can use probes and sensors or patterns. This topic refers to probes and sensors only. See [Discovery basics](#) for
an explanation of these phases. See *Patterns and horizontal discovery* for more information on patterns.

**Probes, sensors, and the ECC queue**

The probe collects the information and the sensor processes it. Both get their instructions from the ECC queue. There is a worker job on the MID Server that monitors the queue for work. The monitor checks for any entries where the Queue is output and the State is ready.

The MID Server then processes all the output ECC messages, runs the necessary probes, and returns the probes results to the ECC queue. These results are put in the ECC Queue as input entries.
ECC queue input

After an entry is inserted in the ECC Queue table, a business rule fires (on insert) that takes that information and runs it through a sensor processor. The sensor processor's job is to take the input data, find any sensors interested in that data, and pass it along to be processed. Those sensors ultimately update the CMDB.
**How probes and sensors work together**

The MID Server launches probes to collect information about a device. The probe sends back information to the sensor to be processed. If the probe has a post-processing script defined, the post-processing script does some data processing on the MID Server before data is sent back to the sensor on the ServiceNow instance. Otherwise, the probe sends back all the data collected and the sensor performs this data processing. In both cases, the sensor updates the CMDB.

A **multi-probe** is a probe that contains probes. A **multi-sensor** processes the data from a multi-probe. To process the data from the multi-probe, the multi-sensor contains individual scripts to process the data returned by each probe contained in the Multiprobe, as well as a main multi-sensor script. The individual scripts pass their processed data to the main multi-sensor script.
### Probe types

<table>
<thead>
<tr>
<th>Device</th>
<th>Probe Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows computers and servers</td>
<td>Remote WMI queries, shell commands</td>
</tr>
<tr>
<td>UNIX and Linux servers</td>
<td>Shell command (via SSH protocol, version 2). Discovery supports any Bourne-compatible shell.</td>
</tr>
<tr>
<td>Storage</td>
<td>CIM/WBEM queries</td>
</tr>
<tr>
<td>Printers</td>
<td>SNMP queries</td>
</tr>
<tr>
<td>Network gear (switches, routers, etc.)</td>
<td>SNMP queries</td>
</tr>
<tr>
<td>Web servers</td>
<td>HTTP header examination</td>
</tr>
<tr>
<td>Uninterruptible Power Supplies (UPS)</td>
<td>SNMP queries</td>
</tr>
</tbody>
</table>

### List of Discovery probes

A wide variety of probes exist for the Discovery application to detect elements on your network. These probes are included with the Discovery application.

The *PPP script* designation in the table indicates whether the probe includes a probe post-processing (PPP) script that runs on the MID Server. The PPP script transforms probe results into a JSON string and returns the string to the ServiceNow instance for sensor processing.

To view probes and their descriptions, navigate to Discovery Definition > Probes.

#### CIM probe

The CIM probe uses WBEM protocols to query a particular CIM server, the CIM Object Manager, for a set of data objects and properties.

For instructions on configuring probe parameters, see Set probe parameters.

The following parameters may be passed to the CIM probe:

#### CIM Probe

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td><em>(Required)</em> The initial host to connect to.</td>
<td>None</td>
</tr>
<tr>
<td>port</td>
<td>The port to connect to. If empty, the value is determined by the &quot;schema&quot; parameter: http = 5988, https = 5989.</td>
<td>5988 or 5989</td>
</tr>
<tr>
<td>schema</td>
<td><em>(Required)</em> The schema to use: &quot;http&quot; or &quot;https&quot;</td>
<td>http</td>
</tr>
<tr>
<td>namespace</td>
<td><em>(Required)</em> The CIM namespace. May be overridden by a query.</td>
<td>None</td>
</tr>
<tr>
<td>queries</td>
<td><em>(Required)</em> A semicolon-delimited list of CIM probe queries to process and return results for.</td>
<td>None</td>
</tr>
<tr>
<td>retries</td>
<td>The number of times to retry a query if it fails due to network connectivity issues.</td>
<td>2</td>
</tr>
</tbody>
</table>
The CIM Intermediate Query Language (CimIQL) uses keys, filters, and dot-walking to traverse the CIM schema.

**Parameter Expansion**

The CIM query language supports standard SNC preprocessed probe parameter expansion. Place variables in queries by encapsulating their names like this:

\[
${\text{foobar}}.\text{CIM\_RunningOS}[0].\text{Name} \\
\text{CIM\_ComputerSystem.}${\text{barfoo}}
\]

The text \${\text{foobar}} is replaced with the contents of the foobars probe parameter passed to the CIM probe; likewise for \text{barfoo}.

**CimIQL**

The CIM Intermediate Query Language (CimIQL) is an intermediate language designed to simplify the process of querying CIM providers.

CimIQL currently supports the standard Web-Based Enterprise Management (WBEM) protocol stack, but others, such as Web Services-Management (WS-MAN), may be added in the future. The query language syntax borrows from elements of Microsoft’s WMI query language and UNIX’s wbemcli command. The CimIQL library is a pure Java implementation.

**Note:** CimIQL is pronounced “simicle”.

**CimIQL Syntax**

CimIQL syntax consists of several elements, including a query and different tokens.

**CimIQL Syntax Element Descriptions**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Statement</td>
<td>The most basic element of CimIQL is a valid ,. A statement contains multiple queries delimited by a period . character.</td>
</tr>
<tr>
<td>Query</td>
<td>A \text{represents a single high-level protocol-independent request. Each query is comprised of nested language components and sub-components known as tokens.}</td>
</tr>
<tr>
<td>Token</td>
<td>A \text{describes a specific lexical aspect of the CimIQL syntax.}</td>
</tr>
<tr>
<td>\text{Operation Token}</td>
<td>\text{The first token of each query must be an \text{operation token, which represents the overall logical operation to be performed.}}</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>connection_timeout</td>
<td>The number of milliseconds the probe has to connect to a server.</td>
<td>5000</td>
</tr>
<tr>
<td>socket_timeout</td>
<td>The number of milliseconds the probe has to read data.</td>
<td>5000</td>
</tr>
<tr>
<td>Element</td>
<td>Description</td>
<td></td>
</tr>
<tr>

<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>Component Token</td>
<td>A is a sub-component of an operation token.</td>
<td></td>
</tr>
<tr>
<td>Result</td>
<td>Each query is paired with a result, which is then provided as input to the next query in the statement. A result is comprised of a set of objects and their properties.</td>
<td></td>
</tr>
</tbody>
</table>

CimIQL operation tokens

The CimIQL probe requires operation tokens.

Each of the following core operations has a counterpart in the [CIM Operations over HTTP](https://www.dmtf.org/standards/cim) standard.

**CimIQL Operation Token Summary**

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Details</th>
<th>Equivalent CIM Operation over HTTP</th>
</tr>
</thead>
<tbody>
<tr>
<td>class object</td>
<td>Get Object</td>
<td>GetInstance</td>
</tr>
<tr>
<td></td>
<td>- Retrieves a single object of a specific class by specifying all of its unique keys (as key tokens) and any optional parameter tokens, separated by commas.</td>
<td></td>
</tr>
<tr>
<td>class object</td>
<td>Enumerate Objects</td>
<td>EnumerateInstances</td>
</tr>
<tr>
<td></td>
<td>- Retrieves objects that match a set of condition tokens and parameter tokens.</td>
<td></td>
</tr>
<tr>
<td>class object</td>
<td>Enumerate Associated Objects</td>
<td>Associates</td>
</tr>
<tr>
<td></td>
<td>- Retrieves objects associated with each result from the preceding query.</td>
<td></td>
</tr>
<tr>
<td>statement results</td>
<td>Substitution</td>
<td>Reference the results of a named statement</td>
</tr>
<tr>
<td></td>
<td>- A no-op token that feeds the results of a previous named statement as input into the next query of its own statement.</td>
<td></td>
</tr>
</tbody>
</table>

**Get Object Token**

```
<classname>{<key token>,<parameter token>,...}
```

- Retrieves a single object of a specific class by specifying all of its unique keys (as key tokens) and any optional parameter tokens, separated by commas. This token is also known as the token.
• The `<classname>` is the case-sensitive CIM class name of the desired object. By default, objects of the specified class and of any extended classes are retrieved.
• The key and parameter tokens are enclosed by a single pair of curly brackets `{ ... }.
• This token must only be used as the first query in a statement.
• Returns: class object
• Example:

  ```
  CIM_ComputerSystem{'CreationClassName='Linux_ComputerSystem',Name='runtime'}}.*
  ```

**Enumerate Objects Token**

```classname>[(<condition token>,<parameter token>...,])<array index token> OR
```classname><array index token>```

• Retrieves objects that match a set of condition tokens and parameter tokens. This token is also known as the .
• The condition tokens and parameter tokens are enclosed by two pairs of curly brackets { { ... }}. The curly brackets are optional if there are no conditions or parameters necessary.
• The `<classname>` is the case-sensitive CIM class name of the desired objects. By default, objects of the specified class and of any extended classes are retrieved.
• The index token is optional.
• This token must only be used as the first query in a statement.
• Returns: class object
• Example:

  ```
  CIM_ComputerSystem{['Name='runtime']}}.*
  ```

**Enumerate Associated Objects Token**

```association classname>[(<property filter token>,<parameter token>...,)]<array index token> OR
```association classname><array index token>```

• Retrieves objects associated with each result from the preceding query.
• The condition tokens and parameter tokens are enclosed by two pairs of curly brackets { { ... }}. The curly brackets are optional if there are no properties filters or parameters necessary.
• The `<association classname>` is the name of the many-to-many or one-to-many class that associates two objects together. By default, objects of the specified class and of any extended classes are retrieved.
• The `<parameter token>`, ResultClass, may be specified to filter results based on the resulting object's classname.
• The index token is optional.
• This token must not be used as the first query in a statement.
• Returns: class object
• Example:

  ```
  CIM_ComputerSystem{['Name='runtime']}[2].*
  ```
Substitution Token

${<statement name>}

- A no-op token that feeds the results of a previous named statement as input into the next query of its own statement.
- Returns: void
- Example:

```
$(lastComputer).ElementName
```

CimIQL component tokens

The CimIQL probe requires component tokens, which are sub-components of operational tokens. The following tokens are sub-components of operation tokens.

CimIQL Component Token Summary

<table>
<thead>
<tr>
<th>Token</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Properties token</td>
<td>* OR &lt;property name&gt;,&lt;property name&gt;,...</td>
</tr>
<tr>
<td></td>
<td>- Specifies which properties are to be returned for each object of the final result set.</td>
</tr>
<tr>
<td>Query Delimiter Token</td>
<td>. (Period)</td>
</tr>
<tr>
<td></td>
<td>- Separates queries.</td>
</tr>
<tr>
<td>Index Token</td>
<td>[index]</td>
</tr>
<tr>
<td></td>
<td>- Reduces a preceding query's results to a single object at the specified integer index.</td>
</tr>
<tr>
<td>Key Token</td>
<td>&lt;key name&gt;='value'</td>
</tr>
<tr>
<td></td>
<td>- Matches an object property designated as a key by exact value.</td>
</tr>
<tr>
<td>Condition Token</td>
<td>&lt;property name&gt;&lt;conditional operator&gt;&lt;enclosed value&gt;</td>
</tr>
<tr>
<td></td>
<td>- Matches a single property of an object based on the condition specified.</td>
</tr>
<tr>
<td>Parameter Token</td>
<td>&lt;parameter name&gt;='value'</td>
</tr>
<tr>
<td></td>
<td>- Passes a parameter by &lt;parameter name&gt; to the operation being called. The parameter may be consumed during CimIQL preprocessing or by the CIMOM via request, depending on the parameter.</td>
</tr>
</tbody>
</table>

Properties Token

* OR <property name>,<property name>,...
• Specifies which properties are to be returned for each object of the final result set.
• The wildcard * returns all properties available. Otherwise, each property name desired is provided within a comma-separated list.
• This token is required at the end of each statement.
• Example:

```
CIM_ComputerSystem[0].*
```

**Query Delimiter Token**

, (Period)
• Separates queries.
• Example:

```
CIM_ComputerSystem.PrimaryOwnerContact
```

**Index Token**

(index)
• Reduces a preceding query's results to a single object at the specified integer index.
• This token is always optional.
• Example:

```
CIM_ComputerSystem[0].*
```

**Key Token**

<key name>=<value>
• Matches an object property designated as a key by exact value.
• The <key name> is the name of the property used as a key.
• Example:

```
CIM_ComputerSystem{CreationClassName='Linux_ComputerSystem',Name='runtime'}.*
```

**Condition Token**

<property name><conditional operator><enclosed value>
• Matches a single property of an object based on the condition specified.
• The <property name> is the name of the property to match against.
• The <conditional operator> determines how the property's actual value is compared to its expected value. The operators available are equality (=) and inequality (!=).
• The <enclosed value> should be one of the following:
  • Literal value enclosed in single-quotes ‘...’. For example, foo='bar'
- Regular expression, enclosed by a pair of slashes \(/ \ldots \)/. For example, foo=/bar/*/.

- Example:

```cimql
CIM_ComputerSystem{{Name!='runtime'}}.*
```

### Parameter Token

<parameter name>:©<value>©

- Passes a parameter by `<parameter name>` to the operation being called. The parameter may be consumed during CimIQL pre-processing or by the Common Information Model Object Manager (CIMOM) via request, depending on the parameter.

- Example:

```cimql
CIM_ComputerSystem.CIM_RunningOS{{ResultClass:'Win32_ComputerSystem'}}.*
```

### CimIQL tutorial

This is a tutorial by example where each example builds on the previous example.

<table>
<thead>
<tr>
<th>Order</th>
<th>CimIQL Statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>CIM_ComputerSystem(0).*</code></td>
<td>Retrieves the <strong>first result</strong> of all instances of <code>CIM_ComputerSystem</code> and its descendants. Retrieves all <strong>properties</strong>.</td>
</tr>
<tr>
<td>2</td>
<td><code>CIM_ComputerSystem.PrimaryOwnerContact</code></td>
<td>Retrieves all instances of <code>CIM_ComputerSystem</code> and their descendants. Retrieves only one <strong>property</strong>, <code>PrimaryOwnerContact</code>.</td>

<td></td>
<td>The middle-token, CIM_RunningOS, is the name of the <strong>Associator class</strong>, not the end-result.</td>
</tr>
<tr>
<td>8</td>
<td>CIM_ComputerSystem.CIM_RunningOS(CentOS/)(0).Name</td>
<td>Retrieves the Name property for the first CIM_OperatingSystem instance of each CIM_ComputerSystem instance, where each CIM_OperatingSystem instance has a Name property containing 'CentOS'.</td>
</tr>
</tbody>
</table>

**CimIQL results**

CIM Probe results are passed to the probe sensor as an XML document embedded within the <output> element.
The following is a commented example of a CimQuery batch result.

```xml
<!-- document root -->
<cimqueryset>
  <!-- A single query and query result. Multiple <cimquery> tags may be provided. -->
  <cimquery>
    <!-- The original query, enclosed by CDATA. -->
    <query><![CDATA[<CIM_ComputerSystem[0].PrimaryOwnerContact]]></query>
    <!-- The resulting data is enclosed within a single <result> tag. -->
    <result>
      <!-- A single class instance result. Multiple <instance> tags may be provided. -->
      <instance>
        <!-- The instance's CIM classname -->
        <_classname>Linux_ComputerSystem</_classname>
        <!-- A set of this instances identifying keys. Always provided, regardless of property filters. -->
        <_key>
          <!-- The instance's CreationClassName -->
          <CreationClassName><![CDATA[Linux_ComputerSystem]]></CreationClassName>
          <!-- The instance's Name -->
          <Name><![CDATA[runtime]]></Name>
        </_key>
        <!-- Each property that matches the query's property filter will be provided here, in the same format as keys; As <PropertyName>VALUE<PropertyName> where VALUE is enclosed as CDATA -->
        <PrimaryOwnerContact><![CDATA[root@runtime]]></PrimaryOwnerContact>
      </instance>
    </result>
  </cimquery>
</cimqueryset>
```

**DNS probe**

DNS probes determine the DNS names for configuration items (CI).

The default DNS Name Resolver probe is a lightweight and fast probe. It achieves its speed by executing in parallel on the MID Server. The probe utilizes DNS lookup by the MID Server host OS to make use of the maintained DNS cache. The probe also leverages the hosts file on the OS.

These performance improvements can be disabled by reverting to the legacy DNS probe with either MID Server properties or parameters. The names of the MID Server properties/parameters are [mid.probe.use_legacy_forward_dns] and [mid.probe.use_legacy_reverse_dns]. For more information, see MID Server parameters and MID Server properties.

**DNS probe definitions**

<table>
<thead>
<tr>
<th>Probe</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNS</td>
<td>Determines DNS names for devices. It has the parameter ip_addresses.</td>
</tr>
<tr>
<td>DNSLookupProbe</td>
<td>Resolves the IP address of a host.</td>
</tr>
<tr>
<td>DNSNameResolver</td>
<td>Resolves the DNS name of an IP address.</td>
</tr>
</tbody>
</table>
**Horizontal Pattern probe**

Discovery uses the Horizontal Pattern probe to launch patterns for horizontal discovery.

The Horizontal Pattern probe works with the Horizontal Discovery sensor to enable Discovery to use patterns for discovery. When you see messages in the ECC Queue from this probe, they appear with the ECC queue name **Pattern Launcher**, followed by the name of the pattern. The probe contains a sensor named **Horizontal Discovery Sensor**, which performs the actual updates of the CMDB based on identification rules.

If you create your own device or process classifier and you want to use patterns for discovery, you must specify this probe in the classifier record. You do not need to modify this probe or the Horizontal Discovery sensor.

**Splitting payload**

When Discovery uses patterns to find certain devices like load balancers, large amounts of data could be sent to the ECC Queue. To better handle large amounts of data, the horizontal pattern probe can split the payload into chunks, and then create multiple ECC Queue records.

Control how the MID Server splits payloads and handles payloads using properties. See **MID Server properties** for more information.

**PowerShell probe**

The PowerShell Probe executes PowerShell V2 scripts on the MID Server host.

PowerShell scripts are defined as probe parameters with the filename as the parameter name. It is available as a Probe probe type by specifying PowerShell as the probe's ECC queue topic.

**PowerShell probe parameters**

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>(Required) The initial host to connect to.</td>
<td>none</td>
</tr>
<tr>

</tbody>
</table>
Scripting requirements

Any custom PowerShell scripts must use environment variables to pass any non-Boolean command line parameter. Replace non-Boolean parameters in the Param() portion of the script with script variables of the same name. Define the script variable as part of the environment with an SNC_ prefix. So a string parameter such as this:

```powershell
Param([string]$paramName)
```

Becomes a script variable such as the following:

```powershell
if(test-path env:\SNC_paramName) {
    $paramName = $env:SNC_paramName
}
```

For example, this parameter definition from the PSScript.ps1 script contains several string parameters that need to be redefined as script variables:

```powershell
```

Defining the non-Boolean parameters as script variables would result in this type of script:

```powershell
Param([boolean]$useCred, [boolean]$isDiscovery, [boolean]$debug)
# Copy the environment variables to the params
if(test-path env:\SNC_computer) {
    $computer=$env:SNC_computer
}
if(test-path env:\SNC_script) {
    $script=$env:SNC_script
}
if(test-path env:\SNC_user) {
    $user=$env:SNC_user
    $password=$env:SNC_password
}
```

Create a custom PowerShell probe

You can create your own PowerShell probe and configure probe parameters.

1. Navigate to Discovery Definition > Probes.
2. Click New.
3. Enter the following values.
   - Name: Any unique name
   - Probe Type: Probe
   - ecc_queue_topic: Powershell
4. Right-click the form header and click Save.
5. From the Probe parameters related list, click New.
6. Create a probe parameter record for each parameter.
7. Click Submit.

SCP Relay probe

The SCP Relay Probe copies a single file or the contents of a directory from one host to another, using the MID Server as a relay.
The SCP Relay probe uses the same parameters as SSHCommand. The commands may be sent in or out of the context of a terminal (tty), and with or without sudo (for those commands, such as lsof, that require being executed in the context of root to cough up the information we need). When commands are sent in the context of a terminal, the path is automatically widened to include a set of default paths (and this can be further widened with the path\_override parameter). If the target machine is the local machine, SSH is not used; instead, a local shell is run to execute the command.

For instructions on configuring probe parameters, see [Set probe parameters](#).

The following parameters may be passed to the SCP Relay probe:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>debug</td>
<td>Enables debug logging.</td>
<td>false</td>
</tr>
<tr>
<td>debug_ssh</td>
<td>Enables J2SSH debug logging (into ssh.log, which can get very large - be careful!)</td>
<td>false</td>
</tr>
<tr>
<td>timeout</td>
<td>Sets the socket connection timeout, in ms.</td>
<td>60000</td>
</tr>
<tr>
<td>path_override</td>
<td>Overrides the default paths set before executing a command.</td>
<td>none</td>
</tr>
<tr>
<td>keyboard_interactive</td>
<td>If true, forces the use of keyboard_interactive SSH login mode.</td>
<td>false</td>
</tr>
<tr>
<td>must_sudo</td>
<td>If true, forces the command to be executed through sudo.</td>
<td>false</td>
</tr>
<tr>
<td>run_in_terminal</td>
<td>If false, disables SSH commands from running in an SSH terminal (this will break many commands).</td>
<td>true</td>
</tr>
<tr>
<td>long_runner</td>
<td>If present, indicates a long-running SSH command.</td>
<td>false</td>
</tr>
<tr>
<td>set_path</td>
<td>If false, disables setting the path environment variable before running the command.</td>
<td>true</td>
</tr>
<tr>
<td>rm_override</td>
<td>If present, overrides the default rm command (&quot;/sbin/rm -f&quot;) with the provided value.</td>
<td>none</td>
</tr>
<tr>
<td>source</td>
<td>Source host or IP to copy from.</td>
<td>required</td>
</tr>
<tr>
<td>source_port</td>
<td>SSH port on the source (defaults to 22).</td>
<td>required</td>
</tr>
<tr>

<td>Name of the file to copy from the source.</td>
<td>required</td>
</tr>
<tr>
<td>target</td>
<td>Target host or IP to copy to.</td>
<td>required</td>
</tr>
<tr>
<td>target_port</td>
<td>SSH port on the target (defaults to 22).</td>
<td>required</td>
</tr>
<tr>
<td>to_file</td>
<td>Name of the file to copy to the target.</td>
<td>required</td>
</tr>
</tbody>
</table>
SNMP probes
The SNMP probes use the SNMP protocol to query a particular device for a list of OIDs, which are then traversed and the results passed back to the sensors.

Discovery supports SNMP versions 1, 2c, and 3. Discovery uses version 1 and 2c by default. You must enable support for version 3. MID Servers support all SNMP protocol versions by default. You can set a MID Server to only support specific versions of SNMP.

SNMP patterns
The Network Router pattern replaces the several SNMP-related probes for the discovery of routers and switches. See Pattern updates for the New York release.

SNMP probe parameters
This list of parameters may be passed to the SNMP probes.

For instructions on configuring probe parameters, see Set probe parameters.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>oid_spec_list</td>
<td>A list of OID specifications, one per line. Each specification must be in one of the following two forms:</td>
<td>required</td>
</tr>
<tr>
<td></td>
<td>• walk (OID): Walks the OID and all its children</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• table (OID) {OID Children}: Walks all entries in the table, returning only the given children (for example, “iso.org.dod.internet”)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>(OID Children) refers to a comma-delimited list of child nodes within the entries for the given table. For example, “ifEntry.ifIndex.ifEntry.ifDescr.ifEntry.ifType” are OID children of the table “iso.org.dod.internet.mgmt.mib-2.interfaces.ifTable”. As a convenience, the table entry prefix may be left off. (The preceding children could be specified as “ifIndex.ifDescr.ifType”.)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Any child may include a filter qualifier in parentheses. For example, the child “entPhysicalContainedIn(=0)” specifies returning table entries only if the value of “entPhysicalContainedIn” equals 0. The operators supported in the expression are:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>= equals</td>
<td></td>
</tr>
<tr>
<td></td>
<td>!= does not equal</td>
<td></td>
</tr>
<tr>
<td></td>
<td># contains</td>
<td></td>
</tr>
<tr>
<td></td>
<td>If more than one child has a filter expression, a match on any one of the children causes that entry to be read.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Any content including and after a ‘/’ is ignored (comments). Any OID that does not start with “1.3.6.1” or “iso.org.dod.internet” automatically prefixes with “1.3.6.1.” as a convenience.</td>
<td></td>
</tr>
<tr>
<td>source</td>
<td>The IP address or host name of the device to query SNMP on.</td>
<td>required</td>
</tr>
<tr>
<td>index</td>
<td>The index to apply after the community string, for Cisco-style community string indexing (for VLAN interrogation).</td>
<td>0</td>
</tr>
<tr>
<td>credential_id</td>
<td>The sys_id of a specific credential that is preferred for use above the rest. This parameter is for internal use only and is not supported.</td>
<td>none</td>
</tr>
<tr>
<td>credential_tag</td>
<td>The credential tag that must be used. This parameter is for internal use only and is not supported.</td>
<td>none</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Default Value</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------</td>
</tr>
<tr>
<td>timeout</td>
<td>The timeout value (in milliseconds) to wait for a response, instead of the default. You can use this parameter to override the <code>mid.snmp.request.timeout</code> SNMP MID Server configuration parameter.</td>
<td>1500</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> When <code>use_getbulk</code> is set to <code>true</code>, the timeout value is for an individual GETBULK request.</td>
<td></td>
</tr>
<tr>
<td>established_session_timeout</td>
<td>The interval (in milliseconds) to wait for a response after at least one response has been received. Longer values can be useful for collecting complete and accurate data. You can use this parameter to override the <code>mid.snmp.session.timeout</code> SNMP MID Server configuration parameter.</td>
<td>500</td>
</tr>
<tr>
<td>debug</td>
<td>Enables debug logging. Set to true for debug mode.</td>
<td>false</td>
</tr>
<tr>
<td>request_interval</td>
<td>The interval (in milliseconds) between successive requests for an OID when a response has not been received, until the timeout (or established_session_timeout) value is reached. If this value is set to at least as long as the timeout (or established_session_timeout) value, then only a single request is sent for any particular OID. If you change the timeout (or established_session_timeout) value, adjust the request_interval at the same time to avoid sending too many or too few requests for the same OID, as appropriate for a given environment.</td>
<td>400</td>
</tr>
<tr>
<td>request_delay</td>
<td>The interval (in milliseconds) between the receipt of a response and the transmission of the next request. The default is 0 (no delay). This value may be set to slow the overall rate of an SNMP query.</td>
<td>0</td>
</tr>
</tbody>
</table>
| result_format      | Returns JSON formatted payloads for these probes:  
  - SNMP - F5 BIG-IP - System  
  - SNMP - Netscaler - System  
  - SNMP - Routing  

  This parameter returns data in a more compact format to prevent sensor failure or memory problems on a node when the payload becomes large. Do not change this value or delete this parameter.  

  **Caution:** Use of this parameter with any other probes causes the sensor to fail.                                                                 | JSON          |
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
</table>
| use_getbulk   | Enables the use of SNMP GETBULK requests to retrieve tabular data from SNMP devices instead of using multiple SNMP GETNEXT requests. For tabular data, GETBULK is more efficient. Regardless of the request type, certain devices may not return any results when they are busy with other tasks. This parameter is used to configure at the probe level. GETBULK can also be set for an individual MID Server or globally for all MID servers. Settings are listed in the order of precedence:  
  - SNMP probe parameter  
  - MID Server configuration parameter  
  - MID Server properties  

The established_session_timeout, request_interval, and request_delay parameters are ignored when use_getbulk is set to true. Instead, the retries parameter is available. The timeout configuration is the same one used by use_getscalar.

By default, the following probes use GETBULK requests (the parameter value is true):  
  - SNMP - Switch - Vlan  
  - SNMP - Switch - BridgePortTable  
  - SNMP - Switch - ForwardingTable  
  - SNMP - Switch - SpanningTreeTable  
  - SNMP - Network - ArpTable  
  - SNMP - Layer 2 Protocol Caches  
  - SNMP - F5 BIG IP - System (only for Service Mapping customers)

**Note:** These probes have a **timeout** value of 5000.

| use_getscalar | Enables the use of simplified retrieval and handling of scalar values from SNMP devices.  

The established_session_timeout, request_interval, and request_delay parameters are ignored when use_getscalar is set to true. Instead, the retries and timeout parameters are available. The timeout configuration is the same one used by use_getbulk.

| retries       | The number of additional attempts Discovery makes to complete an individual GETBULK request (see use_getbulk) or a GETNEXT request when the use_getscalar parameter is set to true. | 2 |

**Load a MIB module**

You can load an additional MIB module by creating a new ecc_agent_mib record and attaching the actual MIB file to the record.

MIBs are only loaded during MID Server startup. When the MID Server starts up, the following management information base (MIB) modules are loaded:

- Modules that are bundled with the MID Server software. These MIBs are defined industry standards.
- Modules that are included in each instance. These MIBs are provided by manufacturers for Discovery to extract specific information from a device.

You can view any errors associated with loading a MIB module in the agent log.

1. Navigate to **MID Server > SNMP MIBs**.
2. Check whether dependencies are met. If your new MIB has dependencies on another MIB, the MIB that fills the dependency must exist before you create your new record. Search the existing MIBs to check that the required MIBs are already loaded. If they are not, use this procedure to also add them to the instance.

3. Click **New** to create a new record. The MID Server MIB File form opens to create a new ecc_agent_mib record.

4. Use the following information to fill out the form:
   - **Name**: The name of the MIB.
   - **Version**: The version of the MIB.
   - **Source**: Use this field to note where the MIB was acquired, such as a URL.
   - **Description**: The description that appears in the ecc_agent_mib table.
   - **Active**: This check box denotes whether the MIB module is enabled or disabled in the instance.

5. Click the Add Attachment icon (_attach) in the upper right to attach the actual MIB file to the new record. The MIB name must begin with an alphabetical character. Remaining characters must be one of the following: alphanumeric, hyphen (-), or underscore (_). The file name must not have an extension. You can reference the existing MIBs for examples. Use the actual name of the MIB for both the MIB record name and the attachment name, but it is not required.

SNMP probe MIB modules
A management information base module (MIB) is a database that is used to manage elements in a network.
Your instance includes object definitions from the most common management information base (MIB) files. Before adding a new object definition, consult the list of MIB modules to ensure that the object definitions are not already available. The instance includes object definitions from the most common management information base (MIB) files. The MID Server MIB File (ecc_agent_mib) table is domain separated. You can create versions of these policies that only a MID Server from the same domain can use. For instructions, see Set up domain separation for MID servers.

The following table contains the MIBs that load automatically. The MIBs that are bundled with the MID Server are not visible in the instance. The MIBs that are in the ecc_agent_mib table are included in the instance by default and can be viewed in the MID Server > SNMP MIBs module.

**Important:** MIB files in a ServiceNow instance do not use a file extension. If the glide.attachment.extensions system property in your instance contains a list of file extensions permitted for import, MIB files do not load. To ensure that MIB files can load, add a temporary extension to the files prior to loading, such as .mib, and then list that extension in the glide.attachment.extensions property. When you load the file, a business rule called MIB filename compliance strips this extension from the file before it inserts the record into the ecc_agent_mib table.

SSHCommand probe

A probe using the ECC queue topic name SSHCommand executes a shell command on the target host, and returns the resulting output to the sensor.

Discovery supports Bourne Shell (sh) and Bourne-again Shell (bash) commands. Enter shell script commands in the probe’s ECC queue name field. The shell script can use variables and file operations supported by the target UNIX shell.

- The SSH engine is active by default on new instances.
- Customers on upgraded instances can manually enable ServiceNow SSH for a particular probe by setting the use_snc_ssh parameter to true. Alternatively, enable it for all probes on the MID Server by setting the MID Server parameter mid.ssh.use_snc to true.

**Note:** To discover network devices, such as routers and switches, use SNMP credentials, not SSH credentials.

SSHCommand parameters

Several parameters are available for the SSHCommand probe.

For instructions on configuring probe parameters, see [Set probe parameters](#).

Parameters Table

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>allow_unsupported_shells</td>
<td>Allows a probe designer to attempt to run a command on a device that does not have a supported shell. With no shell, the following is true:</td>
</tr>
<tr>
<td></td>
<td>- No path information can be provided.</td>
</tr>
<tr>
<td></td>
<td>- No scripts can function, because there is no ability to handle script parameters.</td>
</tr>
<tr>
<td></td>
<td>- The text that is specified in the ECC queue name field of the probe form is the raw command that is run on the device.</td>
</tr>
<tr>
<td></td>
<td>For example, you may design a probe to display the version of a Cisco switch running NX-OS. The command that the switch understands is show version. To accomplish this, put the show version command in the ECC queue name field, and add the parameter name allow_unsupported_shells with a value of true.</td>
</tr>
<tr>
<td></td>
<td>For example, you may design a probe to display the version of a Cisco switch running NX-OS. The command that the switch understands is show version. To accomplish this, put the show version command in the ECC queue name field, and add the parameter name allow_unsupported_shells with a value of true.</td>
</tr>
<tr>
<td></td>
<td>This parameter is only effective for sncssh. It is not supported with j2ssh. Currently supported shells are sh, bash, ksh, csh, and tcsh.</td>
</tr>
<tr>
<td></td>
<td>- Type: string, true or false</td>
</tr>
<tr>
<td></td>
<td>- Default value: false</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| source    | (Required) Specifies the initial host to connect to.  
  - Type: string (URL)  
  - Default value: None |
| port      | Specifies the target port to connect to.  
  - Type: integer (port)  
  - Default value: 22 |
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>debug</td>
<td>Specifies whether to write SSH debug information to the log file. The parameter usage depends on whether the ServiceNow SSH client is enabled. When the ServiceNow SSH client is enabled, this parameter functions as follows:</td>
</tr>
<tr>
<td></td>
<td>• Type: string</td>
</tr>
<tr>
<td></td>
<td>• Default value: false</td>
</tr>
<tr>
<td></td>
<td>The following string values are valid for the ServiceNow SSH client:</td>
</tr>
<tr>
<td></td>
<td>• true: Enables SSH debug information in the log file.</td>
</tr>
<tr>
<td></td>
<td>• false: Disables SSH debug information in the log file.</td>
</tr>
<tr>
<td></td>
<td>• &lt;IP Addresses&gt;: Specifies which IP ranges to enable SSH debug information in the log file. You can enter IP addresses in the following formats:</td>
</tr>
<tr>
<td></td>
<td>• An IP range defined by a slash and the number of bits in the subnetwork. For example, the string 10.10.10.0/24 scans 24 bits of IP addresses from 10.10.10.0 to 10.10.10.254.</td>
</tr>
<tr>
<td></td>
<td>• An IP range defined by a dash. For example, the string 10.10.11.0-10.10.11.165 scans the IP addresses from 10.10.11.0 to 10.10.11.165.</td>
</tr>
<tr>
<td></td>
<td>• A comma-separated list of specific IP addresses. For example the string 10.10.11.200,10.10.11.235 scans the IP addresses 10.10.11.200 and 10.10.11.235.</td>
</tr>
<tr>
<td></td>
<td>• deferred: Specifies to log SSH debug information in memory unless an error or warning occurs. If an error or warning occurs, the platform publishes the debug information to the log file. This ensures that only the part of the log file pertaining to the error or warning is recorded. If no error or warning is detected, the platform deletes the unused log data from memory when the session closes. Each session stores up to 1000 log messages. If the session exceeds 1000 log messages, the deferred log discards the oldest log message to make room for the newest log message.</td>
</tr>
</tbody>
</table>

When the ServiceNow SSH client is disabled, this parameter enables or disables SSH debug information in the log file:

• Type: true | false
• Default value: false
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| debug_ssh       | Specifies whether the legacy SSH client writes debug information into the `agent/logs/ssh.log` log file. This log file can get very large and should be reviewed frequently.  
The ServiceNow SSH client does not use this parameter.  
- Type: true | false  
- Default value: false                                                                                                                                                                                  |
| timeout         | Sets the socket connection timeout for the legacy SSH client.  
The ServiceNow SSH client does not use this parameter.  
- Type: integer (milliseconds)  
- Default value: 60,000                                                                                                                                                                                   |
| path_override   | Specifies how to change the default paths set before executing a command. Type one or more override paths delimited by a colon (:). The default path is `/usr/sbin: /usr/bin: /bin: /sbin`.  
The ServiceNow SSH client accepts the following prefixes in front of the path_overide value:  
- append: Appends the override path to the end of the host’s path. This is the default behavior.  
- replace: Replaces the host path with the path_overide value.  
- prepend: Appends the override path to the front of the host path.  
- Type: string (a colon-separated list of directories)  
- Default value: None                                                                                                                                     |
| keyboard_interactive | Determines whether to enforce keyboard_interactive SSH login mode.  
- Type: true | false  
- Default value: false                                                                                                                                                                      |
| must_sudo       | Determines whether SSH commands run through `sudo`.  
- Type: true | false  
- Default value: false                                                                                                                                                                            |

<tr>
<td>credentials_debug</td>
<td>Displays a <code>&lt;credentials_debug&gt;</code> section in the ECC queue, which can help you troubleshoot credentials. If you set this property to true, credential troubleshooting information is output to the ECC queue, even if the credentials succeed. See <a href="#">Credentials Troubleshooting</a> for more information.</td>
</tr>
</tbody>
</table>

### SSHCommand path

The SSHCommand probe computes the default path from the following sources:

- MID Server parameter: mid.ssh.path_override
- SSH Command probe parameter: path_override
- User’s default path: Shell configuration file

If you set the MID Server path override parameter, Discovery appends this path to the default path. If you set the probe path parameter, Discovery uses this path instead of the default path. Discovery always appends a user's default execution path to the MID Server and probe parameter paths.

### Default Path

By default, the MID Server searches for SSH commands in the following paths:

- `/usr/sbin`
- `/usr/bin`
- `/bin`
- `/sbin`

### Shell script options

The SSHCommand probe supports the following scripting options in the ECC queue name field.

#### Shell Scripting Options Table

<table>
<thead>
<tr>
<th>Summary</th>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable</td>
<td><code>$(variable)</code></td>
<td>Replaces the token with the value of the variable. For example, <code>$(catalina_home)</code> specifies the installation location of a Tomcat server.</td>
</tr>
<tr>
<td>Include File</td>
<td><code>$(File:file_name.sh)</code></td>
<td>Treats the contents of the specified file as a shell script. For example, <code>$(File:findcat.sh)</code> runs the findcat shell script.</td>
</tr>
</tbody>
</table>
SSH commands for Discovery

These tables display the SSH commands run by Discovery probes on target devices, including parameters.

These SSH commands do not require elevated privileges to run.

**vCenter probes and probe parameters**

vCenter probes scan virtual machines using VMware's vSphere product suite. Each probe scans for different kinds of data, such as networks, NICs, and tags. The VMware - vCenter probe that discovered all vCenter objects in previous releases is deprecated in the Istanbul release and replaced by multiple probes.

### Upgrade changes

In upgraded systems, the vCenter process classifier and the vmapp port probe are configured to trigger the VMware - vCenter Datacenters probe. This probe then triggers the probes that
discover individual vCenter objects such as hosts, storage, and datastores. The legacy probe, VMware - vCenter, is still in the system but is not triggered to run in the updated instance.

**Available vCenter probes and probe parameters**

vCenter probe parameters allow you to disable the probes for the objects you are not interested in discovering. You can also reduce the size of the payload of a probe by specifying a page size.

**Important:** Before disabling a probe, be aware of any dependencies the probe might have. If the probe you disable triggers another probe, the dependent probe is also disabled, and cannot collect data.

**Relationship of vCenter elements to probe parameters**

These parameters are available for vCenter probes.

**Note:** By default, these parameters are not set in the platform, except where noted.

**vCenter probe parameters**

<table>
<thead>
<tr>
<th>Probe</th>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMWare - vCenter Datacenters</td>
<td>• datacenter_only (Cloud Management)</td>
</tr>
<tr>
<td></td>
<td>• debug</td>
</tr>
<tr>
<td></td>
<td>• disable_vm_probe</td>
</tr>
<tr>
<td></td>
<td>• disable_network_probe</td>
</tr>
<tr>
<td></td>
<td>• disable_datastore_probe</td>
</tr>
<tr>
<td></td>
<td>• disable_cluster_probe</td>
</tr>
<tr>
<td></td>
<td>• datacenters_only</td>
</tr>
<tr>
<td></td>
<td>• fixed_credential_id (Cloud Management)</td>
</tr>
<tr>
<td></td>
<td>• disable_vm_nic_probe</td>
</tr>
<tr>
<td></td>
<td>• disable_host_probe</td>
</tr>
<tr>
<td></td>
<td>• disable_host_storage_probe</td>
</tr>
<tr>
<td></td>
<td>• vcenter_timeout: default 10000 milliseconds (10 seconds).</td>
</tr>
<tr>
<td>VMWare - vCenter VMs</td>
<td>• disable_vm_nic_probe</td>
</tr>
<tr>
<td></td>
<td>• disable_vm_nics_vnics (set to false)</td>
</tr>
<tr>
<td></td>
<td>• disable_vm_nic_vdisks (set to true for Discovery only and false when Cloud Management is enabled)</td>
</tr>
<tr>
<td></td>
<td>• disable_vm_tags_probe</td>
</tr>
<tr>
<td></td>
<td>• refresh_state (Cloud Management)</td>
</tr>
<tr>
<td></td>
<td>• page_size (100)</td>
</tr>
</tbody>
</table>

**Note:** The settings for the vnics and vdisks parameters preserves the default behavior of vCenter Discovery.

*For more information, see [VMware tags](#).*

Consider the following when setting these parameters:

- **Disable**: You disable a probe by setting the parameter in the triggering probe. For example, if you are not interested in discovering storage, set the `disable_host_storage_probe` parameter to `true` in the VMWare - vCenter ESX Hosts probe.
- **Page size**: Page size parameters control the number of CIs to discover with a single probe. Use this parameter to limit payload size by reducing the number of vCenter elements discovered at a time by any probe. The page size expressed in parentheses is the default in the base system.
- **Debug**: Set the debug parameter in the VMWare - vCenter Datacenters probe to allow debugging for all the vCenter probes. Debugging returns the raw vCenter data in each probe payload.

Trigger custom probes with the vCenter Discovery extension

vCenter Discovery extension allows you to collect additional attributes of currently discovered CI types or collect attributes of new CI types by triggering custom probes from an existing sensor.

vCenter sensor records support triggering custom probes that use conditional scripts for gathering data not typically collected by Discovery or for discovering CI types that you create.

Role required: admin

**Caution**: The vCenter extension is intended to be used to create a single custom probe that extends existing Discovery functionality. Unless you are a user who is familiar with advanced scripting, do not attempt to configure your new probe/sensor to launch an additional probe.

1. Navigate to Discovery Definition > Sensors.
2. Select a vCenter sensor record.
   It is important to trigger a new probe at the correct time. For example, if you want to discover additional information about virtual machines in your network, trigger your probe from the VMWare - vCenter VMs sensor. If you trigger your custom probe from the VMWare - vCenter Datacenters sensor, your new probe and the existing VM probe execute in parallel. This might prevent VM records from being created or updated.
3. Select the Triggers probes related list.
4. Click New to create a new probe to be triggered by this sensor or Edit to add an existing probe to the list.
You can also use an existing probe record as a template for your new probe by opening the record and selecting the **Insert and Stay** option from the context menu.

5. Click the information icon to the right of the probe name to open the **Conditional Probes Triggered by Sensor** record.

6. View the script.

The script passes the **parms** and **data** arguments to the function, using values passed to them from the triggering sensor. The script configures the **parms** object, from which the probe parameters are derived. The script returns **true** to trigger the probe or **false** to cancel it.

In this example, the VMWare – vCenter Datacenters sensor **parms** are all probe parameters that are supported by the Datacenters probe. The **data** argument is an object containing up to 4 arrays, named **vm**, **datastore**, **network**, and **cluster**.

---

**Conditional Probes Triggered by Sensor record**

```javascript
function(parms, data) {
  var disableNic = g_probe.getParameter('disable_vm_nic_vnic1'),
      disableDisks = g_probe.getParameter('disable_vm_nic_vdisk1'),
      disableNicProbe = g_probe.getParameter('disable_vm_nic_probe');

  // Support the old probe parameter to disable the VM probe
  if ('' + g_probe.getParameter('disable_vm_probe') == 'true')
    return false;

  // Copy VM specific parameters that need to be available to
  // sensors for triggered probes.
  if (disableNic)
    parms.disable_vm_nic_vnic1 = disableNic;
  if (disableDisks)
    parms.disable_vm_nic_vdisk1 = disableDisks;
  if (disableNicProbe)
    parms.disable_vm_nic_probe = disableNicProbe;

  data.vm_ids = JSON.stringify(data.vm);
  return !!data.vm;
}
```
Windows probes and permissions
Discovery accesses devices and software by executing commands as a specific user on Windows computers.

Most probes require access to Windows classes, properties, and registry entries. Certain probes also require additional access to Windows directories and resources. Security policies vary by organization, so there is no one specific role or right to grant. Ensure that the Windows user has local admin permission for these Windows components.

Administrative shares
Windows administrative shares are hidden server resources that Discovery uses to temporarily store the results of processes run by specific probes. The MID Server script file LaunchProc.psm1 launches the process, writes its output to the administrative share on the machine, and then retrieves the results for the MID Server. Access to administrative shares is restricted to users with administrative rights to the target, such as users, local or on the domain, who belong to the local Administrators group.

With the New York release, all Windows probes using WMI protocol call the LaunchProc.psm1 script file and write to admin$ share folder as default. If another network share is mounted on each Window's target, the folder may be changed by updating the MID Server property mid.powershell.target_base_dir.

Windows Classes
Most Windows probes access Windows classes and properties contained in those classes. Some Windows classes do not specify a file namespace path. ServiceNow uses root\cimv2\<Class> by default if an explicit path is not specified.

### Windows Registry entries

Several Windows Registry entries are available for Discovery Windows probes.

**Note:** The Windows - Installed Software sensor appends a timestamp of 00:00:00 to the install_date retrieved from the registry. The installation time of all Windows software is independent of the timezone and is set to midnight of the day it was installed. For example, an install date of **2.19.2017** in the Windows registry appears as **2.19.2017 00:00:00** in the CMDB.

**WMIRunner probe**

WMIRunner is a probe type that fetches data from Windows operating systems via the Windows Management Instrumentation (WMI) interface.

The probe handles multiple user-specified WMI Paths to be queried, using a basic form of native WMI query. Each field to be probed must be uniquely named (within the domain of the probe). The probe results returned to the sensor will provide the data found for each field queried, indexed by its name.
When creating a WMI probe, the probe type must be set to WMI Probe and the ECC Queue Topic must be set to WMIRunner.

For instructions on configuring probe parameters, see Set probe parameters.

The following parameters may be passed to the WMI Probe:

### WMIRunner probe parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>Host to connect to.</td>
<td></td>
</tr>
<tr>
<td>port</td>
<td>Port to connect to.</td>
<td></td>
</tr>
<tr>
<td>debug</td>
<td>Enables debug logging.</td>
<td>false</td>
</tr>
<tr>
<td>wmi_timeout</td>
<td>Timeout for the actual WMI probe, in seconds. Use this parameter to change the timeout interval for individual Windows probes. This value overrides the value in the windows_probe_timeout MID Server parameter, which sets a timeout for all probes launched by a specific MID Server. Windows - Installed Software probe is configured with a timeout value of 15 minutes.</td>
<td>300 (seconds)</td>
</tr>
<tr>
<td>process_timeout</td>
<td>Timeout for the process running the script, in seconds. This parameter is for internal use only and is not supported.</td>
<td>wmi_timeout + 10 (seconds)</td>
</tr>
<tr>
<td>credentials_debug</td>
<td>Displays a &lt;credentials_debug&gt; section in the ECC queue, which can help you troubleshoot credentials. If you set this property to true, credential troubleshooting information is output to the ECC queue, even if the credentials succeed. See Credentials troubleshooting for more information.</td>
<td>false</td>
</tr>
</tbody>
</table>

**Note:** The default timeout for WMI/Powershell is 5 minutes, except for the Windows Installed Software probe, which has a default timeout value of 15 minutes. Adding `wmi_timeout` to a probe parameter can change the default timeout of a Windows probe.

**Port probes**

Port probes are used in Discovery by the Shazzam probe to detect protocol activity on open ports on devices it encounters.

When a port probe encounters a protocol in use, the Shazzam sensor checks the port probe record to determine which classification probe to launch. The common protocols WMI, SSH, SNMP, and HTTP in the base system have priority numbers that control the order in which they are launched.

The priority is as follows:

- 1 - WMI
2 - SSH
3 - SNMP
4 - HTTP

In the base system, the WMI probe is always launched first, and if it is successful on a device, no other port probes are launched for that device. If the WMI probe is not successful, then the SSH probe is launched to gather information on the device. If it is not successful, the SNMP probe is launched. This method allows Discovery to classify a device correctly if the device is running more than one protocol (e.g. SSH, SNMP, and HTTP).

**Discovery Port Probe form**

To access the Port Probe form, navigate to **Discovery Definition > Port Probes**.
The Port Probe form provides the following fields:
## Port probes

<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Simple name for the port probe that reflects its function (e.g. snmp).</td>
</tr>
<tr>
<td>Description</td>
<td>Definition of the acronym for the protocol. (e.g. ssh is Secure Shell Login).</td>
</tr>
<tr>
<td>Scanner</td>
<td>Shazzam techniques for exploring a port. Some of these are protocol specific, and others are generic. For example, a WMI port probe will use a Scanner value of Generic TCP, and the snmp port probe uses a value of SNMP.</td>
</tr>
<tr>
<td>Active</td>
<td>Indicates whether this port probe is enabled or disabled.</td>
</tr>
<tr>
<td>CIs</td>
<td>Indicates whether this port probe is enabled or disabled for discovering “Configuration Items”.</td>
</tr>
<tr>
<td>IPs</td>
<td>Indicates whether this port probe is enabled or disabled for discovering “IP addresses”.</td>
</tr>
<tr>
<td>Triggered by services</td>
<td>Indicates which services define the port usage. Use this setting to define non-standard port usage and pair the port number with the protocol.</td>
</tr>
<tr>
<td>Triggers probe</td>
<td>Indicates which probe is triggered by the results of this port probe. This is the name of the appropriate classify probe.</td>
</tr>
<tr>
<td>Use classification</td>
<td>Names the appropriate classification table, based on the protocol being explored.</td>
</tr>
<tr>
<td>Classification priority</td>
<td>Establishes the priority in which this port probe runs. If the first port probe fails, then the next probe runs on the device, and so forth, until the correct data is returned. This allows for the proper classification of a device that has two running protocols, such as SSH and SNMP. The default priorities for the Discovery protocols are:</td>
</tr>
<tr>
<td></td>
<td>· 1 - WMI</td>
</tr>
<tr>
<td></td>
<td>· 2 - SSH</td>
</tr>
<tr>
<td></td>
<td>· 3 - SNMP</td>
</tr>
<tr>
<td></td>
<td>· 4 - HTTP</td>
</tr>
<tr>
<td>Supplementary</td>
<td>Launches supplementary classifications after a higher-priority identification succeeds, once again in order of priority.</td>
</tr>
<tr>
<td>Conditional</td>
<td>Runs this port probe if any one of the non-conditional probes return an open port. The conditional port probes in the out-of-box system attempt to resolve the names of Windows devices and DNS names. These ports probes take additional resources and are not used unless activity is detected on open ports.</td>
</tr>
<tr>
<td>Script</td>
<td>Script to run.</td>
</tr>
</tbody>
</table>

Shazzam probe, port probes, and protocols
Port scanning is the first step in the Discovery process. The Shazzam probe performs port scanning, regardless of whether you use patterns for horizontal discovery. The following table lists the known ports and protocols used by Discovery.

Several port probes are available in the base system. Each port probe uses an IP Service, which is a record that tells Discovery which port to use for a specific protocol. Review this table before you block any ports with a firewall.

**Caution:** Make sure that you do not block any ports that Discovery needs.

### Default port probes and default IP services

**Windows and dynamic ports**

Supported Windows machines can have dynamic ports ranges: 49152-65535 for both TCP and UDP.

**Configure Shazzam probe**

When you run Discovery, the Shazzam probe finds your active network devices by scanning specified ports on specified IP address ranges. If the list of IP ranges being scanned is large, you can configure the Shazzam payload for JSON encoding to reduce its size.

**Role required: admin**

You control the behavior of individual Shazzam probes using basic and advanced parameters.

For instructions on configuring probe parameters, see [Set probe parameters](#).
**Note:** The Shazzam payload is controlled by the following **MID Server properties**. These properties do not need to be added to the MID Server. The Shazzam probe will fall back on their default values.

- The `shazzam.chunk_size` property controls the maximum number of IP addresses Shazzam can scan in parallel.
- The `mid.shazzam.regulator.interval_ms` property sets the interval in which Shazzam can launch packets.
- The `mid.shazzam.regulator.packets_per_interval` property sets the number of packets that Shazzam can launch in that time interval.

1. Navigate to **Discovery Definition > Probes**.
2. Select **Shazzam**.
3. Add or edit parameters in the **Probe Parameters** related list.
4. Configure the Shazzam parameters.

These parameters are available for fine-tuning the Shazzam probe. These values are defined in the probe record only.

### Shazzam advanced parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>BannerTCP_waitForConnectMS</code></td>
<td>Sets the number of milliseconds the BannerTCP scanner waits for a connection and banner. Default: 1500</td>
</tr>
<tr>
<td><code>debug</code></td>
<td>Enables debug logging if set to <code>true</code>. Default: <code>false</code></td>
</tr>
<tr>
<td><code>delay_webem</code></td>
<td>Delays classification of systems with a WBEM port open until the final Shazzam sensor job. For a large schedule discovering many WBEM ports, delaying classification until the last sensor job could cause the node to run out of memory. Setting this parameter to <code>false</code> allows classification of these systems to occur across all Shazzam sensor jobs. Default: <code>true</code></td>
</tr>
<tr>
<td><code>DNS_alternativePort</code></td>
<td>Deprecated</td>
</tr>
<tr>
<td><code>DNS_waitForResponseMS</code></td>
<td>Sets the number of milliseconds the DNS scanner waits for a response. Default: 1000</td>
</tr>
<tr>
<td><code>GenericTCP_waitForConnectMS</code></td>
<td>Sets the number of milliseconds the GenericTCP scanner waits for a connection. Default: 1000</td>
</tr>
<tr>
<td><code>HTTP_waitForConnectMS</code></td>
<td>Sets the number of milliseconds the HTTP scanner waits for a connection. Default: 500</td>
</tr>
</tbody>
</table>
### Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>

<td>Deprecated</td>
</tr>
<tr>
<td>NBT_waitForResponseMS</td>
<td>Sets the number of milliseconds the NBT scanner waits for a response.</td>
</tr>
<tr>
<td></td>
<td>Default: 500</td>
</tr>
<tr>
<td>report_inactive</td>
<td>When true, reports devices that are alive but inactive. For example, a device has no ports open but refuses at least one port connection request.</td>
</tr>
<tr>
<td></td>
<td>Default: true</td>
</tr>
<tr>
<td>scanner_log</td>
<td>Enables scanner logging if set to true. This logging information appears in the Shazzam probe response.</td>
</tr>
<tr>
<td></td>
<td>Default: false</td>
</tr>
<tr>
<td>shazzam_report_dead</td>
<td>When true, reports devices with dead IP addresses. For example, a device that has all ports closed.</td>
</tr>
<tr>
<td></td>
<td>Default: false</td>
</tr>
<tr>
<td>SNMP_alternativePort</td>
<td>Deprecated</td>
</tr>
<tr>
<td>SNMP_tapIntervalMS</td>
<td>Sets the number of milliseconds the SNMP scanner waits between taps.</td>
</tr>
<tr>
<td></td>
<td>Default: 1000</td>
</tr>
<tr>
<td>SNMP_taps</td>
<td>Sets the number of taps (requests) the SNMP scanner attempts.</td>
</tr>
<tr>
<td></td>
<td>Default: 2</td>
</tr>
<tr>
<td>SNMP_waitForResponseMS</td>
<td>Sets the number of milliseconds the SNMP scanner waits for a response after the last tap.</td>
</tr>
<tr>
<td></td>
<td>Default: 1000</td>
</tr>
</tbody>
</table>

**Control Shazzam payload size**

A system property converts Shazzam payloads into JSON strings, which dramatically reduces their size. This setting prevents nodes from running out of memory when a single schedule discovers large numbers of IP ranges.

**Role required:** admin

The `glide.discovery.shazzam_ranges_json` property is set to `true` for new instances. This setting encodes the payload as a JSON string. The property is configurable by administrators and is available in the Discovery Definition > Properties module. The property label is Use JSON for IP ranges in Shazzam in the module.

This property is set to `false` in upgraded instances and is not visible by default. Adding the property manually to your upgraded instance enables the feature, but does not add it to the...
Discovery Definition > Properties module. To enable JSON encoding and add it to the module, import the update set attached to KB0687626.

1. In the navigation filter, type sys_properties.list and press Enter.
2. In the list of system properties, click New.
3. Complete the form, using these field values:
   - **Name**: glide.discovery.shazzam_ranges_json
   - **Description**: Encodes the Shazzam payload in JSON.
   - **Value**: true
4. Click Submit.

Discovery sensors

Every probe in Discovery must have a corresponding sensor to process the data returned. For example, if incoming data is the result of a WMI probe, then the WMI sensor is triggered to process the payload.

**Note:** If you create a multiprobe, you must create a multisensor to process the data returned from this probe. For details, see Multiprobes and Multisensors.

Navigate to Discovery > Discovery Definition > Sensors and edit or create a sensor.

**Sensor Fields Table**

<table>

</tbody>
</table>
Cancel sensor transaction by duration
By default, this rule cancels the sensor transaction if it takes more than 20 minutes to complete.

Role required: admin
If the Discovery sensor transaction takes more than 20 minutes to complete, the following actions occur:

- The associated ECC Queue input record is set to the error state.
- The Discovery Status Completed Count is updated.
- An error message is logged, for example:

```
Sensor error when processing Linux - Storage: Transaction cancelled: maximum execution time exceeded
```

- The remainder of the discovery continues to run.

This behavior is provided by the Discovery Sensors Transaction Quota Rule. This rule is active by default.

You can disable the rule and you can modify the amount of time that has elapsed before the rule takes effect. Accessing this record requires the admin role.

1. To disable the rule, navigate to **System Definition > Quota Rules**.
   The Transaction Quotas plugin must be active.
2. Search on the name *Discovery to filter the list of rules.
3. In the name column, click Discovery Sensors.
4. To modify the amount of time, edit the Maximum Duration field of the rule.
   The value is in seconds.

Discovery probe management

Several discovery probes and their associated sensors are included with Discovery. You rarely need to modify probes or sensors. But you might need to set parameters to control the behavior of a particular probe or align versions of customized probes.

**Note:** With each release, patterns are replacing many probes and sensors for Discovery. Consider creating new patterns or editing existing ones if you want to customize what Discovery can find. The information on probes and sensors is intended for customers who are not using patterns yet and for customers who already have customized probes that are retained upon upgrade. See Patterns and horizontal discovery for more information on patterns.

What you can do

These are the things you can do with probes and sensors:

**Review the base system probes**

Review the List of Discovery probes to see the probes that exist in the base system. Probes need to be active on classifiers for Discovery to trigger the probes. However, not all probes are active on classifiers as more patterns replace probes and sensors. To see which patterns replace probes and sensors, see Pattern updates for the New York release.

**Create or modify a probe**

You can create a new probe to discover additional CIs that Discovery does not find with the base system probes or patterns, or modify an existing probe to collect additional information on
the type of CI. After you create or modify a probe, test it. You can also create multiprobes and multisensors. See Create a Discovery multiprobe for more information.

**Upgrade to the latest version of a probe or sensor**

If you upgrade your instance, the Discovery application is also updated, along with components like probes and sensors. However, if you customized any probes or sensors, they do not upgrade. You need to copy your customizations to a text file, upgrade the probes and sensors, and reapply your customizations. See Align versions of customized probes and sensors for more information.

**Set probe parameters**

Probe parameters control several aspects about how probes function. With each probe provided in the base system, certain parameters are allowed. These are specified in the list of Discovery probes. See Set probe parameters for instructions on how to set a parameter.

**Review probe permissions**

Certain probes need permissions to run on the target machines or CIs that you are trying to discover. See Discovery probe permissions for more information.

**Create or modify a probe**

Create a new probe to discover additional CIs or modify an existing probe to collect additional information. After you create or modify a probe, test it.

Role required: admin

**Important:** You need an advanced knowledge of scripting to modify probes or their associated sensors. Many existing probes provide parameters that you can set, rather than modifying the probe itself. See Set probe parameters for more information.

1. Navigate to Discovery > Discovery Definition > Probes.
2. Click the name of the probe that you want to modify.
3. Modify the form fields (see table).

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Class</td>
<td>Select the probe for the operating system of the device it will query.</td>
</tr>
<tr>
<td></td>
<td>- AWS Probe: Select this class to query your resources inside an AWS cloud.</td>
</tr>
<tr>
<td></td>
<td>- CIM Probe: Select this probe type to query a CIM server using WBEM protocols.</td>
</tr>
<tr>
<td></td>
<td>- Multiprobe: Select this probe type to run one or more simple probes of any type or mix probes of different types. This type of probe can make several queries simultaneously that return all the results at the same time. You cannot add multiprobes to other multiprobes.</td>
</tr>
<tr>
<td></td>
<td>- Probe: Select this generic type to define a probe class. Specify the name of the probe class in the ECC queue topic field.</td>
</tr>
<tr>
<td></td>
<td>- SNMP Probe: Select this probe type for network devices, such as routers.</td>
</tr>
<tr>
<td></td>
<td>- WMI Probe: Select this probe type for Windows devices.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| ECC queue topic     | Enter a descriptive term for the function of the probe. The probe uses this label as the **Topic** field for incoming ECC queue messages. The term does not have to be unique. For example, all the UNIX probes might have an ECC queue topic value of **SSHCommand**. By default, probes use the following ECC queue topics:  
  - CimProbe  
  - Multiprobe  
  - Powershell probe  
  - SCP Relay  
  - SSHCommand  
  - SNMP  
  - WMIRunner |
| ECC queue name      | Enter either a descriptive name for human use, or the actual command the probe is to run. For example, if the value in the ECC queue topic field is **SSHCommand**, then enter the actual shell command to run in this field. |
| Cache results       | Select this option to cache this probe’s results to improve overall discovery performance. The probe results cache should be enabled only for those probes and sensors whose output is unlikely to change. For example, the Linux – CPU sensor is cached because CPU information seldom changes. The cache is turned on by default for base system probes and sensors whose output is unlikely to change.  
  Warning: Do not turn on the cache for classification and identification probes. Furthermore, do not turn on the cache for probes that trigger additional probes because this may prevent them from being triggered. |
<p>| Classic Mode        | Select this option to cache this probe’s results in the Starting in Fuji, select this option to debug the post-processing script on the ServiceNow instance instead of the MID Server. This mode is only valid if a post-processor script exists. Use the Classic mode to debug post-processing scripts in the test environment. ServiceNow does not recommend use of the Classic mode in the production environment. |</p>
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Post processor script</td>
<td>Define an optional post-processing script that runs on the MID Server. The script accepts probe results as an input and outputs a JSON string that is sent back to the instance for a sensor to use as input. Use this type of script to accomplish tasks like parsing data.</td>
</tr>
<tr>
<td></td>
<td>All probe post-processing scripts and their corresponding sensors have access to the following global variables:</td>
</tr>
<tr>
<td></td>
<td>- <strong>current</strong>: Sets the attribute to current. Same functionality that exists in sensors. They are attributes of the device that is discovered.</td>
</tr>
<tr>
<td></td>
<td>- <strong>related_data</strong>: Any additional data to be passed from the probes post-processing scripts, such as related_list.</td>
</tr>
<tr>
<td></td>
<td>All probe post-processing scripts and their corresponding sensors have access to the following methods:</td>
</tr>
<tr>
<td></td>
<td>- <strong>log(string)</strong>: Logs the string to the MID Server and the ServiceNow instance log files.</td>
</tr>
<tr>
<td></td>
<td>- <strong>getParameter(param)</strong>: Gets the parameter from the ECC queue payload.</td>
</tr>
</tbody>
</table>

4. Right-click the form header and select **Save**.
5. Modify these related lists if necessary.

<table>
<thead>
<tr>
<th>Related list</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Probe Parameters</td>
<td>Parameters that control the functionality of the probe. See <a href="#">Set probe parameters</a> for instructions.</td>
</tr>
<tr>
<td>Sensors that react to this probe or Sensors</td>
<td>The sensors that this probe utilizes.</td>
</tr>
<tr>
<td>Included by MultiProbe</td>
<td>If this probe is included with other probes as a MultiProbe.</td>
</tr>
<tr>
<td>MultiSensor Scripts</td>
<td>Scripts that run for multiple sensors.</td>
</tr>
<tr>
<td>Versions</td>
<td>The version of the probe. If the <strong>State</strong> is <strong>Current</strong>, the probe is the most up to date with your version of the instance. If not, you do not have the most current version and you might need to realign it. See <a href="#">Align versions of customized probes and sensors</a> for instructions.</td>
</tr>
</tbody>
</table>

6. Click **Test probe**.
7. On the Test Probe window, enter the IP address of the target and select the MID Server. Only **Up** and **Validated** MID Servers are able to be selected.
8. Click **OK**.
9. **Check the ECC Queue** for the MID Server to see the results.

Add the probe to the **Triggers Probe** related list on the appropriate classifier. See **Create a Discovery CI classification** for a description of the fields and related lists on the classifier form.

**Discovery probe permissions**
Several probes require additional permissions to run.

### Discovering Active Connections

Discovery uses the Windows - Active Connections probe to access active connection information. The **application dependency mapping** feature requires this probe to function.

<table>
<thead>
<tr>
<th>Probes</th>
<th>Additional Permissions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows - Active Connections</td>
<td>Ability to invoke the \root\CIMV2:Win32_Process object</td>
</tr>
<tr>
<td></td>

<td>Access to the admin$ share</td>
</tr>
<tr>
<td>Windows - Get APD Version File Content</td>
<td>Access to the %SystemRoot%\temp directory</td>
</tr>
</tbody>
</table>

### Discovering VMware Workstation

**Attention:** The Discovery of VMware Workstation is not supported in releases after Kingston. The VMware workstation probe and sensor are not included in new instances of London. However, customers who upgrade from a release prior to Kingston can continue to use the probe and sensor to discover VMware Workstation.

Discovery uses the **Windows - Get VMware Workstation** probe to access information about VMware virtual machines installed on Windows.
Discovering VMware Workstation

<table>
<thead>
<tr>
<th>Probes</th>
<th>Additional Permissions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows - Get VMware Workstation</td>
<td>Ability to invoke the \root\CIMV2:Win32_Process object</td>
</tr>
<tr>
<td></td>
<td>Access to the admin$ share</td>
</tr>
<tr>
<td></td>
<td>Access to the %SystemRoot%\temp directory</td>
</tr>
<tr>
<td></td>
<td>Configure the PATH variable to include the path to the vmrun.exe command. This command is typically found in the VMware Workstation install directory.</td>
</tr>
</tbody>
</table>

Discovering MSSQL

Discovery uses the Windows - MSSQL probe to access information about Microsoft SQL Server installed on Windows.

<table>
<thead>
<tr>
<th>Probes</th>
<th>Additional Permissions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows - MSSQL</td>
<td>• Access to the Win32_Process object</td>
</tr>
<tr>
<td></td>
<td>• Access to the Win32_Service object</td>
</tr>
<tr>
<td></td>
<td>• Access to the Win32_NetworkAdapterConfiguration object</td>
</tr>
<tr>
<td></td>
<td>• Access to the Microsoft.SqlServer.Management.Smo object</td>
</tr>
<tr>
<td></td>
<td>• Access to run the nbtstat command</td>
</tr>
<tr>
<td></td>
<td>• Access to HKLM\SOFTWARE\Microsoft\Microsoft SQL Server\InstalledInstances</td>
</tr>
<tr>
<td></td>
<td>• Access to HKLM\SOFTWARE\Microsoft\MSSQLServer$instanceName\SuperSocketNetLib\Tcp\TcpPort where $instanceName is an array of possible values.</td>
</tr>
</tbody>
</table>

Set probe parameters

Use probe parameters to control the behavior of a particular probe every time it is triggered.

Required role: admin.

The following parameters are available for all probe types:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>(Required) The initial host to connect to.</td>
</tr>
<tr>
<td></td>
<td>• Type: string (URL)</td>
</tr>
<tr>
<td></td>
<td>• Default value: None</td>
</tr>
</tbody>
</table>

1. Create or select the **probe** you want to set parameters for.
2. From the Probe Parameters related list, click **New**.
3. Fill in the fields, as appropriate (see table).
The Probe parameter form has the following fields.

### Probe Parameter Form Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter the parameter name. Each probe type has its own list of available parameters.</td>
</tr>
<tr>
<td>Value</td>
<td>Enter the parameter value or script as required by the parameter.</td>
</tr>
<tr>
<td>Value script</td>
<td>(Optional) Enter the script you want the parameter to run if you have not already specified a script in the Value field.</td>
</tr>
<tr>
<td>Probe</td>
<td>Displays the probe this parameter relates to.</td>
</tr>
</tbody>
</table>

### Align versions of customized probes and sensors

If you customized a probe or sensor and upgraded to a new version of an instance, you need to realign the versions of the customized probe and sensor to the most current version.

Role required: admin

Probes and sensors have a major and a minor version.

**Major version**

A major version change reflects a change in the expected output of a probe, such as the addition or subtraction of a targeted attribute, a format change, such as XML versus JSON, or a probe parameter script change.

**Minor version**

A minor version change reflects small fixes that do not impact the result or the processing of the data.

A sensor and its corresponding probe must have the same major version. It is recommended they also have the same minor version. This version matching ensures that the data sent back from the probe is understood and properly processed by the sensor. All members of a multi-probes bundle must have the same major and minor version.

By default, Discovery tracks major version mismatches and displays version mismatch errors in the Active Discovery Errors section on the Discovery Dashboard and in the Discovery Log. You can control whether or not Discovery tracks minor versions mismatches by setting the Warn on Minor Version Mismatch (glide.discovery.warn_minor_version) Discovery property. Minor version mismatches are tracked in the Discovery log, but are not displayed on the Discovery Dashboard.

Versions for multi-probes and multi-sensors are checked as follows:

- The versions of the individual probes contained in the multi-probes are compared with the Responds to Probes scripts that process their data.
- The versions of the Responds to Probes scripts and the main multi-sensors script are compared.

If a probe and its corresponding sensor do not have the same major version, a sensor does not process information during a discovery and sends error messages to the log file. Errors also show up on the Discovery Dashboard when you run a discovery job. If the major version is the same, but the minor version is not, a sensor processes information during a discovery.

See the Discovery Probe and Sensor Versioning video for a tutorial on how to resolve version conflicts.
To use the most up-to-date version of a probe that is available:

1. Save the customizations that you made with your probe or sensor into a text file so you can re-apply them later.
2. Navigate to Discovery > Dashboard.
3. Look for version mismatch errors in the Active Discovery Errors section, and note the probe or sensor that caused the error.
4. Navigate to Discovery Definition > Probes or Discovery Definition > Sensors and select the probe or sensor that you want to upgrade.
5. Add the Major version and Minor version fields to the form if you want to display the versions on the form.
6. In a multi-sensor, you can verify the major version with the versions of the probes that use the sensor in the Responds to Probes related list.
7. Click the **Versions** related list.
8. Look for version where the **State** is **Previous** and the **Source** is **System upgrades**.
9. Click the date link in the **Created** column for that version to open the version record.
10. Click **Revert to this version**.
11. Navigate back to the probe or sensor form and verify that the major version is correct.
12. Reapply your customizations to the probe or the sensor.
13. Verify that your customizations are valid with the new version of the probe or sensor by running a Discovery in your test environment.

### Discovery multiprobes and multisensors

Multiprobes contain one or more simple probes configured to extract specific information from manageable devices by executing multiple queries with a single authentication.

You can schedule multiprobes to run any time in the discovery process to make exploration more efficient. One common use for multiprobes is as **identity probes**. Identity probes ask a device for information such as its name and serial number, and then use the results of those queries to update existing CIs in the CMDB.

To process the data returned from a multiprobe, you must create multisensors, which run scripts that process the data returned by the multiprobes. Multisensors typically use the same name as their corresponding multiprobes.

**Note:** The corresponding multisensors have the same names as the multiprobes.

The following multiprobes are included with the base system.

<table>
<thead>
<tr>
<th>Multiprobe</th>
<th>Includes These Probes</th>
</tr>
</thead>
<tbody>
<tr>
<td>AIX - ADM</td>
<td>• AIX - Active Processes: Gets active running processes.</td>
</tr>
<tr>
<td></td>
<td>• Unix - Active Connections: Gets active connections information.</td>
</tr>
<tr>
<td>AIX - Identity</td>
<td>• AIX - Network: Determines network interfaces, IPs, and MACs.</td>

Note: ↑ This probe requires the installation of a command line tool from Oracle called SNEEP. To download and install this tool, log in to the Oracle website. After this tool is installed, the Solaris - Serial Number probe runs automatically when Discovery detects a Solaris device. For Fujitsu PRIMEPOWER devices, you must run this probe with root credentials.

Add a simple probe to a multiprobe
You can add simple probes to your multiprobe in the Includes Probes related list.

Role required: admin

You can add simple probes of any type to a multiprobe and mix probe types if necessary.

Warning: Do not add a multiprobe to the Includes Probes related list.

1. Navigate to Discovery Definitions > Probes.
2. Open a multiprobe from the list.
   You can see the MultiProbe designation in the ECC queue topic column.
3. In the MultiProbe record, click **New** in the **Includes probes** related list.
4. Select a simple probe from the collection list in the left column and move it into the included list.

5. Click **Save**.

*Create a Discovery multiprobe*

You can use the default multiprobes and multisensors provided in the platform or create your own.

1. Navigate to **Discovery** > **Discovery Definition** > **Probes**.
2. Click **New**.
3. Complete the **form** using the following settings:
   - Probe type: Multiprobe.
   - ECC queue topic: MultiProbe.
4. In the Includes probes related list, *add the probes* you want to include in the multiprobe.
5. Click *Save*.

*Create a Discovery multisensor*
Create a multisensor to process data returned from a multiprobe.
1. Navigate to Discovery > Discovery Definition > Sensors.
2. Click **New**.
3. Complete the form using the following settings:
   - Sensor type: MultiSensor.
   - ECC queue topic: MultiSensor.
   - Reacts to probe: Select the probe whose payload this sensor must process.
   - Sensor type: Select one of these options.
     - Javascript: Returned data from the probe is processed in the sensor itself, outside the application, and is visible to the user. This is the most common sensor type.
     - XML: The XML data from the probe is broken into pieces. Some pieces can be used to launch other probes that the original sensor needs to complete all the necessary information about a device.
4. Right-click the form header, and click **Save**.
5. In the Responds to Probes related list, click **New**.
6. Complete the form using the following settings:
   - Reacts to probe: Select the probe within the multiprobe that this sensor reacts to. The sensor must be linked to the probe by function, such as network identification or serial number.
   - Script: Enter a script to run before the script in the multisensor. This script defines how the data returned from each probe should be processed.
7. Click **Save**.

**Example custom Discovery probe and sensor: populate a CI with text file values**

This custom Discovery probe helps you if you need to read a text file from a Windows computer and populate a CI in the CMDB with the values from the file.

In this example the user wanted to read files created by BGinfo.

**Note:** When you have completed the probe and sensor, place the probe in the appropriate Windows classifier at **Discovery Definition > CI Classification > Windows**.

1. Navigate to **Discovery Definition > Probes**, and then click **New**.
2. Complete the following fields:
   - Name: Unique and descriptive name for the probe
   - Probe type: Select **Probe**.
   - Description: Describe the function of this probe.
   - Used by Discovery: Select this check box
   - ECC queue topic: This is name of the probe the MID server is to run. In this example, we use WMIRunner.
   - ECC queue name: In this example, we use the descriptive name WMI: BGInfo files.
3. Right-click in the header bar and select **Save** from the context menu.
4. Select the Probe Parameters tab in the Probe form, and then click **New**.
5. Enter **WMI_GetFiles.js** as the Name of this parameter.
6. Copy the script below into the Script field and edit as needed.
7. Click **Submit**.

```bash
//
// Use ServiceNow WMIAPI to gather stats
```
//
var CMD_RETRIES = 3;
var scanner = getScanner();
if (scanner) {
    var output = "";
    for(var i = 0; i < CMD_RETRIES; i++) {
        output = scanner.winExec("%SystemRoot%\system32\cmd.exe /C type \n"C:\\Information Systems\\BgInfo\\*.txt\\\\"");
        if (output)
            break;
    }
    scanner.appendToRoot("output", output);
}

8. Navigate to Discovery Definition > Sensors, and then click New.

Complete the following fields:
- **Name**: Use the same name as the matching probe. In this example, we use Windows - Get BGInfo files.
- **React to probe**: The name of the probe created in the previous procedure: Windows - Get BGInfo files
- **Sensor type**: Select the type of sensor to create - in this example Sensor.
- **Description**: Describes the function of this sensor.
- **Script**: Copy the script below into the Script field and edit as needed.
- **Sensor type**: Determines how the answer from the probe is processed - in this example JavaScript.

9. Click Submit.

```javascript
new DiscoverySensor({
    data: {},
    process: function(result) {
        this.parseOutput(result.output);
        this.update(this.data);
    },
    parseOutput: function(output) {
        var currentFile;
        var files = {};

        if (output.startsWith("<wmi")) {
            var bgout = new XMLHelper(output).ToObject();
            if (!bgout)
                return;
            output = bgout.output;
        }

        var lines = output.split(/
/);

        for(var i = 0; i < lines.length; i++) {
            var line = lines[i];
            if (line.startsWith("C:\Information Systems\BgInfo\") {  
                var currentFile = line.substr(30);  
                if (!files[currentFile])
                    return;
                currentFile = line.substr(30);
                files[currentFile] = ";
                } else if (currentFile) {
                    var newLine = line.trim();
                    if (newLine)
                        files[currentFile] += (files[currentFile]?
"\n" &nbsp; : "") + newLine;
```
Advanced Discovery configuration

You can configure several additional components of Discovery such as Application Dependency Mapping, the ECC queue, and extensions for the MID server.

Credential-less Discovery with Nmap

If the instance fails to identify a configuration item (CI) because of authentication failure, Discovery or Service Mapping can run selected Network Mapper (Nmap) commands with a MID Server to collect some basic information about the CI without using credentials.

A MID Server administrator can install Nmap on individual MID Servers running on a Windows host. Those MID Servers can then discover some basic information about CIs in your network when normal authentication fails.

Attention: Self-hosted customers whose network security does not permit downloads from install.service-now.com must install and configure Nmap manually on their system. Refer to Install Nmap on a self-hosted system for instructions.

Credential-less Discovery can create or modify host and application CIs when credentials are missing or misconfigured. If a credential-based Discovery is performed successfully after Nmap creates a CI, the system reconciles the information gathered from each type of discovery.

What Nmap can discover

The Nmap commands executed during credential-less Discovery can:

- Perform reverse DNS name resolution to identify the host from the IPv4 address.
- Return the MAC address of the host if that host is on the same subnet as the host executing the Nmap command.
- Detect applications installed on a target host.
- Detect the operating system of a target host and the OS version.

Note: Credential-less Discovery classifies routers and switches as hardware. It does not create or update CIs specifically for them.

Nmap credential-less Discovery scans in cloud computing platforms

It is often against the terms of service to run Nmap scans to or from any resource within a cloud computing service such as Amazon Web Service, Microsoft Azure, IBM Cloud, or Google Cloud Platform. For example, the Amazon Web Service (AWS) environment is tightly regulated and requires the permission of AWS through the AWS Vulnerability/Penetration Testing Request form. Unauthorized tests against AWS services or AWS-owned resources are prohibited. For this reason,
credential-less Discovery within a cloud computing service environment is not appropriate, and if a violation of their policy occurs, could result in expulsion from the service. Please contact your platform service provider for information on limitations or permission requirements for running Nmap.

**Components installed with Nmap**

The Discovery - IP Based (com.snc.discovery.ip_based) plugin that provides the Nmap functionality is activated automatically when either Discovery or Service Mapping is active. These Nmap components are provided by the Discovery - IP Based plugin:

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>System property</td>
<td>The <code>mid.discovery.credentialless.enable</code> property enables or disables Nmap for all MID Servers on which Nmap is installed that are connected to the instance. This property is installed with the Discovery plugin and is enabled by default. It is configurable by a system administrator.</td>
</tr>
<tr>
<td>MID Server properties</td>
<td>These properties, from the MID Server Property (ecc_agent_property) table, are not intended to be configured:</td>
</tr>
<tr>
<td></td>
<td>· mid.nmap.version: Version of Nmap that is installed on MID Servers in your environment. This field is visible on the MID Server (ecc_agent) form after Nmap is installed.</td>
</tr>
<tr>
<td></td>
<td>· nmap.safe.scripts: Defines the list of Nmap scripts that are classified as safe for use during execution of Nmap’s Application Version Detection phase (-sV command option).</td>
</tr>
<tr>
<td></td>
<td>· nmap.npcap.version: The version of Npcap that is installed with Nmap. The Nmap installer can only perform upgrades of existing Npcap installations it encounters.</td>
</tr>
<tr>
<td>Fields</td>
<td>· Credentialless Discovery Port (cl_port): Optional field on the Application (cmdb_ci_appl) table that displays the number of a port scanned by credential-less Discovery. This port number is used to determine whether an application returned by Nmap has a matching CI in the CMDB or if a new CI must be created.</td>
</tr>
<tr>
<td></td>
<td>· Discovery source (discovery_source): Optional field in the Configuration Item (cmdb_ci) table to which the CredentiallessDiscovery choice is added. This option shows that credential-less Discovery was used to create a CI.</td>
</tr>
<tr>
<td>Component</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Nmap MID Server capability</td>
<td>The <strong>Nmap capability</strong> is added to the MID Server when Nmap is installed and removed automatically when Nmap is uninstalled. Only MID Servers with this capability can perform credential-less Discovery. A system administrator cannot add or remove this capability manually. Self-hosted customers who have the maint role can modify or delete the Nmap capability, but <em>should not do so</em>. Service Mapping does not check for the presence of the <strong>Nmap capability</strong> and selects the MID Server based on the IP address only. To ensure that Service Mapping does not select a MID Server without the <strong>Nmap capability</strong>, install Nmap on all MID Servers assigned to the IP address ranges for which you want credential-less Discovery to be available. If Service Mapping selects a MID Server for credential-less Discovery that does not have Nmap capabilities, this error message appears in the map, at the site of the CI being discovered: <em>Nmap is not installed on MID Server. Verify all MIDs configured to handle selected IP Address have Nmap Capability. Nmap root directory path does not exist:</em> &lt;path&gt;</td>
</tr>
<tr>
<td>Npcap</td>
<td><strong>Npcap</strong> is Nmap©’s packet capture library for Windows. Npcap allows Nmap to perform port scans quickly and to identify the family of the operating system running on the target. Only one copy of Npcap is installed per MID Server host. Because Npcap can be used by other applications, uninstalling Nmap does not automatically uninstall Npcap. You must uninstall Npcap manually, after determining that no other dependencies exist.</td>
</tr>
</tbody>
</table>

**Note:** The ALL MID Server capability does not include the **Nmap capability**.
<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
</table>
| Patterns  | • **Credentialless Discovery Network Device**: Scans a host IP address using an Nmap command to identify the host. This pattern launches the **Credentialless Discovery Network Device – PreLaunch** script to retrieve the list of ports to explore from the IP Service (cmdb_ip_service) table. Do not modify this script.  
  • **Credentialless Discovery Application**: Scans a port at an IP address using an Nmap command to identify the application service actively listening on that port. Service Mapping launches this pattern when all credential-based port classification steps fail. Discovery creates a CI in the Application (cmdb_ci_appl) table if the port is open and it can identify the service by name and product. If the service does not respond to any of the scan attempts, Nmap consults its nmap-services registry and guesses at which service is most likely running on that port. If Nmap has to guess what application is running on a scanned port, the Credentialless Discovery Application pattern does not create an application CI or update an existing CI. |
| MID Server script includes | • **SetCredentialLessDeviceClassName**: Determines which host CI to create or update after the successful execution of the Nmap command. Do not modify this script.  
  • **CredentialLessApplicationClassNameMapper**: Maps the service product, service name, and extra service information supplied by Nmap for the scanned port to a supported application table in the instance. System administrators can modify this script.  
  • **SetCredentialLessApplicationClassName**: Ensures that the CredentialLessApplicationClassNameMapper script is invoked only once. Do not modify this script. |
| System script include | The **CredentiallessDiscoveryAjax** script include runs on the instance and handles the installation and uninstallation of Nmap on Windows MID Servers, executed from UI actions on the form. Do not modify this script. |

**Credential-less host Discovery**

Credential-less host discovery occurs when a scanned host is found to be alive, but not active, or when all configured credential-based classification probes have failed.
How the host Discovery pattern is launched

If the Shazzam probe scans a host that is alive but not active, and if credential-based classification probes fail, horizontal Discovery launches the Credentialless Discovery Network Device pattern to gather host information. If the host being scanned does not have a CI defined, Service Mapping launches the HorizontalDiscoveryProbe probe, which in turn launches the Credentialless Discovery Network Device pattern. This pattern attempts to create a new CI if one does not already exist for the scanned host or to update an existing CI in the Hardware (cmdb_ci_hardware) table.

**Important:** To allow the Credentialless Discovery Network Device pattern to launch, ensure that the `mid.discovery.credentialless.enable` system property is set to `true`.

ECC Queue entries

The system creates these entries in the ECC queue during execution of the HorizontalDiscoveryProbe.
Log messages

These log messages are published during execution of the HorizontalDiscoveryProbe.

The Nmap command

The Nmap command executed on the MID Server determines if the host is up. Using the IP address and a list of ports passed to Nmap by the pattern, Nmap performs reverse DNS name resolution to identify the host name associated with the IP address. If multiple host names are configured, the first name returned by Nmap is used. If no host name is configured, then the IP address of the remote host is used to create the host CI. The Npcap packet capture library, included with the Nmap installation, identifies the host operating system family. If the scanned host is located on the same subnet as the Windows MID Server host that executes Nmap, the remote host's MAC address is returned.

Note: The list of ports that Nmap is configured to scan during credential-less host Discovery is stored in the IP Service (cmdb_ip_service) table, which is editable. By default, all ports are available for scanning. To block the use of any port for an Nmap scan, set the value in the Credentialless Discovery (cl_discovery) column to false.
Creating or updating host CIs

After successful execution of the Credentialless Discovery Network Device pattern, the SetCredentialLessDeviceClassName MID Server script runs to identify the operating system family of the discovered host. The system class of the host CI is based on the operating system family that is returned by Nmap. If the OS family matches one of the six supported server operating systems, then the system uses a server class derived from the Hardware (cmdb_ci_hardware) base class, such as Linux Server (cmdb_ci_linux_server). If no match is found, the system uses the base class.

**Note:** When the issue with the credentials is resolved and Discovery runs again, the instance uses the serial number, host name, and system class provided by credential-based discovery to update the host CI that was created by credential-less Discovery.

### Supported OS families

</tr>
</tbody>
</table>
Hardware identification

The Discovery - IP Based (com.snc.discovery.ip_based) plugin adds an identifier to the Hardware Rule for the Hardware (cmdb_ci_hardware) base table that matches on the host CI name for Nmap scans. The Hardware Rule is used by both credential-based and credential-less Discovery.

Credential-less Application Discovery

Credential-less Application Discovery attempts to identify an application service actively listening on a specific port at a given IP address.

The application discovery pattern

Service Mapping launches the Credentialless Discovery Application pattern when all credential-based port classification steps fail. The pattern executes an Nmap command on a Windows MID Server with Nmap installed, that is configured to perform application/version detection against a specific remote host IP address and port. If the port being scanned by Nmap is open, the pattern executes the CredentialLessApplicationClassNameMapper MID Server script include, which maps the service product, service name, and any extra information supplied by Nmap to a supported ServiceNow application table. If the script can map the returned product to an appropriate table derived from the base Application (cmdb_ci_appl) table, the script passes this information to the pattern. The pattern passes the match to the Discovery identifier for eventual CI creation or reconciliation. If the information returned by Nmap does not match any derived table, then the instance uses the base Application (cmdb_ci_appl) table to create the CI.

Important: To allow the Credentialless Discovery Application pattern to launch, ensure that the mid.discovery.credentialless.enable system property is set to true.
**Example scan**

This information was returned by an Nmap Application/Version Detection port scan on a Linux test system and illustrates the type of application data Nmap scans can return.

<table>
<thead>
<tr>
<th>Information</th>
<th>Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port state</td>
<td>open</td>
</tr>
<tr>
<td>Service name</td>
<td>ssh</td>
</tr>
<tr>
<td>Service product</td>
<td>OpenSSH</td>
</tr>
<tr>
<td>Extra service information</td>
<td>Protocol 2.0</td>
</tr>
</tbody>
</table>

**Default application mappings**

The `CredentialLessApplicationClassNameMapper` MID Server script include is configured with a subset of the most common application tables available for Discovery and Service Mapping. A user with the agent_admin role can edit this script include to add additional CI tables that credential-less application Discovery can use for mapping to a derived application CI class.

Shown in this table are examples of close matches returned by Nmap on a test system that `CMDB Identification and Reconciliation` was able to resolve into defined products. In many cases, the service name returned by Nmap was not needed to determine a match. Service names that appear in the table were required to determine a match.

Products returned by Nmap that cannot be resolved into defined Discovery products use the following naming format: `<serviceProduct>:<serviceExtrainfo>:<serviceName>`. If any value in this string is null, it is dropped from the name.

- **serviceProduct**: Service product information returned by Nmap.
- **serviceExtrainfo**: Any additional information that Nmap returns about the application that might help identify it, such as protocol information.
- **serviceName**: The installed name of the service or daemon of the product.

**Examples of close matches that were resolved**

<table>
<thead>
<tr>
<th>Service product</th>
<th>Service name</th>
<th>Service extra information</th>
<th>Discovered product</th>
<th>CI application table</th>
</tr>
</thead>
<tbody>
<tr>
<td>Apache Tomcat/ Coyote JSP engine 1.1</td>

Actions on selected rows...
Nmap commands and data collected with credential-less Discovery
Nmap executes in phases when collecting data and runs a controlled set of safe commands with two patterns for exploring applications and devices.

Data returned by Nmap from host Discovery
Nmap returns the following data for a host it determines is up:

- **Operating system family**: If the operating system family is one of the six supported server operating system families, then a host CI associated with the appropriate server class is used to create or update the host CI. If the operating system family returned by Nmap is not one of the supported server operating systems, then a host CI is created or updated using the base Hardware (cmdb_ci_hardware) class.

- **MAC address**: If the scanned host is located on the same subnet as the Windows MID Server host that is executing the Nmap commands, then Nmap returns the remote host's MAC address.

Commands run by Nmap during host Discovery
The MID Server passes the IP address of a remote host to the Nmap command and a set of ports, taken from the IP Service table. The host must be reported by Nmap to be up. The host is up if the port state returned by Nmap is **open** or **open/filtered**. If the host is reported to be up, then the operating system family returned is examined to determine the class used to create or update the host CI.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
</table>
| -PS     | TCP SYN option determines if the host is online. This option that sends an empty, raw TCP packet with the SYN flag set to all the specified ports on the scan list. Nmap reports the host is online if a SYN/ACK TCP packet is returned and if an RST is returned, indicating that the port is closed. The Nmap host machine tears down the nascent connection with an RST, instead of an ACK, since the SYN/ACK response is unexpected from its perspective. If multiple port probes are specified, they are sent in parallel. Requirements:  
  - Raw packet privileges.  
  - Must run as root on UNIX.  
  - Administrator privileges on Windows. |
<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
</table>
| -PA     | Detects packet-filtering devices. This option is a TCP ACK host Discovery, using a specified list of ports. If no list is defined, the default port 80 is used. Nmap sends an empty, raw TCP packet with the ACK flag set. This action acknowledges data over an established TCP connection, causing the remote host to respond with an RST packet. If the remote host does respond with an RST packet, Nmap knows the host is online. The ACK ping probe may get past packet filtering of TCP SYN packets by stateless packet filtering, network entities, such as firewalls, routers, and host routing tables/firewall software. Stateful firewalls drop unexpected packets, causing the ACK packet to be dropped, which increases the likelihood of the SYN TCP probe getting through. Requirements:  
  - Raw packet privileges.  
  - Must run as root on UNIX.  
  - Administrator privileges on Windows.  

  **Note:** Both Ping SYN (-PS) and Ping ACK (-PA) packets types can be configured together in the same scan attempt. |
| -O      | Enables OS detection against a remote host providing the vendor name, underlying OS, OS generation, and device type, such as a router or a switch.  
  Nmap uses TCP/IP stack fingerprinting to determine the OS family running on the host. Nmap sends a series of TCP and UDP packets to the host and examines the responses. After testing the responses thoroughly, Nmap compares results to its `nmap-os-db` database and prints the OS details, if there is a match. If Nmap is not able to guess the OS, and at least one open port and one closed port were found, then it generates a fingerprint and a URL to submit to `nmap.org`.  
  OS detection does not use scripts from the Nmap Scripting Engine (NSE). OS detection runs after Application/Service Version detection, which helps the accuracy of OS Detection. However, the results of the two scan types might be contradictory. OS Detection runs at the TCP transport layer, while Application/Service Version Detection runs at a higher level in the TCP stack.  
  Requirements:  
  - Raw packet privileges.  
  - Must run as root on UNIX.  
  - Administrator privileges on Windows. |
<p>| -p      | List of ports to scan. |
| -T4     | Nmap aggressive timing template. |
| -v      | Enable verbose detail. This command is normally used to provide progress indication to viewers of standard output. However, it can cause the Nmap Scripting Engine (NSE) scripts to provide additional detail. |
| -Pn     | Disable the default ping. This command skips the initial Nmap host discovery scan phase and treats all hosts as if they are online. Use this command if you want a port scan even if the set of ports run by the default Discovery probes will not find an open port. |
| -r      | Scan ports consecutively, without randomizing. |
| --reason | Explains why Nmap classified a port with a specific state. |</p>

**Data returned by Nmap during application Discovery**

Nmap returns the following application data from a host it determines is up:

- **Port state:**
  - **open**: An application is actively accepting TCP (or UDP) packets on the port.
  - **open|filtered**: Nmap cannot determine if the port is open or filtered. An open port may not return a response when using Nmap’s UDP, IP protocol, FIN, NULL and Xmas scans.

- **Service name**: Name of the service actively accepting TCP (or UDP) packets on the service port.

- **Service product**: Name of the application running on the open port, as identified by Nmap.

- **Extra service information**: Any additional information returned by Nmap that Discovery can use to identify the application.

**Commands run by Nmap during application Discovery**

The MID Server passes one IP address for a remote host to the Nmap command and one port to scan. Nmap attempts to identify the application actively listening on the port and then determines whether it should create a new CI or update an existing one. The host must be reported by Nmap to be up.

Nmap uses this information to determine which course to take:

- Service product
- Service name
- Extra service information
- State of the scanned port

**Note**: The service product and service name values cannot be NULL, and the service name cannot end with a question mark. Nmap appends a question mark to a service name when it guesses at the application listening on the scanned port. The instance does not create or update an application CI if Nmap cannot retrieve the application name from its static nmap-services registry file.
**Command** | **Description**
---|---
-sS | TCP SYN (stealth) port scan. This is the default scan option and never completes TCP connections. Scans can differentiate between ports that are open, closed, or filtered.

TCP SYN scan implements a half-open reset that aborts the request before the connection can be established. The port is open (the application is listening) if a SYN/ACK is returned. The port is closed if an RST is returned. If no response is received after multiple retransmissions, the port is marked filtered. The port is also marked filtered if an ICMP unreachable error (type 3, code 1,2,3,9,10,13) is received.

Requirements:
- Raw packet privileges
- Must run as root
- Windows administrator privileges

-sV | Probes open ports to determine the service protocol, application name, version number, hostname, device type, OS Family and miscellaneous details such as the SSH protocol version.

When Nmap receives a response it cannot match to the database it prints out a fingerprint and URL for submission to nmap.org. It looks for the port number in its static nmap-services registry file to determine the name of an application service that might be actively listening on the port.

The service name returned by Nmap is appended with a question mark, indicating that Nmap had to guess at its identity. The instance does not create or update an application CI when Nmap guesses at the application running on an open port.

**Note:** This command does not require raw-packet privileges.

--datadir | Path to the directory containing the safe set of Nmap scripts to be run during Application/Version detection.

-p | Single port to scan.

-T4 | Nmap aggressive timing template.

-v | Enable verbose detail. This command is normally used to provide progress indication to viewers of standard output. However, it can cause the Nmap Scripting Engine (NSE) scripts to provide additional detail.

-Pn | Disable the default ping. This command skips the initial Nmap host discovery scan phase and treats all hosts as if they are online. Use this command if you want a port scan even if the set of ports run by the default Discovery probes will not find an open port.

-r | Scan ports consecutively, without randomizing.

--reason | Explains why Nmap classified a port with a specific state.

--system-dns | Use the DNS resolver of the operating system for reverse DNS lookup, rather than the DNS name servers. This option is slower than using DNS servers, since it can only resolve one IP address at a time, while multiple rDNS requests are performed in parallel. However, the value returned matches the value returned by the MID Server that is used to create host CIs.

-X | Redirects stdout to a XML file.

2> <file-path> | Redirects errors messages written by Nmap to stderr to the specified file.
PowerShell for Discovery and Service Mapping

MID Servers use PowerShell and PowerShell Remoting for accessing configuration items (CIs) during horizontal and top-down discovery. Review MID Server parameters and script includes, probe parameters, and credentials for using PowerShell.

PowerShell is used to control and automate the administration of Windows servers and applications.

MID Servers can use PowerShell to directly communicate with Windows servers using both WMI and WinRM protocols. For Windows services using the WinRM protocol, the PowerShell process establishes a secure PSSession (PowerShell Remoting session) that stays open until the MID Server finishes querying a Windows server. For Windows servers using the WMI protocol, the PowerShell process sends every PowerShell command with credentials.

As default, MID Servers use a WMI (Windows Management Instrumentation) Collector service that helps MID Servers to communicate with Windows servers. Patterns used to discover Windows servers or applications running on them, contain WMI and WinRM queries and commands to run on Windows servers. A WMI Collector service transfers WMI and WinRM queries and commands from the MID Server to Windows-based CIs and brings the results of the queries to the MID Server.

PowerShell is also the preferred method for performing discovery over multiple Windows domains. PowerShell allows a single MID Server to authenticate on servers on different domains using credentials stored on the instance.

If you do not configure MID Servers to use PowerShell and PowerShell Remoting, MID Servers use WMI Collector.

How PowerShell Discovery Works

The following descriptions explain how MID Servers use PowerShell to deploy probes.

Probe and sensor

When a Windows machine is classified with PowerShell, and an MSSQL instance is detected, a probe called Windows - MSSQL is launched. The probe returns the SQL database catalogs and version to a matching sensor.

Probe parameter

The WMI_ActiveConnections.ps1 probe parameter contains a script that runs netstat.exe on a target server when PowerShell is enabled. This script extracts the information on Windows server connections, such as process IDs, ports, and IP addresses.

Credentials

Discovery uses Windows PowerShell credentials from the Credentials (discovery_credentials) table or the domain administrator credentials of the MID Server service. If Discovery cannot find PowerShell credentials in the Credentials table of the type, Windows), it uses the login credentials of the MID Server service.

MID Server Script Includes

The following script includes were added for PowerShell discoveries. These scripts run on the MID Server to generate the scripts that Discovery uses for WMIRunner and PowerShell.

- GenerateWMIScriptJS: Generates a Javascript script for the WMIRunner probe.
- GenerateWMIScriptPS1: Generates a PowerShell script for PowerShell discovery.
MID Server parameters for PowerShell

Optional parameters for the MID Server can be found at [MID Server parameters for PowerShell](#). After changing the setting for any parameter, be sure to restart the MID Server service.

PowerShell version requirements

MID Servers using PowerShell must be installed on a supported Windows operating system. ServiceNow supports these PowerShell versions:

**Version 2.0**
- Regular Discovery

**Version 3.0**
- Regular Discovery
- Application Dependency Mapping (ADM)
- File-based Discovery
- PowerShell version 3.0 does not support Windows Server 2003.

**Version 4.0**
- Regular Discovery
- Application Dependency Mapping (ADM)
- File-based Discovery

**Version 5.0**
- Regular Discovery
- Application Dependency Mapping (ADM)
- File-based Discovery

**Note:** PowerShell version 6.0 is **not** supported. Many of the cmdlets that discovery relies on have been removed from this version. For example, only cmdlets using WinRM are available for remote operations.

Windows PowerShell execution policies

Windows PowerShell has four different execution policies. Customers can set the script execution policies with their group policy settings. For more information, see the Microsoft website for [PowerShell](#) documentation.

- **Restricted:** No scripts can be run. Windows PowerShell can be used only in interactive mode.
- **AllSigned:** Only scripts signed by a trusted publisher can be run.
- **RemoteSigned:** Downloaded scripts must be signed by a trusted publisher before they can be run.
- **Unrestricted:** No restrictions; all scripts can be run.

**Note:** If you have any policy other than Unrestricted, the script needs to be signed.
Set up MID Servers to use PowerShell
Configure MID Servers in your organization to use PowerShell for horizontal and top-down discovery of Windows servers.

Role required: admin

1. Download PowerShell and install it on each MID Server configured to discover Windows computers.
2. Enable PowerShell-based discovery by setting the `mid.use_powershell` MID Server parameter to true on all the MID Servers.
3. Enable discovery using PowerShell Remoting by setting the `mid.sa.prefer_powershell` MID Server property to true on all the MID Servers.
4. Determine which credentials MID Servers use for PowerShell.
   - To discover Windows computers using credentials from the credentials table, set the `mid.powershell.use_credentials` parameter to true. Using credentials form the credentials table is the default behavior when PowerShell is enabled.
   - To force Discovery and Service Mapping to use the credentials of the MID Server service user, set the `mid.powershell.use_credentials` parameter to false on the MID Server. The MID Server service must have domain admin credentials to have access to the Windows machines in the domain.
5. Optional: If necessary, configure advanced parameters for PowerShell and PowerShell Remoting on each MID Server separately.

PowerShell remoting for Discovery
Probe developers can use the PowerShell remote execution framework to automatically handle remote execution of scripts on target devices. The unified framework removes inconsistencies in remote execution, increases efficiency, and improves stability.

Requirements
To use PowerShell remote execution framework, the following requirements must be met:
- The MID Server must be able to write to and read from the network share of the target.
- The remote target must have PowerShell 2 or higher.
- For MID Servers using WinRM or WMI which choose to copy the script to the remote target, the `MachinePolicy` and `UserPolicy` scopes must be set to Undefined. If the script is not copied, the execution policy can be any other setting up to Restrictive.

Application discovery
The PowerShell remote execution framework has options for copying files to the remote target when executing a scan. Copying files to the target is important for probes like Windows — File discovery because its script invokes itself on the remote target to spawn off a new process. MID Servers using WMI to execute scripts remotely can experience an error with launchProcess if the script is too long. Copying the script to the remote target resolves this error. Copying a script to a remote target may result in anti-virus software on the target flagging the script. To avoid issues with anti-virus software, add the scripts to the permitted list in the anti-virus app.
Probe configuration

The following is the configuration page for the Windows — Active Connections probe, which is included in the Windows — ADM multiprobe.

The **Execute script remotely** check box is visible when the ECC queue topic is WMIRunner or PowerShell. When checked, the script executes on the remote target. Otherwise the script executes on the MID Server.

The **Copy script to target** check box is visible when **Execute script remotely** is checked. If **Copy script to target** is checked, then the script is copied to, and run on, the target. If **Copy script to target** is unchecked, then the script is executed on the target without copying it.

PowerShell probe development

PowerShell remote execution framework is a unified method of executing PowerShell scripts, contained in a probe parameter, on a remote target server. The framework removes the need for probe developers to write their own remote execution code, which can cause inconsistencies between developers. The probe developer writes the script as if the probe was collecting
information locally because the remote execution framework automatically handles remote script execution.

The framework handles remote execution whether the MID Server is configured to use WMI or WinRM. If the MID Server is configured for WMI, the probe uses launchProcess to execute commands on the remote target. Using launchProcess complicates remote execution and can cause failures. However, a MID Server configured for WinRM does not use launchProcess, and so is more efficient and stable.

**PowerShell commands run by Discovery**

These are the PowerShell cmdlets and their parameters that Discovery runs to control and automate the administration of Windows servers and applications. Included are the probe parameters and MID Server scripts that contain the commands.

</table>
| **New-Variable**  | Creates a new variable in Windows PowerShell. You can assign a value to the variable while creating it or assign or change the value after it is created.  
**MID Server script**  
PSScript.ps1 |
| **New-PSSession** | Creates a Windows PowerShell session (PSSession) on a local or remote computer. When you create a PSSession, Windows PowerShell establishes a persistent connection to the remote computer.  
**MID Server script**  
PSRemoteSession.psm1 |
| **New-PSSessionOption** | Creates an object that contains advanced options for a user-managed session. You can use the object as the value of the SessionOption parameter of cmdlets that create a PSSession, such as a New-PSSession, Enter-PSSession, and Invoke-Command.  
**MID Server script**  
PSRemoteSession.psm1 |
| **New-Timespan**  | Creates a timespan object which represents an interval. You can use to add or subtract time from a DateTime object.  
**Probes**  
Windows - File Discovery (filebaseddiscovery.ps1) |
| **Out-File**      | Sends output to a file. You can use this instead of > operator when you need to use its parameters.  
**Probes**  
Windows - File Discovery (filebaseddiscovery.ps1) |
| **Out-Null**      | Sends output to NULL, in effect, deleting it.  
**MID Server script**  
Get-PEB.psm1 |
| **Out-String**    | Converts the objects that Windows PowerShell manages into an array of strings. By default, Out-String accumulates the strings and returns them as a single string, but you can use the stream parameter to direct Out-String to return one string at a time. This cmdlet lets you search and manipulate string output as you would in traditional shells when object manipulation is less convenient.  
**MID Server script**  
Get-PEB.psm1 |

### MID Server parameters for PowerShell

Parameters control the behavior of a particular MID Server and have lower precedence than MID Server properties.

The following parameters are optional.

**Note:** After changing the setting for any parameter, be sure to restart the MID Server service.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mid.monitoring.force_sigar_cpu_monitoring</td>
<td>Enables CPU monitoring on Windows MID Server hosts using Java 11. An outdated SIGAR library causes the MID Server to crash. If you patch the SIGAR library, set this value to True to enable CPU Monitoring for Windows with Java 11.</td>
</tr>
<tr>
<td>· Type: True</td>
<td>False</td>
</tr>
<tr>
<td>· Default value: false</td>
<td></td>
</tr>
<tr>
<td>mid.powershell_api.session_pool.max_size</td>
<td>Specifies the maximum number of sessions allowed in the session pool.</td>
</tr>
<tr>
<td><strong>Note:</strong> Setting or changing this parameter requires restarting the MID Server.</td>
<td></td>
</tr>
<tr>
<td>· Type: Integer</td>
<td></td>

<tr>
<td></td>
<td>• Type: True</td>
</tr>
<tr>
<td></td>
<td>• Default value: false</td>
</tr>
<tr>
<td>mid.powershell_api.winrm.skip_ssl_cert_check_options</td>
<td>Skips specific SSL certificate checks when using WinRM for HTTPS connections. Configure the MID Server to skip checks for certificates from a Certification Authority (CA), from the Common Name (CN) that identifies the host associated with the certificate, and for revoked certificates.</td>
</tr>
<tr>
<td></td>
<td>• Type: String</td>
</tr>
<tr>
<td></td>
<td>• Default value: -SkipCACheck -SkipCNCheck -SkipRevocationCheck</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>mid.powershell.use_credentials</td>
<td>Determines the credentials to use for Discovery with PowerShell. A setting of true directs the MID Server to run probes with the Windows credentials from the credentials table. To run probes with the credentials of the user for the MID Server service, set this parameter to false.</td>
</tr>
<tr>
<td></td>
<td>• Type: true</td>
</tr>
<tr>
<td></td>
<td>• Default value: true</td>
</tr>
<tr>
<td>mid.use_powershell</td>
<td>Enables or disables PowerShell for Discovery. Restart the MID Server after changing the value. If PowerShell is not installed or the version installed is less than version 2.0, Discovery reverts to using WMIRunner.</td>
</tr>
<tr>
<td></td>
<td>• Type: true</td>
</tr>
<tr>
<td></td>
<td>• Default value: true, in the Fuji release.</td>
</tr>
<tr>
<td></td>
<td>• Default value: false, in releases prior to Fuji.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>mid.powershell.path</td>
<td>Enables an administrator to point to a specific PowerShell on a MID Server in cases where more than one PowerShell is installed. Supply the path to the folder containing the PowerShell executable, for example, C:\mypowershell or C:\mypowershell\ServiceNow automatically appends the string powershell.exe to the path. Configure this parameter when both a 32-bit and 64-bit PowerShells are active on the same MID Server, and it becomes necessary to launch the correct PowerShell for the context. 64-bit Windows employs file system redirection and the MID Server runs as a 32-bit application. If trying to specify a path in %WinDir%\System32, Windows automatically redirects to %WinDir%\SysWOW64. To avoid redirection, specify the path as %WinDir%\Sysnative. For example, instead of C:\WINDOWS\system32\WindowsPowerShell\v1.0, specify C:\WINDOWS\sysnative\WindowsPowerShell\v1.0. Note: On a 64-bit version of Windows XP, a Microsoft hotfix may be required to enable this. To discover applications running on a 64-bit Windows machine, the MID Server must be running on a 64-bit Windows host machine.</td>
</tr>
<tr>
<td>mid.powershell.enforce_utf8</td>
<td>Enable this parameter to force commands on a target Windows system to return UTF-8 encoded output. Disabling it allows the target system to use its default encoding. This parameter is only valid when PowerShell is enabled. Setting this value to false may result in incorrect values in the CMDB when non-ASCII characters are returned by a probe.</td>
</tr>
<tr>
<td></td>
<td>· Type: string (path)</td>
</tr>
<tr>
<td></td>
<td>· Default value: none</td>
</tr>
<tr>
<td></td>
<td>· Type: true</td>
</tr>
<tr>
<td></td>
<td>· Default value: true</td>
</tr>
</tbody>
</table>
### Application Dependency Mapping (ADM) for Discovery

Application Dependency Mapping (ADM) discovers CIs by detecting TCP connections between devices.
When ADM discovery is enabled, Discovery always runs the ADM probes during the exploration stage to find the TCP traffic on your network. Using these TCP connections, Discovery can find additional CIs and create relationships between them.

**Standard and enhanced ADM discovery**

**Standard ADM discovery**

Triggers an ADM probe to take a single snapshot of TCP connections on target machines using `netstat` and `lsof` commands. However, it does not detect new TCP connections that occur between these 24-hour intervals.

Standard ADM discovery is enabled by default.

**Enhanced ADM discovery**

Triggers an enhanced ADM probe that installs a script on host machines on which Discovery takes regular samples of active TCP connections. You can use a set of properties and probe parameters that control several aspects of enhanced ADM discovery.

Enhanced ADM discovery is not enabled by default.

Service Mapping uses the ADM probes for traffic-based discovery. See [Traffic-based discovery in Service Mapping](#) for more information.

**Requirements**

Both standard and enhanced ADM discovery support the following operating systems:

- Windows
- Unix
- Solaris (On Solaris machines, enhanced ADM is available in global zones. Only standard ADM is available for local zones.)
- AIX
- HP-UX

To use the WMI protocol, **version 3.0 of PowerShell** is required.

**TCP tracking file for enhanced ADM**

The first time that Discovery launches the enhanced probe, no TCP information is gathered. Rather, the enhanced probe only deploys the TCP tracking file, in which information about detected TCP connections is saved. After Discovery runs again, the enhanced probe relays the contents of the TCP tracking file back to the instance via the MID Server. The information is saved in the CMDB.

The TCP tracking file is saved in these locations by default:

- **Windows**: `admin$\temp\{your_instance_name}`. While TCP connections are being monitored, the information is stored in memory and then later saved to the file.
- **Linux**: `/tmp/{your_instance_name}`.

You can change the location and other aspects of the tracking file with ADM properties. If you disable enhanced ADM, Discovery cleans up the folders from the host file system the next time Discovery runs, but the TCP tracking file remains.
Requirements for Enhanced ADM on Linux machines

Modify the sudoers file to include these commands:

**Windows**
- Utility tool support: netstat
- Required sudoer commands: None
- Additional requirements: None

**AIX**
- Utility tool support:
  - netstat
  - lsof (if netstat does not work)
- Required sudoer commands:
  - `Cmd_Alias ADME_CMDS=/usr/bin/netstat -Aan, /usr/sbin/lsof -iTCP -n -P`
  - `discoUser ALL=(root) NOPASSWD:ADME_CMDS`
  - `Defaults:discoUser ! requiretty`
- Additional requirements: None

**Solaris**
- Utility tool support:
  - netstat (for Solaris version 11.2)
  - lsof (for Solaris versions prior to 11.2)
- Required sudoer commands:
  - `Cmd_Alias ADME_CMDS = /usr/bin/netstat,/opt/csw/bin/lsof -iTCP -n -P -zglobal`
  - `discoUser ALL=(root) NOPASSWD:ADME_CMDS`
  - `Defaults!ADME_CMDS !requiretty`
  - `Cmd_Alias ADME_PS = /usr/ucb/ps`
  - `discoUser ALL=(root) NOPASSWD:ADME_PS`
  - `Defaults!ADME_PS !requiretty`

- **Note:** You must add `-zglobal` for lsof to run.

- Additional requirements: Add the lsof path to the secure path. For example, if the path to lsof is `/opt/csw/bin`, the secure path should be `secure_path = /usr/bin:/usr/sbin:/bin:/sbin:/opt/csw/bin`

- **Note:** The commands with `PS` apply to standard ADM as well as enhanced ADM.

**HP UX**
- Utility tool support: lsof
- Required sudoer commands:
  - `Cmd_Alias ADME_CMDS = /usr/local/bin/lsof -iTCP -n -P`
**What to do (enhanced ADM)**

To set up and use enhanced ADM, perform these steps:

1. *Enable enhanced ADM with the glide.discovery.enable_adme Discovery property.*
2. Determine the base directory where the TCP tracking file is placed on the host computers. If you want to change the location, *specify it in these Discovery properties:*
   - glide.discovery.adme.base_dir_unix
   - glide.discovery.adme.base_dir_windows
3. Do either of the following based on the operating systems of the host computers:
   - Linux: *modify the sudoers file* to include the necessary commands.
   - Windows: Set the mid.windows.management_protocol parameter on the MID Server to use WinRM or WMI. This parameter sets the protocol that your MID Server uses to communicate with remote Windows hosts.
4. *Create a schedule and run Discovery.*
5. *View the results in the TCP tables.*
6. Optionally control both the size of the TCP tracking file and the payload using parameters on the enhanced ADM probes. See *TCP connection discovery* for the names of the probes and parameters.

**Configure ADM discovery parameters and properties**

Using properties, you can enable or disable ADM discovery, and you can set the location of the TCP tracking file for enhanced ADM.

Role required: admin

---

**Centos and Ubuntu**

- **Utility tool support:** None
- **Required sudoer commands:**
  - Cmnd_Alias ADME_CMDS = /usr/sbin/lsof -iTCP -n -P, /usr/bin/netstat -antp
  - discoUser ALL=(root) NOPASSWD:ADME_CMDS
  - Defaults!ADME_CMDS !requiretty
- **Additional requirements:** None

Note the following for the sudo commands:

- ADME_CMDS is a variable referring to a list of commands.
- /usr/bin/ is the directory where your lsof and netstat resides.
- discoUser is a user that must have root access.

---

**Note:** Netstat is not supported.
You can also control both the size of the TCP tracking file and the payload using parameters on
the enhanced ADM probes. See TCP connection discovery for the names of the probes and
parameters.

1. Navigate to System Properties > Discovery.
2. Configure the following properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Type</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.discovery.enable_adme</td>
<td>ADME: Enable enhanced ADM probe. If “yes”, the ADM Enhanced probe will be triggered and only fall back to the ADM probe as needed.</td>
<td>true</td>
<td>false</td>
</tr>
<tr>
<td>glide.discovery.application_mapping</td>
<td>Enable the application mapping feature. When this property is set to true, all discoveries trigger the relevant ADM probe during the exploration phase if Discovery finds a server.</td>
<td>true</td>
<td>true</td>
</tr>
<tr>
<td>glide.discovery.adme.sampling_interval</td>
<td>ADME - Sampling interval (sec): How often to sample process and connection data in seconds. Must be a minimum of 5 seconds.</td>
<td>integer</td>
<td>120</td>
</tr>
<tr>
<td>glide.discovery.adme.base_dir_unix</td>
<td>ADME: Unix Base Dir: An existing directory on the target Unix machines to be used as a workspace. Must be an absolute path to the directory. The UNIX and Linux credentials that you use to connect to the device must also be able to access this folder.</td>
<td>string</td>
<td>/tmp</td>
</tr>
<tr>
<td>glide.discovery.adme.base_dir_windows</td>
<td>ADME: Windows Base Dir: A network share on the target Windows machines to be used as a workspace. If you change the directory, it must also be a network shared folder.</td>
<td>string</td>
<td>admin$\temp</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
<td></td>
<td></td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| glide.discovery.adme.aggregation_interval | ADME - Aggregation interval (sec): How often to aggregate instantaneous data into chunks in seconds. It must be a minimum of 60 seconds and it must be a multiple of ADME Sampling interval.  
  - **Type**: integer  
  - **Default value**: 3600 |
| glide.discovery.adme.rolling_window_size | ADME - Rolling window size: How many recently aggregated chunks to keep. An aggregated chunk consists of ADME Aggregation interval divided by ADME Sampling interval samples. Only the newest chunks will be kept.  
  - **Type**: integer  
  - **Default value**: 24 |
| glide.discovery.adme.max_total_samples | ADME - Max total samples: The limit of samples being taken by the script. The script will stop running after this amount of samples are taken.  
  - **Type**: integer  
  - **Default value**: 100 |

3. **Click Save.**

**Discovery behaviors**

Discovery behaviors determine the probes that Shazzam launches, and from which MID Servers these probes are launched.

Unlike a scan performed by a single MID Server on a designated IP address range, a behavior can assign different tasks to multiple MID Servers on the same IP address segment or on different network segments. Behaviors are available in **Discovery schedules** for discoveries in which configuration items (CI) are updated in the CMDB.

Behaviors can be used in the following scenarios:

- **Load balancing**: A behavior enables load balancing in systems that use multiple MID Servers deployed across one or more domains.
- **Multiple protocols in multiple domains**: Configure one MID Server to scan for all protocols on one domain and another MID Server to perform a WMI scan on a second domain.
- **Access Control Lists (ACL)**: Discovery can scan SNMP devices protected by an ACL if the MID Server host machine is granted access by that ACL. Use a behavior to configure a MID Server to scan devices protected by an ACL.
- **Devices running two protocols**: Some devices might have two protocols running at the same time. Examples of this are the SSH and SNMP protocols running concurrently on one device (most common). A behavior can control which of the two protocols is explored for certain devices. The behavior then prevents the other protocol from being explored.
Behaviors and domain separation

Behaviors also enable the efficient Discovery of SSH and SNMP devices and WMI devices running on multiple Windows domains, using multiple MID Servers.

For example, an organization has two Windows domains in its network and a variety of UNIX computers and SNMP devices. The challenge is to discover all the devices efficiently, without duplicating effort. Each domain contains a Windows MID Server which is used to scan the IP addresses from the two domains specified in the Discovery Schedule, as well as the SSH and SNMP devices. We need a Behavior that divides the work appropriately to avoid scanning anything twice. In this example, we assume that both domains are in the same geographical location, and that a single schedule is sufficient.

Note: The preferred method for running Discovery over multiple Windows domains is to use PowerShell, which allows a single MID Server to authenticate on machines on different domains using credentials stored on the instance.

Create a Discovery behavior

Create a Discovery behavior to determine which probes Shazzam launches and which MID Server is used.

Role required: discovery_admin

1. Navigate to Discovery Definition > Behavior and click New.
2. Enter a name.
3. Right-click the form header and select Save.
4. In the Discovery Functionality related list, click **New**.
   Discovery Functionality defines what each MID Server in this behavior must do, specifically which protocols to detect.

5. Fill out the form fields:
### Field | Description
--- | ---
**Phase** | Enter an integer that represents an arbitrary phase. The phase is used to group one or more functionalities together. All the functionalities within a specified phase are executed together, and all phases are executed in numerical order. All functionalities in a behavior can have the same phase.

The Shazzam probe runs once for each phase in a behavior, which makes fewer phases desirable. Run multiple phases for behaviors only when devices in the network are running multiple protocols, such as SSH and SNMP. In that example, set one phase for the SSH scan and another phase for the SNMP scan.

**Active** | Keep this option selected to apply the discovery functionality.

**Functionality definition** | Click the lookup icon, and then select a pre-configured functionality that defines the protocol or list of protocols that each MID Server scans.

**Match criteria** | Define criteria here for Windows MID Servers.

**MID Servers** | Select one or more MID Servers to perform this functionality for the following Discovery types:
- IP Scan
- CI Scan

Discovery automatically balances the load when multiple MID Servers are selected.

---

6. Right-click the form header and select **Save**.

7. To add criteria that the functionality must meet in order to be triggered, click **New** in the Functionality Criteria related list, fill out the form fields, and then click **Submit**.

### Field | Input Value
--- | ---
**Name** | The name in the criteria is the variable that passes the following information:
- `mid_server`: MID Server that processes the results from the Shazzam probe.
- `win_domain`: Windows domain of the target device.

**Operator** | Select a logical operator.
Enter the actual name of the MID Server (\texttt{mid	extunderscore server}) or domain (\texttt{win	extunderscore domain}) to pass to Discovery for this criteria. This field can also have a value of \texttt{mid	extunderscore domain}, which defines the Windows domain of the MID Server that is processing the Shazzam results.

\textbf{Note:} Functionality criteria are required for Windows MID Servers only, and only when the behavior controls Discovery across multiple domains. When the instance launches the Shazzam probe for a Discovery in which a behavior defines multiple MID Servers to scan multiple domains, the functionality criteria determine which MID Server process the results of the probe.

The following graphic shows an example of functionality criteria.

\textit{Create a Discovery Schedule} of type \textbf{Configuration Item}, and select \textbf{Use Behavior} for the MID Server selection method.

\textit{Set up a load balancing behavior}

When multiple MID Servers are configured to scan the same protocol, users can set up a load balancing behavior to automatically balance the work between the MID Servers.

Behaviors enable load balancing when multiple MID Servers are configured to scan the same protocol. For example, an organization has fifty remote locations, varying in size from 10 devices to several hundred devices. All the satellite offices are part of the same Windows domain, which is administered from a central location. There are three MID Servers installed at this central location: two to scan all the Windows devices and one to scan the remaining devices. Because some of the remote offices are in different time zones, different schedules must be created to run Discovery at off-peak hours in each time zone. The same behavior can be used for each schedule, and the behavior will load-balance the two Windows MID Servers automatically.

1. Create the behavior record.
   a) Create a new Discovery behavior record, and name it something descriptive, such as \texttt{LoadBalanced}.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
b) Right-click in the header bar and select **Save** from the pop-up menu.

   This action saves the record and creates the Discovery Functionality related list in the form.

2. Define the Windows functionality.
   a) Click **New** in the Discovery Functionality related list.
   b) Create a new record using the fields described here.
   c) Right-click in the header bar and select **Save** from the pop-up menu.

<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Phase</td>
<td>Type a phase number of 1 in this field.</td>
</tr>
<tr>
<td>Functionality</td>
<td>Select Windows only (WMI) from the list. This functionality defines the protocol that will be scanned. Because we selected to scan WMI, we must select Windows MID Servers for this functionality.</td>
</tr>
<tr>
<td>MID Servers</td>
<td>We select the two MID Servers that we want to share the load for the WMI probes. By entering multiple MID Servers in this field, we tell Discovery to balance the load between these servers automatically. If we were to create separate functionality for each server, load balancing would not occur.</td>
</tr>
<tr>
<td>Active</td>
<td>Make sure this check box is selected to enable this behavior.</td>
</tr>
<tr>
<td>Match criteria</td>
<td>Leave the default criteria of Any.</td>
</tr>
</tbody>
</table>
3. Create Functionality Criteria.

**Note:** All Windows functionality requires criteria to identify the Windows domain and define any special behavior for the MID Servers named.

a) Click **New** in the related list.

b) Enter the following values:

<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>We enter <code>win_domain</code> to name the Windows domain that Discovery will scan with the MID Servers we have defined.</td>
</tr>
<tr>
<td>Field</td>
<td>Input Value</td>
</tr>
<tr>
<td>---------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Operator</td>
<td>Select equals as the operator in this criteria.</td>
</tr>
<tr>
<td>Value</td>
<td>This is the name of the Windows domain that these MID Servers will scan for devices.</td>
</tr>
<tr>
<td>Active</td>
<td>Be sure to enable the criteria by selecting this check box (true).</td>
</tr>
</tbody>
</table>

The completed criteria appear in the Discovery Functionality form for the Windows MID Servers.
4. Define the functionality for the remaining scans.

Create a second record to scan for all the remaining protocols (SSH, SNMP, etc), using the following settings:
<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Phase</td>
<td>Type a phase number of 1 in this field. This phase will be executed at the same time as the WMI scans and with the same Shazzam probe. We use the same phase number for efficiency and because we know that none of the devices in the target IP ranges are running multiple protocols (e.g. SSH and SNMP). If any devices were running multiple protocols, we would want to specify a second or even a third phase to discover the correct protocol first for each device.</td>
</tr>
<tr>
<td>Functionality</td>
<td>Select All except Windows (no WMI) from the list. This functionality causes the MID Server to scan all remaining protocols after Discovery has run the WMI scans.</td>
</tr>
<tr>
<td>MID Servers</td>
<td>Name the MID Server that will scan for all other devices. If we want to use automatic load balancing, we can add an additional MID Server to this field.</td>
</tr>
</tbody>
</table>

The completed Discovery Behavior form looks like this. It is not necessary to create Functionality Criteria for this MID Server.
5. Create a **Discovery schedule** for each time zone and name the behavior we just created.
   a) Navigate to **Discovery** > **Discovery Schedules** and click **New** in the record list.
   b) Select a **Discover** type of Configuration items.
      This action displays the Behavior field.
   c) Click the magnifier icon and select the behavior to use. In our example, we select **LoadBalanced**.
   d) Select the appropriate time to run Discovery for this location.
e) Click **Quick Ranges** and define the IP address ranges, networks, or lists to scan for this location.

f) Save the record.

g) Create additional schedules for each time zone or region in the network and select the same behavior.
### Discovery Schedule

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>My Disco Schedule</td>
</tr>
<tr>
<td>Discover</td>
<td>Configuration Items</td>
</tr>
<tr>
<td>NIS Server selection method</td>
<td>Auto-Select NIS Server</td>
</tr>
<tr>
<td>Max run time</td>
<td>Days: 0, Hours: 10, 00, 00</td>
</tr>
<tr>
<td>Run</td>
<td>Weekly</td>
</tr>
<tr>
<td>Day (run, day, week)</td>
<td>Monday</td>
</tr>
<tr>
<td>Time</td>
<td>Hours: 02, 00, 00</td>
</tr>
</tbody>
</table>

### Advanced

- Include alive: **on**
- Shazzam batch size: 1,000
- Log state changes: **on**
- Shazzam cluster support: **on**
- Use SNMP version: 1.3.6.1.2.

Examples of Discovery behavior functionalities
This example of a Discovery behavior requires three functionalities for the behavior.

We will create three functionalities for this Behavior: one MID Server to scan Domain A for Windows devices only; a second functionality for the same MID Server to scan for all SSH and SNMP devices; and a third functionality that names a second MID Server to scan Domain B for Windows devices. The rationale for this is as follows:

- A Windows MID Server can only discover Windows machines on the Windows domain to which it is joined. This is entirely due to the way Windows authentication works. For this reason, we need a WMI functionality for each domain.
- A Windows MID Server, provided with the correct credentials, can discover SSH and SNMP devices anywhere; however, we cannot combine WMI, SSH, and SNMP functionalities across Windows domains. This is because the functionality criteria for the WMI scans locks in the Discovery to one specific domain. For this reason, SSH and SNMP discoveries require a separate functionality.
- We want to scan each machine only once.

Functionality 1: WMI Scanning on Domain A

We configure a MID Server to scan for the WMI protocol on Domain A. WMI scans authenticate on Windows machines using the domain credentials of the Windows MID Server machine. Windows MID Servers cannot scan for the WMI protocol outside their own domains.

Create the first functionality using the following values:

<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Phase</td>
<td>Type a phase number of 1 in this field. All functionalities in this example use the same phase number, which launches a single Shazzam probe for all the functionalities in that phase. A single phase, when feasible, is the most efficient use of the Shazzam probe.</td>
</tr>
<tr>
<td>Functionality</td>
<td>Select Windows, DNS, and WINS from the list. This functionality defines the WMI protocol that will be scanned and resolves the domain. Because we selected to scan for WMI, we must select a Windows MID Server for this functionality.</td>
</tr>
<tr>
<td>MID Servers</td>
<td>We select a Windows MID Server from Domain A - in this case sandb01-358.</td>
</tr>
<tr>
<td>Active</td>
<td>Make sure this check box is selected to enable this behavior.</td>
</tr>
<tr>
<td>Match criteria</td>
<td>Change the criteria to All.</td>
</tr>
</tbody>
</table>

Create Functionality Criteria

All Windows functionality requires criteria to identify the domain and the MID Server. In our example, we will create two criteria for this functionality. To create Functionality Criteria, click New in the Related List and enter the following values for the MID Server doing the WMI scanning on Domain A:
Create the following criteria:

- Enter `mid_server` to name the MID Server that will execute the WMI scans on Domain A.
- Enter `win_domain` to name the Windows domain that Discovery will scan with the MID Server defined.

**Operator**

Select **equals** as the operator in this criteria.

**Value**

- For the `mid_server` value, enter the name of the MID Server that will scan Domain A for Windows devices.
- For the `win_domain` value, enter the name of Domain A that this MID Server will scan for Windows devices.

Be sure to enable the criteria by selecting this check box (true).

The completed criteria appear in the Discovery Functionality form for this behavior.

**Functionality 2: SSH and SNMP**

In our network, we want to scan for UNIX computers and netgear, but we don’t want to classify these devices twice. One of our MID Servers will be configured to classify SSH and SNMP using a different functionality than it does for WMI scans. We do not need to create criteria for non-WMI functionality.

Create the second functionality using the following values:

<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Phase</td>
<td>Type a phase number of 1 in this field. All functionalities in this example use the same phase number, which launches a single Shazzam probe for all the functionalities in that phase. A single phase, when feasible, is the most efficient use of the Shazzam probe.</td>
</tr>
<tr>
<td>Functionality</td>
<td>Select <strong>All except Windows (no WMI)</strong> from the list. This functionality will scan SSH and SNMP protocols only.</td>
</tr>
<tr>
<td>MID Servers</td>
<td>We select the MID Server from Domain A - in this case <strong>sandb01-358</strong>.</td>
</tr>
<tr>
<td>Active</td>
<td>Make sure this check box is selected to enable this behavior.</td>
</tr>
<tr>
<td>Match criteria</td>
<td>Leave the default criteria of Any. Criteria are not used for non-WMI functionalities.</td>
</tr>
</tbody>
</table>
Functionality 3: WMI Scanning on Domain B

All that remains is to create a functionality for the WMI scans on Domain B. Because of the Windows authentication mechanism, we must configure a Windows MID Server to scan Domain B that is a member of that domain.

Create the third functionality using the following values:

<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Phase</td>
<td>Type a phase number of 1 in this field. All functionalities in this example use the same phase number, which launches a single Shazzam probe for all the functionalities in that phase. A single phase, when feasible, is the most efficient use of the Shazzam probe.</td>
</tr>
<tr>
<td>Functionality</td>
<td>Select Windows, DNS, and WINS from the list. This functionality defines the WMI protocol that will be scanned and resolves the domain. Because we selected to scan for WMI, we must select a Windows MID Server for this functionality.</td>
</tr>
<tr>
<td>MID Servers</td>
<td>We select a Windows MID Server from Domain B - in this case disco-win2003.</td>
</tr>
<tr>
<td>Active</td>
<td>Make sure this check box is selected to enable this behavior.</td>
</tr>
<tr>
<td>Match criteria</td>
<td>Change the criteria to All.</td>
</tr>
</tbody>
</table>

Create Functionality Criteria

All Windows functionality requires criteria to identify the Windows domain and the MID Server. In our example, we will create two criteria for this functionality. To create Functionality Criteria, click New in the Related List and enter the following values for the MID Server doing the WMI scanning on Domain B:

<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Create the following criteria:</td>
</tr>
<tr>
<td></td>
<td>• Enter mid_server to name the MID Server that will execute the WMI scans on Domain B.</td>
</tr>
<tr>
<td></td>
<td>• Enter win_domain to name the Windows domain that Discovery will scan with the MID Server defined.</td>
</tr>
<tr>
<td>Operator</td>
<td>Select equals as the operator in this criteria.</td>
</tr>
<tr>
<td>Value</td>
<td>• For the mid_server value, enter the name of the MID Server that will scan Domain B for Windows devices.</td>
</tr>
<tr>
<td></td>
<td>• For the win_domain value, enter the name of Domain B that this MID Server will scan for Windows devices.</td>
</tr>
<tr>
<td>Active</td>
<td>Be sure to enable the criteria by selecting this check box (true).</td>
</tr>
</tbody>
</table>
The completed criteria appear in the Discovery Functionality form for this behavior.

**Discovery behavior example: access an ACL protected SNMP device**

This topic explains how to access an SNMP device protected by an ACL using a Discovery behavior.

**Role required:** admin

A specific type of Access Control List (ACL) on an SNMP device can prevent Discovery from identifying that device. This list defines host machines by IP addresses that are permitted to run agents on SNMP devices. In this example, we want to classify, identify, and update all the devices in an IP range, including the SNMP devices protected by an ACL. To do this, we must install a MID Server with access to the protected SNMP devices and then create a Behavior that allows us to scan for all protocols without missing any devices or doing any extra work.

1. **Install a MID Server on a host permitted by the ACL.**

   To scan the SNMP devices in a network protected by an ACL, a MID Server must be installed on a host machine specified by IP address in the ACL as having access to the SNMP devices. Because this MID Server is scanning SNMP devices only, it can be installed on any supported operating system. The other MID Server, configured to discover WMI and SSH, can be installed on any Windows host that has visibility to the specified IP ranges.

2. **Install additional MID Servers if you intend to configure either functionality to load balance.**

3. **Create the behavior record.**

   a) Create a new Discovery Behavior record, and name it something descriptive, such as Southwest-SNMP.

   b) Right-click in the header bar and select **Save** from the pop-up menu.

      This action saves the record and creates the Discovery Functionality related list in the form.

   c) To complete this behavior (as shown in **Figure 1**) we must create functionalities using the MID Servers we installed for that purpose.

      For the functionality that scans for the WMI protocol, we must define criteria that specify the Windows domain and MID Server being used. Because this Discovery is being performed on one Windows domain, we can configure a functionality for WMI and SSH (**All except SNMP**) using the same MID Server.

<table>
<thead>
<tr>
<th>Discovery Functionality</th>
<th>Name</th>
<th>Discovery Behavior = Southwest-SNMP</th>
</tr>
</thead>
<tbody>
<tr>
<td># Phase 1</td>
<td># MID Servers</td>
<td># Functionality</td>
</tr>
<tr>
<td>1</td>
<td>discover2003</td>
<td>All except SNMP</td>
</tr>
<tr>
<td>1</td>
<td>sassa2012_Softnet</td>
<td>SNMP only</td>
</tr>
</tbody>
</table>

**Completed Discovery Behavior**

4. **Define the functionalities.**
For this behavior, we create two functionalities, one for SNMP on the MID Server installed on the host specified in the ACL and another for WMI and SSH on a second MID Server.

a) Click **New** in the Discovery Functionality related list to add functionalities.

b) **Note:** We configure the MID Server installed on the privileged host machine to scan for the SNMP protocol only.

Create the first functionality using the following values:

<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Phase</td>
<td>Type a phase number of 1 in this field. Both functionalities in this example use the same phase number, which launches a single Shazzam probe for all the functionalities in that phase. A single phase, when feasible, is the most efficient use of the Shazzam probe.</td>
</tr>
<tr>
<td>Functionality</td>
<td>Select SNMP only from the list. This functionality defines the protocol that will be scanned.</td>
</tr>
<tr>
<td>MID Servers</td>
<td>We select a MID Server (sansol02_Solaris) installed on a Solaris host that is granted access to the SNMP devices by the ACL. You can select multiple MID Servers if you want Discovery to load balance this functionality automatically.</td>
</tr>
<tr>
<td>Active</td>
<td>Make sure this check box is selected to enable this behavior.</td>
</tr>
<tr>
<td>Match criteria</td>
<td>Leave the default criteria of Any. Criteria are not used for SNMP functionalities.</td>
</tr>
</tbody>
</table>

**Scan for SNMP Only**

c) **Note:** In the second functionality, Discovery will scan our domain for WMI and SSH protocols. Because WMI is one of the protocols, the MID Server for this functionality must be installed on a Windows machine and must have criteria.
Create the second functionality using the following values:

<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Phase</td>
<td>Type a phase number of 1 in this field. All functionalities in this example use the same phase number, which launches a single Shazzam probe for all protocol scans. A single phase, when feasible, is the most efficient use of the Shazzam probe.</td>
</tr>
<tr>
<td>Functionality</td>
<td>Select All except SNMP from the list. This functionality defines the protocols for which scanning will occur. Because WMI is one of the protocols selected, we must use a Windows MID Server for this functionality.</td>
</tr>
<tr>
<td>MID Servers</td>
<td>We select a Windows MID Server from our domain. In this case we select disco-win2003. You can select multiple MID Servers if you want Discovery to load balance this functionality automatically.</td>
</tr>
<tr>
<td>Active</td>
<td>Make sure this check box is selected to enable this behavior.</td>
</tr>
<tr>
<td>Match criteria</td>
<td>Change the criteria to All.</td>
</tr>
</tbody>
</table>

**Note:** Functionalities that scan for WMI require criteria to identify the domain and the MID Server. In our example, we will create two criteria for this functionality.

To create functionality criteria for a WMI scan, click **New** in the related list.

**e)** Enter the following values for the MID Server doing the WMI scanning on our domain:
<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Create the following criteria:</td>
<td>· Enter <code>mid_server</code> to name the MID Server that will execute the WMI scans.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>· Enter <code>win_domain</code> to name the Windows domain that Discovery will scan with the MID Server defined.</td>
</tr>
<tr>
<td>Operator</td>
<td>Select equals as the operator in this criteria.</td>
<td></td>
</tr>
<tr>
<td>Value</td>
<td></td>
<td>· For the <code>mid_server</code> value, enter the name of the MID Server that will scan our domain for Windows devices.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>· For the <code>win_domain</code> value, enter the name of our Windows domain.</td>
</tr>
<tr>
<td>Active</td>
<td>Be sure to enable the criteria by selecting this check box (<code>true</code>).</td>
<td></td>
</tr>
</tbody>
</table>

The completed criteria appear as follows in the Discovery Functionality form for this behavior.

Functionality Criteria for a WMI Scan

5. Create the schedule.
   a) Create a Discovery Schedule record and name the behavior we just created.
   b) Navigate to Discovery > Discovery Schedules and click New in the record list.
   c) Select a Discover mode of Configuration items. This action displays the Behavior field.
   d) Click the magnifier icon and select the behavior to use. In our example, we select Southwest-SNMP.
e) Select the appropriate time to run Discovery for this location.

f) Click **Quick Ranges** and define the IP address ranges, networks, or lists to scan for this domain.

g) Save the record.

---

**Discovery Schedule Record**

**CI deletion strategies for pattern discovery**

When you perform discovery with a pattern, you can choose what to do with CIs that are in the CMDB but Discovery can no longer find.

**Note:** Deletion strategies are available only with patterns, not probes/sensors.

When you use a pattern to perform discovery, you identify a CI Type, which is the main CI you are trying to find, such as an IIS web server or Tomcat server. Discovery can also find related CIs and populate the CMDB accordingly. For example, after Discovery finds an IIS server with the IIS pattern, it can also find these related CIs:

- The Windows machine that hosts the web server
- The configuration files for the IIS server
The web site that the IIS server hosts

The dependency map on the main CI also shows the related CIs, as illustrated by the following graphic:

An example of an IIS server main CI and its related CIs

After you discover the main CI and its related CIs for the first time with a pattern, Discovery puts an entry into the Related CI Types (sa_ci_to_pattern) table for each relation between the main CI and a related CI type. These records are where you determine the deletion strategy for each related CI by the type to which it belongs. You cannot set a deletion strategy for the main CI, except for AWS and Azure cloud databases.

You can view a list of the relations as the following image illustrates:
Example CIs related to an IIS server

The deletion strategy on a related CI takes effect when both of these conditions occur:

- After you run Discovery with the pattern again.
- Discovery successfully finds the main CI but cannot find the related CI.

These deletion strategy options are available:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Keep</td>
<td>Preserves the configuration file CI record and makes no other changes to the record. This option is the default setting.</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletes the configuration file CI record from the CMDB, and the relationship to the main CI.</td>
</tr>
<tr>
<td>Mark as absent</td>
<td>Marks the Status (install_status) field of the configuration file CI record as Absent, meaning that Discovery cannot find the tracked configuration file. This status does not instruct the system to delete the actual CI or the relationship.</td>
</tr>
</tbody>
</table>

**Note:** There are two tables that do have their CIs deleted if marked as absent: cmdb_ci_network_adapter and cmdb_ci_ip_address.

| Delete relations | Deletes only the CI relationships between the related CI and the main CI. |

Set a deletion strategy

Set a deletion strategy when you want to take action on a related CI that Discovery can no longer find through pattern discovery. You can delete the main CI only when it is an AWS or Azure cloud database.

- Role required: cloud_admin, sm_admin, or admin
- CIs: a main CI and related CIs that the discovery process found through pattern discovery
You can set a deletion strategy for all discovered CIs, including configuration file CIs. However, the way you access the deletion strategy for tracked configuration files differs from the procedure in this topic. See Set the deletion strategy for tracked configuration files for instructions.

1. Open the list of related CI types by entering `sa_ci_to_pattern.list` in the application filter.
2. Filter the list to find the CI type that is related to a main CI through pattern discovery. If you want to set a deletion strategy for a cloud database, search the list for `cmdb_ci_cloud_database` CI type.

Notice that the `cmdb_ci_cloud_database` CI types have the `Is Main CI` value set to `true`. This indicates that you can set a deletion strategy for both AWS and Azure databases, even if they are the main CI that cloud discovery finds.

3. From the list view, double click the value in the field in the `Deletion Strategy` column.
4. Select a new value:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Keep</td>
<td>Preserves the configuration file CI record and makes no other changes to the record. This option is the default setting.</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletes the configuration file CI record from the CMDB, and the relationship to the main CI.</td>
</tr>
<tr>
<td>Mark as absent</td>
<td>Marks the <code>Status (install_status)</code> field of the configuration file CI record as <code>Absent</code>, meaning that Discovery cannot find the tracked configuration file. This status does not instruct the system to delete the actual CI or the relationship.</td>
</tr>
</tbody>
</table>

**Note:** There are two tables that do have their CIs deleted if marked as absent: `cmdb_ci_network_adapter` and `cmdb_ci_ip_address`.

5. Select a new value:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delete relations</td>
<td>Deletes only the CI relationships between the related CI and the main CI.</td>
</tr>
</tbody>
</table>

### Configuration file tracking

The horizontal discovery process can find configuration files that belong to certain applications and add those configuration files to the CMDB. You can track the changes to these files by comparing them to previous versions.

**Warning:** Configuration files contain sensitive system information. To prevent unauthorized access, ensure that access control lists (ACL) are placed on the Tracked Configuration file table (`cmdb_ci_config_file_tracked`). Only allow authorized users to view this table or uncheck the `Save Content` setting.
Components for configuration file tracking

CI type

All applications and hosts in your organization must have a corresponding configuration item (CI) type, which is necessary for discovering and processing applications and hosts correctly. In a base system, many CI types have configuration file paths defined for them. You can add new or modify existing definitions for tracking configuration files. See Modify tracking changes in configuration files for instructions.

Patterns

Configuration file tracking is available for patterns that discover applications. On the pattern, you can create tracked file definitions that specify the CI type to which the application CI belongs and the path of the configuration file. Specify as many tracked file definitions as needed. You can also specify whether you want to save the contents of configuration files so you can view and compare the contents of different versions.

Note:

Configuration file tracking is not available for discoveries performed by traditional probes and sensors.

The classifier that triggers the pattern must specify the Horizontal Pattern probe, which in turn, must specify the pattern. If you upgrade your instance to the current version, not all classifiers are configured to use patterns for discovery by default.

CMDB

All configuration files are saved as a CI in the Tracked Configuration file (cmdb_ci_config_file_tracked) table. If you enable the content to be saved, these CI records provide the contents of the configuration files, including previous versions. From the configuration file CI record, you can compare different versions.

Dependency maps and application service maps

Both dependency maps and application service maps display tracked configuration files. The relationship between a configuration file and its host is a contains relationship. The application contains the configuration file.

For example, this IIS web server contains three tracked configuration files:
Sometimes you organize CI types as a main CI type and its related CI types. On an application service map, Service Mapping shows changes to configuration files of related CIs for the main CIs in inclusions. In inclusions, the system treats applications hosted on a server as independent objects. For example, the Tomcat WAR CI appears separate from its host, the Tomcat CIs. In this case, Service Mapping shows changes to configuration files of Tomcat WAR when you select Tomcat. In addition, Service Mapping displays changes to configuration files of the hardware server hosting inclusions. In this example, it is a Linux server:

**Deletion strategy**

You can specify what you want to do with tracked configuration file CI records when discovery can no longer find them. You can keep the configuration file CI record, automatically delete it, delete only the CI relationships to it, or mark it absent.

**Discovery patterns that support configuration file tracking by default**

These patterns provide tracked file definitions by default:
<table>
<thead>
<tr>
<th>Classifier</th>
<th>Pattern</th>
<th>CI Type</th>
<th>File path of tracked file</th>
</tr>
</thead>
<tbody>
<tr>

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
What to do

1. **Enable configuration file tracking** by setting the glide.discovery.enable_file_tracking Discovery property to true.
   
   You can also configure other properties to control the size and number of tracked configuration files, the time window during which changes to configuration files are tracked for a given version, and the number of changes allowed on a configuration file during that time window. See [Discovery properties](#) for details.

2. **To prevent unauthorized access to the sensitive information from configuration files,** perform the following steps:
   
   a. Ensure that access control rules (ACL) are placed on the Tracked Configuration file table (cmdb_ci_config_file_tracked). Only allow authorized users to view this table or uncheck the **Save Content** setting.
   
   b. Ensuring that the tracked_file_reader role that controls access to configuration file data is assigned to correct users and user groups. By default, the itil role contains the tracked_file_reader role giving all users with the itil role access to the configuration file information.

3. **Verify that the Horizontal Discovery probe is active on the classifier for the software** that you want to discovery. If not, you can enable it, specify the pattern, and then disable the other probes. See [Add the Horizontal Pattern probe to a classifier](#) for instructions.

4. **Add or modify tracked file definitions** to change the CI type or file path.

5. **Set the tracked files deletion strategy** to specify what you want to do with tracked configuration file CI records when pattern discovery can no longer find them.

6. **Run horizontal discovery** on the hosts that are running the applications you want to discover with patterns, open the application CI record, and check the Tracked Configuration Files related list.

7. **Compare two versions** of tracked CI configuration files to see the actual changes made to them.

**Modify tracking changes in configuration files**

Configure the system to collect information about changes in configuration files belonging to a configuration item (CI). Service Mapping uses this information to notify users that CI configuration files changed and to view actual changes to configuration files directly in the application service maps.

Role required: cloud_admin, sm_admin or admin

To enable tracking configuration files for a CI for which the system does track files, configure classification for the CI type to which this CI belongs:

- For CI types representing applications, [create a Discovery process classification](#) for the relevant pattern. Add the **Horizontal Pattern** probe in the **Probe** column, and then specify your pattern in the **Pattern** column.
- For CI types representing SNMP devices, perform configuration as described in [Create a Discovery CI classification](#).

**Note:** There is no need to create CI classifications for hosts because these classifications are included in the base system.
The system tracks configuration files as part of horizontal discovery process of a CI to which these files belong. Configuration files contain CI settings and parameters. Service Mapping uses this information to notify users that CI configuration files changed and to view actual changes to configuration files directly in the application service maps. To learn about how the system tracks configuration files, stores and updates information about these files, see Configuration file tracking.

The system tracks configuration files for CI types with process classifiers that trigger patterns. The patterns contain tracked file definitions, which specify the CI type that the application belongs to and the path of the configuration file. Several patterns, such as the IIS pattern, provide tracked file definitions by default. You can use these default definitions or create your own for any pattern a process classifier triggers.

1. Navigate to Pattern Designer &gt; Discovery Patterns.
2. Click the pattern for the relevant CI.

**Attention:** Enabling configuration file tracking does not modify the contents of a pattern.

3. Click the Tracked Files tab.

One or more tracked file definitions appear by default for Discovery patterns that support configuration file tracking.

If you do not see the Tracked Files tab, verify that the pattern is specified process classifier. See Add the Horizontal Pattern probe to a classifier for instructions.

4. Click **Edit** to modify an existing definition or click **New** to create a new one.
5. Fill out or modify the form fields (see table):

---

**Related Links**

Edit deletion strategy for the configuration files of this pattern

---

Tracked files on the IIS pattern
**Tracked File Definition**

Define the file path for the selected CI type. File path consists of CI attributes in variable or wildcard format. For example, $install_directory+"/conf/*.xml"

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CI Type</td>
<td>Select either the primary or related CI type to which the configuration file belongs.</td>
</tr>
<tr>
<td>File Path</td>
<td>Define the path of the configuration file to track. You can use pattern variables and wildcards. For example, for the following path: &lt;the folder with the &quot;install_directory&quot; parameter&gt;/conf/&lt;any xml file&gt;, enter $install_directory+&quot;/conf/*.xml&quot;</td>
</tr>
<tr>
<td>Save Content</td>
<td>Select this check box to make this file available for viewing and comparing directly the ServiceNow instance.</td>
</tr>
<tr>
<td>Active</td>
<td>Select this check box to enable tracking of this configuration file.</td>
</tr>
</tbody>
</table>

6. Click **Done**.
7. If necessary, set the tracked files deletion strategy as described in [Set the deletion strategy for tracked configuration files](#).

Run discovery on the hosts that are running the applications you want to discover with patterns, open the application CI record, and check the Tracked Configuration Files related list.
If you are using Service Mapping, verify that it started collecting information about changes to configuration files:

1. Navigate to the application service map containing the CIs.
2. On the Changes tab, check that the list includes a record of the change you made. For example, that the configuration file was added, modified or deleted.
Compare versions of CI configuration files

You can compare two versions of tracked CI configuration files to see the actual changes made to them.

If Discovery and Service Mapping do not track a configuration file you want to track, perform advanced configuration as described in Modify tracking changes in configuration files.

Role required: pd_admin or pd_user

Discovery and Service Mapping check configuration files for changes during horizontal discovery using patterns. If a configuration file is modified, the system saves the version of the file. You can use the timestamp to differentiate between versions.

Changes to configuration files are associated with CIs to which these files belong. Maps show configuration file changes as changes to related CIs.

1. To compare the latest and the previous version of the CI configuration file from Service Mapping:
   a) Navigate to Service Mapping > Services > Business Services.
   b) Click View Map next to the required business service.
   c) On the Changes tab, locate the change record for the modified CI configuration file.

   **Important:** The name of the change must be File Modified.

   d) Right-click the change record for the modified CI configuration file, and select View Change in Tracked File Content.

   The Tracked Configuration File Comparison tab opens, displaying the most recent and the previous versions of the configuration file.

   e) Continue with 3.

2. To compare any two versions of the CI configuration file from the list of versions from Discovery:
   - Navigate to Discovery > Tracked Configuration Files and sort or filter the list by criteria such as Related CI or Host.
   - Open a CI record from the Configuration module for the CI type to which the configuration file belongs. For example, to find a Tomcat server, navigate to Configuration > Applications Servers > Tomcat, then select the specific Tomcat server. The list of configuration files appear in the Tracked Configuration files related list.

   a) Select the configuration file from the list.

   The tracked configuration file record shows:
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>File Name</td>
<td>The name and file path of the file.</td>
</tr>
<tr>
<td>File Size</td>
<td>The file size.</td>
</tr>
<tr>
<td>Last Modified</td>
<td>The date the file was last modified.</td>
</tr>
<tr>
<td>File Content</td>
<td>The contents of the file, if you selected the option to save the contents on the file tracking definition.</td>
</tr>
</tbody>
</table>

b) In the **Content Versions** related list, click one of the versions in the **Update time** related list. The same information about the configuration file appears along with the update time.

c) Click **Compare**.

The Tracked Configuration File Comparison tab opens, displaying the configuration file versions you selected.

3. Review actual changes.

Highlight colors indicate the type of change:
- Purple — Updated line
- Pink — New line
- Gray — Deleted line

4. Navigate between the changes using the arrows in the upper right corner.

*Set the deletion strategy for tracked configuration files*

You can specify what you want to do with tracked configuration file CI records when pattern discovery can no longer find them.

- Role required: discovery_admin, sm_admin, or admin
- A pattern that specifies tracked configuration files.

You can set a deletion strategy for all discovered CIs, not just configuration file CIs. However the way you access the deletion strategy for standard CIs differs from configuration file CIs. See **Set a deletion strategy** for instructions.

1. Navigate to **Pattern Designer > Discovery Patterns** and open the desired pattern.
2. Click the **Tracked Files** tab.
3. Under **Related Links**, click **Edit deletion strategy for the configuration files of this pattern**.
   The Related CI Types list appears showing you filtered records in the Related CI Type (sa_ci_to_pattern) table. The filter shows you only records with the CI type of Tracked Configuration files (cmdb_ci_config_file_tracked), which is the table where the system saves configuration file CIs.
4. From the list view, double-click the value in the field in the **Deletion Strategy** column for the tracked configuration file.
5. Select a new value:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Keep</td>
<td>Preserves the configuration file CI record and makes no other changes to the record. This option is the default setting.</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletes the configuration file CI record from the CMDB, and the relationship to the main CI.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Mark as absent</td>
<td>Marks the Status (install_status) field of the configuration file CI record as Absent, meaning that Discovery cannot find the tracked configuration file. This status does not instruct the system to delete the actual CI or the relationship.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> There are two tables that do have their CIs deleted if marked as absent: cmdb_ci_network_adapter and cmdb_ci_ip_address.</td>
</tr>
<tr>
<td>Delete relations</td>
<td>Deletes only the CI relationships between the related CI and the main CI.</td>
</tr>
</tbody>
</table>

6.

**Change the source name of Discovery results**

You have the option of changing the source name of discovery results. This might be desirable if Discovery is running on your network together with another discovery product, and you want to use customized identifiers.

Role required: admin

The Source (sys_object_source) table stores information identifying the source of a discovery, the ID of that source, and the date/time of the last scan.

To view this information, configure a CI form and add the **Sources** related list. This table is populated automatically when the Discovery plugin is enabled.

---

**Sources List**

To migrate your Discovery Source to ServiceNow:

1. Update the **glide.discovery.source_name** system property to have a value of ServiceNow.
2. Edit the dictionary entry for the Configuration Item (cmdb_ci) table.
3. Update the choice list for the discovery_source column to only have the value ServiceNow for a discovery product.
4. Open a list for the Configuration Item (cmdb_ci) table and filter on a discovery source field value you want to change.
5. Use the Update All option to change the value to ServiceNow.
6. Open a list for the Source (sys_object_source) table and filter on a name field value you want to change.
7. Use the Update All option to change the value to ServiceNow.

**Discovery API plugin**

The Discovery API plugin provides APIs for scoped applications and is loaded when the Discovery plugin is activated.

Details about these Discovery API methods are available on the ServiceNow Developer Portal. They are listed here by class.

**Note:** Java API methods are not customizable.

**DiscoveryAPI - Scoped**

The methods in this class launch a quick Discovery of a single IPv4 address and return summaries of previously launched Discovery statuses for a single CI or for all scanned CIs. A MID Server is selected automatically, based on the IP address provided or the application specified.

- **discoverIpAddress()**: Discovers a single IPv4 address.
- **reportCiIpAddressStatus()**: Returns a summary of a configuration item’s Discovery status given the specific status sys_id and IPv4 address.
- **reportCiStatus()**: Returns a summary of a CI Discovery status given a specific Discovery Status sys_id.

**ReportCiStatusOutputJS**

The methods are getters that return specific object properties for the DiscoveryAPI reportCiIpAddressStatus method and then convert the information into a JSON string.

- **getCiOperationStatus()**: Used to return the state of the scanned CI.
- **getCmdbCi()**: Used to return the value in the cmdb_ci field from the discovery_device_history table for the CI being scanned.
- **getDiscoveryState()**: Used to return the value from the State field in the Discovery Status (discovery_status) table.
- **getIpAddress()**: Used to return the value from the source field in the discovery_device_history table for the CI being scanned.
- **getIssues()**: Used to return the value from the issues field in the discovery_device_history table for the CI being scanned.
- **getIssuesLink()**: Used to return the value from the issues_link field in the discovery_device_history table for the CI being scanned.
- **toJson()**: Used to serialized the ReportCiStatusOutputJS object.

**Data collected by Discovery**

Discovery collects unique data for each type of device and stores it in dedicated tables, fields, and relationships.
Computers and servers
Find servers and computers based on the machine's operating system:
- Windows
- Solaris
- Linux
- OS/X
- HPUX
- AIX
- VMware virtual machines
- Hyper-V
- JBOSS on Windows and Linux

Network devices
Detect several types of network-related CIs:
- Load balancers
- Routers and switches
- IP networks and specific IP addresses
- Cisco UCS devices
- Printers and power supplies
- IP services and daemons
- IBM Websphere datapower devices

You can also find devices based on TCP connections and Layer-2, SNMP-level discovery.

Software
Find a variety of software, including:
- Web and email servers, including Microsoft IIS, Apache, Tomcat, Exchange mailbox
- Puppet automation software
- WebLogic and WebSphere servers
- Clustered applications
- Tibco, Microsoft, IBM, HP, and SAP applications
- General software

Databases
Discover databases, including:
- Oracle
- MySQL
- MSSQL
- MongoDB
- SAP HANA
- PostgreSQL discovery
- Sybase discovery
**Storage**

Discover these types of storage devices:
- Direct Attached Storage (DAS)
- Storage Area Networks (SAN)
- Network Attached Storage (NAS)
- Host bus adapters (HBA)

**AWS and Azure resources**

Discover resources in Amazon and Azure clouds:
- Datacenters
- Virtual machines
- Availability zones
- Cloud networks and subnets
- Network interfaces and load balancers

**Operating system level virtualization**

Collect OSLV information:
- Containers, engines, images, and tags
- Docker components

**Computer and server discovery**

Discovery identifies the following computers, clusters, and virtual machines.

**AIX server discovery**

Discovery identifies and classifies information about AIX servers.

**Credentials**

Configure **SSH credentials**.

For a list of privileged commands that you need for Discovery and Service Mapping, see [Service Mapping commands requiring a privileged user](#) for a list of the commands that require elevated rights to discover and map Unix-based hosts in your organization.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.
Classifier, probes, and pattern

<table>
<thead>
<tr>
<th>Classifier</th>
<th>Probes</th>

</thead>
<tbody>
<tr>
<td>AIX</td>
<td>Horizontal discovery probe: launches patterns</td>
<td>AIX server</td>
</tr>
</tbody>
</table>
| (UNIX Classification) | AIX - Installed Software^  
|                 | AIX - ADM^  
|                 | AIX - Identity*  
|                 | AIX - CPU*  
|                 | AIX - Hardware Model*  
|                 | AIX - Memory*  
|                 | AIX - OS Patches*  
|                 | AIX - OS Release*  
|                 | AIX - OS Revision*  
|                 | UNIX - Find FQDN  
|                 | UNIX - OS Filesystems  
|                 | UNIX - OS Uptime  |

*For new instances, these probes are inactive on the classifier. Discovery uses patterns for discovery.

^These probes remain active by default, even when Discovery uses pattern discovery.

To use patterns, verify that the correct pattern is specified in the horizontal pattern probe on the classifier. See Add the Horizontal Pattern probe to a classifier for instructions.

**HBase instance discovery**

Discovery creates or updates a CMDB record when it detects a running instance of HBase on a UNIX server.

In the following table, the *HBase Instance@hostname* source may contain the information on whether the instance is a master or a slave. The name contains *Hmaster* if the instance is a master instance. The name contains *HRegionServer* if the name is a slave instance.

#### Data collected

| Label | Table Name | Field Name | Source  
--- | --- | --- | ---  
Name | cmdb_ci_db_hbase_instance | name | HBase Instance@hostname  
Root Directory | cmdb_ci_db_hbase_instance | root_dir | hbase-site.xml

Hyper-V discovery

Microsoft Hyper-V is a virtualization application that is included with the Windows Server 2008 operating system.

A physical machine running Hyper-V is divided into partitions (virtual machines), including a parent partition running Windows Server 2008 and child partitions running supported guests. The parent partition manages the virtual machines with the Hyper-V Manager application. On Windows Server 2008 this is done through the Microsoft Management Console (MMC) service. On Windows 7, use the Remote Server Admin tools.

Hyper-V supports the following functionality:

- **Failover clustering**: Failover is managed with Failover Cluster Manager.
- **Live migration**: Virtual machines can be moved between failover cluster nodes without bringing down the virtual machine.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

**Supported versions**

Discovery is supported for these Hyper-V Server versions:

- 2008
- 2012
- 2012 R2
- 2016
Important: Discovery of Hyper-V running on Windows 2016 is supported for patterns only. If you upgraded and are still using probes and sensors for Discovery, see KB0694773 for instructions on configuring Hyper-V probes.

Credentials

Configure Windows credentials with Domain administrator rights. You should also Enable PowerShell for the MID Server used to discover Hyper-V servers and instances.

</tbody>
</table>

Relationships

Discovery creates records in the CMDB for the host machine, the parent partition running Windows Server 2008, and all the virtual machines running on the Hyper-V server. Discovery finds the stored templates and maps all the relationships between components.

The instance modifies these tables for use with multiple virtualization products:
<table>
<thead>
<tr>
<th>Table</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtualization Server (cmdb_ci_virtualization_server)</td>
<td>Contains data on all discovered virtualization servers.</td>
</tr>
<tr>
<td>Virtual Machine Instance (cmdb_ci_vm_instance)</td>
<td>Contains data on all discovered virtual machine instances.</td>
</tr>
<tr>
<td>Virtual Machine Object (cmdb_ci_vm_object)</td>
<td>Contains data about various objects associated with a Hyper-V server, such as partitions, networks, resource pools, and clusters.</td>
</tr>
</tbody>
</table>

</tbody>
</table>

**Clone Hyper-V virtual machines**

When importing (cloning) Hyper-V virtual machines, make sure each virtual machine has a unique ID. Discovery identifies virtual machines with duplicate IDs as the same machine.

1. Export the virtual machine from the Hyper-V server.
2. Import the virtual machine into a different server, making one of the these choices:
   - **Move or restore the virtual machine**: This selection clones the image, using the same ID, and moves it to another server. The original image remains on the Hyper-V server.
   - **Copy the virtual machine**: This selection copies the virtual machine, using a different ID, and moves it from the Hyper-V server. This is the best selection and does not require any further action before you run Discovery.
3. If you import the Hyper-V clone using the **Move or restore** selection, be sure to delete the original image from the Hyper-V server.
When Discovery encounters two virtual machines with the same equivalent serial numbers, it creates only one configuration item (CI).

**JBoss server discovery**

Discovery can detect JBoss application servers running on Linux and Windows systems.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

### Requirements

For JBoss application servers running on Linux systems.

- Set probe permissions to use these Bourne shell commands: `find`, `cat`, and `dirname`.
- Enable SSH on the JBoss application server. The SSH credential must also have read permissions on the `web.xml` and `jboss-service.xml` files.

For JBoss application servers running on Windows systems, enable *PowerShell* on the MID Server.

### Credentials

- [Applicative credentials](#)
- [Windows credentials](#)
- [SSH credentials](#)

For a list of privileged commands that you need for Discovery and Service Mapping, see *Service Mapping commands requiring a privileged user* for a list of the commands that require elevated rights to discover and map Unix-based hosts in your organization.

### Classifiers, patterns, and probes

<table>
<thead>
<tr>
<th>Classifier</th>
<th>Trigger probes</th>
<th>Patterns</th>
</tr>
</thead>
<tbody>
<tr>

Legacy: JBoss probes and sensors

Discovery identifies a Linux JBoss application server using probes and sensors.

Linux

This process describes the use of probes, which are active on your instance if you upgrade. For new instances, Discovery uses the JBoss pattern.
1. The UNIX - Active Processes probe detects a running process that matches an `org.jboss.main` entry point parameter.

2. If there is a match, a record is created in the JBoss Application Server (`cmdb_ci_app_server_jboss`) table. The following probes are also triggered:
   - JBoss - Find web.xml list: The sensor of this probe populates information in the Web Application (`cmdb_ci_web_application`) table if applicable.
   - JBoss - Get jboss-service.xml: The sensor of this probe populates information in the Web Service (`cmdb_ci_web_service`) table.

3. The JBoss - Find web.xml list probe searches for the `web.xml` files of JBoss application server. The probe uses the `classpath` parameter in the running process, and then searches in the related `server\default\deploy` directory for the JBoss installation.

4. If associated web applications reside in the `server\default\deploy` directory, the JBoss - Get web.xml probe triggers for each application. This probe reads the `web.xml` file for each web application and the sensor populates additional information to the Web Service (`cmdb_ci_web_service`) table.

5. The JBoss - Get jboss-service.xml probe uses the `classpath` parameter in the running process to search for the `jboss-service.xml` file in the related `server\default\conf\` directory for the JBoss installation.

6. If the probe successfully finds the `jboss-service.xml` file in the `server\default\conf\` directory, the sensor reads the contents of the XML file. It then creates additional records in the Web Service (`cmdb_ci_web_service`) table as necessary.

Windows

This process describes the use of probes, which are active on your instance if you upgrade. For new instances, Discovery uses the JBoss pattern.

1. The Windows - Active Processes probe detects a running process that matches an `org.jboss.main` entry point parameter.

2. If there is a match, a record is created in the JBoss Application Server (`cmdb_ci_app_server_jboss`) table. The following probes are also triggered:
   - JBoss - Find web.xml list: The sensor of this probe populates information in the Web Application (`cmdb_ci_web_application`) table if applicable.
   - JBoss - Get jboss-service.xml: The sensor of this probe populates information in the Web Service (`cmdb_ci_web_service`) table.

3. The JBoss - Find web.xml list probe searches for the `web.xml` files of JBoss application server. The probe uses the `classpath` parameter in the running process, and then searches in the related `server\default\deploy` directory for the JBoss installation.

4. If associated web applications reside in the `server\default\deploy` directory, the JBoss - Get web.xml probe triggers for each application. This probe reads the `web.xml` file for each web application and the sensor populates additional information to the Web Service (`cmdb_ci_web_service`) table.

5. The JBoss - Get jboss-service.xml probe uses the `classpath` parameter in the running process to search for the `jboss-service.xml` file in the related `server\default\conf\` directory for the JBoss installation.
6. If the probe successfully finds the `jboss-service.xml` file in the `server\default\conf\` directory, the sensor reads the contents of the XML file. It then creates additional records in the Web Service (cmdb_ci_web_service) table as necessary.

**Linux discovery**

Discovery identifies and classifies information about Linux computers.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

**Supported Linux Operating Systems**

These types of Linux OS's are supported:

- Red Hat
- Fedora
- Debian
- SUSE
- CentOS
- Ubuntu

**Required credentials**

Configure [SSH credentials](#).

For a list of privileged commands that you need for Discovery and Service Mapping, see [Service Mapping commands requiring a privileged user](#) for a list of the commands that require elevated rights to discover and map Unix-based hosts in your organization.

**Classifier, probes, and pattern**

Discovery uses patterns to find several types of devices, operating systems, and applications. See [Pattern updates for the New York release](#) for more information.
<table>

* The value in the **disk_space** field is an aggregation of the disk space for all non-removable disks, including both directly attached and SAN storage.

Discovery also identifies and classifies information about Linux KVM. Discovery identifies Linux kernel-based virtual machines (KVM) when the process classifier detects `libvirtd` running on a Linux server. The classification triggers the creation of a `cmdb_ci_kvm` record, and launches the SSHCommand probes to explore the Linux server with `virsh`, `lvbvert` utility, and virtual machine configuration data.

Discovery creates a `cmdb_ci_kvm_instance` record for each virtual machine on the server, and then matches the `cmdb_ci_kvm_instance` record to a corresponding `cmdb_ci_computer` record using the MAC addresses of installed network adapters.

Linux Red Hat cluster discovery
Discovery can find Linux Red Hat clusters that offer high availability and load balancing.

**Required credentials**

Configure [SSH credentials](#).

**Additional requirements**

You also need permissions to read the `/etc/hosts/` and `/etc/cluster/cluster.conf` file, which associates host names with IP addresses.

The following commands are run for Oracle clusterware:

<table>
<thead>
<tr>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>ps -ef</td>
</tr>
<tr>
<td>clustat -x</td>
</tr>
<tr>
<td>ifconfig</td>
</tr>
<tr>
<td>hostname -s</td>
</tr>
<tr>
<td>hostname -s</td>
</tr>
</tbody>
</table>

*Sudo permission to run:* sudo `/u01/app/12.1.0.2/grid/bin/ocrcheck | egrep -v 'error| return code'`
Classifier, probes, and pattern

**Solaris discovery**
Discovery identifies and classifies information about Solaris computers.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KBO694477](#) for more information.

**Supported operating systems**
- Oracle Solaris 10
- Oracle Solaris 11
Prerequisites

Discovery stores data in the (cmdb_running_process) table with truncated command line parameters up to 80 characters. This can cause multiple applications to be merged into one CI. To get the full command line and prevent this issue, run `pargs -a` and parse the result.

For Discovery to use patterns to find Solaris computers, you must install `SNEEP`. Otherwise, Discovery cannot find the serial number.

If using Solaris zones, each zone should be configured to return a unique value for the serial number. Otherwise, each zone will return the same number causing issues with CI identification.

Credentials

Configure SSH credentials for the systems you want to discover.

For a list of privileged commands that you need for Discovery and Service Mapping, see Service Mapping commands requiring a privileged user for a list of the commands that require elevated rights to discover and map Unix-based hosts in your organization.

Classifier, probes, and pattern

<table>
<thead>
<tr>
<th>Classifier</th>
<th>Probes</th>
<th>Pattern</th>
</tr>
</thead>
</table>
| Solaris (UNIX Classification) | • Horizontal discovery probe: launches patterns  
  • Solaris - Installed Software^  
  • Solaris - Identity*  
  • Solaris - CPU*  
  • Solaris - Hardware Model*  
  • Solaris - Memory*  
  • Solaris - Network ARP Tables*  
  • Solaris - OS Patches*  
  • Solaris - Storage*  
  • Solaris - Zones*  
  • Solaris - Disks*  
  • DNS* | Solaris Server |

*For new instances, these probes are inactive on the classifier. Discovery uses patterns for discovery.

^This probe remains active by default, even when Discovery uses pattern discovery.

To use patterns, verify that the correct pattern is specified in the horizontal pattern probe on the classifier. See Add the Horizontal Pattern probe to a classifier for instructions.

* To discover Fujitsu PRIMEPOWER devices, you must install Oracle SNEEP and run Solaris discovery with root credentials.

**Solaris zone discovery**

Discovery maps the relationships between global and local Solaris zones upon detection.

In the following example, a Solaris global zone contains two local zones: zone01 and zone02. Each local zone is represented by a physical Solaris CI record and a Virtual Machine Instance record. Each of the local zones is tied to a Zone Server, demonstrating how virtualization relates to the global zone (mmp1).
The TCP connection and process information for local zone servers must be collected by running commands on their parent global zone. The relationship path between the local and global zone physical machines must be established before TCP connection and process information for local zone servers can be collected.

Case 1: Global zone discovered first.
- The system creates the Solaris server CI for the global zone.
- Discovery detects the local zones, creates a hypervisor zone server record, and creates a virtual machine instance record for each Solaris device in the local zone.
- Discovery creates the relationship between the hypervisor record and the VM instance record.

Case 2: Local zone discovered first.
- The system creates the Solaris server CI for the local zone.
- Discovery sets the correlation ID, so that it can be reconciled during later global zone discoveries.

Case 3: Global zone discovered after creation of local zone Solaris server CIs.
- Global zone Discovery detects local zones.
- Discovery creates a hypervisor zone server record, and creates a virtual machine instance record for each Solaris device in the local zone.
- Discovery creates the relationship between the hypervisor record and the VM instance record.
  In addition, it creates the relationship between the physical local zone VM and its virtual machine instance record.
- The global zone runs the Solaris - ADM probe on itself, filtering by the local zone, and updates the physical local zone VMs with this data.

Case 4: The relationship path between physical local and global zone machines is established.

Subsequent discoveries of the global zone refresh the TCP connection and process information for the contained local zones.

When the system discovers a global zone, the Solaris - Zones & ADM Launcher probe triggers the Solaris - ADM probe to explore the global zone and each local zone found. Because the Solaris - ADM probe must run on the global zone to detect TCP connection and process information from its local zones, you might see multiple ECC queue records that appear identical.
ECC queue entries for a zone Discovery

Upon examining the payload, however, you will see that each probe is actually targeting a different zone CI to filter on and update.

```xml
<parameter name="sequence" value="1523a01c9470000001"/>
<parameter name="from host" value=""/>
<parameter name="zone" value="zone01"/>
<parameter name="sys_created_on" value="2016-01-13 02:02:29"/>
<parameter name="used_by_discovery" value="true"/>
```

**Virtual machine (vm) discovery**

Discovery identifies and classifies information about virtual machines.
### VMware discovery

A Discovery schedule can discover VMware vCenter and ESX hosts.

These options are available for getting VMware vCenter data:

- Discovery runs the **VMware - vCenter Datacenters** probe when it identifies a VMware vCenter process running on a Windows machine or detects activity with the vmapp port probe.
- **Orchestration** can run any of the vCenter probes from a workflow.

#### Discovery for VMware vCenter

Discovery can explore the VMware vCenter process running on a Windows or Linux host.

### Tested vCenter versions

The ServiceNow® platform supports vCenter API versions 4.0 and higher. The following versions were tested with the New York release:

- vCenter versions 6.7 and earlier
- vSphere version 5.5
- vCenter appliance version 6.7 and earlier

**Note:** If you are discovering SUSE Linux hosts for vCenter appliances, version 6.0 and earlier, observe these **SSH restrictions**.

See [Data collected for VMware vCenter Server](#) for a description of the VMware architecture and component relationships.

### vCenter discovery process

After classifying vCenter, Discovery launches the VMware - vCenter Datacenters probe, which in turn launches specific probes that return information about ESX machines, virtual machines, and other vCenter objects. The vmapp port probe is also configured to launch the VMware - vCenter Datacenters probe.
VMware credentials

If you use a domain account to access vCenter, specify the domain with the user name in the credential record in one of the supported formats, such as Domain\UserName.

Attention: Windows credentials are not necessary for vCenter Discovery, when valid VMware credentials are used.

Note: The VMware credentials must have the read-only role and License Admin privilege in vCenter.

Updating the CMDB with vCenter event collector

In addition to finding vCenter data through the standard discovery process, Discovery can also update the CMDB by detecting vCenter events through a MID Server extension called the vCenter event collector.

The event collector allows the CMDB to be updated with changes to virtual machines (VMs), in addition to the updates detected by Discovery. A change to a VM is sent as an event from the vCenter server to the vCenter event collector. When an event is received, the CMDB is updated accordingly. Full vCenter Discovery does not need to rerun. For some events, such as powered on and powered off events, Discovery does not need to run again at all. For most events, Discovery runs only on the necessary vCenter resource.

For instructions on configuring vCenter events, see Configure and run the vCenter event collector extension.

CIs removed from vCenter

When a vCenter CI, such as a virtual machine, is removed, the ServiceNow instance marks it as “stale” in the CMDB, using either of these procedures:

- When Discovery runs, it creates an audit record in the CMDB Health Result (cmdb_health_result) table for the missing CI and marks the CI “stale”.
- If the instance is configured to collect vCenter events, the system can also create a “stale” audit record for the CI in the CMDB Health Result (cmdb_health_result) table from the VmRemovedEvent event, without having to run Discovery.

Note: When the Staleness setting is configured, the dependency view (BSM map) grays out stale CIs in its relationship diagram to indicate that they were removed from vCenter.
vCenter CI marked as “stale”

You have the option of creating a CMDB remediation rule to automatically execute a remediation workflow that can, for example, delete stale CIs. For more information on stale CIs, see CMDB Health Metrics.

vCenter Discovery on Windows host

Windows credentials are not necessary for vCenter Discovery, when valid VMware credentials are used.

Configure an alternate port for vCenter

You can specify an alternate port for the VMWare - vCenter Datacenters probe.

Role required: admin

By default, the VMWare - vCenter Datacenters probe runs on port 443, which is the standard port for the https protocol. The port probes for vCenter run on these ports:

- **vmapp6_https**: 9443
• vmapp_https: 5480

1. Hard code the port information.
   a) Navigate to Configuration > VMware > vCenter.
   b) Select the specific instance from the list of instances.
   c) Edit the URL field to include the port.
      For example, https://10.0.0.1:444
   d) Click Submit.

2. Specify an alternate port number for vCenter in the VMWare - vCenter Datacenters probe.
   a) Navigate to Discovery > Probes.
   b) Open the VMware - vCenter Datacenters probe record.
   c) In the Probe Parameters related list, click New.
   d) In the Name field of the Probe parameter record, enter vcenter_port.
   e) In the Value field, enter your alternate port number.
   f) Click Submit.

Data collected for VMware vCenter Server
Discovery identifies and classifies information about VMware vCenter servers.

vCenter table schema

The vCenter table schema is illustrated in the following diagram:
Several tables are cloud-agnostic tables, meaning that they can be populated for any cloud resource, not just vCenter resources. Look in the sub tables that extend the cloud-agnostic tables to find discovered CIs.

<table>
<thead>
<tr>
<th>Cloud-agnostic table</th>
<th>Look in this vCenter-specific table</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual Machine Instance (cmdb_ci_vm_instance)</td>
<td>VMware Virtual Machine Instance (cmdb_ci_vmware_instance)</td>
</tr>
<tr>
<td>Operating System Template (cmdb_ci_os_template)</td>
<td>VMware Virtual Machine Template (cmdb_ci_vmware_template)</td>
</tr>
<tr>
<td>Logical Datacenter (cmdb_ci_logical_datacenter)</td>
<td>VMware vCenter Datacenter (cmdb_ci_vcenter_datacenter)</td>
</tr>
<tr>
<td>Cloud Networks (cmdb_ci_network)</td>
<td>VMware vCenter Network (cmdb_ci_vcenter_network)</td>
</tr>
</tbody>
</table>
Cloud-agnostic table | Look in this vCenter-specific table
--- | ---
Datastore (cmdb_ci_datastore) | VMware vCenter Datastore (cmdb_ci_vcenter_datastore)
Host Cluster (cmdb_ci_host_cluster) | VMware vCenter Cluster (cmdb_ci_vcenter_cluster)

vCenter data

Discovery uses multiple vCenter probes to collect this data from vCenter. The data is saved in tables extend from the Configuration item (cmdb_ci) table.

**VMware vCenter Instance (cmdb_ci_vcenter)**

<table>
<thead>
<tr>
<th>Field label</th>
<th>Column name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>
<td>Full name</td>
<td>fullname</td>
</tr>
<tr>
<td>Instance UUID</td>
<td>instance_uuid</td>
</tr>
<tr>
<td>URL</td>
<td>url</td>
</tr>
<tr>
<td>Effective CPU</td>
<td>effectivecpu</td>
</tr>
</tbody>
</table>

The combination of the vCenter instance in the cmdb_ci_vcenter table and the object ID in the cmdb_ci_vm_object table identifies a specific vCenter.

The tables extend from the Virtual Machine Objects (cmdb_ci_vm_object) table, which holds object IDs for all cloud-based resources, except virtualization servers.

**DRS VM Config (cmdb_ci_drs_vm_config)**

<table>
<thead>
<tr>
<th>Field label</th>
<th>Column name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cluster</td>
<td>cluster</td>
</tr>
<tr>
<td>DRS behavior</td>
<td>drs_behavior</td>
</tr>
<tr>
<td>DRS enabled</td>
<td>drs_enabled</td>
</tr>
<tr>
<td>Virtual machine</td>
<td>virtual_machine</td>
</tr>
</tbody>
</table>

This table stores DRS behavior for the VMs that override the cluster behavior. For more information on DRS, see VMware's documentation on Distributed Resource Scheduler.

**VMware Virtual Machine Instance (cmdb_ci_vmware_instance)**

<table>
<thead>
<tr>
<th>Field label</th>
<th>Column name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>
<td>Template</td>
<td>template</td>
</tr>
<tr>
<td>CPUs</td>
<td>cpus</td>
</tr>
<tr>
<td>Disks</td>
<td>disks</td>
</tr>
<tr>
<td>Disks size (GB)</td>
<td>disks_size</td>
</tr>
</tbody>
</table>
**Field label | Column name**
--- | ---
Memory (MB) | memory
Network adapters | nics
Image path | image_path
State | state
vCenter Instance UUID | vcenter_uuid
vCenter Reference | vcenter_ref
Base name | base_name
VM namer | vm_namer
BIOS UUID | bios_uuid
VM Instance UUID | vm_instance_uuid

**VMware Distributed Virtual Port Groups (cmdb_ci_vcenter_dv_port_group)**

| Field Label | Column name |
--- | --- |
Name | name
vCenter Instance UUID | vcenter_uuid
Distributed Virtual Switch Reference | dvs_ref

**VMware Virtual Machine Template (cmdb_ci_vmware_template)**

| Field label | Column name |
--- | --- |
Name | The template name from VMWare.
CPUs | cpus
Disks size (GB) | disks_size
Guest ID | guest_id
Memory (MB) | memory
Image path | image_path
State | state
vCenter Instance UUID | vcenter_uuid
vCenter Reference | vcenter_ref
Network adapters | nics
Base name | base_name
VM namer | vm_namer
BIOS UUID | bios_uuid
VM Instance UUID | vm_instance_uuid
**VMware vCenter Object (cmdb_ci_vcenter_object)**

<table>
<thead>
<tr>
<th>Field label</th>
<th>Column name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Managed object reference ID</td>
<td>morid</td>
</tr>
<tr>
<td>vCenter Instance UUID</td>
<td>vcenter_uuid</td>
</tr>
<tr>
<td>vCenter Reference</td>
<td>vcenter_ref</td>
</tr>
</tbody>
</table>

**VMware vCenter Datacenter (cmdb_ci_vcenter_datacenter)**

<table>
<thead>
<tr>
<th>Field label</th>
<th>Column name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Region</td>
<td>region</td>
</tr>
<tr>
<td>Managed object reference ID</td>
<td>morid</td>
</tr>
<tr>
<td>vCenter Instance UUID</td>
<td>vcenter_uuid</td>
</tr>
<tr>
<td>vCenter Reference</td>
<td>vcenter_ref</td>
</tr>
<tr>
<td>Top level folder for VMs</td>
<td>folder_moreid</td>
</tr>
<tr>
<td>Top level folder for hosts</td>
<td>host_morid</td>
</tr>
</tbody>
</table>

*The VMware vCenter Datacenter (cmdb_ci_vcenter_datacenter) table is extended from the (cmdb_ci_logical_datacenter) table.*

**VMware vCenter Network (cmdb_ci_vcenter_network)**

<table>
<thead>
<tr>
<th>Field label</th>
<th>Column name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Managed object reference ID</td>
<td>morid</td>
</tr>
<tr>
<td>vCenter Instance UUID</td>
<td>vcenter_uuid</td>
</tr>
<tr>
<td>vCenter Reference</td>
<td>vcenter_ref</td>
</tr>
<tr>
<td>Network accessible by either hosts or virtual machines</td>
<td>accessible</td>
</tr>
</tbody>
</table>

*The VMware vCenter Network (cmdb_ci_vcenter_network) table is extended from the (cmdb_ci_network) table.*

**VMware Distributed Virtual Switch (cmdb_ci_vcenter_dvs)**

<table>
<thead>
<tr>
<th>Field label</th>
<th>Column name</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMCount</td>
<td>vm_count</td>
</tr>
<tr>
<td>Host count</td>
<td>host_count</td>
</tr>
</tbody>
</table>

**VMware vCenter Folder (cmdb_ci_vcenter_folder)**

<table>
<thead>
<tr>
<th>Field label</th>
<th>Column name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Managed object reference ID</td>
<td>morid</td>
</tr>
<tr>
<td>vCenter Instance UUID</td>
<td>vcenter_uuid</td>
</tr>
<tr>
<td>vCenter Reference</td>
<td>vcenter_ref</td>
</tr>
</tbody>
</table>
### ESX Resource Pool (cmdb_ci_esx_resource_pool)

<table>
<thead>
<tr>
<th>Field label</th>
<th>Column name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Managed object reference ID</td>
<td>morid</td>
</tr>
<tr>
<td>vCenter Instance UUID</td>
<td>vcenter</td>
</tr>
<tr>
<td>vCenter Reference</td>
<td>vcenter_ref</td>
</tr>
<tr>
<td>Owner</td>
<td>owner</td>
</tr>
<tr>
<td>Owner Managed Object Reference ID</td>
<td>owner_morid</td>
</tr>
<tr>
<td>CPU expandable</td>
<td>cpu_expandable</td>
</tr>
<tr>
<td>CPU limit (MHz)</td>
<td>cpu_limit_mhz</td>
</tr>
<tr>
<td>CPU reserved (MHz)</td>
<td>cpu_reserved_mhz</td>
</tr>
<tr>
<td>CPU shares</td>
<td>cpu_shares</td>
</tr>
<tr>
<td>Full path</td>
<td>fullpath</td>
</tr>
<tr>
<td>Memory expandable</td>
<td>mem_expandable</td>

<tr>
<td>Memory limit (MB)</td>
<td>mem_limit_mb</td>
</tr>
<tr>
<td>Memory reserved (MB)</td>
<td>mem_reserved_mb</td>
</tr>
<tr>
<td>Memory shares</td>
<td>mem_shares</td>
</tr>
</tbody>
</table>

### VMware vCenter Datastore (cmdb_ci_vcenter_datastore)

<table>
<thead>
<tr>
<th>Field label</th>
<th>Column name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Managed object reference ID</td>
<td>morid</td>
</tr>
<tr>
<td>vCenter Instance UUID</td>
<td>vcenter_uuid</td>
</tr>
<tr>
<td>Accessible</td>
<td>accessible</td>
</tr>
<tr>
<td>vCenter Reference</td>
<td>vcenter_ref</td>
</tr>
<tr>
<td>Type</td>
<td>type</td>
</tr>
<tr>
<td>Capacity (GB)</td>
<td>capacity</td>
</tr>
<tr>
<td>Free space (GB)</td>
<td>freespace</td>
</tr>
<tr>
<td>URL</td>
<td>url</td>
</tr>
<tr>
<td>Clustered</td>
<td>clustered</td>
</tr>
</tbody>
</table>

The VMware vCenter Datastore (cmdb_ci_vcenter_datastore) table is extended from the (cmdb_ci_datastore) table.

### VMware vCenter Cluster (cmdb_ci_vcenter_cluster)*

<table>
<thead>
<tr>
<th>Field label</th>
<th>Column name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Managed object reference ID</td>
<td>morid</td>
</tr>
<tr>
<td>Field label</td>
<td>Column name</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------</td>
</tr>
<tr>
<td>vCenter Instance UUID</td>
<td>vcenter_uuid</td>
</tr>
<tr>
<td>Effective hosts</td>
<td>effectivehosts</td>
</tr>
<tr>
<td>vCenter Reference</td>
<td>vcenter_ref</td>
</tr>
<tr>
<td>Effective CPU</td>
<td>effectivecpu</td>
</tr>
<tr>
<td>Effective memory</td>
<td>effectivememory</td>
</tr>
<tr>
<td>Number of effective hosts</td>
<td>effectivehosts</td>
</tr>
<tr>
<td>Number of hosts</td>
<td>numhosts</td>
</tr>
<tr>
<td>Total CPU</td>
<td>totalcpu</td>
</tr>
<tr>
<td>Total memory</td>
<td>totalmemory</td>
</tr>
<tr>
<td>Number of CPU cores</td>
<td>numcpucores</td>
</tr>
<tr>
<td>Number of CPU threads</td>
<td>numcputhreads</td>
</tr>
<tr>
<td>DRS Behavior</td>
<td>drs_behavior</td>
</tr>
<tr>
<td>DRS Enabled</td>
<td>drs_enabled</td>
</tr>
<tr>
<td>DRS VMotion Rate</td>
<td>drs_vmotion_rate</td>
</tr>
</tbody>
</table>

*The VMware vCenter Cluster (cmdb_ci_vcenter_cluster) table is extended from the (cmdb_ci_host_cluster) table.

**VMware Distributed Virtual Switch (cmdb_ci_vcenter_dvs)**

<table>
<thead>
<tr>
<th>Field label</th>
<th>Column name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>
<td>VMCount</td>
<td>vm_count</td>
</tr>
<tr>
<td>Host count</td>
<td>host_count</td>
</tr>
</tbody>
</table>

Discovery also maps the relationships to VMs and to distributed virtual port groups.

**VMware Distributed Virtual Port Group (cmdb_ci_vcenter_dv_port_group)**

<table>
<thead>
<tr>
<th>Field label</th>
<th>Column name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>
<td>vCenter Instance UUID</td>
<td>vcenter_uuid</td>
</tr>
<tr>
<td>Distributed Virtual Switch Reference</td>
<td>dvs_ref</td>
</tr>
</tbody>
</table>

Discovery also maps the relationship to the distributed virtual switch.

You can add these related lists to view additional discovered data:

- **Storage Volumes**
  
The virtual disks for this virtual machine. This data is saved in the Storage Volume (cmdb_ci_storage_volume) table with the value type=v Disk.
Storage Volume (cmdb_ci_storage_volume)

<table>
<thead>
<tr>
<th>Field label</th>
<th>Column name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>
<td>Size</td>
<td>size</td>
</tr>
</tbody>
</table>

- **Network Adapters**

  The virtual network adapters for the virtual disks. This data is saved in the Network Adapter (cmdb_ci_network_adapter) table.

  **Network Adapter (cmdb_ci_network_adapter)**

<table>
<thead>
<tr>
<th>Field label</th>
<th>Column name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>
<td>IP Address</td>
<td>ip_address</td>
</tr>
<tr>
<td>MAC address</td>
<td>mac_address</td>
</tr>
<tr>
<td>Netmask</td>
<td>netmask</td>
</tr>
</tbody>
</table>

**vCenter discovery with Software Asset Management**

If Software Asset Management is active, Discovery populates these vCenter tables using the VMWare - vCenter ESX Hosts License probe.

**VMWare License Key (samp_vmware_license_key)**

<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>Rights Used</td>
<td>rights_used</td>
</tr>
<tr>
<td>Expiration Date</td>
<td>expiration_date</td>
</tr>
<tr>
<td>Used Features</td>
<td>used_features</td>
</tr>
</tbody>
</table>
### vCenter relationships

Discovery automatically creates relationships for vCenter components using data from a key class. Subsequent discoveries use the same key class to automatically validate and remove relationships that are no longer valid.

vCenter CIs can be members of folders or clusters, which affect how Discovery creates their relationships.

- If a CI is in a folder, Discovery creates a relationship between that CI and the folder. If that CI is not in a folder, Discovery creates the relationship between the CI and the datacenter. These vCenter CIs can be in a folder:
  - VM Instance
  - VM Template
  - vCenter Network
  - Datastore
  - vCenter Folder
  - vCenter Cluster

- If an ESX server is in a cluster, Discovery creates a relationship between the ESX server and the cluster. If an ESX server is not a member of a cluster, then Discovery creates a relationship to the datacenter.

- If a resource pool is in a cluster, Discovery creates a relationship between the resource pool and the cluster. If the resource pool is not a member of a cluster, then Discovery creates a relationship to the ESX server.

This diagram illustrates vCenter relationships:

VMware tags

You can attach tags to vSphere objects, such as virtual machines, through the vSphere interface. The tags can then be grouped into categories. Objects with tags are sortable and searchable based on the parameters you give the tags and categories. The VMWare — vCenter VM Tags probe discovers these tags. You can view the discovered tags by opening the virtual machine record in `cmdb_ci_vmware_instance`. Then go to the Key Values tab.

**Key Values (cmdb_key_value)**

<table>
<thead>

</tr>
<tr>
<td>Value (value)</td>
<td>Tag name that is applied to the resource in vCenter.</td>
</tr>
</tbody>
</table>

Datastore data collected by Discovery

Discovery identifies each datastore in the system and creates the relationships with the virtual machines and the ESX servers that use these datastores.

**Datastores**

Discovery uses the VMWare - vCenter Datastores probe to collect this data from datastores.

<table>
<thead>
<tr>
<th>Field Label</th>
<th>Table Name</th>
<th>Column Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

ESX server discovery

Discovery identifies and classifies information about ESX servers and ESX resource pools through the discovery of vCenter and not from the direct discovery of any ESX servers.

**Important:** ESX server discovery is done through vCenter. Do not specify the IP address of the ESX server in a Discovery Schedule. Instead, discover the vCenter through the Discovery Schedule.

For a description of the VMware architecture and component relationships, see [Data collected for VMware vCenter Server](#).

For a discussion of how Discovery collects information on datastores and establishes the relationships between the ESX hosts and the storage disks attached to the datastores, see [Datastore Discovery](#).

**Required Roles**

Users with the `itil` and `asset` roles can access ESXi and ESXi configuration item (CI) records. To run discovery on vCenter servers, users must have the `discovery_admin` role.
Credentials

To run a complete Discovery of vCenter/ESX servers, you need vCenter credentials. If the vmapp port probe is disabled, you must use Windows credentials to access the Windows host on which the vCenter server runs.

**Note:** Make sure to select a credential Type of VMware.

ESX server Discovery components

Discovery identifies ESX servers based on the combination of correlation ID (BIOS UUID) and Managed Object Reference ID, when the hardware manufacturer is on a certified white list. Manufacturers not on this list are identified by serial number. After running the vCenter classifier, Discovery launches the VMware - vCenter Datacenters probe, which launches the probes that explore the ESX server. For the complete list of vCenter probes, see [List of Discovery probes](#).

</table>
## ESX resource pools

Resource pools are configured in vCenter and define the maximum amount of resources that virtual machines using that pool can consume. An ESX server property enables resource pools to expand when necessary if the ESX server has additional resources to spare. The **Name** and **Owner** fields of each resource pool on the ESX server must be configured within the Now Platform in the ESX Resource Pool (cmdb_ci_esx_resource_pool) table. When Orchestration for VMware executes its manual provisioning tasks, the provisioner must select the proper resource pool for the virtual server requested. Discovery finds resource pools on ESX machines and populates the fields on the ESX Resource Pool form automatically. For more information, see [Configure ESX resource pools](#). ESX resource pools requires the Orchestration - VMware Support plugin.

**Note:** Ensure that vCenter and the ESX server have been fully configured, including the creation of the templates and resource pools.

### Configure ESX resource pools
The ESX server has a default resource pool called Resources that defines normal resources for a virtual machine.

Role required: admin

Resource levels are dynamically generated from shares of the total resources allocated to virtual machines on the ESX server. For details about how these resources are calculated, review the VMware Knowledge Base https://www.vmware.com/. ServiceNow Discovery finds this default resource pool and adds a record to the ESX Resource Pools module automatically. If Discovery is not running on the ServiceNow instance, create a record for the Resources pool. Ensure that the Owner field is correct and leave the resource fields blank. If a provisioner selects the Resources pool when provisioning a virtual server, the ESX server will create a virtual machine for use under a normal load.

2. Click New in the list.
3. Create a new record for each resource pool in the ESX server, ensuring that the Name and Owner fields are correct.
4. Select the CPU expandable and Memory expandable check boxes to allow for expansion of the CPU and memory limits when needed, if those resources are available on the ESX server.

When granted, these extra resources can be revoked if needed to provision other virtual machines. The additional fields on the form are for display purposes only.
5. Click Submit.
ServiceNow New York IT Operations Management

VMware virtual machines

Discovery gathers information about virtual machines managed by vCenter.

The Discovery product can extract information from VMware configuration items (CI), including their relationships. Discovery is configured to work with the Orchestration VMware Support Plugin, which enables the automatic cloning of virtual machines by an ESX server managed by vCenter. For information about data collected by Discovery on vCenter, see Data collected for VMware vCenter Server.

VMware Workstation - Legacy

In the basic VMware system, the VMware Workstation runs on a Windows or Linux host machine.

**Attention:** The Discovery of VMware Workstation is not supported in releases after Kingston. The VMware workstation probe and sensor are not included in new instances of London. However, customers who upgrade from a release prior to Kingston can continue to use the probe and sensor to discover VMware Workstation.

This system can clone instances from templates, but cannot be automated. The relationships between VMware components for this type of installation are shown in the following diagram:

![VMware Workstation relationships](image)

Datastore Discovery
A datastore is a storage object for virtual machines that are hosted on an ESX server. A datastore is a collection of one or more physical disks, such as an iSCSI disk, and can be used by more than one ESX host. However, a physical disk can only connect to one datastore. Because ESX hosts can share datastores, it is easy to move virtual machine between hosts that have a common datastore.

**Note:** From the perspective of a virtual machine attached to a datastore, storage is provided by a single disk.

The advantages to connecting a datastore to multiple disks are:
- The ability to mirror the disks for failover protection.
- The ease of adding storage to the datastore.

For information about the tables used by Discovery to store the data for physical disks and their relationship to datastores and ESX hosts, see [ESX server discovery](#).

In this example configuration, two ESX hosts share a common datastore that uses different types of storage.
Relationships

ServiceNow provides tables that contain the relationships between an ESX host and its datastore and the specific disks to which the datastore is connected.

ServiceNow Discovery establishes the relationships between a datastore, the disks attached to the datastore, and the ESX server that hosts the virtual machines using that datastore. From the perspective of the ESX host, iSCSI and fibre channel disks connected to the datastore are treated as physical disks. Discovery does not show the direct relationship of the storage disks to the ESX host.

Note: Storage can be hosted on computers that are not discovered by Discovery. ESX hosts are discovered through vCenter, and storage is discovered separately through CIM. The system can only establish the relationship between the two when storage is discovered before ESX.

Datastore tables

<table>
<thead>
<tr>
<th>Table</th>

Windows discovery

Discovery identifies and classifies information about Windows computers.

Note: Probe-to-pattern migration is supported for the New York release and later. See the knowledge article KB0694477 for more information.

Supported Windows versions

- Windows Workstation 7, 8, 10
- Windows Server versions:
  - 2008
  - 2008R2
  - 2012R2
  - 2016
  - 2019
**Note:** For fiber channel discovery on a Windows 2008 host, the Microsoft Fibre Channel Information Tool (fcinfo.exe) must be installed on that machine. The fcinfo executable should be available on the environment path. The Microsoft Fibre Channel Information Tool is available for download at [http://www.microsoft.com](http://www.microsoft.com).

**Credentials**

Configure **Windows credentials**. The user configured in the credentials must have local admin access to the Windows machine.

The credential that you configure must have the following:

- Access to the WMI service to the current namespace and sub-namespaces.
- Access to the Powershell service.
- Membership in the Distributed COM Users local security group.

Windows 2019 Server   Windows OS - Server

*For new instances, these probes are inactive on the classifier. Discovery uses patterns for discovery.

^These probes remain active by default, even when Discovery uses pattern discovery.

To use patterns, verify that the correct pattern is specified in the horizontal pattern probe on the classifier. See [Add the Horizontal Pattern probe to a classifier](#) for instructions.

* Core counts and threads per core might not be accurate, due to issues with Microsoft reporting.

** The value in the **disk_space** field is an aggregation of the disk space for all non-removable disks, including both directly attached and SAN storage.

### The Windows registry

Discovery can find software that has been installed on a Windows machine by looking at the Windows Registry. Discovery can find the following attributes of discovered software:

- **Product Name**: Combination of name and version, such as Windows Imaging Component 3.0.
- **Name**: Name of the product only without the version.
- **Version**: Version of the product.
- **Uninstall String**: Path to the uninstaller, such as `C:\Program Files\Notepad++\uninstall.exe`.
- **Part of**: Update for which this is a part, such as Windows Internet Explorer 8 - Software U.
- **Install Date**: Date the software was installed. The Windows - Installed Software sensor appends a timestamp of 00:00:00 to the install_date retrieved from the registry. The installation time of all Windows software is independent of the timezone and is set to midnight of the day it was installed. For example, an install date of 2.19.2017 in the Windows registry appears as 2.19.2017 00:00:00 in the CMDB.
- **Installed on**: Name of the asset on which the software is installed.

### Windows server cluster discovery

Discovery establishes the relationships between a Windows server cluster and its nodes. When a Windows server is found, and Discovery detects that it is part of a cluster, the system launches the Windows - Cluster probe. Navigate to **Discovery Definition > Probes** and open the record for the Windows - Cluster probe to see the specific data Discovery collects.

*Note*: Discovery collects cluster resources based on the MSCluster_ResourceType WMI class. To see a list of default cluster resources, see **Resource Types**. To understand how cluster resources are related to process classifiers, see **Relate the process classifier to Windows cluster resources**.

### Cluster data tables

Discovery creates CIs for clusters in these tables:

- **Windows Cluster (cmdb_ci_win_cluster)**
- **Windows Cluster Resource(s) (cmdb_ci_win_cluster_resource)**
Cluster relationships

Discovery creates a CI Relationship (cmdb_rel_ci) record for each node, using these relationships:

- **Cluster of::Cluster**: Relationship between the cluster nodes and the cluster. Service Mapping uses this relationship to map the Windows cluster and its nodes.
- **Members::Member of**: Relationship between the cluster and the cluster node.
- **Hosted on::Hosts**: Relationship between the cluster nodes and the Windows server.

Windows cluster map

Windows cluster node relationships

Cluster references

Discovery creates the following cluster references:

- From Windows Cluster Nodes to the associated Windows Cluster.
- From Windows Cluster Resources to the associated Windows Cluster.
- From Cluster Virtual IPs to the associated Windows Cluster.
- From Cluster Node Resources to the associated Windows Cluster Node.

**Note:** References are maintained in Discovery to provide backward compatibility for systems that use them.

Help the Help Desk discovery on Windows
Help the Help Desk identifies and classifies information about Windows computers.

**Supported Windows Operating Systems**

- Windows 2008 and 2012 Server
- Windows XP and Vista
- Windows 7, 8, and 10

**Data collected**

Help the Help Desk stores information about Windows computers in the following tables and fields.

<table>

**z/OS discovery**
Discovery finds computers running the z/OS operating system.

ℹ️ **Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](https://www.servicenow.com/knowledgearticle/KB0694477) for more information.

**Requirements**

The USS service must be running on port 22 on z/OS.

These commands may be run on the host machine:

- `uname`
- `hostname`
- `sysvar SYSNAME`
- `netstat`
- `df`
- `ls`
- `cat`
- `grep`
- `ps`
- `cut`

**Credentials**

Create [SSH credentials](https://www.servicenow.com/knowledgearticle/KB0694477). The user must have permission to write to `/tmp`, have read access to all user processes, and be able to run REXX scripts.
Classifier, probe, and pattern

<table>
<thead>
<tr>
<th>Classifier</th>
<th>Trigger probe</th>
<th>Pattern</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBM z/OS</td>
<td>Horizontal Pattern: launches patterns</td>
<td>IBM zOS Server</td>
</tr>
</tbody>
</table>

Data collected

Discovery populates the IBM zOS server (cmdb_ci_ibm_zos_server) table with the following information:

<table>
<thead>
<tr>
<th>Label</th>
<th>Field name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>

<tr>
<td>Manufacturer</td>
<td>manufacturer</td>
</tr>
<tr>
<td>Serial number</td>
<td>serial_number</td>
</tr>
</tbody>
</table>

Network device discovery

Discovery identifies several network devices, including load balancers, routers, TCP connections, IP networks, and so on. It can find devices through traditional port probes, and then through identifications and exploration probes, or through patterns. It also supports discovery by identifying HTTP and TCP connections.

Load balancer discovery

Discovery can collect data about network routers, switches, and applications.

Discovery supports data collection from the following applications and hardware:

- A10
- Apache mod_jk and Apache mod_proxy
- Big-IP F5 Traffic Manager
- Cisco
- Citrix NetScaler
- HAProxy
- NGINX
- Alteon
- ACE
- Radware

**Important:** Discovery treats hardware load balancers as network devices and attempts to discover them primarily using SNMP. If a load balancer in your system, running on a Linux host, has SNMP and SSH ports open, Discovery might classify it based on the SSH port. This classification has priority over SNMP. To ensure that Discovery properly classifies your hardware load balancers, create a Discovery behavior for load balancers that includes SNMP but not SSH. Software load balancers are treated as applications.
Load balancer patterns

Starting with the Jakarta release, Discovery uses out-of-box patterns to find some types load balancers for new instances (see table).

Note: Probe-to-pattern migration is supported for the New York release and later. See the knowledge article KB0694477 for more information.

<table>
<thead>
<tr>
<th>Load balancer</th>
<th>Pattern names and description</th>
<th>Main CI table populated</th>
</tr>
</thead>
<tbody>
<tr>
<td>A10</td>
<td>A10 LoadBalancer</td>
<td>A10 Load Balancer (cmdb_ci_lb_a10)</td>

</tr>
<tr>
<td>Radware - AppDirector</td>
<td>AppDirector Load Balancer</td>
<td>Radware Load Balancer (cmdb_ci_lb_radware)</td>
</tr>
</tbody>
</table>

To use patterns, verify that the correct pattern is specified in the horizontal pattern probe on the classifier. See Add the Horizontal Pattern probe to a classifier for instructions.

Load balancer discovery, Service Mapping, and customized CI fields

Discovery collects information about the install status and operational status of load balancers. If you are using Discovery with Service Mapping, do not customize the (operational_status) or (install_status) fields. By default, Service Mapping ignores all host CIs for which the value of the (operational_status) field is not 1 (Operational) or the value of the status (install_status) field is 100 (absent). For additional information, see Preparing customized ServiceNow deployments to work with Service Mapping (KB0647574) in the HI Knowledge Base.

Load Balancer: A10
Discovery identifies and classifies information about A.10 load balancers.

Note: Probe-to-pattern migration is supported for the New York release and later. See the knowledge article KB0694477 for more information.

Prerequisites and important information

Important: Discovery treats hardware load balancers as network devices and attempts to discover them primarily using SNMP. If a load balancer in your system, running on a Linux host, has SNMP and SSH ports open, Discovery might classify it based on the SSH port. This classification has priority over SNMP. To ensure that Discovery properly classifies your hardware load balancers, create a Discovery behavior for load balancers that includes SNMP but not SSH. Software load balancers are treated as applications.
## Credentials

Configure **SNMP credentials** or (optionally) **SSH credentials**.

## Classifier, pattern, and probe

<table>
<thead>
<tr>
<th>Classifier</th>
<th>Trigger probes</th>
<th>Pattern</th>
</tr>
</thead>
<tbody>
<tr>
<td>A10 Load Balancer</td>
<td>• Horizontal discovery probe: launches patterns</td>
<td>A10 Load Balancer</td>
</tr>
</tbody>
</table>

## Data collected

The following data is collected on the A10 Load Balancers [cmdb_ci_lb_a10] table.

<table>
<thead>
<tr>
<th>Label</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Serial Number</td>
<td>serial_number</td>
</tr>

<td>install_status</td>
</tr>
</tbody>
</table>

The following data is collected on the DNS [cmdb_ci_dns_name] table.

<table>
<thead>
<tr>
<th>Label</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>
<td>IP Address</td>
<td>ip_address</td>
</tr>
</tbody>
</table>

**Relationships**

In this example from the dependency view, an A10 load balancer is represented by these elements:

- **Vip1**: A load balancer service that is the entry point for all business services attempting to contact the load balancer.
- **vthunder**: Actual A10 load balancer CI created by Discovery.
- **webApp-group1**: A load balancer pool containing the web server pool members IBM web01 and IBM web02.
A10 load balancer dependency view (BSM map)

Discovery creates these relationships from the perspective of the load balancer group:

A10 load balancer relationships

ServiceWatch maps an A10 load balancer like this:
A10 load balancer ServiceWatch map

For the top-down discovery of an A10 load balancer, relationships between the application and the load balance service are created only if the application CI exists.

To use patterns, verify that the correct pattern is specified in the horizontal pattern probe on the classifier. See [Add the Horizontal Pattern probe to a classifier](#) for instructions.

**Load balancer: ACE**

Discovery identifies and classifies information about ACE load balancers.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

**Credentials**

Configure [SNMP community credentials](#) or [SSH credentials](#).

**Classifier, pattern, and probe**

<table>
<thead>
<tr>
<th>Classifier</th>

Load balancer: Cisco GSS

Discovery of Cisco GSS load balancers is performed by both SNMP and SSH.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

**Classifiers**

Discovery uses the Cisco GSS Load Balancer classifier, which contains the condition: `sysdescr contains Global Site Selector` to classify the device.
Probes

Discovery uses several probes, including an SNMP probe to discover the specific GSS device and a Serial Number probe to identify the serial number of the device. See the table below for the list of related probes.

⚠️ Warning: You must have SNMP and SSH credentials configured correctly for the GSS load balancers on your network.

The following probes are triggered after classification:

<table>
<thead>
<tr>
<th>Probe</th>
<th>Description</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cisco GSS - Identity</td>
<td>A multiprobe that identifies the GSS device and serial number.</td>
<td>MultiProbe</td>
</tr>
<tr>
<td>Cisco GSS - Network</td>
<td>This is included in the Cisco GSS - Identify probe.</td>
<td>Java- SNMP</td>
</tr>
<tr>
<td>Cisco GSS - Serial Number</td>
<td>This is included in the Cisco GSS - Identify probe.</td>
<td>JavaScript</td>
</tr>
<tr>
<td>Cisco GSS - Get Domains</td>
<td>A probe that discovers global domain names corresponding to the device.</td>
<td>JavaScript</td>
</tr>
</tbody>
</table>

Tables

Discovery creates a record for each GSS device in the Cisco GSS (cmdb_ci_lb_cisco_gss) table. Domains are populated in the DNS Names (cmdb_ci_dns_name) table. Host names and IP addresses are stored in the IP Address to DNS Name (cmdb_ip_address_dns_name) table. Service Mapping uses this information. You can see the DNS name information on the DNS Names for CIs related list of the Load Balancer form.

ℹ️ Note: The Cisco GSS pattern is available by default to use with the Pattern Designer.

Load balancer: Cisco CSS

Discovery of Cisco CSS load balancers is performed by SNMP.

ℹ️ Note: Probe-to-pattern migration is supported for the New York release and later. See the knowledge article KB0694477 for more information.

Classifiers

Discovery uses the Cisco CSS Load Balancer classifier, which contains the OID Classification: 1.3.6.141.9.9.368.4:

Probes

The following probes are triggered:
<table>
<thead>
<tr>
<th>Probe</th>
<th>Description</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>SNMP - Load Balancer - Identity</td>
<td>A multiprobe that identifies load balancers.</td>
<td>Java-SNMP</td>
</tr>
<tr>
<td>Cisco CSS - Get Services</td>
<td>A Java probe that includes the Cisco CSS sensor to identify services defined on the load balancer in the Load Balancer Services (cmdb_ci_lb_service) table. For every service, Discovery populates Name, ip_address and port.</td>
<td>Java-SNMP</td>
</tr>
</tbody>
</table>

**Tables**

Discovery creates a record for each CSS device in the Cisco CSS (cmdb_ci_lb_cisco_css) table, which includes the device's Name, Model, Serial Number, Manufacture, and NIC (ip_address). It also creates a record for each service in the Load Balancer Services (cmdb_ci_lb_service) table.

Load balancer: Citrix NetScaler

Discovery and Service Mapping find Citrix NetScaler load balancers including Server Load Balancing (GSLB).

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

**Requirements and support**

**Important:** Discovery treats hardware load balancers as network devices and attempts to discover them primarily using SNMP. If a load balancer in your system, running on a Linux host, has SNMP and SSH ports open, Discovery might classify it based on the SSH port. This classification has priority over SNMP. To ensure that Discovery properly classifies your hardware load balancers, create a Discovery behavior for load balancers that includes SNMP but not SSH. Software load balancers are treated as applications.

Virtual NetScaler load balancers are not fully supported. Discovery supports local server load balancers and GSLB.

**Credentials**

- Configure [SNMP credentials](#).

  **Note:** You also have the option of using [SSH credentials](#). However, if the payload size of the data that is returned to the instance is large, the discovery process can fail. In this case, use SNMP credentials instead.

- (Optional) Provide a user with the read access to the NS.conf configuration file if you do not want to provide SNMP or SSH credentials.

- Use [basic authentication](#) credentials for discovery via REST.
For a list of privileged commands that you need for Discovery and Service Mapping, see Service Mapping commands requiring a privileged user for a list of the commands that require elevated rights to discover and map Unix-based hosts in your organization.

Classifier, pattern, and probes

<table>
<thead>
<tr>
<th>Classifier</th>
<th>Trigger probes</th>
<th>Patterns</th>
</tr>
</thead>
<tbody>
<tr>
<td>NetScaler Load Balancer</td>
<td>• Horizontal discovery probe: launches patterns (see the Patterns column)</td>
<td>• NetScaler Load Balancer</td>
</tr>
<tr>
<td></td>
<td>• NetScaler - Network Path Information (multiprobe)</td>
<td>• NetScaler Load Balancer NS.CONF</td>
</tr>
<tr>
<td></td>
<td>• NetScaler - ARP Information</td>
<td>• NetScaler Load Balancer SSH</td>
</tr>
<tr>
<td></td>
<td>• NetScaler - Route Information</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• SNMP - NetScaler - Identity</td>
<td></td>

<td>• SNMP - NetScaler - Identity - Serial</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• SNMP - NetScaler - Identity Info</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• SNMP - NetScaler - System</td>
<td></td>
</tr>
<tr>
<td></td>
<td>[cmdb_ci_lb_netscaler]</td>
<td></td>
</tr>
</tbody>
</table>

Horizontal discovery probe: launches patterns (see the Patterns column)

NetScaler - Network Path Information (multiprobe)

NetScaler - ARP Information

NetScaler - Route Information

SNMP - NetScaler - Identity

SNMP - NetScaler - Identity - Serial

SNMP - NetScaler - Identity Info

SNMP - NetScaler - System

SNMP - NetScaler - Identity Info

SNMP - NetScaler - Identity - Serial

SNMP - NetScaler - System

To use probes for the horizontal discovery, make sure that the NetScaler - Network Path Information multiprobe is active on the Trigger probes related list for the NetScaler Load Balancer classifier. Then deactivate or remove the Horizontal discovery probe from the Trigger probes related list.

To use patterns, verify that the correct pattern is specified in the horizontal pattern probe on the classifier. See Add the Horizontal Pattern probe to a classifier for instructions.

Connections discovered by Service Mapping during the top-down discovery

Service Mapping performs the top-down discovery of the NetScaler Global Server Load Balancer in the context of application services. It discovers configured URLs of the NetScaler Global Server Load Balancer.

Data collected by Discovery during horizontal discovery

<table>
<thead>
<tr>

To see the DNS names and aliases for a NetScaler load balancer, you must configure the form and add the **DNS Names for CIs** related list. DNS names also include aliases.

**Note:** Discovery populates load balancer interface information that is necessary to map the `network path` in Service Mapping.

**Configuration item (CI) Relationships**

These relationships are created to support NetScaler Global Server Load Balancer discovery:
Load balancer: F5 BIG-IP

Discovery and Service Mapping can find F5 BIG-IP load balancers via SNMP, SSH, and through the REST API.

Note: Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](https://www.servicenow.com/knowledgearticle/KB0694477) for more information.

### Prerequisites and important information

**Important:** Discovery treats hardware load balancers as network devices and attempts to discover them primarily using SNMP. If a load balancer in your system, running on a Linux host, has SNMP and SSH ports open, Discovery might classify it based on the SSH port. This classification has priority over SNMP. To ensure that Discovery properly classifies your hardware load balancers, create a Discovery behavior for load balancers that includes SNMP but not SSH. Software load balancers are treated as applications.

You can download VMware images of BIG-IP with a free 90-day key from [https://www.f5.com/](https://www.f5.com/)

For F5 Global Traffic Manager (GTM) GIB-IP load balancers, Discovery can resolve the DNS name of the F5 GTM hardware as well as the DNS names of all the servers associated with the load balancer that receive distributed traffic. To view this data, navigate to **Configuration > Load Balancers > LB Hardware** and open the F5 load balancer record. Then select the **DNS Names for CIs** related list. **Service Mapping** uses this information to map F5 relationships.

### Credentials

- Configure **SNMP credentials**.

  Note: If you do not want to use SSH credentials, you can use the REST API to create a connection to F5 BIG-IP devices.

- (Optional) If there are iRules or SNMP community credentials are not enough for discovering outgoing connections, configure **SSH credentials** on Now Platform.

  Service Mapping uses the SSH credentials to retrieve connections not from the CMDB. Discovering connections using the SSH protocol is a failover mechanism for the SNMP-based discovery.

- Use **basic authentication** credentials for discovery via REST.

- (Optional) For top-down discovery with Service Mapping, configure **applicative credentials**.

- (Optional) For top-down discovery with Service Mapping, provide a user with permissions to run the following commands:
  - bigpipe commands (for BIG-IP LTM F5 or BIG-IP GTM F5 version 9)
  - bigpipe and Traffic Management Shell (TMSH) commands (for BIG-IP LTM F5 or BIG-IP GTM F5 version 10)
  - Traffic Management Shell (TMSH) commands (for BIG-IP LTM F5 or BIG-IP GTM F5 version 11)
• Traffic Management Shell (TMSH) advanced commands (for BIG-IP LTM F5 or BIG-IP GTM F5 version 10, 11, and 12)
• The `show cm traffic-group - get` command for discovering F5 BIG-IP Device Service Clustering

• (Optional) For top-down discovery with Service Mapping, give the user elevated rights to be able to run Service Mapping commands requiring a privileged user.

F5 cluster discovery

The horizontal discovery process can find F5 clusters. To discover clusters, the credentials must have read permission to traffic groups. For SNMP, this is the regular read permission. For SSH, you need to have Traffic Management Shell (TMSH shell) enabled and accessible.

**Note:** Because F5 clusters share the same virtual IPs and addresses for all devices, the horizontal discovery process cannot find specific IP addresses for each device.

Classifier, patterns, and probes

Discovery uses these classifiers, probes, and pattern for F5 discovery:

<table>
<thead>
<tr>
<th>Classifiers</th>
<th>Trigger probes</th>
<th>Patterns</th>
</tr>
</thead>
<tbody>
<tr>
<td>F5 BIG-IP Load Balancer</td>
<td>• Horizontal discovery probe: launches patterns</td>
<td>These patterns are used for standard horizontal discovery including identifying clusters:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• F5 Load Balancer</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• F5 Load Balancer SSH</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• F5 Load Balancer REST</td>
</tr>
<tr>
<td>F5 HTTP</td>
<td>The F5 HTTP classifier does not use a trigger probe. It triggers the F5 Load Balancer REST pattern to perform data collection via REST.</td>
<td>These patterns use iRules to get information via REST. Service Mapping uses these patterns for top-down discovery:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• F5 Load Balancer REST</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• F5 BigIP GTM</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• F5 BigIP LTM</td>
</tr>
</tbody>
</table>

To use patterns, verify that the correct pattern is specified in the horizontal pattern probe on the classifier. See [Add the Horizontal Pattern probe to a classifier](#) for instructions.

Connections discovered by Service Mapping during the top-down discovery

Service Mapping performs the top-down discovery of the GTM GIB-IP load balancer in the context of application services. It discovers configured URLs of the GTM GIB-IP load balancers.

Data collected by Discovery during horizontal discovery

The following data is collected on the F5 Big-IP [cmdb_ci_lb_bigip] table.
<table>
<thead>
<tr>
<th>Table and field</th>
<th>Description</th>

**Load balancer: HAProxy**

Discovery of HAProxy load balancers is performed by SSH.

*Note:* Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](https:// kb0694477) for more information.

HAProxy is an open-source load balancer that can manage any TCP service. It is particularly suited for HTTP load balancing because it supports session persistence and Layer 7 processing. Discovery supports HAProxy for HTTP load balancing. TCP load-balancing is not supported.

Consider the following requirements for discovering the HAProxy:

- The HAProxy software is installed and running on a Linux server.
- The MID Server is deployed to explore the server and the MID Server has access to the server HAProxy configuration file.
- The configuration probe checks for the `haproxy.cfg` file using one of the following methods:
  - Using the `f` parameter for the HAProxy process output.
  - Using the default `/etc/haproxy/haproxy.cfg` path.
- The HAProxy probes require credentials and execute privileges to run commands.

Discovery uses the **Unix - Active Processes** probe to identify an HAProxy load balancer when the name of the process is `haproxy`. If this criterion matches, a record is created in the HAProxy Load Balancers (cmdb_ci_lb_haproxy) table if one does not already exist for that running process.
The following probes are triggered after classification:

### HAProxy probes

<table>
<thead>
<tr>
<th>Probe</th>
<th>Description</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>HAProxy – Version</td>
<td>The sensor of this probe populates the HAProxy version in the HAProxy Load Balancers (cmdb_ci_lb_haproxy) table.</td>
<td>haproxy</td>
</tr>
<tr>
<td>HAProxy – Get Configuration</td>
<td>The sensor of this probe populates additional information in the HAProxy Load Balancers (cmdb_ci_lb_haproxy) table. The probe also populates information in the Load Balancer Service (cmdb_ci_lb_service), Load Balancer Pool (cmdb_ci_lb_pool), Load Balancer Pool Member (cmdb_ci_lb_pool_member), Load Balancer Interface (cmdb_ci_lb_interface), and Load Balancer Application (cmdb_ci_lb_apple) tables.</td>
<td>echo, sed, cut, grep, egrep (within the Borne shell script)</td>
</tr>
</tbody>
</table>

In addition to populating the data, the following relationships records are created in CI Relationships (cmdb_rel_ci) table:

- The records in the cmdb_ci_lb_appl table run on the cmdb_ci_web_server table records.
- The records in the cmdb_ci_lb_service table use the cmdb_ci_lb_pool table records.
- The records in the cmdb_ci_pool table are used by the cmdb_ci_service table records.
- The records in the cmdb_ci_pool table are members of the cmdb_ci_pool_member table records.
- The records in the cmdb_ci_pool_member table are members of the cmdb_ci_pool table records.

Load balancer: NGINX

Discovery of NGINX load balancers is performed by SSH.

NGINX is an open source web server with a load balancer. Discovery identifies the web server and information related to the load balancer.

Consider the following requirements for discovering NGINX servers:

- Ensure that the NGINX software is installed and running on the server.
- Grant the MID Server has access to the NGINX configuration file, which is /etc/nginx/nginx.conf by default.
- Enable secure shell (SSH) commands.
- The NGINX probes require credentials and execute privileges to run commands.

For a list of privileged commands that you need for Discovery and Service Mapping, see Service Mapping commands requiring a privileged user for a list of the commands that require elevated rights to discover and map Unix-based hosts in your organization.

The Nginx Process Classifier detects a running process that matches the following criteria during the exploration of a UNIX server:
The name of the process starts with nginx.
The name of the process contains master.

Both of these conditions must match:

- A record is created in the Web Server (cmdb_ci_web_server) table.
- A Runs on relationship is created in the CI Relationship (cmdb_rel_ci) table for the Linux Server (cmdb_ci_linux_server) table and the Web Server (cmdb_ci_web_server) table.

The following probes are triggered after classification:

**NGINX probes**

<table>
<thead>
<tr>
<th>Probe</th>
<th>Description</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nginx – Version</td>
<td>This probe contains a Bourne shell script. It determines the version of NGINX and populates the Web Server (cmdb_ci_web_server) table.</td>
<td>nginx</td>
</tr>
<tr>
<td>Nginx – Get Configuration</td>
<td>This probe contains a Bourne shell script and an argument that determines the path of the NGINX configuration file. The probe identifies configuration parameters based on keywords within the configuration file and returns them as a single payload result.</td>
<td>echo, sed, cut, grep, egrep (within the Bourne shell script)</td>
</tr>
</tbody>
</table>

In addition to populating the data, the following relationships records are created in CI Relationships (cmdb_rel_ci) table:

- The records in the cmdb_ci_web_server table run on the cmdb_ci_linux_server table records.
- The records in the cmdb_ci_lb_service table use the cmdb_ci_lb_pool table records.
- The records in the cmdb_ci_pool table are used by the cmdb_ci_service table records.
- The records in the cmdb_ci_pool table are members of the cmdb_ci_pool_member table records.
- The records in the cmdb_ci_pool_member table are members of the cmdb_ci_pool table records.

Load balancer: Radware-appDirector

Discovery of Radware load balancers is performed by SNMP.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

**Requirements**

**Important:** Discovery treats hardware load balancers as network devices and attempts to discover them primarily using SNMP. If a load balancer in your system, running on a Linux host, has SNMP and SSH ports open, Discovery might classify it based on the SSH port. This classification has priority over SNMP. To ensure that Discovery properly classifies your...
hardware load balancers, create a Discovery behavior for load balancers that includes SNMP but not SSH. Software load balancers are treated as applications.

Credentials

Configure SNMP credentials.

Load balancer fields and probes

Discovery stores load balancer information in several tables.

The information in this topic pertains to discovery with probes and sensors only. If you are using patterns, such as to discover F5 Big-IP load balancers, see the relevant topic for that type of load balancer.
**Note:** By default, the system uses the discovered IP address of a load balancer for the CI record. This can be the management IP created for the device that is used in the Discovery schedule. For instructions on how to force Discovery to use the IP address of the load balancer’s NIC rather than that of a management IP, see [IP address selection properties](#).

Apache web server data

Discovery also collects data on Apache web server load balancing modules using SSH. See Apache mod_jk and mod_proxy discovery for more information on probes for Apache web server data. For information on the tables, fields, and data sources that discovery populates for Apache web servers, see Apache web server discovery.

Layer 2 discovery

Discovery can detect the physical connections, known as layer 2, between network devices.

Layer 2 discovery process

Discovery uses multiple probes to gather information about network adapters and their Layer 2 connections. The following diagram shows the probes that Discovery launches for network Discovery, including those used for Layer 2 Discovery.
For example, if Discovery finds a switch in a network, it triggers the **SNMP - Switch - Vlan** probe and the **SNMP - Network - ARPTable** probe. For every Vlan that Discovery finds, it triggers various switch probes. If a switch has routing capabilities, Discovery triggers the **SNMP - Routing** probe to collect network adapter information in the Network Adapter (cmdb_ci_network_adapter) table. If Discovery finds a server, it triggers the appropriate Address Resolution Protocol (ARP) probe for that operating system. Discovery also supports the use of patterns, such as the **Network Switch** and **Network Router** patterns, which are available by default in Discovery. See **Router and switch discovery** for more information.

During the discovery of a network device, Discovery creates records in the Router Interface (dscy_router_interface) table and the Switchport (dscy_switchport) table. This information contains network adapter information for that device. For SNMP-enabled devices, Discovery gathers the information from a routing probe during the exploration phase. The Layer 2 protocol cache probe runs next to collect neighbor data from the device.

### Retrieving neighbor data

As Discovery gathers network information from the probes on a device, the **SNMP - Layer 2 Protocol Caches** identifies device neighbors via CDP and LLDP. This probe updates the Device Neighbors (discovery_device_neighbors) table, which contains the Layer 2 connections between switches. Sometimes, the neighbors of this device might not yet be known to the instance. The neighbor's interface cannot be resolved to a record until Discovery eventually finds the neighbor's side of the relationship. When Discovery runs on the neighboring device, Discovery completes the information for the neighbor's interface for the original reporting device.

Discovery can retrieve neighbor data from these caches on a network device:

- **Cisco Discovery Protocol (CDP):** Cache on Cisco devices that contains device neighbor information in the form of a protocol specific neighbor ID. Cisco Discovery Protocol (CDP).
- **Link Layer Discovery Protocol (LLDP):** Generic cache that contains device neighbor information in the form of a protocol specific neighbor ID.
- **Address Resolution Protocol (ARP):** Cache that contains the IP and MAC addresses of all connecting devices and servers.

### How Layer 2 Discovery works

When device discovery is complete, the system runs the Service Discovery - Device Complete business rule on the Device (discovery_device_history) table. This business rule uses several strategies, together with information from various tables to create **Connects to**: **Connected by** relationships in the CMDB. Relationships can be created between:

- A server and a switch
- Two switches
- A device and the port of another device
- The ports of two devices

In the following example, Discovery found a server running AIX, and was also able to find two IP switches on the network. These relationships were created:

- An **IP Connection** relationship between the AIX Server and the two IP switches A and B.
- A reference between the AIX server and its own network adapter.
- A **Connects to** relationship between the adapters on the two IP switches (not shown in the following image).
- A **Connects to** relationship between the network adapter of the AIX server and the switch port of IP switch A (highlighted in red). This kind of relationship is created by default.

To view these relationships, open the dependency view for the server. To view the relationship between the two IP switches, open the dependency view from one of the switches and select the **Physical Network Connections** option for the **Dependency Type** in the map settings.

**Layer 2 connection strategies**

Layer 2 Discovery uses the following strategies to create relationships between devices in a network:

**PhysicalHostConnectionStrategy**

This strategy creates a connection between a discovered server, which is not a network device, and a network device. This strategy can only create a Layer 2 connection if there is a single MAC address on the port in the switch's forwarding table. If the port has multiple MAC addresses, Discovery does not create a connection between the server and the switch.

If the switch's port is identified, Discovery creates a **Connects to::Connected by** relationship between the server port and the switch port. Otherwise, Discovery creates a **Connects to::Connected by** relationship between the server port and the switch itself.

**VMLayer2ConnectionStrategy**

This strategy creates a connection between a VM and a network device. If the number of exceptional MAC addresses is very low (less than 3 and less than 15% of all MAC address of the ESX server and its VMs), Discovery creates a Layer 2 connection.

**NetworkDeviceLayer2ConnectionStrategy**

This strategy creates a connection between a network device and its neighbors. Discovery creates a Layer 2 connection if there is a single neighbor with a neighbor address, a neighbor interface, or both. If the neighbor's interface exists, Discovery creates a **Connects to::Connected by** relationship between the origin interface and the neighbor's interface. Otherwise, Discovery creates a **Connects to::Connected by** relationship between the origin interface and the switch with the neighbor's address.

**SpanningTreeLayer2ConnectionStrategy**
This strategy creates a connection between a network device and the parent of the network device in the spanning tree.

**JavaScriptLayer2ConnectionStrategy**

This strategy calls a Javascript function with empty implementation. This allows for the creation of an additional strategy.

**Address Resolution Protocol (ARP) in Layer 2 discovery**

The probes for Address Resolution Protocol (ARP) map the IP address of a computer or network device to a MAC address. These probes retrieve the IP address and MAC address for a CI from the Network Infrastructure Item (dscy_net_base) table. Devices that support SNMP, such as Linux computers and network devices, cache two types of address information:

- **Static**: Manually added address resolutions.
- **Dynamic**: Hardware name and IP address pairs added to the cache by previous, successful ARP resolutions.

When the ARP table Discovery completes, the system collects all static and dynamic table entries from devices via SNMP. If a new ARP entry is available, it is added to the Network ARP Table (discovery_net_arp_table). If any previously discovered ARP entries are no longer cached in the device ARP table, the system removes the corresponding records from the CMDB using the reconciliation process.

**Note:** If new ARP entries are created after Discovery runs, they are not discovered until the next Discovery schedule. If ARP entries are removed from the device after Discovery runs, the CMDB ARP table is not updated until Discovery runs again.

Discovery provides these probes for extracting IP and MAC address resolution information:

<table>
<thead>
<tr>
<th>Probe</th>
<th>ECC queue topic</th>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux - Network ARP Tables</td>
<td>SSHCommand</td>
<td>arp -n</td>
<td>SSH command probe that retrieves the network information from the ARP table on a Linux server.</td>
</tr>
<tr>
<td>Solaris - Network ARP Tables</td>
<td>SSHCommand</td>
<td>arp -an</td>
<td>SSH command probe that retrieves the network information from the ARP table on a Solaris server.</td>
</tr>
<tr>
<td>Windows - Network ARP Table</td>
<td>Powershell</td>
<td>arp -a</td>
<td>Powershell probe that retrieves the network information from the ARP table on a Windows server.</td>
</tr>
</tbody>
</table>
SNMP - Network - ArpTable

The SNMP probe uses this OID first:

iso.org.dod.internet.mgmt.mib-2.ip.ipNetToMediaTable
ipNetToMediaPhysAddress, ipNetToMediaNetAddress.

If the probe fails to return results, it uses this OID:

iso.org.dod.internet.mgmt.mib-2.ip.ipNetToPhysicalTable
ipNetToPhysicalNetAddress, ipNetToPhysicalPhysAddress.

These probes return bridging information from VLANs connected across network switches, including port selection, forwarding tables, and the use of the spanning tree protocol.

SNMP - Switch - BridgePortTable

This probe returns all the ports from a switch that are used to create a bridge between network segments.

Bridging data returned

<table>
<thead>
<tr>
<th>Table</th>
<th>Switch Bridge Port Table (discovery_switch_bridge_port_table) This table is used to map between a port number in the discovery_switch_fwd_table and an interface index.</th>
</tr>
</thead>
<tbody>
<tr>
<td>OID</td>
<td>iso.org.dod.internet.mgmt.mib-2.dot1dBridge.dot1dBase.dot1dBasePortTable, dot1dBasePort, dot1dBasePortIfIndex</td>
</tr>
</tbody>
</table>
| Fields populated | • cmdb_ci  
• port  
• interface_index |

SNMP - Switch - SpanningTreeTable

This probe returns the active path between any two network nodes bridged by a switch.

Spanning tree data returned

<table>
<thead>
<tr>
<th>Table</th>
<th>Switch Spanning Tree Table (discovery_switch_spanning_tree_table). This table is used to find Layer 2 connections between switches.</th>
</tr>
</thead>
<tbody>
<tr>
<td>OID</td>
<td>iso.org.dod.internet.mgmt.mib-2.dot1dBridge.dot1dStp.dot1dStpPortTable, dot1dStpPort, dot1dStpPortState, dot1dStpPortEnable, dot1dStpPortDesignatedRoot, dot1dStpPortDesignatedBridge</td>
</tr>
</tbody>
</table>

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
Fields populated
- cmdb_ci
- port
- port_state
- port_enable
- designated_root
- designated_bridge_mac

SNMP - Switch - ForwardingTable

This probe returns information from a switch's forwarding table.

Forwarding table data returned

<table>
<thead>
<tr>
<th>Table</th>
<th>Switch Forwarding Table (discovery_switch_fwd_table) This is the forwarding table for the switches.</th>
</tr>
</thead>
</table>

OIDs
These OIDs are built as needed by the DiscoveryVlanSwitchProcessor script include.

- **Non-Cisco**:  
  - **Q-BRIDGE MIB**: oid_spec_list = 'table iso.org.dod.internet.mgmt.mib-2.dot1dBridge.qBridgeMIB.qBridge qBridgeMIBObjects.dot1qTp.dot1qTpFdbTable dot1qTpFdbAddress,' + vlanIndex + ' ,dot1qTpFdbPort.' + vlanIndex + ' ,dot1qTpFdbStatus.' + vlanIndex;
  - **BRIDGE MIB**: oid_spec_list = 'table iso.org.dod.internet.mgmt.mib-2.dot1dBridge.dot1dTp.dot1dTpFdbTable dot1dTpFdbAddress,dot1dTpFdbPort,dot1dTpFdbStatus';
  - **Cisco BRIDGE MIB**: oid_spec_list = 'table iso.org.dod.internet.mgmt.mib-2.dot1dBridge.dot1dTp.dot1dTpFdbTable dot1dTpFdbAddress,dot1dTpFdbPort,dot1dTpFdbStatus';

Additional probe called
The SSH probe Switch - MAC Table can be triggered by the DiscoveryVlanSwitchProcessor script include to populate additional Layer 2 data. If you are missing Layer 2 data after you run discovery on multiple VLANs, you should enable the triggering of the Switch - MAC Table probe and run discovery again.

To do this, add this property to the System Property (sys_properties) table: glide.discovery.sensors.forwardingtable.ssh. Set the value of the property to true. By default this property is false.

Command
show mac address-table

Fields populated
- cmdb_ci
- vlan_id
- port
- status
- mac_address (from the cmdb_ci field in the Network Infrastructure Item (discovery_net_base) table)

SNMP - Switch - Vlan

© 2020 ServiceNow, Inc. All rights reserved.

This probe returns VLAN IDs from a network switch and these OIDs:

- `iso.org.dod.internet.private.enterprises.cisco.ciscoMgmt.ciscoVtpMIB.vtpMIBObjects.vlanInfo.vtpVlanTable vtpVlanState`
- `iso.org.dod.internet.private.enterprises.cisco.ciscoMgmt.ciscoVlanMembershipMIB.ciscoVlanMembershipMIBObjects.vmMembership.vmMembershipSummaryTable vmMembershipSummaryVlanIndex,vmMembershipSummaryMemberPorts,vmMembershipSummaryMember2kPorts`
- `iso.org.dod.internet.private.enterprises.juniperMIB.jnxMibs.jnxExMibRoot.jnxExSwitching.jnxExVlan.jnxVlanMIBObjects.jnxExVlanTable jnxExVlanTag`
- `iso.org.dod.internet.mgmt.mib-2.system.sysDescr`

Other switch types are not supported.

**Port tables**

These port tables are populated during horizontal Discovery of a device:

- Network Adapter (`cmdb_ci_network_adapter`)
- Switchport (`dscy_switchport`)
- Router Interface (`dscy_router_interface`)
- Load Balancer Interface (`cmdb_ci_lb_interface`)

**TCP connection discovery**

Discovery identifies and classifies information about TCP connections using the ADM and ADME probes.

Discovery populates this data in the TCP Connections (`cmdb_tcp`) table.

<table>
<thead>
<tr>
<th>Label</th>
<th>Table Name</th>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Absent</td>
<td>cmdb_tcp</td>
<td>absent</td>
<td>If the process is no longer running on this device. The first time the process is detected, the value is not selected (meaning that it is not absent). If Discovery runs again and does not detect the process, it is selected.</td>
</tr>
<tr>
<td>Computer</td>
<td>cmdb_tcp</td>
<td>computer</td>

<td>count</td>
<td>The number of times that Discovery detects a specific TCP connection. This field is used by ADM enhanced probes.</td>
</tr>
</tbody>
</table>

### Standard ADM probes

Discovery launches these probes with standard ADM discovery:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Includes these sub-probes</th>
</tr>
</thead>
<tbody>
<tr>
<td>AIX - ADM</td>
<td>Queries for information about active (running) AIX processes and active connections - the information required to perform application dependency mapping.</td>
<td>AIX - Active Connections, AIX - Active Processes</td>
</tr>
<tr>
<td>HP-UX - ADM</td>
<td>Queries for information about active (running) HP-UX processes and active connections - the information required to perform application dependency mapping. This probe requires that Isol be installed and the UNIX - Active Connections probe be activated, which is inactive by default.</td>
<td>UNIX - Active Connections, HP-UX - Active Processes</td>
</tr>
<tr>
<td>Solaris - ADM</td>
<td>Queries for information about active (running) Solaris processes and active connections - the information required to perform application dependency mapping. This probe is triggered by the Solaris Zones probe. The system triggers an ADM probe for each local zone contained in a global zone. This probe requires that Isol be installed on the global zone.</td>
<td>Solaris - Active Processes, Solaris - Active Connections</td>
</tr>
<tr>
<td>UNIX - ADM</td>
<td>Queries for information about active (running) UNIX processes and active connections - the information required to perform application dependency mapping.</td>
<td>UNIX - Active Connections, UNIX - Active Processes</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
<td>Includes these sub-probes</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| Windows - ADM               | Queries for information about active (running) Windows processes and active connections - the information required to perform application dependency mapping. | • Windows - Active Connections  
• Windows - Active Processes                                                                 |
| UNIX - ADM netstat          | Performs the same functions as the UNIX ADM probe relying on netstat to support continuous TCP-based discovery. Service Mapping uses this probe for traffic-based discovery. | • UNIX - Active Connections with Netstat. This probe retrieves TCP connections to populate the cmdb_tcp and cmdb_tcp_connection tables.  
• UNIX - Active Processes. This probe retrieves TCP processes and populates the cmdb_running_process table. |

### Enhanced ADM probes

Discovery launches these probes when enhanced ADM is activated:

<table>
<thead>
<tr>
<th>Probe</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows - ADM Enhanced</td>
<td>Performs the same functions as the Windows ADM probe with additional parameters to control continuous TCP-based discovery. This probe is compatible with WinRM and non-WinRM supported MID Servers. Configure your MID Server using the mid.windows.management_protocol parameter. See MID Server parameters for the values you can use for this parameter.</td>
</tr>
<tr>
<td>UNIX - ADM Enhanced</td>
<td>Performs the same functions as the UNIX ADM probe with additional parameters to control continuous TCP-based discovery.</td>
</tr>
</tbody>
</table>

Use these probe parameters with the enhanced ADM probes:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mid.adme.max_result_size</td>
<td>Control the size of the TCP tracking file.</td>
</tr>
<tr>
<td>max.adme_result_payload_size</td>
<td>Controls the size of the result, including the payload.</td>
</tr>
</tbody>
</table>

**Note:** If this is greater than the MID server property mid.discovery.max_payload_size, a configuration error can occur.
**IP address discovery**
Discovery identifies and classifies information about IP addresses.

<table>
<thead>
<tr>
<th>Label</th>
<th>Table Name</th>
<th>Field Name</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>

<td>SNMP, IP MIB</td>
</tr>
</tbody>
</table>
### Router and switch discovery

Discovery identifies and classifies information about network routers and switches.

Network routers and switches often have very similar capabilities. It is very common for some switches known as Layer 3 switches to have IP routing. Larger routers with optional modules might accept switching modules. Because of these overlaps and the resulting ambiguity of a particular device's classification, Discovery collects the same data for both routers and switches, if it is available in any given device. For details on how Discovery collects data about connections between network devices and other components, see [Layer 2 discovery](#).

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

### Prerequisites for server and network device discovery

- The server or network device needs to have IP Address information.
- The system property `glide.discovery.L3_mapping` is set to true to discover routers and switches.
- The router or Layer 3 switch that provides the IP Address needs to have been successfully discovered with populated Exit Interface Routing Rules.

### System properties

You can configure many aspects of Discovery to work according to your personal preferences. The following properties apply to network routers and switches. To view the properties, navigate to [Discovery Definition > Properties](#) unless indicated otherwise.

### Property Description

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| glide.discovery.L3_mapping | Provides a logical mapping of the TCP/IP layer for network gears. This is not Layer 2 mapping.  
  - **Type:** string  
  - **Default value:** true  
  - **Location:** System Property (sys_properties) table |
| glide.discovery.max_concurrent_invocations_per_schedule | Sets a maximum number of scheduled invocations of the same Discovery schedule. It prevents a backlog of scheduled runs if Discovery does not finish before the next invocation is scheduled to run. The value is an integer that represents the max number of automated invocations of the same schedule that may proceed at one time. If the limit has been reached, subsequent scheduled invocations are canceled. A value of 0 or any negative number disables this property.  
  - **Type:** integer  
  - **Default value:** 3  
  - **Location:** Discovery Definition > Properties |

### Credentials

Discovery explores many kinds of devices, such as switches, routers, and printers, using the SNMP protocol. SNMP Community Credentials do not include a user name, just a password, which is the community string. The default read-only community string for many SNMP devices is public, and Discovery will try that automatically. SNMPv3 credentials require a user name and a key, depending on the protocol selected. Enter the appropriate SNMP credentials if they differ from the public community string.

**Note:** SSH is not supported for routers and switches, but is supported for load balancers.

### Classifier, pattern, and probes

<table>
<thead>
<tr>
<th>Classifiers</th>
<th>Trigger probes</th>
<th>Pattern</th>
</tr>
</thead>
</table>
| Standard Network Router  
Standard Network Switch |  
- Horizontal Pattern: launches patterns  
- SNMP-Routing*  
- DNS*  
- SNMP-Identity*  
- SNMP-Switch-Vlan*  
- SNMP-Switching*  
- SNMP - Network - ArpTable* (Standard Network Switch only) | Network Router  
Network Switch |
*For new instances, these probes are inactive on the classifier. Discovery uses patterns for discovery.

^This probe remains active by default for the Standard Network Router classifier, even when Discovery uses pattern discovery.

To use patterns, verify that the correct pattern is specified in the horizontal pattern probe on the classifier. See [Add the Horizontal Pattern probe to a classifier](#) for instructions.

**Discovering stacked switches**

The Network Switch shared library supports stacked switches. The CI table for this is IP Switch (`cmdb_ci_ip_switch`). Multiple switches in the stack are identified by the master’s IP address. Each member of the stack is identified by a combination of elements, including the master IP address, a name associated with the switch, and the stack mode. The relationship is created between a master and all of its slaves.

Turn off collection of port data for SNMP network devices

In some environments you may not want to collect the port data for SNMP network devices. If the network devices contain an extremely large number of ports and each individual port's information is not critical to the overall management of the devices, you may not want to collect the port data for SNMP network devices. This would affect records from being created in the Switchports table (dscy_switchport). This process only impacts probe discovery.

1. Navigate to Discovery Definition > Probes.
2. Go to the SNMP - Switching probe.
3. In the SNMP Fields tab, find the field named ports. Double-click the value in the Active column. Change the value to false.

The collection and processing of ports information for switches is then disabled. The ports field for the switch CI should have the correct ports count even though the related list switchports is empty.

4. Click the check mark to save the change.

IP service and daemon discovery
Discovery identifies and classifies information about services and daemons.

### IBM WebSphere DataPower discovery

Discovery identifies and classifies information about DataPower devices.

### Pattern

By default, Discovery uses the DataPower Server pattern to perform the discovery.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

### Credentials

Configure both [SNMP credentials](#) and [applicative credentials](#).

### Classifier and OIDs

The **DataPower Server** classifier uses these OIDs:

<table>
<thead>
<tr>
<th>OID</th>
<th>Manufacturer</th>
<th>Model</th>
<th>Table</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.3.6.1.4.1.14685.1.3</td>
<td>IBM</td>
<td>Data Power Hosting Server (cmdb_ci_datapower_server)</td>
<td></td>
</tr>
<tr>
<td>1.3.6.1.4.1.14685.1.8</td>
<td>IBM</td>
<td>Data Power Hosting Server (cmdb_ci_datapower_server)</td>
<td></td>
</tr>
<tr>
<td>1.3.6.1.4.1.14685.1.4</td>
<td>IBM</td>
<td>DataPower XB62</td>
<td>Data Power Hosting Server (cmdb_ci_datapower_server)</td>
</tr>
</tbody>
</table>
The classifier kicks off the *Horizontal Pattern probe* to perform identification and exploration of the device.

### Data collected

The following data is collected on the Data Power Hosting Server \([\text{cmdb\_ci\_datapower\_server}]\) table.

<table>
<thead>
<tr>
<th>Label</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model name</td>
<td>model_name</td>
</tr>
<tr>
<td>Host name</td>
<td>host_name</td>
</tr>
<tr>
<td>Serial number</td>
<td>serial_number</td>
</tr>
</tbody>
</table>

The following data is collected on the Network Adapters \([\text{cmdb\_ci\_network\_adapter}]\) table.

<table>
<thead>

* Cisco Unified Computing System (UCS)-HD device discovery
  Discovery identifies and classifies information about Cisco UCS equipment, including chassis and blades.

  **Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

### Credentials

Configure both *SNMP credentials* and *applicative credentials*.

### Classifier, pattern, and OIDs

The *UCS* classifier uses *HorizontalDiscoveryProbe* to launch the *UCS - HD* pattern. The classifier also uses these SNMP OIDs, which specify the Cisco UCS Equipment \([\text{cmdb\_ci\_ucs\_equipment}]\) table:

<table>
<thead>
<tr>
<th>OID</th>
<th>Manufacturer</th>
<th>Model</th>
<th>Table</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.3.6.1.4.1.9.12.3.1.3.847</td>
<td>Unified Computing Cisco UCS 6120XP 20-Port Fabric Interconnect</td>
<td>1.4(3u)(NX-OS) 5.0 Aggregation Switch</td>
<td>Cisco UCS Equipment</td>
</tr>
<tr>
<td>1.3.6.1.4.1.9.12.3.1.3.899</td>
<td>Unified Computing Cisco UCS 6140XP 40-Port Fabric Interconnect</td>
<td>1.4(3u)(NX-OS) 5.0 Aggregation Switch</td>
<td>Cisco UCS Equipment</td>
</tr>
</tbody>
</table>
Data collected

Only B-series devices are discovered. The UCS - HD pattern does not find C, S, or E series devices. The following data is collected on the Cisco UCS Equipment \texttt{[cmdb\_ci\_ucs\_equipment]} table.

<table>
<thead>
<tr>
<th>Label</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>
<td>IP address</td>
<td>ip_address</td>
</tr>
<tr>
<td>Model</td>
<td>model_id</td>
</tr>

Dell Remote Assistant Card discovery

The Dell™ Remote Assistant Card (DRAC) provides users with tools and functionality to monitor, troubleshoot, and repair servers. You can generate DNS URLs to access out-of-band devices when security prevents access from IP addresses.

To identify the DRAC, Discovery uses the SNMP – DRAC probe. This probe uses SNMPv1 and SNMPv2c. Out-of-band devices have a dedicated management channel for device maintenance. System administrators can remotely monitor and manage devices with the dedicated management channel, including hardware sensor monitoring, access to local media drives, or adjusting BIOS settings. DNS URLs can be generated for out-of-band devices to access the out-of-band device page when the SSL certificate forbids navigating through the IP address.

Data collected

Data collected by Discovery for Dell DRAC

<table>
<thead>
<tr>
<th>Label</th>
<th>Table</th>
<th>Name</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Type</td>
<td>cmdb_ci_outofband_device</td>
<td>type</td>
<td>SNMP walk: drsProductType</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(racType for iDRAC7)</td>
</tr>
<tr>
<td>URL</td>
<td>cmdb_ci_outofband_device</td>
<td>url</td>
<td>SNMP walk: drsProductURL</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(racURL for iDRAC7)</td>
</tr>
</tbody>
</table>

* Host is a reference to the cmdb_ci_computer table via the serial number. For the cmdb_ci_outofband_device.host field to be populated correctly, the host machine must be discoverable or exist within the CMDB with the appropriate serial number.

Out-of-band devices

A DNS URL is generated for configuration items in the Out-Of-Band Device list if the configuration item has a Name and DNS Domain. The DNS URL enables you to access the out-of-band device page when the SSL certificate forbids navigating through the IP URL. The DNS URL has the format https://Name.DNS_Domain. If either the Name or DNS Domain field is empty, the DNS URL contains the value in the URL field.

HTTP device discovery

Discovery can find devices that use the HTTP protocol.
Note: Probe-to-pattern migration is supported for the New York release and later. See the knowledge article KB0694477 for more information.

Credentials

Classifier, probes, and patterns

HTTP discovery relies on a the HTTP port probe, which Discovery runs after trying to run SSH and SNMP port probes. This port probe launches the HTTP - Classify probe which runs an HTTP GET request for every entry in the HTTP classification table. You should configure your own classifications that the HTTP - Classify probe can access.

The HTTP port probe uses mappings between a protocol and port number in the IP Service (cmdb_ip_service) table. You can add additional port-to-protocol definitions in this table, or you can override the protocol used for a specific HTTP classifier.

<table>
<thead>
<tr>
<th>Classifier</th>
<th>Probes</th>
<th>Pattern</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• HTTP (port probe):</td>
<td>HTTP (port probe): this probe launches the HTTP - Classify probe, which runs an HTTP GET request for every entry in the HTTP classification table.</td>
</tr>
</tbody>
</table>

Data collected

Run discovery through an HTTP or HTTPS REST call

Discovery can classify devices using the HTTP(S) protocol. You can create your own HTTP classifier to find devices and access them with Basic Auth credentials, rather than using SNMP or SSH credentials.

Role required: discovery_admin

1. Navigate to Discovery > Credentials.
2. Click New.
3. Select Basic Auth Credentials. In most cases, you can use Basic Auth Credentials to access a device through an HTTP or HTTPS REST call.
4. Add the user name and password you need to access the device.
5. Click Submit.
6. Set up an HTTP classifier by navigating to Discovery Definition > CI Classification > HTTP.
7. Click New.
8. Fill out the form fields (see table):

### The F5 HTTP classification

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a name for the classifier.</td>
</tr>
<tr>
<td>Path</td>
<td>Enter the path for the HTTP GET request.</td>
</tr>
<tr>
<td>Headers</td>
<td>Add an option header with a value. You can use a variable in the format ${variable} instead of a static value. Supported headers depend on the REST web service provider you want to connect to. See the documentation for your web service provider to identify which headers are valid or required.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Port (IP Service)</td>
<td>If you want this classifier to use a custom port that is not already a default value in the IP Service (cmdb_ip_service) table, do the following:</td>
</tr>
<tr>
<td></td>
<td>1. Click the lookup icon to see the list of IP Services.</td>
</tr>
<tr>
<td></td>
<td>2. Click <strong>New</strong> and create a new port-to-protocol mapping.</td>
</tr>
<tr>
<td></td>
<td>3. Select that port-to-protocol mapping for this <strong>Port</strong> field.</td>
</tr>
<tr>
<td></td>
<td>Many commonly used protocols are already mapped to ports by default, such as <strong>http</strong> to port 80 and the <strong>https</strong> to port 443.</td>
</tr>
<tr>
<td></td>
<td>If you want to use one of these default port-to-protocol mappings, do not enter any values in the <strong>Port</strong> field. The HTTP port probe uses the correct one by default.</td>
</tr>
<tr>
<td>Order</td>
<td>Enter a number that represents the priority of this classifier. If Discovery finds more than one classifier that applies, it uses the classifier with lower <strong>Order</strong> number.</td>
</tr>
<tr>
<td>Protocol (optional)</td>
<td>If you configure a unique port-to-protocol mapping for the <strong>Port</strong> field, enter an optional protocol override that Discovery uses with this classifier.</td>
</tr>
<tr>
<td></td>
<td>For example, if you want to use port 5000 and the HTTP protocol, add the 5000/HTTP port-to-protocol mapping to the <strong>Port</strong> field, and then choose <strong>http</strong> in the <strong>Protocol</strong> field.</td>
</tr>
</tbody>
</table>

9. Right-click the header and select **Save**.

   The HTTP Classification Match related list appears. This related list shows criteria that you can configure to match against the body of the response to the GET Request that Discovery sent.

10. In the HTTP Classification Match related list, define the match criteria and specify the pattern to launch for this classifier:
   a) Click **New**.
   b) On the HTTP Classification Match form, fill in the form fields (see table).
c) Click **Submit**.

d) Define as many HTTP Classification Matches as necessary. You might want to do this if there are different patterns for different versions of the device you are trying to discover.

In this example, HTTP classification is configured to use the f5 load balancer API:

If you do not have other types of credentials that can find devices, such as Linux credentials or SNMP credentials, you can see how the Discovery application processes HTTP discovery:

1. Navigate to **Discovery** > **Discovery Schedules** and run a discovery.
2. After the discovery process completes, check the ECC Queue to see the results of the HTTP discovery.

You should see that after the Shazzam probe was launched, and that Unix and SNMP classification probes failed. Both the HTTP - Classify probe and the pattern that you specify in the HTTP classification record should launch.

<table>
<thead>
<tr>
<th>Topic</th>
<th>Name</th>

<td>See Payload</td>
<td>output</td>
</tr>
</tbody>
</table>

**Software discovery**

Discovery identifies several types of software.

**Active Directory Domain Controller discovery**

Discovery creates or updates a CMDB record when it detects a running instance of Active Directory Domain Controller on Windows machines.

By default, Discovery uses the **Active Directory Domain Controller On Windows** pattern to perform the discovery.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

The following data is collected on the Active Directory Domain Controllers [cmdb_ci_ad_controller] table:

<table>
<thead>
<tr>
<th>Label</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>
<td>Version</td>
<td>version</td>
</tr>
<tr>
<td>Class</td>
<td>sys_class_name</td>
</tr>
</tbody>
</table>
Adobe JRun discovery
Discovery creates or updates a CMDB record when it detects a running instance of Adobe JRun. By default, Discovery uses the Jrun pattern to perform the Discovery.

Note: Probe-to-pattern migration is supported for the New York release and later. See the knowledge article KB0694477 for more information.

Privileged commands
For a list of privileged commands that you need for Discovery and Service Mapping, see Service Mapping commands requiring a privileged user for a list of the commands that require elevated rights to discover and map Unix-based hosts in your organization.

Data collected for Adobe JRun
The following data is collected in the Jrun [cmdb_ci_app_server_jrun] table:

<table>
<thead>
<tr>
<th>Label</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fully qualified domain name</td>
<td>fqdn</td>
</tr>
<tr>
<td>IP Address</td>
<td>ip_address</td>
</tr>
<tr>
<td>Installation directory</td>
<td>install_directory</td>
</tr>
<tr>
<td>Type</td>
<td>type</td>
</tr>
</tbody>
</table>

Apache web server discovery
Discovery identifies and classifies information about Apache web servers on both Windows and Linux computers.

Note: Probe-to-pattern migration is supported for the New York release and later. See the knowledge article KB0694477 for more information.

Credentials
- Applicative credentials
- Windows credentials
- SSH credentials
For a list of privileged commands that you need for Discovery and Service Mapping, see Service Mapping commands requiring a privileged user for a list of the commands that require elevated rights to discover and map Unix-based hosts in your organization.

**Classifier, patterns, and probes**

<table>
<thead>
<tr>
<th>Classifier</th>
<th>Trigger probes</th>
<th>Patterns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Apache Server</td>
<td>• Horizontal discovery probe: launches patterns</td>
<td>• Apache On Windows Pattern</td>
</tr>
<tr>
<td></td>
<td>• Apache - Version*</td>
<td>• Apache On Unix Pattern</td>
</tr>
<tr>
<td></td>
<td>• Apache - Get Configuration*</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Apache - Get JK Module</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Apache - Get Proxy Module</td>
<td></td>
</tr>
</tbody>
</table>

*For new instances, these probes are inactive on the classifier. Discovery uses patterns for discovery.

To use patterns, verify that the correct pattern is specified in the horizontal pattern probe on the classifier. See Add the Horizontal Pattern probe to a classifier for instructions.

**Data collected**

Discovery collects the following data on the Apache (cmdb_ci_apache_web_server) table for both Unix and Windows:

<table>
<thead>
<tr>
<th>Label</th>
<th>Field name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>
<td>Version</td>
<td>version</td>
</tr>
<tr>
<td>Description</td>
<td>description</td>
</tr>
<tr>
<td>TCP port(s)</td>
<td>tcp_port</td>
</tr>
</tbody>
</table>

Apache mod_jk and mod_proxy discovery

Discovery uses SSH to find Apache connectors mod_jk and mod_proxy.

Discovery uses the Unix - Active Processes probe to identify an Apache web server process by matching one of the following criteria: the name of the process is:

- httpd, or
- apache, or
- httpd2, or
- httpd2-prefork

If there is a match on one of these criteria, a record is created in the Web Server (cmdb_ci_web_server) table if one does not already exist for that running process.

The following probes are triggered after classification:
Apache web server probes

<table>
<thead>
<tr>
<th>Probe</th>
<th>Description</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Apache – Version</td>
<td>The sensor of this probe populates the Apache version information in the Web Server record.</td>
<td>httpd</td>
</tr>
<tr>
<td>Apache – Get Configuration</td>
<td>This probe contains a Bourne shell script and an argument that determines the path of the Apache configuration file. The sensor of this probe populates some additional information in the Web Server record.</td>
<td>echo, sed, httpd, cut, grep, egrep (within the Bourne shell script)</td>
</tr>
</tbody>
</table>

The sensor processing of the Apache – Get Configuration probe identifies whether either the mod_jk or mod_proxy modules are present and triggers the appropriate probe.

Apache module probes

<table>
<thead>
<tr>
<th>Probe</th>
<th>Description</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Apache – Get JK Module</td>
<td>If the mod_jk module is running as a load balancer on the server, the sensor of this probe populates the information in the Load Balancer Service (cmdb_ci_lb_service), Load Balancer Pool (cmdb_ci_lb_pool) and Load Balancer Pool Member (cmdb_ci_lb_pool_member) tables.</td>
<td>echo, sed, httpd, cut, grep, egrep (within the Bourne shell script)</td>
</tr>
<tr>
<td>Apache – Get Proxy Module</td>
<td>If the mod_proxy module is running as a load balancer on the server, the sensor of this probe populates the information in the Load Balancer Service (cmdb_ci_lb_service), Load Balancer Pool (cmdb_ci_lb_pool) and Load Balancer Pool Member (cmdb_ci_lb_pool_member) tables.</td>
<td>grep, egrep (within the Bourne shell script)</td>
</tr>
</tbody>
</table>

In addition to data population, the following relationships are created in the CI Relationship (cmdb_rel_ci) table:

- The records in the cmdb_ci_lb_appl table run on the cmdb_ci_web_server table records.
- The records in the cmdb_ci_lb_service table use the cmdb_ci_lb_pool table records.
- The records in the cmdb_ci_pool table are used by the cmdb_ci_service table record.
- The records in the cmdb_ci_pool table are members of the cmdb_ci_pool_member table.
- The records in the cmdb_ci_pool_member table are members of the cmdb_ci_pool table.

Legacy: Add sudo access for the Unix - Active Processes probe

For an Apache web server the Unix - Active Processes probe requires sudo privileges.
Role required: admin

You can configure the Unix - Active Processes probe to elevate privileges.

1. Navigate to Discovery > Probes.
2. In the Search field, search for Unix - Active Processes.
3. Click field, search for Unix - Active Processes probe.
4. In the Probe Parameters related list, click New.
5. Click New
6. Use the following information to fill out the form:

<table>
<thead>
<tr>
<th>Probe</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>must_sudo</td>
</tr>
<tr>
<td>Value</td>
<td>true</td>
</tr>
</tbody>
</table>

7. Click Submit

Data collected by Mod_jk module

The Apache mod_jk module forwards requests from the Apache web server to a Servlet container, such as Tomcat.

Additional mod_jk directives can also manage load balancing. Discovery populates the CMDB when it detects an Apache Server. When the Apache Web Server process is detected, if the mod_jk module is running on the web server as a load balancer, the related information populates to the CMDB.

- The MID Server user account to explore the target server must have access to the httpd.conf configuration file in the /etc/httpd/conf/ folder.
- Discovery uses secure shell (SSH) commands to identify the following associated elements:
  - Apache Get Configuration
  - Apache Version
  - Apache Get JK Module
- The following probes require execute privileges to run commands:

<table>
<thead>
<tr>
<th>Probes that require execute privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>Probe</td>
</tr>
<tr>
<td>Apache – Get Configuration</td>
</tr>
<tr>
<td>echo, sed, httpd, cut, grep, egrep (within the Borne shell script)</td>
</tr>
<tr>
<td>Apache – Version</td>
</tr>
<tr>
<td>httpd</td>
</tr>
<tr>
<td>Apache – Get JK Module</td>
</tr>
<tr>
<td>echo, sed, httpd, cut, grep, egrep (within the Borne shell script)</td>
</tr>
</tbody>
</table>

Probes and sensors

Discovery uses the Unix - Active Processes probe to identify an Apache server that contains the mod_jk module:

1. The Unix - Active Processes probe detects a running process that matches one of the following criteria:
   - The name of the process is httpd.
• The name of the process is apache.

2. If there is a match on one of these criteria, a record is created in the Web Server table (cmdb_ci_web_server) if one does not already exist for that running process. The following probes are also triggered:

• **Apache – Version**: the sensor of this probe populates the Apache version information in the Web Server record.

• **Apache – Get Configuration**: this probe contains a Bourne shell script and an argument that determines the path of the Apache configuration file. The sensor of this probe populates some additional information in the Web Server record.

3. The sensor processing of Apache – Get configuration probe results triggers the following probes if the mod_jk module is running on the web server:

• **Apache – JK Module**: if the mod_jk module is running as a load balancer on the server, the sensor of this probe populates the information in the Load Balancer Service (cmdb_ci_lb_service), Load Balancer Pool (cmdb_ci_lb_pool) and Load Balancer Pool Member (cmdb_ci_lb_pool_member) tables.

### Data Collected

For the mod_jk module with no load balancer, the following data is collected by default:

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Field and Label Name</th>
<th>Probe</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmdb_ci_web_server</td>
<td>Name (name)</td>
<td>Apache – Get Configuration</td>
</tr>
<tr>
<td>cmdb_ci_web_server</td>
<td>Version (version)</td>
<td>Apache – Version</td>
</tr>
<tr>
<td>cmdb_ci_web_server</td>
<td>Description (short_description)</td>
<td>Apache – Version</td>
</tr>
</tbody>
</table>

If the mod_jk module is enabled for load balancing, Discovery connects the following data:

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Field and Label Name</th>
<th>Probe</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmdb_ci_lb_appl</td>
<td>Name (name)</td>
<td>Apache – Apache - Get JK Module</td>
</tr>
<tr>
<td>cmdb_ci_lb_appl</td>
<td>IP Address (ip_address)</td>
<td>Apache – Apache - Get JK Module</td>
</tr>
<tr>
<td>cmdb_ci_lb_appl</td>
<td>Last Discovered (last_discovered)</td>
<td>Apache – Apache - Get JK Module</td>
</tr>
<tr>
<td>cmdb_ci_lb_pool_member</td>
<td>Name (name)</td>
<td>Apache – Apache - Get JK Module</td>
</tr>
<tr>
<td>cmdb_ci_lb_pool_member</td>
<td>Last Discovered (last_discovered)</td>
<td>Apache – Apache - Get JK Module</td>
</tr>
<tr>
<td>cmdb_ci_lb_pool_member</td>
<td>IP Address (ip_address)</td>
<td>Apache – Apache - Get JK Module</td>
</tr>
</tbody>
</table>
### Table Name | Field and Label Name | Probe
---|---|---
cmdb_ci_lb_pool_member | Load Balancer (load_balancer) | Apache – Apache - Get JK Module

cmdb_ci_lb_pool_member | Port (port) | Apache – Apache - Get JK Module

cmdb_ci_lb_service | Input URL (input_url) | Apache – Apache - Get JK Module

cmdb_ci_lb_service | Last Discovered (last_discovered) | Apache – Apache - Get JK Module

cmdb_ci_lb_service | IP Address (ip_address) | Apache – Apache - Get JK Module

cmdb_ci_lb_service | Name (name) | Apache – Apache - Get JK Module

cmdb_ci_lb_service | Load Balancer (load_balancer) | Apache – Apache - Get JK Module

cmdb_ci_lb_service | Port (port) | Apache – Apache - Get JK Module

cmdb_ci_lb_pool | Last Discovered (last_discovered) | Apache – Apache - Get JK Module

cmdb_ci_lb_pool | Load balancing Method (load_balancing_method) | Apache – Apache - Get JK Module

cmdb_ci_lb_pool | Load Balancer (load_balancer) | Apache – Apache - Get JK Module

cmdb_ci_lb_pool | Name (name) | Apache – Apache - Get JK Module

### Relationships

In addition to data population, the following relationships are created in the CI Relationship (cmdb_rel_ci) table:

- The records in the cmdb_ci_lb_appl table run on the cmdb_ci_web_server table records.
- The records in the cmdb_ci_lb_service table use the cmdb_ci_lb_pool table records.
- The records in the cmdb_ci_pool table are used by the cmdb_ci_service table record.
- The records in the cmdb_ci_pool table are members of the cmdb_ci_pool_member table.
- The records in the cmdb_ci_pool_member table are members of the cmdb_ci_pool table.

### Data collected by Mod_proxy module

The Apache mod_proxy module implements a proxy, gateway, or cache for the Apache web server.

An additional mod_proxy_balancer can also manage load balancing. Discovery populates the CMDB when it detects an Apache server. When the Apache Web Server process is detected, if the mod_proxy module is running on the web server as a load balancer the related information populates to the CMDB.

Consider the following requirements for discovering an Apache server that contains the mod_proxy module:

- The MID Server user account to explore the target server must have access to the httpd.conf configuration file in the /etc/httpd/conf folder.
• Discovery uses secure shell (SSH) commands to identify the following associated elements:
  • Apache Get Configuration
  • Apache Version
  • Apache Get Proxy Module

• The following probes require execute privileges to run commands:

<table>
<thead>
<tr>
<th>Data collected from the mod_jk module</th>
</tr>
</thead>
<tbody>
<tr>
<td>Probe</td>
</tr>
<tr>
<td>------------------------</td>
</tr>
<tr>
<td>Apache – Get Configuration</td>

<tr>
<td>Apache – Get Proxy Module</td>
</tr>
<tr>
<td>Apache – Version</td>
</tr>
</tbody>
</table>

Probes and sensors

Discovery uses the Unix - Active Processes probe to identify an Apache server that contains the mod_proxy module. The probes and sensors operate in the following manner:

1. The Unix - Active Processes probe detects a running process that matches one of the following criteria:
   • The name of the process is httpd.
   • The name of the process is apache2.

2. If there is a match on one of these criteria, a record is created in the Web Server table (cmdb_ci_web_server) if one does not already exist for that running process. The following probes are also triggered:
   • **Apache – Version**: the sensor of this probe populates the Apache version information in the Web server (cmdb_ci_web_server) record.
   • **Apache – Get Configuration**: this probe contains a Bourne shell script and an argument that determines the path of the Apache configuration file. The sensor of this probe populates some additional information in the Web server (cmdb_ci_web_server) record.

3. The sensor processing of the Apache – Get configuration probe results triggers the following probes if the mod_proxy module is running on the web server:
   • **Apache - Get Proxy Module**: if the mod_proxy module is running as a load balancer on the server, the sensor of this probe populates the information in the Load Balancer Service (cmdb_ci_lb_service), Load Balancer Pool (cmdb_ci_lb_pool) and Load Balancer Pool Member (cmdb_ci_lb_pool_member) tables.

Data Collected

For the mod_proxy module with no load balancer, the following data is collected by default:
Data collected by Discovery by default

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Field and Label Name</th>
<th>Probe</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmdb_ci_web_server</td>
<td>Name (name)</td>
<td>Apache – Get Configuration</td>
</tr>
<tr>
<td>cmdb_ci_web_server</td>
<td>Version (version)</td>
<td>Apache – Version</td>
</tr>
<tr>
<td>cmdb_ci_web_server</td>
<td>Description (short_description)</td>
<td>Apache – Version</td>
</tr>
</tbody>
</table>

If the mod_proxy module is enabled for load balancing, Discovery connects the following data:

Data collected by Discovery if the mod_proxy module is identified as a load balancer

Relationships

In addition to data population, the following relationships are created in the CI Relationship (cmdb_rel_ci) table:

- The records in the cmdb_ci_lb_appl table run on the cmdb_ci_web_server table records.
- The records in the cmdb_ci_lb_service table use the cmdb_ci_lb_pool table records.
- The records in the cmdb_ci_pool table are used by the cmdb_ci_service table records.
- The records in the cmdb_ci_pool are members of the cmdb_ci_pool_member table records.
• The records in the cmdb_ci_pool_member is a member of the cmdb_ci_pool table records.

Application Mapping for UNIX discovery
To perform the mapping that establishes application relationships, Discovery must be able to detect TCP connections.

The best way to accomplish this is to run the `lsot` command on target machines. However, this command is not available by default on Solaris and AIX machines. To return TCP connection information on these machines, Discovery uses custom shell scripts. For Solaris, the shell script runs the `pfiles` command to query each process. The `pfiles` command causes momentary pauses in the processes it queries on Solaris target machines. These pauses can last from a few milliseconds to a few seconds, during which no other processing can occur. To avoid pausing process threads, the base system disables active connection probes for Solaris machines, but can be configured to use these if the pauses are not an issue. For AIX machines, Discovery is configured to use the active connection probe for AIX targets. However, the user that executes the shell script on AIX machines might require additional privileges to execute commands, such as `kdb`, employed in the script.

On Linux machines, Discovery uses the `lsot` command (installed by default on Linux) to detect TCP connections. The Linux classification probe triggers the Linux - Active Connections probe, which uses `lsot` to discover application relationships and does not produce any pauses. The `lsot` command is the recommended method of returning active TCP connections and can be installed on Solaris and AIX target machines to eliminate any issues produced by the shell script.

**Note:** Discovery of active connections on HP-UX is not supported.

Using the ServiceNow Shell Script
This procedure causes Discovery to run a shell script that uses the `pfiles` command to query processes on a Solaris machine for active connection information. This procedure does not use the `lsot` command to perform application mapping.

1. Navigate to **Discovery Definition > CI Classification > UNIX**.
2. Select **Solaris** from the list.
3. In the UNIX Classification form for Solaris, select the **Triggers probes** related list, and then click **Edit**.
4. Move **Solaris - Active Connections** from the Collections list to the Triggers probe List.
Using the lsof Command

5. Click Save.
Use the ls of command to return active TCP connections and can be installed on Solaris and AIX target machines.

1. Install lsof on the Solaris and AIX machines on which you want to gather application relationship data.
2. In the instance, navigate to Discovery Definition > CI Classification > UNIX.
3. Select Solaris from the list.
4. In the UNIX Classification form for Solaris, select the Triggers probes related list, and then click Edit.
5. Move Linux - Active Connections from the Collections list to the Triggers probe List. This probe is configured to use lsof.
6. Click Save.
7. Repeat this procedure for the AIX classification probe.
Citrix License Server and Delivery Controller discovery
Discovery can find Citrix License Server instances and Delivery Controller components that run on Windows machines.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

**Requirements**

- Configure Windows administrative credentials to access the host machine.
- Make sure that PowerShell for Discovery is installed on your MID Servers. The patterns used for Citrix discovery require the ability to run PowerShell commands.
- (Optional) For top-down discovery with Service Mapping, on Citrix Delivery Controller, install the Citrix.Broker module.
- (Optional) For top-down discovery with Service Mapping, a user with permission to run PowerShell commands.
- (Optional) For discovering using the WinRM protocol, see Configure WinRM trusted hosts on MID Server.

**Patterns**

Discovery uses these patterns to perform horizontal discovery:

<table>
<thead>
<tr>
<th>Pattern</th>
<th>Process detected</th>
</tr>
</thead>
<tbody>
<tr>
<td>Citrix License Server</td>
<td>ladmin.exe</td>
</tr>
<tr>
<td>Delivery Controller</td>
<td>BrokerService</td>
</tr>
</tbody>
</table>

**Data collected and relationships**

Clustered application discovery on Windows
A process and its corresponding resource information can be used to determine whether the process is a clustered process.

The Microsoft SQL Server process classifier that comes with your instance identifies clustered SQL Servers. You can leverage the same technique to detect other clustered applications on Windows using Discovery.

To detect Windows clustered applications with Discovery, you create a process classifier that detects whether a process is a clustered process. Perform the following steps:

Create a classifier for clustered processes
To detect Windows clustered applications, create a process classifier for that CI type.

1. Navigate to Discovery Definition > CI Classification > Processes.
2. Click New.
3. Fill out the form using the fields from the table.
4. Click Submit.
### Process classification form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name for the process classifier.</td>
</tr>
<tr>
<td>Table</td>
<td>Select <strong>Application</strong>.</td>
</tr>
<tr>
<td>Relation type</td>
<td>Select the CI relationship type for this classification. The relationship field is only available for Process and Scan Application classifications. Discovery process classifications typically use one of these relationship types:</td>
</tr>
<tr>
<td></td>
<td>- <strong>Runs on::Runs</strong>: Defines the relationship of an application to the host on which it runs. This relationship is expressed from the perspective of the host and the application. For example: My database application runs on server001::server001 runs my database application.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Depends on::Used by</strong>: Defines the relationship of an application that communicates with another application. This relationship is expressed from the perspective of each application. For example: The Tomcat application depends on the MySQL database:: The MySQL database is used by Tomcat.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Virtualized by::Virtualizes</strong>: Defines the relationship of a virtual machine to its host. This relationship is expressed from the perspective of the virtual machine and of the host. For example: server001 is virtualized by ServerESX::Server ESX virtualizes server001.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Cluster of::Cluster</strong>: Defines the relationship of a cluster node to the cluster to which it belongs. This relationship is expressed from the perspective of the cluster node and of the cluster.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Hosted on::Hosts</strong>: Defines the relationship of a cluster node and the Windows host. This relationship is expressed from the perspective of the cluster node and of the Windows host.</td>
</tr>
<tr>
<td>Active</td>
<td>Select this box to activate the process classification. Deselect to deactivate it.</td>
</tr>
<tr>
<td>Order</td>
<td>Enter the order in which Discovery should run this process classification when there are multiple classifications available for a table. Discovery runs process classifications from the lowest to the highest order.</td>
</tr>
<tr>
<td>Test with</td>
<td>Lists the host CI where an automatically generated process classification conditions were met. Use this field to test changes to the process classification to ensure that the updated classification behaves as expected.</td>
</tr>
</tbody>
</table>
## Relate the process classifier to Windows cluster resources

In the second step, relate the process classifier to the information that is in the Windows Cluster resources table.

The **Windows Cluster** resources table is `cmdb_ci_win_cluster_resource`. This relationship is built through JavaScript.

1. Navigate back to the process classification you just made.
2. Click the **Parameters** tab.
3. Click **New**.
4. Fill out the fields on the form as appropriate (see table).
5. Click **Submit**.

### Classifier parameter form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Select a unique name.</td>
</tr>
<tr>
<td>Application</td>
<td>Select <strong>Global</strong>.</td>
</tr>
<tr>
<td>Type</td>
<td>Enter <strong>Cluster</strong>.</td>
</tr>
<tr>
<td>Value</td>
<td>This field defines two JavaScript objects, called <code>resourceType</code> and <code>isMatch</code>. For more information, see Populate the Value field on the Classifier Parameter form.</td>
</tr>
</tbody>
</table>
Populate the Value field on the Classifier Parameter form

The value field defines two JavaScript objects, called `resourceType` and `isMatch`.

The `resourceType` value refers to the Resource Type column in the Windows Cluster Resources table (`cmdb_ci_win_cluster_resource`). The `resourceType` value cannot be empty or null.

1. Navigate to a Windows cluster page to access the Windows Cluster Resources table.
2. Click the Windows Cluster Resources tab.

The `isMatch` value evaluates whether the process is a clustered process.

- An evaluation that returns `true` indicates the process is a clustered application, and the process is classified as a clustered application in the cluster.
- An evaluation that returns `false` classifies the process as a regular application running on the cluster node.

The `isMatch` value is a function that contains two input variables, process and resource:

- `process`: Process is the GlideRecord of the process application. It is determined by the Table field in the classifier. In this example, it is the GlideRecord entry of the Application table (`cmdb_ci_app`) for the process that is being classified. You have access to any field values for the CI type such as name or version.
- `resource`: Resource is the GlideRecord entry in the Windows Cluster Resource table after the resourceType condition has been applied. In the example, it is the GlideRecord entry of the sixth row.

Examples of JavaScript for the Value field

In the following example code: `resourceType: "SQL Server"` the query filters the Windows Cluster Resources table entry for the Resource Type field that has a value that is equal to SQL Server. In the following example table, the sixth record would be returned.

The following script indicates that if there is a resource of type SQL Server, the process is classified as a clustered application.

```javascript
resourceType: "SQL Server"
isMatch: function(process, resource) {
  return true;
}
```

The following script indicates that if there is a resource of type SQL Server, and the application name is equal to the resource name, then the process is classified as a clustered application.

```javascript
resourceType: "SQL Server"
isMatch: function(process, resource) {
  if (process.name == resource.name)
    return true;
}
```

If there are multiple matches to the resourceType condition, the matching function is called multiple times. For the following resourceType example, the matching
function is called twice because there are two entries that have **Physical Disk** in the **Resource Type** column in the sample Windows Cluster Resources table.

```
resourceType: "Physical Disk"
```

**Windows Cluster Resources**

![Windows Cluster Resources table]

---

**Discovery with Software Asset Management**

The table structure for managing software installations behaves differently when the Software Asset Management (SAM) application is activated.

The presence of this application affects the way Discovery stores the software installation data it returns from a scan and require additional configuration within configuration item (CI) records.

The following tables are created when the Software Asset Management plugin is activated:

- Software Discovery Model (cmdb_sam_sw_discovery_model)
- Software Model (cmdb_software_product_model)
- Software Installation (cmdb_sam_sw_install)

**Note:** The original schema used by previous versions is not affected when the Software Asset Management plugin is not activated.

When it runs, Discovery populates the Software Installation (cmdb_sam_sw_install) table. The appropriate configuration item (CI) references the software data. A business rule on this table runs, searching for a matching record on the Software Discovery Model (cmdb_sam_sw_discovery_model) table. If a record exists in the Software Discovery Model table, then the Software Installation table updates the record. If no record exists in the Software Discovery Model table, then one is created.

These tables are **not** used by Discovery with Software Asset Management:
- Software (cmdb_ci_spkg)
- Software Model (cmdb_software_product_model)

**Important:** When SAM is installed, the Software Installation (cmdb_sam_sw_install) table is the appropriate source for all current software data. This means you need to update any related lists or customized reference fields you added to CI records.

Starting with the Kingston release, the Discovery populates the VMWare License Key (samp_vmware_license_key) and VMWare License Key Usage (samp_vmware_license_key_usage) tables. See Data collected for VMware vCenter Server for more information on where Discovery saves vCenter data.

Configure a CI to display Software Asset Management data

After you activate the Software Asset Management plugin, configure the form for any computer CI that you want to discover to show data from the Software Installation (cmdb_sam_sw_install) table.

**Role required:** admin

1. Open any computer CI record.
2. Configure the form to add the Software Installation related list and remove the Software Installed related list.

**Exchange Client Access Server (CAS) discovery**

Discovery creates or updates a CMDB record when it detects a running instance of Exchange Client Access Server.

By default, Discovery uses the CAS On Windows pattern to discover the Exchange Client Access Server.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article KB0694477 for more information.

**Data collected by Discovery on the Exchange Client Access Server**

The following data is collected on the Exchange Client Access Server (cmdb_ci_exchange_cas) table:

<table>
<thead>
<tr>
<th>Label</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>
<td>Version</td>
<td>version</td>
</tr>
<tr>
<td>Class</td>
<td>sys_class_name</td>
</tr>
<tr>
<td>Fully qualified domain name</td>
<td>fqdn</td>
</tr>
<tr>
<td>IP Address</td>
<td>ip_address</td>
</tr>
<tr>
<td>Installation directory</td>
<td>install_directory</td>
</tr>
<tr>
<td>Type</td>
<td>type</td>
</tr>
</tbody>
</table>

**Exchange Hub Transport Servers discovery**

Discovery creates or updates a CMDB record when it detects a running instance of Exchange Hub.
By default, Discovery uses the **Hub Transport Server On Windows** pattern to discover Exchange Hub Transport Servers.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

### Data collected by Discovery on Exchange Hub Transport Servers

The following data is collected on the Exchange Hub Transport Servers 
[cmdb_ci_exchange_hub_transport_server] table:

<table>
<thead>
<tr>
<th>Label</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>
<td>Version</td>
<td>version</td>
</tr>
<tr>
<td>Class</td>
<td>sys_class_name</td>
</tr>
<tr>
<td>Fully qualified domain name</td>
<td>fqdn</td>
</tr>
<tr>
<td>IP Address</td>
<td>ip_address</td>
</tr>
<tr>
<td>Installation directory</td>
<td>install_directory</td>
</tr>
<tr>
<td>Type</td>
<td>type</td>
</tr>
</tbody>
</table>

**Exchange MailBox discovery**

Discovery creates or updates a CMDB record when it detects a running instance of Exchange Mailbox.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

### Prerequisites

The service `winRM` must be running on the host machine. Run the following command in the PowerShell window to verify:

```powershell
```

**Pattern**

By default, Discovery uses the **MailBox On Windows** pattern to discover Exchange MailBox.

**Credentials**

Configure these credentials:
<table>
<thead>
<tr>
<th>Credential type</th>
<th>Additional notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applicative credentials</td>
<td>The user must be able to run Powershell commands against the Exchange hosts.</td>
</tr>
<tr>
<td></td>
<td>Use <strong>Exchange Mailbox</strong> as the CI type for the applicative credential.</td>
</tr>
<tr>
<td></td>
<td><strong>Attention:</strong> Do not use the <strong>Exchange Mailbox server</strong> CI type.</td>
</tr>
<tr>
<td>Windows credentials</td>
<td>The OS user must be a domain user, not a local user for the server.</td>
</tr>
</tbody>
</table>

### Data collected

The following data is collected on the Exchange Mailboxes (cmdb_ci_exchange_mailbox) table:

<table>
<thead>
<tr>
<th>Label</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>
<td>Version</td>
<td>version</td>

<td>port</td>
</tr>
</tbody>
</table>

**HP Operations Manager discovery**

Discovery creates or updates a CMDB record when it detects a running instance of HP Operations Manager.

By default, Discovery uses the **HP Operations Manager for Windows** pattern to discover the HP Operations Manager.

*Note: Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.*

Data collected by Discovery for HP Operations Manager

The following data is collected in the HP Operations Manager [cmdb_ci_appl_hp_operations] table:

<table>
<thead>
<tr>
<th>Label</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
</tbody>
</table>

**HP Service Manager discovery**

Discovery creates or updates a CMDB record when it detects a running instance of HP Service Manager.

By default, Discovery uses the **HP Service Manager Application Server** pattern to discover HP Service Manager.
**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

## Data collected by Discovery for HP Service Manager

The following data is collected on the HP Service Manager `{cmdb_ci_appl_hp_service}` table.

<table>
<thead>
<tr>
<th>Label</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>

**IBM WebSphere Message Broker (WMB) and WMB HTTP Listener discovery**

Discovery creates or updates a CMDB record when it detects a running instance of IBM WMB and the WMB HTTP listener for both Linux and Windows.

By default, Discovery uses the following patterns to perform the discovery:

- WMB On Unix
- WMB On Windows
- WMB HTTP Listener On Unix
- WMB HTTP Listener On Windows

**Note:** SNOW OOB WMB patterns support WMB versions 6, 7, and 8.

For a list of privileged commands that you need for Discovery and Service Mapping, see [Service Mapping commands requiring a privileged user](#) for a list of the commands that require elevated rights to discover and map Unix-based hosts in your organization.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

## Data collected by Discovery for IBM WebSphere Message Brokers and IBM WMB Http Listener

The following data is collected in the IBM WebSphere Message Brokers `{cmdb_ci_appl_ibm_wmb}` table and the IBM WMB Http Listener `{cmdb_ci_appl_ibm_wmb_listener}` table:

<table>
<thead>
<tr>
<th>Label</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>

</table>

Microsoft IIS server discovery
Discovery identifies and classifies information about Microsoft IIS servers.

Prerequisites

Install IIS Management Scripts and Tools on a Microsoft IIS Server.

Credentials

Configure these credentials:

- Applicative credentials
- Windows credentials

Classifier, pattern, and probe

Note: Probe-to-pattern migration is supported for the New York release and later. See the knowledge article KB0694477 for more information.
Discovery uses these classifiers, probes, and patterns for IIS discovery:

<table>
<thead>
<tr>
<th>Classifier</th>
<th>Trigger probes</th>
<th>Pattern</th>
</tr>
</thead>
</table>
| Microsoft IIS Server | • Horizontal discovery probe: launches patterns  
|                  | • Windows - Get IIS Information*                                               | IIS     |

*Probes inactive on new instances.

To use patterns, verify that the correct pattern is specified in the horizontal pattern probe on the classifier. See [Add the Horizontal Pattern probe to a classifier](#) for instructions.

**Data collected by Discovery for IIS Web Server**

The following data is collected in the IIS Web Server (cmdb_ci_microsoft_iis_web_server) table:

<table>
<thead>
<tr>
<th>Label</th>
<th>Field name</th>

</table>

**Microsoft SharePoint discovery**

Discovery creates or updates a CMDB record when it detects a running instance of Microsoft SharePoint.

By default, Discovery uses the SharePoint pattern to discover Microsoft SharePoint.

*Note: Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.*

**Data collected by Discovery for Microsoft SharePoint**

The following data is collected in the SharePoints [cmdb_ci_appl_sharepoint] table:
<table>
<thead>
<tr>
<th>Label</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>
<td>Class</td>
<td>sys_class_name</td>
</tr>
<tr>
<td>Fully qualified domain name</td>

<td>ip_address</td>
</tr>
<tr>
<td>Version</td>
<td>version</td>
</tr>
<tr>
<td>Category</td>
<td>category</td>
</tr>
<tr>
<td>Type</td>
<td>type</td>
</tr>
</tbody>
</table>

**NGINX web server discovery**

NGINX is an open source web server with a load balancer. Discovery identifies the web server and information related to the load balancer.

Discovery identifies NGINX server software using the following process:

1. The NGINX Process Classifier detects a running process that matches the following criteria during the exploration of a Linux server:
   - Name starts with nginx
   - Name contains master

2. If there is a match:
   - A record is created in the NGINX Web Server (`cmdb_ci_nginx_web_server`) table.
   - A Runs on relationship is created in the CI Relationship (`cmdb_rel_ci`) table for a Linux server (Linux Server (`cmdb_ci_linux_server`)) and for an NGINX web server (NGINX Web Server (`cmdb_ci_nginx_web_server`)).

   The following two probes are triggered:
   - NGINX - Version: This probe contains a Bourne shell script. It determines the version of NGINX and populates the NGINX Web Server (`cmdb_ci_nginx_web_server`) table.
   - NGINX - Get Configuration: This probe contains a Bourne shell script and an argument that determines the path of the NGINX configuration file. The probe identifies configuration parameters based on keywords within the configuration file and returns them as a single payload result.

   The sensor on the ServiceNow instance parses the payload result and populates the CMDB.

You must have the following requirements to discover an NGINX webserver:

- NGINX is installed and running on the server.
- The MID Server has access to the NGINX configuration file, which is `/etc/nginx/nginx.conf` by default.

**Requirements**

For NGINX servers:

- Ensure that the NGINX software is installed and running on the server.
- Grant the MID Server has access to the NGINX configuration file, which is `/etc/nginx/nginx.conf` by default.
- Enable secure shell (SSH) commands to identify the following associated elements:
The following probes require execute privileges to run commands:

<table>
<thead>
<tr>
<th>Probe</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nginx ± Version</td>
<td>nginx</td>
</tr>
<tr>
<td>Nginx ± Get Configuration</td>
<td>echo, sed, httpd, cut, grep, egrep (within the Bourne shell script)</td>
</tr>
</tbody>
</table>

**Probes and Sensors**

Discovery identifies NGINX server software using the following process:

1. The Nginx Process Classifier detects a running process that matches the following criteria during the exploration of a UNIX server:
   - The name of the process starts with `nginx`.
   - The name of the process contains `master`.

2. If there is a match:
   - A record is created in the Web Server (cmdb_ci_web_server) table.
   - A Runs on relationship is created in the CI Relationship (cmdb_rel_ci) table for the Linux Server (cmdb_ci_linux_server) table and the Web Server (cmdb_ci_web_server) table.

3. The following two probes are triggered:
   - **Nginx – Version**: this probe contains a Bourne shell script. It determines the version of NGINX and populates the Web Server (cmdb_ci_web_server) table.
   - **Nginx – Get Configuration**: this probe contains a Bourne shell script and an argument that determines the path of the NGINX configuration file. The probe identifies configuration parameters based on keywords within the configuration file and returns them as a single payload result.

4. The sensor on the ServiceNow instance processes the payload and populates the CMDB.

**Data Collected**

Discovery creates or updates CMDB records when it detects a running NGINX process. The following data is collected.

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Field and Label Name</th>
<th>Probe</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>cmdb_ci_lb_appl (name)</td>
<td>Nginx– Get Configuration</td>

<tr>
<td>Fully Qualified Domain Name</td>
<td>cmdb_ci_lb_pool_member (fqdn)</td>
<td>Nginx– Get Configuration</td>
</tr>
<tr>
<td>Port</td>
<td>cmdb_ci_lb_pool_member (port)</td>
<td>Nginx– Get Configuration</td>
</tr>
<tr>
<td>Last Discovered</td>
<td>cmdb_ci_lb_service (last_discovered)</td>
<td>Nginx– Get Configuration</td>
</tr>
<tr>
<td>IP Address</td>
<td>cmdb_ci_lb_service (ip_address)</td>
<td>Nginx– Get Configuration</td>
</tr>
<tr>
<td>Name</td>
<td>cmdb_ci_lb_service (name)</td>
<td>Nginx– Get Configuration</td>
</tr>
<tr>
<td>Load Balancer</td>
<td>cmdb_ci_lb_service (load_balancer)</td>
<td>Nginx– Get Configuration</td>
</tr>
<tr>
<td>Input URL</td>
<td>cmdb_ci_lb_service (input_url)</td>
<td>NGINX – Get Configuration</td>
</tr>
</tbody>
</table>

### Relationships

In the table (cmdb_rel_ci) the following relationships are populated:
- The records in the cmdb_ci_lb_appl table run on the cmdb_ci_web_server table records.
- The records in the cmdb_ci_lb_service table use the cmdb_ci_lb_pool table records.
- The records in the cmdb_ci_pool table are used by the cmdb_ci_service table records.
- The records in the cmdb_ci_pool table are members of the cmdb_ci_pool_member table.
- The records in the cmdb_ci_pool_member table are members of cmdb_ci_pool table.

**Oracle Tuxedo discovery**

Discovery creates or updates a CMDB record when it detects a running instance of Oracle Tuxedo.

By default, Discovery uses the **Tuxedo** pattern to discover Oracle Tuxedo.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

### Data collected by Discovery for Oracle Tuxedo

The following data is collected the Tuxedo (cmdb_ci_appl_tuxedo) table:
Puppet automation software discovery
Discovery identifies Puppet Masters running on UNIX servers.
Discovery uses secure shell (SSH) commands to collect information.
To access Puppet Master records, navigate to Configuration > Automation Servers > Puppet Masters. You can view the resources in the related list of the Puppet Master record.

How the Puppet Master probe works
Discovery identifies the Puppet Master using the following process:

1. The UNIX - Active Processes probe detects a running process that matches one of the following criteria:
   - The name of the process is `pe-httpd`.
   - The name of the process is `ruby` and the parameters of the process contain `puppet master`.

2. If there is a match on one of these criteria:
   - A record is created in the Puppet Master table (cmdb_ci_puppet_master) if one does not already exist for that running process.
   - The Puppet - Master Info probe is triggered. The sensor of this probe populates additional information in the Puppet Master (cmdb_ci_puppet_master) record.

3. With the activation of the Puppet Configuration Management plugin, the sensor processing of Puppet - Master Info triggers the following simultaneously:
   - Puppet – Certificate Requests: The sensor of this probe populates the Puppet Certificate Request (puppet_certificate_request table) with open requests. Open requests are requests that are not already signed or rejected.
   - MultiProbe Puppet – Resources: This probe contains the following probes:
     - Puppet – Module: The sensor of this probe populates records within the Puppet Module (puppet_module) table.
     - Puppet – Manifests: The sensor of this probe populates records within the Puppet Manifest (puppet_manifest), Puppet Class (puppet_class), and Puppet Parameter (puppet_parameter) tables.

Requirements to discover a Puppet master
By default, Discovery identifies Puppet Masters running on UNIX servers. Discovery uses secure shell (SSH) commands to collect information.
With the addition of the Puppet Configuration Management plugin, Discovery identifies the following associated elements:

- Puppet Certification Requests
- Puppet Manifests
- Puppet Modules

The credentials used to discover the UNIX server must have privileges to execute the following commands. The use of `sudo` is supported, but you must add the `must_sudo` parameter to the probe.

<table>
<thead>
<tr>
<th>Probe</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Puppet – Master Info</td>
<td>puppet, echo, hostname (within the Borne shell script)</td>
</tr>
<tr>
<td>Puppet – Certificate Requests</td>
<td>puppet</td>
</tr>
<tr>
<td>Puppet – Manifests</td>
<td>echo, sed, find (within the Bourne shell script)</td>
</tr>
<tr>
<td>Puppet – Modules</td>
<td>puppet</td>
</tr>
</tbody>
</table>

Data collected

Data collected by Discovery for Puppet automation software, by default

<table>
<thead>
<tr>
<th>Name</th>
<th>Puppet Master</th>
<th>puppet_module (cmdb_ci_puppet_master)</th>
<th>Puppet - Master Info</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configuration directory</td>
<td>Puppet Master</td>
<td>config_directory (cmdb_ci_puppet_master)</td>
<td>Puppet - Master Info</td>
</tr>
<tr>
<td>Manifest directory</td>
<td>Puppet Master</td>
<td>manifestdir (cmdb_ci_puppet_master)</td>
<td>Puppet - Master Info</td>
</tr>
<tr>
<td>Module path</td>
<td>Puppet Master</td>
<td>modulepath (cmdb_ci_puppet_master)</td>
<td>Puppet - Master Info</td>
</tr>
<tr>
<td>Fully qualified domain name</td>
<td>Puppet Master</td>
<td>fqdn (cmdb_ci_puppet_master)</td>

<td>Puppet - Manifests</td>
</tr>
</tbody>
</table>
Add the must_sudo parameter to the Puppet probe

To use the Puppet probe with sudo, you must add the must_sudo parameter to each probe that requires it.

Role required: admin

You add the must_sudo parameter for each Puppet probe.

1. Navigate to Discovery > Probes.
2. In the Search field, search on the name Puppet.
3. Click the name of the probe.
   
   For example, Puppet Master - Info.
4. In the Related Links pane, select the Probe parameters tab.
5. Click New.
6. In the Name field, enter must_sudo
7. In the Value field, enter true.
8. Click Submit.

SAP ABAP SAP Central Services (ASCS) discovery

Discovery creates or updates a CMDB record when it detects a running instance of SAP ASCS.

By default, Discovery uses the SAP ASCS Application pattern to discover SAP ASCS.

For a list of privileged commands that you need for Discovery and Service Mapping, see Service Mapping commands requiring a privileged user for a list of the commands that require elevated rights to discover and map Unix-based hosts in your organization.

Note: Probe-to-pattern migration is supported for the New York release and later. See the knowledge article KB0694477 for more information.

Data collected by Discovery for SAP ASCS

The following data is collected in the SAP ASCS [cmdb_ci_appl_sap_ascs] table:

<table>
<thead>
<tr>
<th>Label</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>

</tbody>
</table>

### SAP Business Objects CMS Server discovery

Discovery creates or updates a CMDB record when it detects a running instance of SAP Business Objects CMS Server.

By default, Discovery uses the **SAP Business Objects CMS Server on Windows** pattern to discover SAP Business Objects CMS Server.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

### Data collected by Discovery for SAP Business Objects CMS Server

The following data is collected on the SAP Business Objects CMS server [cmdb_ci_appl_sap_bo] table:

<table>
<thead>
<tr>
<th>Label</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>
<td>Server Name</td>
<td>server_name</td>
</tr>
<tr>
<td>Version</td>
<td>version</td>
</tr>
<tr>
<td>Installation directory</td>
<td>install_directory</td>
</tr>
</tbody>
</table>

### SAP Central Services discovery

Discovery creates or updates a CMDB record when it detects a running instance of SAP Central Services (SAS).

By default, Discovery uses the **SAP SCS Application** pattern to discover SAP Central Services.

For a list of privileged commands that you need for Discovery and Service Mapping, see [Service Mapping commands requiring a privileged user](#) for a list of the commands that require elevated rights to discover and map Unix-based hosts in your organization.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.
### Data collected by Discovery for SAP Central Services

The following data is collected in the SAP SCS Application [cmdb_ci_appl_sap_scs] table:

<table>
<thead>
<tr>
<th>Label</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>
<td>Version</td>

<tr>
<td>System directory</td>
<td>system_directory</td>
</tr>
<tr>
<td>System type</td>
<td>system_type</td>
</tr>
<tr>
<td>Transport domain</td>
<td>transport_domain</td>
</tr>
</tbody>
</table>

### SAP Convergent Invoicing (CI) discovery

Discovery creates or updates a CMDB record when it detects an instance of SAP CI.

By default, Discovery uses the **SAP CI Application** pattern to discover SAP Convergent Invoicing.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](https:// servicenow.com) for more information.

### Data collected by Discovery for SAP Convergent Invoicing

The following data is collected in the SAP CI Application [cmdb_ci_appl_sap_ci] table:

<table>
<thead>
<tr>
<th>Label</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>
<td>Version</td>
<td>version</td>

<tr>
<td>System directory</td>
<td>system_directory</td>
</tr>
<tr>
<td>System type</td>
<td>system_type</td>
</tr>
<tr>
<td>Transport domain</td>
<td>transport_domain</td>
</tr>
</tbody>
</table>
SAP Development Infrastructure (DI) discovery
Discovery creates or updates a CMDB record when it detects a running instance of SAP DI.

By default, Discovery uses the SAP DI Application pattern to discover SAP Development Infrastructure.

Note: Probe-to-pattern migration is supported for the New York release and later. See the knowledge article KB0694477 for more information.

Data collected by Discovery for SAP Development Infrastructure

The following data is collected in the SAP DI Applications [cmdb_ci_appl_sap_di] table:

<table>
<thead>
<tr>
<th>Label</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>
<td>Version</td>

</tr>
<tr>
<td>System type</td>
<td>system_type</td>
</tr>
<tr>
<td>Transport domain</td>
<td>transport_domain</td>
</tr>
</tbody>
</table>

SAP Evaluated Receipt Settlement (ERS) discovery
Discovery creates or updates a CMDB record when it detects a running instance of SAP ERS.

By default, Discovery uses the SAP ERS Application pattern to discover SAP Evaluated Receipt Settlement.

Note: Probe-to-pattern migration is supported for the New York release and later. See the knowledge article KB0694477 for more information.

Data collected by Discovery for SAP Evaluated Receipt Settlement

The following data is collected in the SAP ERS Application [cmdb_ci_appl_sap_ers] table:

<table>
<thead>
<tr>
<th>Label</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>
<td>Version</td>
<td>version</td>
</tr>
<tr>
<td>Installation directory</td>
<td>install_directory</td>
</tr>
<tr>
<td>Configuration directory</td>
<td>config_directory</td>
</tr>
<tr>
<td>Configuration file</td>
<td>config_file</td>
</tr>
</tbody>
</table>
SQL Server Analysis Services (SSAS) discovery
Discovery creates or updates a CMDB record when it detects a running instance of SQL Server Analysis Services.

By default, Discovery uses the **SSAS pattern** pattern to discover SQL Server Analysis Services.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

Data collected by Discovery for SQL Server Analysis Services

The following data is collected in the SQL Server Analysis Services 
[cmdb_ci_db_mssql_analysis] table:

<table>
<thead>
<tr>
<th>Label</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Instance name</td>
<td>instance_name</td>
</tr>
<tr>
<td>Instance number</td>
<td>instance_number</td>

<td>transport_domain</td>
</tr>
</tbody>
</table>

Sun Java Enterprise System (JES) discovery
Discovery creates or updates a CMDB record when it detects a running instance of Sun JES.

By default, Discovery uses the **Sun JES pattern** pattern to discover Sun Java Enterprise System.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

Data collected by Discovery for Sun Java Enterprise System

The following data is collected in the JES [cmdb_ci_email_server_jes] table:
**Tibco ActiveMatrix BusinessWorks discovery**
Discovery creates or updates a CMDB record when it detects a running instance of Tibco ActiveMatrix BusinessWorks.

By default, Discovery uses the following patterns to perform the discovery:

- **ActiveMatrix Business Works**
- **ActiveMatrix Business Works Process**

For a list of privileged commands that you need for Discovery and Service Mapping, see [Service Mapping commands requiring a privileged user](#) for a list of the commands that require elevated rights to discover and map Unix-based hosts in your organization.

**Data collected by Discovery for Tibco ActiveMatrix BusinessWorks**

The following data is collected in the ActiveMatrix Business Works `[cmdb_ci_appl_tibco_matrix]` table.

<table>
<thead>
<tr>
<th>Label</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>

</table>

**Tibco Enterprise Message Service discovery**
Discovery creates or updates a CMDB record when it detects a running instance of Tibco Enterprise Message Service.

By default, Discovery uses the **Enterprise Message Service** pattern to discover Tibco Enterprise Message Service.

For a list of privileged commands that you need for Discovery and Service Mapping, see [Service Mapping commands requiring a privileged user](#) for a list of the commands that require elevated rights to discover and map Unix-based hosts in your organization.
Data collected by Discovery for Tibco Enterprise Message Service

The following data is collected in the Tibco Enterprise Message Services [cmdb_ci_appl_tibco_message] table.

<table>
<thead>
<tr>
<th>Label</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>

**Tomcat server discovery**

Discovery identifies and classifies information about Tomcat servers and Web applications running on Unix machines.

Discovery can identify and classify Web applications present in either the CATALINA_BASE directory or the CATALINA_HOME directory.

The classifier that finds Tomcat server processes uses the condition: (Parameters) (contains) (org.apache.catalina.startup.Bootstrap).

**Credentials**

Configure these credentials:

- **Applicative credentials**
- **SSH credentials**

For a list of privileged commands that you need for Discovery and Service Mapping, see *Service Mapping commands requiring a privileged user* for a list of the commands that require elevated rights to discover and map Unix-based hosts in your organization.
### Classifier, pattern, and probes

<table>
<thead>
<tr>
<th>Classifier</th>
<th>Trigger probes</th>
<th>Pattern</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tomcat</td>
<td>• Horizontal pattern: launches patterns&lt;br&gt;• SSHCommand-Tomcat - Find web.xml List*&lt;br&gt;• SSHCommand-Tomcat - Get server.xml*&lt;br&gt;• SSHCommand-Tomcat - Get Version*</td>
<td>Tomcat</td>
</tr>
</tbody>
</table>

*Probes inactive on new instances.*

To use patterns, verify that the correct pattern is specified in the horizontal pattern probe on the classifier. See [Add the Horizontal Pattern probe to a classifier](#) for instructions.

### Data collected

Discovery collects the following data on the Tomcat (cmdb_ci_app_server_tomcat) table for both Unix and Windows:

<table>
<thead>
<tr>
<th>Label</th>
<th>Field name</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
<td>server.info</td>
</tr>
<tr>

</tbody>
</table>

The following data is collected on the Web Service (cmdb_ci_web_service) table for both Unix and Windows:

<table>
<thead>
<tr>
<th>Label</th>
<th>Field name</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>App Server</td>
<td>app_server</td>
<td>Initial reference</td>
</tr>
</tbody>
</table>

The following data is collected on the Web Application (cmdb_ci_web_application) table for both Unix and Windows:

<table>
<thead>
<tr>
<th>Label</th>
<th>Field name</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>description</td>
<td>web.xml</td>
</tr>
</tbody>
</table>
WebLogic application server discovery

Discovery creates or updates a CMDB record when it detects an instance of an Oracle or BEA Weblogic application server running on a Windows or Linux system.

Requirements

For Windows

- **PowerShell** must be enabled on the MID Server.
- The WebLogic Administration Server instances that start via WebLogic NodeManager must have the `-Dweblogic.RootDirectory=<path>` parameter defined upon server startup. The Windows credential must also have read permissions on the `config.xml` file.

For Linux

- Discovery requires the use of these Bourne shell commands:
  - `find`
  - `cat`
  - `dirname`

- WebLogic administration server instances started via NodeManager must have the `-Dweblogic.RootDirectory=<path>` parameter defined and visible through the Linux `ps` `process` `stat` command (for each AdminServer) for the rest of the Linux WebLogic application server and web application information to be populated in the CMDB.
- The following configuration must be set on the `sudoers` file:
  ```
  User ALL=(root) NOPASSWD: /bin/sh *
  User is the user name on the SSH credential that you create for this discovery.
  ```
- This command must be able to be run:
  ```
  /bin/sh /tmp/snc-*--findcat.sh * *
  ```
- Do not make any changes to `findcat.sh`.
- If you are using probes, not patterns, for Weblogic discovery, the **Linux - Weblogic - Find config.xml** probe must specify this parameter and value: **must_sudo = true**

Note: Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

This relationship is made between an AdminServer and any managed servers it encapsulates.
Add sudo access for the Weblogic - Find config.xml probe

If you are not using the Weblogic pattern, you can add sudo privileges to the Linux, the Weblogic - Find config.xml probe.

Role required: admin

1. Navigate to **Discovery Definition > Probes**.
2. Search for and select the **Linux - Weblogic - Find config.xml** probe.
3. In the **Probe Parameters** related list, click **New**
4. Use the following information to complete the form

<table>
<thead>
<tr>
<th>Probe</th>
<th>Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>must_sudo</td>
</tr>
<tr>
<td>Value</td>
<td>true</td>
</tr>
</tbody>
</table>
5. Click Submit

Identifying Windows WebLogic application servers

If you are not using the Weblogic pattern, Discovery follows this process when it uses the Windows - Active Processes or Linux - Active Processes probes.

This process describes the use of probes, which are active on your instance if you upgrade. For new instances, Discovery uses the Weblogic pattern.

1. The Windows - Active Processes probe or Linux - Active Processes detects a running process that matches one of the following criteria:
   - The parameters of the process contain `weblogic.Server`.
   - The parameters of the process contain `-Dweblogic.name`.

2. If there is a match on one of the criteria:
   - A record is created in the BEA Weblogic (cmdb_ci_app_server_weblogic) table. The record is populated with the server name and TCP port, which is gathered from the running process.
   - The Windows - Weblogic - Find config.xml probe or the Linux - Weblogic - Find config.xml probe triggers. The sensor of this probe populates additional information in the BEA Weblogic (cmdb_ci_app_server_weblogic) record and the Web Application (cmdb_ci_web_application) record if applicable.

3. The Windows - Weblogic - Find config.xml probe or the Linux - Weblogic - Find config.xml probe attempts to find the related `config.xml` file for the server by:
   - Using the `-Dweblogic.RootDirectory=<path>` parameter defined in the running process.
   - (Windows) Searching for `config.xml` files under the `-Dplatform.home=<path>` parameter defined in the running process (not as efficient using the parameters of the process).
   - (Linux) Searching for the parent process that started the WebLogic server (only viable if the weblogic jvm was started via the `startWeblogic.sh` or related custom script and not the init process).

4. If there are associated web applications found in the WebLogic `config.xml` file, the Windows – Weblogic find web.xml probe triggers for each application. This probe reads the WebLogic `web.xml` file for each web application and the sensor, and then populates additional information.

**WebSphere server discovery**

The IBM WebSphere application server is a software framework with middleware that hosts Java-based web applications. Discovery creates or updates a CMDB record when it detects an instance of a WebSphere application server running on a Windows or Linux system.

**WebSphere discovery on Windows**

Requirements for discovery:

For WebSphere application servers running on Windows systems, enable PowerShell on the MID Server.
Linux discovery on Windows

Requirements for discovery:

- Enable SSH on the WebSphere Application Server.
- Set execute privileges to enable the following probes to run commands:
  - WebSphere - Get serverindex.xml: cat/read permissions on the serverindex.xml file
  - WebSphere - Get cell.xml: cat/read permissions on the cell.xml file
  - WebSphere - Get server.xml: cat/read permissions on the server.xml file

For a list of privileged commands that you need for Discovery and Service Mapping, see Service Mapping commands requiring a privileged user for a list of the commands that require elevated rights to discover and map Unix-based hosts in your organization.

Probes and sensors

Discovery uses this process to identify Linux WebSphere application servers:

1. The Unix - Active Processes probe detects a running process that matches the com.ibm.ws.runtime.WsServer. For example, the ...
   com.ibm.ws.bootstr...com.ibm.ws.runtime.WsServer process output has a parameter of /opt/IBM/WPS/profiles/ccmdb/config localhostNode01Cell ccmdb01 server1. The values are:
   - last parameter = server_name = server1
   - last parameter - 1 = node_name = ccmdb01
   - last parameter - 2 = cell_name = localhostNode01Cell
   - last parameter - 3 = config_path = '/opt/IBM/WPS/profiles/ccmdb/config'

2. If there is a match, a record is created in the IBM Websphere (cmdb_ci_app_server_websphere) table. The following probes are triggered:
   - WebSphere - Cell
   - WebSphere - Web Applications
   - WebSphere - Web Services

3. The WebSphere - Cell probe searches for the cell.xml file for the instance by using the parameters in the running process, and then searching in the related \<config_path>\cells \<cell_name>\ directory.

4. If the probe successfully finds the cell.xml file, the sensor reads its contents and populates additional Websphere Cell (cmdb_ci_websphere_cell) table records as necessary.

5. If the probe successfully finds the serverindex.xml file, the sensor reads its contents and populates additional Web Application (cmdb_ci_web_application) table records as necessary.

6. If the probe successfully finds the server.xml file, the sensor reads its contents and populates additional Web Service (cmdb_ci_web_service) table records as necessary.

Discovery uses this process to identify Windows WebSphere application servers:

1. The Windows - Active Processes probe detects a running process that matches the com.ibm.ws.runtime.WsServer. For example, the ...
   com.ibm.ws.bootstr...com.ibm.ws.runtime.WsServer process output has a parameter of /opt/IBM/WPS/profiles/ccmdb/config localhostNode01Cell ccmdb01 server1. The values are:
2. If there is a match, a record is created in the IBM WebSphere (cmdb_ci_app_server_websphere) table. The following probes are triggered:
   - Windows - WebSphere - Cell
   - Windows - WebSphere - Web Applications
   - Windows - WebSphere - Web Services

3. The Windows - WebSphere - Cell probe searches for the cell.xml file for the instance by using the parameters in the running process, and then searching in the related <config_path>/cells/<cell_name>/ directory.

4. If the probe successfully finds the cell.xml file, the sensor reads its contents and populates additional WebSphere Cell (cmdb_ci_websphere_cell) table records as necessary.

5. The Windows - WebSphere - Web Applications probe searches the serverindex.xml file for the instance by using the parameters in the running process, and then searching in the related <config_path>/cells/<cell_name>/nodes/<node_name>/ directory.

6. If the probe successfully finds the serverindex.xml file, the sensor reads its contents and populates additional Web Application (cmdb_ci_web_application) table records as necessary.

7. The Windows WebSphere - Web Services probe searches for the server.xml file for the instance by using the parameters in the running process, and then searching in the related <config_path>/cells/<cell_name>/nodes/<node_name>/servers/<server_name>/ directory.

8. If the probe successfully finds the server.xml file, the sensor reads its contents and populates additional Web Service (cmdb_ci_web_service) table records as necessary.

Database discovery

Discovery can find database applications, such as MySQL, Oracle, and MongoDB. Discovery can also find database management system software, such as MSSQL Server.

Database catalog discovery

The database catalog lists all the catalog objects, or databases, discovered for an instance of a database.

Databases vs. catalogs

Most database manufacturers use the term catalog to mean database, while Microsoft MSSQL uses the term database. Database catalogs can be imported into your instance from a third-party discovery tool, entered into the platform manually, or found by Discovery.

Important: Discovery does not support Oracle or MySQL database catalog discovery in the base system. You must create probes and sensors to find these. However, the Windows - MSSQL probe is available by default for MSSQL discovery. A pattern is also available. However, the pattern and the probes do not populate the same information.

To view a database catalog, navigate to Configuration > Database Catalogs and select a database.
**MSSQL usage of catalogs**

MSSQL database catalogs store metadata about an MSSQL database in the MSFT SQL Catalog (cmdb_ci_db_mssql_catalog) table. In the base system, the MSFT SQL Catalog form contains two fields: Name and Database instance. You can customize the form layout to show additional fields.

To access an MSFT SQL catalog record:

1. Navigate to Configuration > Database Instances > MSSQL and select a record.
2. In the instance record, select the MSFT SQL Catalogs related list.
3. Open an existing record from the list or click New to create a new catalog record.

**MSSQL server discovery**

Discovery identifies and classifies information about MSSQL servers on Windows machines.

A pattern performs the discovery of MSSQL instances. This pattern replaces the Windows - MSSQL probe for new instances. If you want to continue to use probes, you can deactivate the Horizontal discovery probe, which launches the pattern, and then activate the necessary probes.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article KB0694477 for more information.

**Credentials**

Configure these credentials:

<table>
<thead>
<tr>
<th>Credential type</th>
<th>Additional notes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Applicative credentials</strong></td>
<td>Only local credentials are supported. Domain users are not supported.</td>
</tr>
<tr>
<td><strong>Windows credentials</strong></td>
<td>The credentials need access to the following:</td>
</tr>
<tr>
<td></td>
<td>- A database user that can access these MSSQL tables:</td>
</tr>
<tr>
<td></td>
<td>sys.dm_exec_sessions and sys.dm_osSchedulers.</td>
</tr>
<tr>
<td></td>
<td>SERVERPROPERTY.</td>
</tr>
<tr>
<td></td>
<td>- The CI Type MSFT SQL Instance.</td>
</tr>
<tr>
<td>(optional)</td>
<td></td>
</tr>
<tr>
<td><strong>Applicative credentials</strong></td>
<td>The credentials need public access to the following:</td>
</tr>
<tr>
<td></td>
<td>- The target Windows host.</td>
</tr>
<tr>
<td></td>
<td>- The Microsoft SQL Server instance on the target Windows host. You must add the user to the SQL Server configuration.</td>
</tr>
<tr>
<td></td>
<td>- The MID Server host. The SMO libraries locally impersonate the credentials for the target system prior to connecting to the Microsoft SQL Server. This behavior is enforced by Active Directory. Authentication only succeeds if the domain requirements specified here are met.</td>
</tr>
</tbody>
</table>

**Note:** If there are no matching discovery credentials, probes may attempt to connect using the MID Server service credentials. The MID Server service credentials are only valid if the MID Server host is on same domain as the Microsoft SQL Server host.

Specify the CI type on the credential as MSFT SQL Instance.
Classifier, pattern, and probe

Discovery uses these classifiers, probes, and patterns for SQL discovery:

<table>
<thead>
<tr>
<th>Classifier</th>
<th>Trigger probes</th>
<th>Pattern</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microsoft SQL Server</td>
<td>- Horizontal discovery probe:</td>
<td>MSSql DB On Windows Pattern</td>
</tr>
<tr>
<td></td>
<td>- Horizontal discovery probe:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- Windows - MSSQL*</td>
<td></td>
</tr>
</tbody>
</table>

*Probes inactive on new instances.

To use patterns, verify that the correct pattern is specified in the horizontal pattern probe on the classifier. See [Add the Horizontal Pattern probe to a classifier](#) for instructions.

Data collected

The running processes of the database (the actual SQL server) is referred to as the database instance. The following data is collected in the MSFT SQL Instance (cmdb_ci_db_mssql_instance) table:

<table>
<thead>
<tr>
<th>Label</th>
<th>Field name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>
<td>Instance</td>
<td>instance_name</td>
</tr>
<tr>
<td>TCP port</td>
<td>tcp_port</td>
</tr>
<tr>
<td>Port dynamic</td>
<td>port_dynamic</td>
</tr>
<tr>
<td>Version name</td>
<td>version_name</td>
</tr>
<tr>
<td>Edition</td>
<td>edition</td>
</tr>
<tr>
<td>Version</td>
<td>version</td>
</tr>
<tr>
<td>Engine edition</td>
<td>engine_edition</td>
</tr>
<tr>
<td>Install directory*</td>
<td>install_directory</td>
</tr>
<tr>
<td>CPU sockets*</td>
<td>cpu_sockets</td>
</tr>
<tr>
<td>Service Pack*</td>
<td>service_pack</td>
</tr>
</tbody>
</table>

*These fields are populated by the pattern only.

The database is referred to as the catalog. The following data is collected in the MSFT SQL Catalog (cmdb_ci_db_mssql_catalog) table:

**Note:** Only the Windows - MSSQL probe, not the MSSql DB On Windows pattern, populates this table.

<table>
<thead>
<tr>
<th>Label</th>
<th>Field name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>
<td>Status</td>
<td>status</td>
</tr>
</tbody>
</table>
Note: You can find the data for the actual server on which the MSSQL instance and catalogs resides in the Windows computer (cmdb_ci_win_server).

Discovery populates the MSSQL database (cmdb_ci_db_mssql_database) table with the MSSql DB on Windows Pattern:

<table>
<thead>
<tr>
<th>Label</th>
<th>Field name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>
</tr>
<tr>
<td>Operational status</td>
<td>operational_status</td>
</tr>
</tbody>
</table>

For Microsoft SQL2000 servers, Discovery can match instance names to their process ID.

When Software Asset Management is activated, all discovered software is saved in at least two places in the CMDB: in the Software Installation (cmdb_sam_sw_install) table and the tables specific to the application type. A reference field is provided on these application-specific tables to the corresponding record in the Software Installation table.

Microsoft SQL Server cluster Discovery

Discovery identifies Microsoft SQL Server instances that are part of a cluster in the CMDB by the cluster name rather than as individual configuration items (CI). Discovery identifies Microsoft SQL Server instances in the CMDB that are part of a cluster by creating a Runs::Runs on relationship between the instance and its associated cluster, as well as the Runs::Runs on relationship between the instance and the actual host on which it runs.
Viewing discovered relationships

By default, a CI record for a server (node) hosting an SQL Server instance that is part of a cluster does not display the instance or the cluster as related items.

To see the cluster information on a CI record:

1. Add the **Cluster Nodes** related list to the form. This list displays the name of the node and the parent cluster.
### Configuration

<table>
<thead>
<tr>
<th>Name</th>
<th>cluster-node2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Company</td>
<td></td>
</tr>
<tr>
<td>Serial number</td>
<td>VMware-42 1d e6 78 46 f6 a1 6b-0f 9c b7 e1</td>
</tr>
<tr>
<td>Model ID</td>
<td>VMware, Inc. VMware Virtual Platform</td>
</tr>
<tr>
<td>Assigned to</td>
<td></td>
</tr>
<tr>
<td>Default Gateway</td>
<td>10.11.144.1</td>
</tr>
</tbody>
</table>

### Related Links

<table>
<thead>
<tr>
<th>Cluster Nodes</th>
<th>Name</th>
<th>Search</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cluster</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

*Server = cluster-node2*
2. Click the cluster name in the related list to drill into the CI record for that cluster. Individual SQL Server instances running on that cluster are listed in the Related Items hierarchy. The names in the list contain the instance name prepended to the host name with the @ symbol. In this example, MSSQLCLUSTER is the SQL Server instance name, and cluster-node2 is the name of the Windows host.
3. Click the name of the SQL Server instance in the Related Items list to open the record for that CI. The instance name is expressed in the format `instance@host name` and displays the relationship hierarchy to the configured number of levels, including the system databases that the instance uses, the cluster on which the instance runs, and the server on which the cluster runs.
<table>

Defining a clusterable process

1. Open the desired process classifier (Discovery Definition > CI Classification > Process).
2. Add the Parameters related list (if not visible).
3. Click New in the Parameters related list and add a new parameter, using the following values:
   - **Name**: Unique name of your choosing.
   - **Type**: Enter `Cluster`.
   - **Value**: Enter the following statement.

```javascript
resourceType: "Resource Type",
isMatch: function(process, resource) {
   // javascript function that returns true if a resource matches the classified process
}
```

### Defining Clusterable Processes

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>resourceType</td>
<td>Resource type the platform should look for in the cluster's Windows Cluster Resources related list.</td>
</tr>
<tr>
<td>isMatch</td>
<td>Determines if the cluster resource that is found, based on the type, is a match for the classified process being examined.</td>
</tr>
</tbody>
</table>
MySQL discovery
Discovery can identify an instance of MySQL that is running on UNIX or Windows operating systems.

Requirements
Discovery searches for the MySQL configuration file location from the following areas:

- UNIX: Discovery searches for the MySQL configuration file location from the mysqld process, or port 3306.
- Windows: Discovery searches for the MySQL configuration file location from the mysqld.exe process, or port 3306.

For each process, the following process parameters are explored in the following order:

--defaults-extra-file
--defaults-file
If the MYSQL configuration file location is not found from that search, then the following occurs:

- UNIX: The configuration file location defaults to `/etc/my.cnf`.
- Windows: No default configuration file location exists, and the probe to read the configuration file location is skipped.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

### Credentials

Configure these credentials:

- **Windows credentials**
- **SSH credentials**
- (optional) **Applicative credentials**

For a list of privileged commands that you need for Discovery and Service Mapping, see [Service Mapping commands requiring a privileged user](#) for a list of the commands that require elevated rights to discover and map Unix-based hosts in your organization.

### Classifiers, patterns, and probes

Discovery uses these classifiers, probes, and patterns for MySQL discovery:

<table>
<thead>
<tr>
<th>Classifier</th>
<th>Trigger probes</th>
<th>Pattern</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL Server</td>
<td>· Horizontal Pattern: launches patterns</td>
<td>MySQL server On Windows and Linux Patte</td>
</tr>
<tr>
<td></td>
<td>· Windows - MySQL Configuration*</td>
<td></td>
</tr>
<tr>
<td></td>
<td>· Windows - MySQL Version*</td>
<td></td>
</tr>
<tr>
<td></td>
<td>· MySQL - Configuration*</td>
<td></td>
</tr>
<tr>
<td></td>
<td>· MySQL - Version*</td>
<td></td>
</tr>
</tbody>
</table>

*For new instances, these probes are inactive on the classifier. Discovery uses patterns for discovery.

To use patterns, verify that the correct pattern is specified in the horizontal pattern probe on the classifier. See [Add the Horizontal Pattern probe to a classifier](#) for instructions.

### Data collected

Discovery populates these fields in the MySQL Instance (cmdb_ci_db_mysql_instance) table:

<table>
<thead>
<tr>
<th>Label</th>
<th>Field name</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL configuration</td>
<td>myconf</td>
<td>my.cnf</td>
</tr>
<tr>
<td>TCP port(s)</td>
<td>tcp_port</td>
<td>running_process</td>
</tr>
<tr>
<td>Version</td>
<td>version</td>
<td>mysqlld</td>
</tr>
</tbody>
</table>
MongoDB discovery
Discovery creates or updates a CMDB record when it detects a running instance of MongoDB.

The following data is collected:

<table>
<thead>
<tr>
<th>Data Collected by Discovery on MongoDB instances</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Label</strong></td>
</tr>
<tr>
<td>Version</td>
</tr>
<tr>
<td>Mongo configuration</td>
</tr>
<tr>
<td>TCP port(s)</td>
</tr>
</tbody>
</table>

PostgreSQL discovery
Discovery can find running instances of PostgreSQL on Windows and Linux systems.

Credentials and other prerequisites
These credentials are required:

- **SSH credentials**
- (optional) **Applicative credentials**

For a list of privileged commands that you need for Discovery and Service Mapping, see Service Mapping commands requiring a privileged user for a list of the commands that require elevated rights to discover and map Unix-based hosts in your organization.

The user must have root-level access to the database to access the `postgresql.conf` file.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

Oracle database discovery

Discovery can identify an Oracle database instance that is running on UNIX or Windows operating systems. It can also find Oracle clusterware, which runs Real Application Clusters (RAC).

Patterns perform the discovery of Oracle installations. These patterns replace several probes for new instances. If you want to continue to use probes, you can deactivate the Horizontal discovery probe, which launches the pattern, and then activate the necessary probes.

Discovery does not discover the Oracle databases themselves, which are referred to as database catalogs.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

Credentials

Configure these credentials:
### Credential type | Additional information
--- | ---
**Applicative credentials** | Applicative credentials are only mandatory for two use cases:
- Creating connections to database links
- Software Asset Management activated

You must add the database user you configured during Oracle database installation. Specify Oracle instance `[cmdb_ci_db_ora_instance]` as the CI type.

The user must have access to these Oracle tables:
- V$option
- V$PARAMETER
- dba_hist_active_sess_history
- dba_users

The user must also have access to the `tnsnames.ora` parameters file.

**Windows credentials** | You can also use Windows and SSH credentials in addition to applicative credentials. For Windows credentials, the user must have read permissions to the `tnsnames.ora` file. SSH credentials, must allow read permission to the `oratab` file and read permission to the System Parameter file.

For a list of privileged commands that you need for Discovery and Service Mapping, see [Service Mapping commands requiring a privileged user](#).

For a list of the commands that require elevated rights to discover and map Unix-based hosts in your organization.

**SSH credentials** | The following commands are run for Oracle clusterware:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>`ps -ef</td>
<td>grep 'crsd.bin'</td>
</tr>
<tr>
<td>`ps -ef</td>
<td>grep LISTENER</td>
</tr>
<tr>
<td>`/u01/app/12.1.0.2/grid/bin/olsnodes -c</td>
<td>egrep -v 'error</td>
</tr>
</tbody>
</table>

### Additional requirements

Discovery identifies a running instance of an Oracle database on UNIX from the process that starts with `ora_pmon_`. Ensure this process is running in the IP range you designate for Discovery.

Discovery identifies a running instance of an Oracle database on Windows from the `oracle.exe` process. Ensure this process is running in the IP range you designate.

For Oracle clusterware, you also need permissions to read the `/etc/hosts/` file, which associates host names with IP addresses.

The following commands are run for Oracle clusterware:
<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>/u01/app/12.1.0.2/grid/bin/crsctl query crs softwareversion</code></td>
<td>Gets Oracle CRS cluster ID.</td>
</tr>
<tr>
<td><code>/u01/app/12.1.0.2/grid/bin/crsctl query crs softwareversion</code></td>
<td>Gets Oracle CRS version.</td>
</tr>
<tr>
<td><code>/u01/app/12.1.0.2/grid/bin/olsnodes</code></td>
<td>Gets Oracle CRS nodes.</td>
</tr>
<tr>
<td><code>/u01/app/12.1.0.2/grid/bin/crsctl status server</code></td>
<td>Gets Oracle CRS node status.</td>
</tr>
<tr>
<td>`/u01/app/12.1.0.2/grid/bin/crs_stat -f</td>
<td>tr '\n' '#'`</td>
</tr>
<tr>
<td>`/u01/app/12.1.0.2/grid/bin/crsctl stat res -p</td>
<td>grep -v CHECK_R</td>
</tr>
<tr>
<td><code>/u01/app/12.1.0.2/grid/bin/srvctl config scan</code></td>
<td>Gets Oracle RAC SCAN VIP configurations.</td>
</tr>
<tr>
<td><code>/u01/app/12.1.0.2/grid/bin/srvctl config vip -node ol7-121-rac1</code></td>
<td>Gets Oracle CRS VIPs name.</td>
</tr>
<tr>
<td><code>/u01/app/12.1.0.2/grid/bin/srvctl config vip -node ol7-121-rac1</code></td>
<td>Get Oracle CRS VIPs ip_address.</td>
</tr>
</tbody>
</table>

Sudo permission to run: `sudo /u01/app/12.1.0.2/grid/bin/ocrcheck | egrep -v 'error|return code'`

**Classifiers, patterns, and probes**

Discovery uses these classifiers, probes, and patterns for Oracle database discovery:
Oracle Instance

- Horizontal discovery probe: launches patterns
- Powershell-Oracle - Instance PFile (for Windows)*
- Powershell-Oracle - Instance Version (for Windows)*
- SSHCommand-Oracle - Instance Details (for Linux)*

Application patterns:
- Oracle DB On Windows Pattern
- Oracle DB on UNIX Pattern

This shared library pattern used by the Linux Server pattern:
- UNIX Cluster - ORACLE Clusterware

Note: This shared library pattern is triggered if the crsd.bin process is running on the Oracle database server.

Oracle Listener

- SSHCommand-Oracle - Listener Details

none

*Probes inactive for new instances.

To use patterns, verify that the correct pattern is specified in the horizontal pattern probe on the classifier. See Add the Horizontal Pattern probe to a classifier for instructions.

Data collected

The following data is collected on the Oracle Instances (cmdb_ci_db_ora_instance) table for both UNIX and Windows:

Data collected on UNIX machines

<table>
<thead>

### SAP HANA Database discovery

Discovery creates or updates a CMDB record when it detects a running instance of SAP HANA database.

By default, Discovery uses the **SAP HANA DB** pattern to discover the SAP HANA Database.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article **KB0694477** for more information.

### Data collected by Discovery for SAP HANA Database

The following data is collected in the HANA Database `[cmdb_ci_appl_sap_hana_db]` table:

<table>
<thead>
<tr>
<th>Label</th>
<th>Field Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>name</td>

</tr>
</tbody>
</table>

### Sybase discovery

Discovery creates or updates a CMDB record when it detects an instance of Sybase.

By default, Discovery uses the **Sybase** pattern to discover Sybase.

For a list of privileged commands that you need for Discovery and Service Mapping, see **Service Mapping commands requiring a privileged user** for a list of the commands that require elevated rights to discover and map Unix-based hosts in your organization.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article **KB0694477** for more information.

### Data collected by Discovery for Sybase

The following data is collected in the Sybase Instance `[cmdb_ci_db_syb_instance]` table:
Storage discovery

Discovery collects information on Direct Attached Storage (DAS), Storage Area Networks (SAN), and Network Attached Storage (NAS).

Storage can be located on specialized devices, such as Storage Arrays, Fibre Channel Switches, iSCSI disks, or on host operating systems, including Windows, Linux, and Solaris.

Discovery finds and maps dependencies for the following types of storage:

- Direct-attached storage (DAS), network-attached storage (NAS), or storage area network (SAN).
- NAS or SAN storage that is discovered via a Storage Management Initiative Specification (SMI-S) and Common Information Model (CIM).
- Virtual storage for VMware ESX servers and Linux Kernel-based Virtual Machines (KVM).

Discovery maps this storage to the underlying physical storage.

Discovery of storage via a host reconciles data and creates relationships between the host's file systems and associated local storage devices. The local storage devices represent the storage available to the host, whether it's directly attached or provided by Fibre Channel or iSCSI. This reconciliation assumes that the storage server has been discovered first.

Note: Tape storage drivers are not discovered.

Discovery collects and creates CIs in the CMDB for the following information:

- File systems (local and NAS).
- Disks (both SAN disks and DAS drives).
- Fibre Channel (FC) HBAs and ports.
- Linux Volume Manager (LVM) volumes. LVM volume data resides in the Storage Pool (cmdb_ci_storage_pool) table.

- **Veritas Volume Manager** disks, subdisks, disk groups, plexes, and volumes.

Note: For details about the discovery of direct attached or multipath block storage provisioned on a Linux host, see [KB0622583](#).

Probes, sensors, and patterns

- KVM - Storage Pools: identifies storage attached to KVM virtual machines.
- Linux - Storage: identifies storage attached to systems running the Linux operating system.
- Solaris - Storage: identifies storage attached to systems running the Solaris operating system.

- **Windows - Storage 2012**: identifies storage attached to systems running Windows 2012 and later.
  - **Windows - Storage 2012 - PS**: identifies storage attached to Windows systems, using PowerShell.
  - **Windows - Storage 2012 - WMI**: identifies storage attached to Windows systems, using WMI Runner.

- **VMWare - vCenter ESX Hosts Storage**: collects information about ESX servers and creates relationships from datastores to underlying disks.

- **Patterns for NetApp storage discovery**:
  - **NetApp 7-mode**: finds NetApp servers via REST with two nodes.
  - **NetApp cluster mode**: finds NetApp servers via REST when more than two nodes are connected through a cluster interconnect switch.

**Note**: Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

**Requirements**

**Windows**

- For Windows, use one of the following supported host configurations:
  - Windows Server 2012, DAS or NAS with Fibre Channel (FC) or Internet Small Computer System Interface (iSCSI).
  - Windows Server 2008, DAS or NAS with FC or iSCSI.

- Install the `fcinfo.exe` tool on Windows 2008 and 2012 servers that attach to storage via FC.
- Install Windows Management Instrumentation (WMI).
- Enable Powershell on the MID Server host server.
- Provide the instance with the necessary credentials to the host server.
- Put the MID Server and the target machine in the same domain or add the target machine to the trusted host list on the MID Server machine.

**Linux**

- For Linux, use one of the following supported host configurations:
  - Solaris, DAS, NAS, or SAN with iSCSI
  - CentOS, DAS, NAS, or SAN with FC or iSCSI
  - Ubuntu Server, DAS, NAS, or SAN with iSCSI

- Provide the device with SSH credentials that have root or sudo access.
• Provide the MID Server with the necessary credentials to the host server.

Relationships

Discovery creates the following relationships for storage CIs:

<table>
<thead>
<tr>
<th>Parent Component</th>
<th>Relationship</th>
<th>Child Component</th>
</tr>
</thead>
<tbody>
<tr>
<td>Storage Export (cmdb_ci_storage_export)</td>
<td>Exports to::Imports from</td>
<td>Storage Device (cmdb_ci_storage_device)</td>
</tr>
<tr>
<td>Fibre Channel Disk (cmdb_ci_fc_disk)</td>
<td>Provides::Provided by</td>
<td>File System (cmdb_ci_file_system)</td>
</tr>
<tr>
<td>ISCSI Disk (cmdb_ci_iscsi_disk)</td>
<td>Provides::Provided by</td>
<td>File System (cmdb_ci_file_system)</td>
</tr>
<tr>
<td>NAS File System (cmdb_ci_nas_file_system)</td>
<td>Allocated from::Allocated to</td>
<td>Storage File Share (cmdb_ci_storage_fileshare)</td>
</tr>
</tbody>
</table>

Configure discovery of hosts with attached storage
Discovery can find information about UNIX, Linux, and Windows hosts with attached storage.

admin or discovery_admin

Configure Discovery for UNIX or Linux hosts with attached storage
Discovery can find information about a UNIX or Linux host and attached storage.

1. Optional: On the host, assign elevated privileges to the account that Discovery will use.
2. On the ServiceNow instance, add credentials to the Discovery Credentials table.
3. Create a Discovery Schedule for each host IP address.
4. Optional: Create a behavior that uses a functionality definition with a wbem port probe to make the initial port-scanning phase (Shazzam) more efficient.
5. Run network discovery.

Configure Discovery for Windows hosts with attached storage
Discovery can find information about a Windows host and attached storage.

1. For Windows 2008 servers that attach to storage via FC. For servers that are using newer operating systems, similar functionality is present with the operating system; this step is not required:
   b) Set the environment path for the fcinfo executable and run the fcinfo.exe file.
2. For all Windows hosts including Windows 2008, add Windows credentials to the Discovery Credentials table.
3. On the ServiceNow instance, create a Discovery Schedule for each host IP address.
4. Optional: Create a behavior that uses a functionality definition with a wbem port probe to make the initial port-scanning phase (Shazzam) more efficient.
5. Run network discovery.
Note: If the host also connects to a NAS or SAN storage array, set up the SMI-S Provider and CIM credentials.

Discovery data collected for storage via a host
Discovery gathers information about storage units that connect to Linux, Solaris, and Windows hosts via a local I/O port or Host Bus Adapter (HBA).

Probes used to discover storage from a host

---

**Data collected for Veritas Volume Manager on Linux**

Discovery collects disk and volume information for Veritas Volume Manager (VxVM) on Linux hosts and maps file systems mounted on Veritas volumes to the upstream storage provider.

**Note:** Ensure that VxVM is correctly installed and configured. If you are using 3rd party drivers, you must configure sudo permission for `vxdmpadm`.
Displaying data

VxVM Discovery maps file systems to the disks that supply storage. By default this is the only information displayed in the UI. The file system to disk relationship is shown as an upstream Stored on relationship on the File System form. To see the remainder of the information that Discovery captures for VxVM, you must add the appropriate related list to the Linux Server form. The available lists are:

- Veritas Disk Group
- Veritas Disk
- Veritas Plex
- Veritas Subdisk (Computer)
- Veritas Subdisk (Storage)
- Veritas Volume

**Storage Discovery via SMI-S and CIM**

Discovery can explore storage devices that contain a Storage Management Initiative Specification (SMI-S) provider that is a specialized Common Information Model (CIM) server.

To see the current list of vendors and products conforming to SMI-S as tested by SNIA, see the [SNIA website](https://www.snia.org/).

Other types of storage, such as storage that is attached via a host, VM storage that is available on VMware ESX servers, and storage for Kernel VM (KVM), use a separate set of probes and sensors.
Discovery collects information about storage area networks (SAN) and network-attached storage (NAS) from specialized devices, such as storage arrays and Fibre Channel (FC) switches. Discovery collects and creates CIs in the CMDB for the following information items:

- Array disks, pools, and volumes
- Fibre Channel HBAs, ports, and controllers
- FC exports
- Fabrics, including endpoints, zoning, and switches
- Dependencies between storage sub-components

**Requirements**

- A CIM server using SMI-S 1.5 or later.
- NAS and SAN systems from major vendors such as EMC, Hitachi, HP, and NetApp. SAN storage devices must use FC.
- FC switches from major vendors such as Brocade and Cisco.
- The CIM credentials must be available for SMI-S configuration. The CIM credentials can be different than the credentials for the system hosting the CIM server.
- Ensure that SMI-S is enabled for your storage product.

**Note:** Because the SMI-S Provider caches storage device information, the Discovery query to the provider does not affect storage device performance.
SMI-S Discovery architecture

![Diagram of SMI-S Discovery architecture]

CIM architecture

CIM probes can explore any device based on the Common Information Model (CIM) by querying a CIM server, also referred to as a CIMOM - Common Information Model Object Manager. By default, Discovery uses CIM probes to explore storage systems as well as to get the serial numbers of ESX servers.

Discovery queries SMI-S compliant storage devices using CIMIQL queries.

The following components are part of CIM:

- **Common Information Model (CIM):** CIM allows multiple parties to exchange information about managed elements. CIM represents these managed elements and the management information, while providing the mechanism to actively control and manage the elements.
- **Storage Management Initiative Specification (SMI-S):** SMI-S is a standard of use that describes methods for storage discovery on the vendor’s side. ServiceNow uses SMI-S to determine how to discover CIM. SMI-S is based on the Common Information Model (CIM) and the Web-Based
Enterprise Management ( WBEM ) standards, which define management functionality via HTTP. The main objective of SMI-S is to enable management of dissimilar storage products. ServiceNow supports SMI-S version 1.5 or higher.

![CIM SMI-S Standard Diagram](image)

**CIM SMI-S Standard Diagram**

- **Web-Based Enterprise Management ( WBEM )**: WBEM defines a particular implementation of CIM, including protocols for discovering and accessing each CIM implementation.
- **Service Location Protocol ( SLP )**: SLP is an ad hoc protocol for retrieving and associating configuration information about CIM servers, such as default paths, capabilities, and the exact interop namespace. Discovery retrieves the interop namespace of a CIM server via SLP and passes that information to the CIM Classify probe. SLP, referred to here as the SLP server, uses service agents ( SA ) to gather and disseminate information about a CIM server on a subnet. A subnet can have multiple service agents.

**Note:**

The `mid.cim.interop.namespace` system property defines four default storage namespaces:
- interop
- root/interop
- root/pg_interop
- pg_interop

If you are using multiple storage vendors with custom namespaces not specified as one of the defaults, add the new namespaces to the comma-separated list in this property.
If you intend to continue using any of the default namespaces, make sure to include them in the property.

SLP and WBEM support

SLP is required for CIM Discovery as it is part of the Storage Management Initiative Specification (SMI-S) stack. Some storage devices may support the WBEM protocol, but may not support SLP.

You can manually register the WBEM services on SLP using a common Linux tool like `slptool`. This tool has a command line interface that you can use to make SLPv2 User Agent (UA) requests, which usually come with the SLP daemon package. To register a service, provide a URL and list of attributes. An example can be extracted from a working SLP server by using the same tool.

Storage Discovery table schema

This diagram displays the disk hierarchical schema for storage Discovery.
Disk hierarchical schema

Storage Discovery tables and probes

Discovery uses the following tables and probes to gather information about storage devices that are managed by a SMI-S provider.

Data Collected

<table>
<thead>
<tr>
<th>Table</th>
<th>Probe</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disk (cmdb_ci_disk)</td>
<td>SMI 1.5 - Storage Server</td>
</tr>

</tbody>
</table>

These probes are available but not currently used:
- SMI - Storage Server
- SMI - Array - Controllers
- SMI - Array - Disks
- SMI - Array - Pools
- SMI - Array - Ports
- SMI - Array - Volumes

Discovery of storage area networks (SAN)
Discovery collects information about storage area networks from specialized devices, such as storage arrays and Fibre Channel (FC) switches, and creates specific references between the tables in the SAN schema.

**ServiceNow SAN schema**
This diagram shows the tables in the SAN schema and the default references defined between them.
Multipath SAN storage example

This diagram shows the relationship of SAN storage volumes to a host computer. Storage accessible to the Linux host consists of two physical fibre channel (FC) disks, mpatha and mpathb, connected to the host via a multipath FC SAN. The two HBAs on the host interface are connected with two fibre cables each to separate FC switches for failover capability. The FC fabric switches are connected to two FC storage processors on the storage server. In this example, each storage processor is connected to the storage volume's, **LUN 1** and **LUN 2**.

How CIM Discovery works

This is the processing flow for classifying Common Information Model (CIM) storage systems.
Processing flow

1. The Shazzam probe launches the wbem port probe as part of network discovery.
2. The wbem port probe detects activity on target ports SLP 427, CIM 5989 and 5988, and then examines the Service Registry Queries related list, at Discovery Definition > Port Probes, for the SLP query. The base system provides this query is provided to detect the service:wbem service type, which indicates the presence of an SLP server.
3. The Shazzam probe launches a scanner for the WBEM service type. The scanner retrieves:
   - The attributes of the service from the SLP server.
   - The interop namespaces of CIM servers in the network.
4. The scanner appends the namespace values it finds to the port probe results.
5. The wbem port probe appends the SLP data it carries to the CIM Classify probes.
6. The CIM Classify probe uses that information to explore the CIM servers.

CIM Shazzam Processing Diagram

The wbem port Probe

The wbem probe stores the data it retrieves in the CIM Classification [discovery_classy_cim] table. To view the wbem port probe, navigate to Discovery Definition > Port Probes.
SLP query

The SLP query detects the wbem service (service:wbem) on an SLP server and gathers the attributes of the service. To view the SLP Query record, open the wbem port probe record and select SLP Query from the Service Registry Queries related list.

SLP Query record

CIM - Classify probe

The wbem port probe appends the SLP data it carries, including namespaces, to the CIM - Classify probe before launching it. The CIM classification probe extracts VMware ESX serial numbers and connector relationships between the SAN and NAS components from CIM Servers in the network.

To access the CIM classification probe, navigate to Discovery Definition > Probes and select CIM - Classify from the list of probes.
Note:
The **mid.cim.interop.namespace** system property defines four default storage namespaces:
- interop
- root/interop
- root/pg_interop
- pg_interop

If you are using multiple storage vendors with custom namespaces not specified as one of the defaults, add the new namespaces to the comma-separated list in this property. If you intend to continue using any of the default namespaces, make sure to include them in the property.
### CIM Probe

**CIM - Classify**

**Name**: CIM - Classify

**Class**: CIM Probe

**Description**: CIM Classification Object Manager (CIMOM) probes, queries are not provided directly. Rather, they are aggregated from all active CIM Object Manager Classification Criteria.

Queries are dynamically built by collecting all CIM CI Classifications and aggregating their Classification Criteria. Duplicate CIM queries are merged.

CIM Queries are dynamically created by merging all CIM CI Classification Criteria.

Configure Discovery for a standalone storage device

Use this procedure for configuring a standalone storage device with the required SMI-S Provider for Discovery.

Role required: admin

1. On the storage device, if the SMI-S Provider is not present, install the SMI-S Provider software. The SMI-S Provider software is often part of the device management software. For more information, download the SMI-S Provider instructions from the storage provider manufacture. For example, if the SAN contains an EMC storage device, click [here](#) for more information.

2. For NetApp storage devices, install the SMI-S agent on the storage device host.

   **Note:** Discovery can also perform native discovery of NetApp servers without accessing the SMI-S server. See [NetApp server discovery](#) for more information.

3. Start the SMI-S Provider service.

4. In the SMI-S Provider or agent, configure the Discovery Interval with a synchronization rate that allows the wbem probe to receives the most current information during discovery. For example, for EMC storage, set the Discovery Interval.
EMC provider example

5. On the ServiceNow instance, set up **CIM credentials**.
6. Create a Discovery Schedule with the IP addresses of each SMI-S Provider.
7. Optionally, create a **Discovery behavior** that uses a functionality definition with a **wbem** port probe to make the initial port-scanning phase (Shazzam) more efficient.
8. Run a basic IP address Discovery.

Data collected by Discovery on storage devices
Discovery identifies and classifies information about storage devices.

### Storage relationships

Discovery establishes the correct relationships between Network-Attached Storage (NAS) storage devices and remotely mounted client servers that consume the storage. Discovery maps NAS file shares. It maps by taking the IP or hostname of a remote mounted disk on the client computer. It then matches it to the IP or hostname of the storage server providing the exported file system.

Discovery creates the following relationships for storage CIs running on Storage Area Networks.

#### SAN CI relationships

<table>
<thead>
<tr>
<th>Parent Component</th>
<th>Relationship</th>
<th>Child Component</th>
</tr>
</thead>
<tbody>
<tr>
<td>Storage Volume (cmdb_ci_storage_volume)</td>
<td>Exports to::Imports from</td>
<td>Fibre Channel Disk (cmdb_ci_fc_disk)</td>
</tr>
<tr>
<td>Storage Volume (cmdb_ci_storage_volume)</td>
<td>Exports to::Imports from</td>
<td>iSCSI (cmdb_ci_iscsi_disk)</td>
</tr>
</tbody>
</table>

Discovery maps NAS file shares. It maps by resolving the hostname of a remote mounted disk on the client computer to an IP address. It then matches it to the IP address of the storage server that provides the exported file system. Discovery extracts the hostname or IP address from the NAS path to determine the identity of the storage server. If the hostname is an actual hostname, the system immediately resolves that value into an IP address. It also stores it in the `nas_ip_address` field of the NAS File System (cmdb_ci_nas_file_system) table.

Discovery creates the following relationships for storage CIs running on Network Attached Storage (NAS). These relationships are the same between Linux and Windows operating system hosts.
NAS CI relationships

<table>
<thead>
<tr>
<th>Parent Component</th>
<th>Relationship</th>
<th>Child Component</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAS File System</td>
<td>Allocated from::Allocated to</td>
<td>Storage File Share</td>
</tr>
<tr>
<td>(cmdb_ci_nas_file_system)</td>
<td></td>
<td>(cmdb_ci_storage_fileshare)</td>
</tr>
</tbody>
</table>

NetApp server discovery

Discovery can find NetApp servers, using either CIM probes or patterns. The use of patterns, allows you to perform native discovery of the NetApp server without the need to traverse an SMI-S server. We recommend that the target NetApp server disable SSLv3 and enable TLS, since Java Runtime used by the MID Server does not allow SSLv3 by default. The key to encrypt the certificate must be at least 1024 bits.

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article [KB0694477](#) for more information.

NetApp server discovery options

<table>
<thead>
<tr>
<th>Method</th>
<th>Supported modes</th>
<th>Upgrades</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discovery with patterns using ONTAP API</td>
<td>• NetApp 7-mode</td>
<td>Active by default for new instances.</td>
</tr>
<tr>
<td>The patterns support native discovery of NetApp servers, without requiring the need to discover the SMI-S server.</td>
<td>• NetApp cluster mode</td>
<td></td>
</tr>
<tr>
<td>Discovery with probes and sensors using CIM.</td>
<td>• NetApp 7-mode</td>
<td>Active by default for upgrades. To use patterns on upgraded instances, enable the relevant NetApp property (see below).</td>
</tr>
<tr>
<td></td>
<td>• NetApp cluster mode</td>
<td></td>
</tr>
</tbody>
</table>

NetApp discovery does not support the following:

- IP address and port redundancy
- Server Virtual Machines (SVM) redundancy within clusters
- Vserver tunnelling
- IPSpace
- The provisioning location

ONTAP version support

Discovery can find NetApp servers running these versions of the ONTAP operating system:

- For 7-mode: versions 8.3 and below.
- For cluster mode: version 8 or above.
NetApp discovery properties

To use native discovery with patterns, navigate to **Discovery Definition > Properties** and enable these properties:

<table>
<thead>
<tr>
<th>Property label</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>For 7-Mode NetApp storage servers use native discovery instead of SMI-S.</td>
<td>glide.discovery.sensors.netapp_native_7mode</td>
</tr>
<tr>
<td>For Cluster Mode NetApp storage servers use native discovery instead of SMI-S.</td>
<td>glide.discovery.sensors.netapp_native_cluster_mode</td>
</tr>
</tbody>
</table>

**Note:** If you already performed NetApp discovery, and then upgrade to madrid and enable these properties, a migration script runs the next time you perform NetApp discovery. This script could delete CIs for items like storage pools, which probes discover but the patterns do not. It also creates new relationships.

Credentials

<table>
<thead>
<tr>
<th>Credential type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configure <strong>SNMP community credentials</strong> to classify the NetApp server.</td>
</tr>
<tr>
<td>Using local credentials, create a credential of type <strong>basic authentication</strong> to use when identifying and exploring the NetApp server. On the NetApp server, the credential must use the authentication method of &quot;password&quot; and allow read-only access to the ONTAP API. For cluster mode, the user can have a read-only role with default access. For 7-mode, the user must have a custom role with the following capabilities:</td>
</tr>
<tr>
<td>login_snmp, login-ndmp, login-sp, and login-http-admin</td>
</tr>
<tr>
<td>Api-*</td>
</tr>
</tbody>
</table>

Classifiers and patterns

<table>
<thead>
<tr>
<th>Classifiers</th>
<th>Probe</th>
<th>Patterns</th>
</tr>
</thead>
<tbody>
<tr>
<td>NetApp Storage Server 7-Mode</td>
<td>Horizontal discovery probe: launches patterns</td>
<td>NetApp Storage 7-Mode</td>
</tr>
<tr>
<td>NetApp Storage Server Cluster-Mode</td>
<td></td>
<td>NetApp Storage Cluster-Mode</td>
</tr>
</tbody>
</table>

Running Discovery

To run discovery using these patterns, create a Discovery schedule that targets the management IP address of the NetApp server. Make sure that the basic authentication credentials that you configured can access the NetApp server.
Data collected by NetApp patterns

The following tables list the data that Discovery can find when you run the NetApp discovery patterns.

Manage large storage payloads in Linux and Solaris

Large payloads for Linux and Solaris direct attached storage can cause out of memory errors if not configured to serialize the processing of the payload.

Role required: admin or discovery_admin

When Linux or Solaris storage sensors process payloads from large disk arrays, worker threads run simultaneously and can run an instance node out of memory, requiring a restart. To prevent this, the \( \text{discovery_sensor_yield} \) table controls the behavior of worker threads used to process large payloads. When Discovery processes a sensor, it checks the \( \text{discovery_sensor_yield} \) table for that sensor. If the sensor is listed in the table, and if the payload size exceeds the configured limit in the table, then the worker attempts to secure a lock before processing the payload. If the lock is not available because another worker is already processing a large payload, the waiting worker reschedules the next job for 30 seconds later and moves on to other tasks. The job then waits in the Schedule Item (sys_trigger) table for an idle worker to pick it up. This serialization occurs per node, enabling multiple nodes to process large payloads simultaneously. The processing interval of 30 seconds is not configurable.

Caution: These threshold values were created for Linux and Solaris storage sensors only and, in most cases, should not be changed. If your instance is running out of memory while simultaneously processing multiple, large storage payloads, consider scheduling Discovery of these systems to times of lower activity. If this is not possible, examine the ECC queue to determine which storage sensor might be causing the issue and note the size of the payload. If the payload size is below that of the threshold in the \( \text{discovery_sensor_yield} \) table, lower the threshold value enough to serialize that payload. If a sensor other than the Linux or Solaris storage sensor is responsible, you can add that sensor to the \( \text{discovery_sensor_yield} \) table. Make sure to set the threshold value correctly for the payload size. Serializing sensor processing can slow Discovery.

1. In the application navigator filter, enter \text{discovery_sensor_yield.list}.
   The base Discovery system serializes these sensors when their payloads exceed 512 KB:
   - Solaris - Storage
   - Linux - Storage

2. To change the threshold, double-click in the \text{Value} column in the list and edit the size.
Editing the sensor yield threshold

3. To add another sensor and configure it for payload serialization, click **New** and complete the fields in the form.
   - **Sensor**: Storage sensor to configure.
   - **Value**: Threshold size for the sensor.

4. Click **Submit**.

**Storage discovery examples**
Discovery creates configuration items (CI) and CI relationships for physical and logical storage components attached directly to application and database servers or by fibre channel switched fabric in a multi-path configuration.

**Direct attached storage**

In this example of direct attached storage (DAS), a SCSI drive with two partitions, `/dev/sda1` and `/dev/sda2`, is attached to a Linux host. The `/dev/sda1` partition is bootable and supports the system software. The `/dev/sda2` partition contains a logical volume configured as a storage pool and mounted to the Linux root file system by Logical Volume Management (LVM). The storage pool uses only 1.5GB of the partition, leaving 13GB of storage available for additional logical volumes.
### Direct attached storage (DAS) example

</tbody>
</table>

**Multipath fibre channel storage**

In this example of a fibre channel storage area network (SAN), two physical storage devices, mpatha and mpathb, are attached to a Linux host through fibre switches, which provide failover capabilities. The mpatha drive contains two partitions, mpatha1 and mpatha2. The first partition is mounted directly to /boot on the Linux host. Three logical volumes are mapped to the mpatha2 partition and to the physical device mpathb. The logical volumes are mounted as Ext4 file systems in folders on the Linux root structure. This example shows the CIs that Discovery manages for each component and the mounting points for the logical volumes on the Linux host.
Switched fibre fabric details

Discovery creates CIs for the logical sub-components in NAS and SAN environments, such as fibre channel disks and pool components, as well as for host bus adapters (HBA) and physical block storage. In multipath environments, Discovery creates CI relationships within the switched fibre fabrics that connects the Linux host to the physical storage devices. In this diagram, the fibre fabrics have redundant paths that the SAN environment can use for failover if connections fail.
Operating-system-level virtualization (OSLV) discovery

Discovery can collect image and container information from OSLV engines. Discovery can determine container status and size and identify images and their tags provided by operating-system-level virtualization.

Note: Currently, the ServiceNow® platform supports the discovery of Docker virtualization containers only.

Docker virtualization

Discovery can collect data about specific objects in a Docker engine, running on a Linux host. The ServiceNow® platform supports the discovery of Docker release 1.11.0 or later.
Docker configuration items

Discovery creates configuration items (CI) for these Docker objects:

- **Engine**: Software that runs on the Linux host to create the operating environment for distributed applications.
- **Images**: Images on the Docker engine separated into these entities:
  - Global images.
  - Locally stored instances of the images.
  - Tags associated with the locally stored instances of the images.
- **Containers**: Virtual wrappers, found on the Docker engine, which contain running instances of images.

Docker restrictions and considerations

When using Docker virtualization, consider the following:

- The initial Discovery process scan can identify an application in a container and classify it correctly. However, subsequent probes launched to explore that application cannot see inside the container and cannot return details about the application.
- Discovery scans all containers it finds, including inactive containers, which can slow down Discovery. You should delete containers that are not running.
- Only one Docker engine is permitted per computer (on either a physical or virtual machine).

User privileges

The user whose credentials are used to perform Docker Discovery must have privileges defined by one of these methods:

- Provide a user with elevated rights for running commands, since the Docker daemon runs as the root user. The Docker pattern supports the use of privileged commands, such as `sudo` or `pbrun`, to run as the root user.
- Assigned to a group named `docker`, which has special privileges for running Docker commands. For instructions on setting up a group, see [Create a Docker group](#).

Table schema and relationships

The Docker tables are installed with the Discovery plugin and extend tables used to store data on the operating-system-level virtualization (OSLV) engine.

<table>
<thead>
<tr>
<th>Table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Docker Engine (cmdb_ci_docker_engine)</td>
<td>Stores instances of the Docker engine.</td>
</tr>
<tr>
<td>Docker Image (cmdb_ci_docker_image)</td>
<td>Stores the globally unique representation of Docker images.</td>
</tr>
<tr>
<td>Docker Local Image (cmdb_ci_docker_local_image)</td>
<td>Stores local instances of Docker images.</td>
</tr>
<tr>
<td>Table</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------------</td>
<td>--------------------------------------------</td>
</tr>
<tr>
<td>Docker Image Tag (cmdb_ci_docker_image_tag)</td>
<td>Stores tags from local Docker images.</td>
</tr>
<tr>
<td>Docker Container (cmdb_ci_docker_container)</td>
<td>Stores Docker containers found on the host.</td>
</tr>
</tbody>
</table>

Discovery stores these relationships in the CI Relationship (cmdb_rel_ci) table.

- `cmdb_ci_server` Runs::RunUnder `cmdb_ci_docker_engine`
- `cmdb_ci_docker_engine` Manages::ManagedBy `cmdb_ci_docker_container`
- `cmdb_ci_docker_engine` Manages::ManagedBy `cmdb_ci_docker_local_image`
- `cmdb_ci_docker_container` Instantiates::InstantiatedBy `cmdb_ci_docker_local_image`
- `cmdb_ci_docker_image_tag` RegisteredOn::HasRegistered `cmdb_ci_docker_local_image`
- `cmdb_ci_docker_local_image` Instantiates::InstantiatedBy `cmdb_ci_docker_image`
Parent and child relationships for the OSLV and Docker dependent tables
Identification, containment, and hosting rules

Discovery uses an application rule identifiers to find the Docker engine and then applies other rules to identify specific Docker objects.

Application rule identifier

The system creates the cmdb_ci_docker_engine configuration item (CI) during process classification. Based on this, Discovery uses the Application Rule identifier, on the Application [cmdb_ci_appl] table to identify the particular Docker engine encountered. After establishing this identity, Discovery uses the relationships defined in the containment and hosting rules to accurately create and update the individual Docker component CIs related to that engine.

Identifiers

<table>
<thead>
<tr>

<tr>
<td>Docker Image Tag</td>
<td>Docker Image Tag</td>
<td>repository, tag</td>
</tr>
<tr>
<td></td>
<td>(cmdb_ci_docker_image_tag)</td>
<td></td>
</tr>
</tbody>
</table>

Containment and hosting rules

Docker Discovery uses these containment and hosting rules to create configuration items (CI) from the data returned by the Docker Pattern. After Discovery identifies the Docker engine by its relationship to the Application (cmdb_ci_appl) table, it uses these rules to identify the specific CIs connected to that engine from their relationships to one another. By connecting the components to one another in this fashion, from the application down, starting with the engine, Discovery avoids creating duplicate CIs for components from other Docker engines that use the same name or image_id.

Containment rule

<table>

</tbody>
</table>
Pattern

To view the pattern for discovering the docker engine (cmdb_ci_docker_engine) and its components, navigate to Pattern Designer > Discovery Patterns and open Docker Pattern. For more information about Discovery patterns, see Discovery patterns used by ITOM Visibility.

Discovery runs the Docker Engine process classifier in the network. If the classifier identifies the dockerd or docker daemon process, the classifier triggers the Horizontal Pattern (HorizontalDiscoveryProbe) probe, which launches the Docker Pattern and begins collecting data from Docker components.

The pattern collects data for the main CI type, cmdb_ci_docker_engine, and for these related CI types:

- cmdb_ci_docker_image
- cmdb_ci_docker_local_image
- cmdb_ci_docker_image_tag
- cmdb_ci_docker_container

**Note:** Probe-to-pattern migration is supported for the New York release and later. See the knowledge article KB0694477 for more information.

Data collected

These attributes are discovered, in addition to the attributes derived from the parent OSLV tables.

<table>

Discovery resource utilization

Typical transactions on Windows and Unix generate various amounts of network traffic, depending on what is being discovered.
This table shows the bandwidth consumption, by operating system, for each data flow segment of a typical Discovery using probes and patterns; the devices use probes while the applications use patterns. Also shown is the bandwidth comparison between an initial Discovery for three-tier applications and each subsequent Discovery that does not collect hardware data. All measurements are in megabytes.

Note: These measurements were taken with base operating configurations. Your local system results may vary.

This table shows discovery of different OS types using patterns.
Discovery monitoring and issue resolution

Learn how to monitor the progress of your discoveries and how to configure the system to aggregate performance metrics that are important to you. Find descriptions of the error messages you see, as well as possible steps you can take to solve problems. The Knowledge Base on Hi contains several articles to help you troubleshoot discovery issues.

*Discovery Home Page*

Open the Discovery Manager to create or edit schedules for IP-based and Cloud Discovery. View the CI's and cloud resources that your schedules discover and then track any errors that occurred.

*Discovery Dashboard*

Monitor ongoing Discovery operations and manage reports that query the database. View summary information about Discovery status, discovered devices, timelines, and errors.

*Discovery Troubleshooting Guide*

Look at the Discovery troubleshooting guide in the knowledge base if you are experiencing symptoms, such as the inability for Discovery to classify a discovered host, or the Shazzam probe not finding certain types of devices.

*Discovery error messages*

View the list of common error messages and possible solutions.

*Discovery performance metrics*

View performance metrics on probe/pattern and sensor processing times. You can use the roll-up data to monitor the performance of specific discoveries or to compare performance between versions after an upgrade.

**Discovery Home page**

The Discovery Home page provides a summary of discoveries that were triggered by cloud and non-cloud schedules. You can view any errors that occurred during a Discovery and find
remediation suggestions. Use the Home page view to examine the cloud resources discovered for the service accounts you selected in a cloud schedule.

To open the Discovery Home page, navigate to Discovery > Home. The Home page shows the Discovery totals for each of the following categories. Click a tile to see details for that category.

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schedules</td>
<td>The number of Discovery schedules that are configured to find cloud resources and virtual machines (IP addresses). Click View Schedules to open the CI schedule view, where you can see specific details about each CI schedule separately. View the results of your cloud or IP address schedules and create new schedules.</td>
</tr>
<tr>
<td>Discovered Devices</td>
<td>The total number of device CIs discovered. Devices include all the CIs in tables that extend the Hardware (cmdb_ci_hardware) table, such as Computer (cmdb_ci_computer) and Cisco UCS Equipment (cmdb_ci_ucs_equipment).</td>
</tr>
<tr>
<td>Cloud Resources</td>
<td>The total number of resources (virtual machines) discovered for the service accounts selected. See Enable virtual machine Discovery in your cloud environment for details about setting up Discovery for your cloud resources. Click View Cloud Resources to open a list of discovered cloud resources, by type.</td>
</tr>
<tr>
<td>Errors</td>
<td>The total number of unresolved errors that occurred during discovery. Click View Errors to drill down to specific types of errors.</td>
</tr>
</tbody>
</table>

**Viewing all schedules**

The schedule view displays details for each schedule that ran for the selected filter. By default, the list shows all the Discovery schedules in alphabetical order, regardless of their current running status.
Use these controls to filter Discovery results by schedules:

**Schedule filters**

You have the choice of these filters:
- **All**: Results of all Discovery schedules that ran. This is the default filter.
- **Cloud Schedules**: Results of all Cloud Discovery schedules that ran. When you select this filter, a second filter appears, allowing you to display cloud schedules by **Service Account**.

![Cloud Schedules](image)

- **IP Based Schedules**: Results of all Discovery schedules that ran for Configuration Items (CI), using IP ranges. When you select this filter, a second filter appears, allowing you to display the CI schedules by a specific location or all locations.

![IP Based Schedules](image)

**Schedule sorter**

From the schedule selector in the left pane, select a sorting criteria, from left to right:

- Errors for each schedule listed.
- Unidentified IP addresses.
- Recent activity, which lists the schedules that are currently running first.
- Alphabetical listing of schedules.

**Schedule list**

List of available Discovery schedules. Select a schedule to display its details. Click the pencil icon at the top of the page to edit the schedule.
**Date/time indicator**

Date and time the selected schedule ran.

**Schedule topics**

Tiles that show the Discovery result categories for the selected schedule. Click a tile to see more detail.

- **Cloud resources**: Displays the total number of CIs updated or created for this filter.
- **Virtual Machines**: Displays the total number of virtual machines discovered with the selected schedule.
- **Errors**: Displays the total number of errors that occurred from running the selected schedule.
- **Datacenters**: Displays the number of datacenters selected during the creation of the Discovery schedule.

**Cloud resources trend chart**

Trend graph for the selected schedule. Each circle in the graph represents a specific Discovery run.

Place the cursor over any circle to see a summary of that Discovery.

Click the circle to filter the values you see in the Discovery topics. The results populate the appropriate tiles above the graph.

**Errors by category**

Category tiles for the errors encountered during the Discovery for the selected schedule. Click a tile to view the errors in that category and to see recommended actions for remediation. See *Discovery error messages* for additional details.

**Discovered cloud resources**

Breakdown of the cloud resources discovered for the selected schedule, presented in a horizontal bar chart.

**Add schedules**

Types of schedules to add.

**Advanced View**
Displays the Discovery status record for the selected schedule. Use this link to examine the results of the schedule in the ECC Queue and the Discovery log.

**Viewing IP-based schedules**

To display results from IP range discoveries, select **IP Based Schedules** in the primary filter. Use the secondary field that appears to filter the search results by **Location**. The tiles show the result categories for the selected IP-based schedule. Click a tile to see more detail.

- **Discovered devices**: Total count of virtual machines discovered by the IP-based schedule, including both targeted and unidentified IP addresses.
- **Errors**: Displays the total number of errors encountered running the selected IP-based schedule.
- **Unidentified IPs**: Count of unidentified CIs discovered by the IP-based scheduled.
- **Targeted IPs**: Count of CIs found that were configured in the IP-based schedule.
### Discovery Schedules

**Advanced View**
Resolve CI Discovery Schedule errors
From the ServiceNow Home page, you can view the Discovery errors that occurred during a Discovery and get suggestions for resolving these errors. You can view the errors for all schedules or for a single schedule.

Role required: discovery_admin

1. Navigate to Discovery > Home.
The summary page for all schedules appears.

2. View the errors, using one of these methods:
   - Click the Errors tile to see the errors by category for all CI discovery schedules.
   - Click the Schedules tile to display the errors for a single schedule.

1. In the summary screen, select the schedule that you want to investigate for errors.
   If you have numerous schedules, you can filter by location, using the location dropdown list, or filter by the schedule name in the Search by name field.

2. After you select the schedule, click the Errors tile.
3. Scroll down to view the errors by category.
3. Click a category tile to display the specific error codes that occurred in that category.

4. Click the tile for the error code you want to investigate.

The list displays all occurrences of that error code, either for a single CI schedule or for all schedules, depending on the path you took to view the errors. The list shows the IP address of each instance that experienced the error and the error status **Active error**. The **Recommended Actions** pane on the right contains the recommended action for the selected error. The **ACTION ON ALL** pane contains operations you can execute on all the errors in the list.
5. Click **View instructions** to see details and remediation suggestions for the error code.
6. To begin work, either select the check box next to an error to resolve that specific error or select an action for **ALL** to resolve that error code for all instances of that error. In this example, the system recommends creating new Windows credentials to resolve this error code.
7. Complete the suggested remediation tasks before attempting to retry Discovery. In this example, the **Create new Windows Credentials** link opens a form for creating and testing new Windows credentials.
8. After all the recommended tasks are complete, click **Retry Discovery**.
   A possible course of action might be to retry Discovery for **ALL** instances after creating the credentials. The new credentials might solve the issue for all the instances experiencing this error code.

9. Check the **Error Status** column to see the results of your remediation efforts.
   Single retries complete quickly. Retries for large numbers of IP addresses can take several minutes.

An error can have one of these statuses:

- **Active error**: Unresolved error. This is the default status of all new errors.
- **Resolved**: Resolved error. The recommended actions show **Error successfully resolved**.
- **Assigned**: Task assigned to resolve this error. Click **Create a task** to assign a user to a task for all active errors. Assigned errors are considered **Active errors**, and actions can still be performed on them.
- **Pending Discovery**: Waiting for Discovery to start after you execute the **Retry Discovery** action on all errors.
- **In Discovery**: Discovery is currently active.
Discovery Dashboard

The Discovery Dashboard is a central place for Discovery users to monitor ongoing Discovery operations. The dashboard contains reports that query the database and display the results.

Dashboards are the home pages for products on the instance. The Discovery Dashboard provides summary information about your Discovery status, devices, applications, and timeline. It also displays Discovery errors and suggested solutions.

**Note:** All the data on the dashboard is domain separated, and shows only data collected from the domain specified in the **MID Server user account** for the Discovery schedule used.

To display the Discovery Dashboard, navigate to **Discovery > Dashboard**.

**Features of the Discovery dashboard**

The Discovery Dashboard displays:
- The current progress (status) of the actively running Discovery schedules.
- Newly discovered devices and applications, by time discovered.
- Existing devices and applications not updated by Discovery.
- Errors that occurred during a Discovery schedule that has run.
- Credentials that were either not required or unused by a Discovery schedule.

**Adding Discovery reports to the dashboard**

Starting with the Madrid release, **gauges** are no longer supported in dashboards and have been replaced with **widgets**. You can continue using Discovery gauges on existing dashboards. However, you cannot add old Discovery gauges to your dashboards. If you need some reporting capability not offered in the current dashboard, you must create your own reports using widgets.

**Discovery Dashboard components**

You can customize the reports on the dashboard to display statistics important to your environment.

**Active Discovery Status report**

The Active Discovery Status report displays the progress of an actively running Discovery. The information displayed is pulled from the Discovery Status module. The **Progress** field of the status record specifies the percent complete of the Discovery schedule. The percent complete is calculated based on previous runs of the same Discovery schedule. The progress field is empty in the following cases:
- When you use DiscoverNow
- When you use Discovery from a configuration item (CI).
- During the first run of a Discovery schedule.
Active Discovery Status report

Newly Discovered Devices report

The Newly Discovered Devices report displays the count of the devices that the Discovery application has identified in the last 7 days, grouped by the class of the device.
Newly Discovered Devices report

Total Discovered Devices report

The Total Discovered Devices report displays the total count of the devices that the Discovery application has identified in the last 30 days, grouped by the class of the device.
Total Discovered Devices report

Unrefreshed Devices report

The Unrefreshed Devices report displays devices that were discovered up to a year ago, but have not been identified in the last 30 days, grouped by the class of the device.
Unrefreshed Devices report

Newly Discovered Applications report

The New Applications Discovered report displays the count of new applications that the Discovery application has identified in the last 7 days, grouped by the class of the application.
Newly Discovered Applications report

Total Discovered Applications report

The Total Discovered Applications report displays the total count of the applications that the Discovery application has identified in the last 30 days, grouped by the class of the application.
Total Discovered Applications report

Unrefreshed Applications report

The Unrefreshed Applications report displays applications that were discovered up to a year ago, but have not been identified in the last 30 days, grouped by the class of the application.
Unrefreshed Applications report

Active Discovery Errors report

The Active Discovery Errors report lists the errors that are generated by each active Discovery. The errors for a specific Discovery are overwritten when that Discovery runs again. This report displays the following data:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created</td>
<td>Timestamp of the error message.</td>
</tr>
<tr>
<td>Short message</td>
<td>Contents of the error message generated during the Discovery run.</td>
</tr>
<tr>
<td>Help</td>
<td>Link to a suggestion on how to fix the error. In some cases, the link will be specific to the error. In other cases, the link points to a general page that has the solution to a collection of common errors.</td>
</tr>
<tr>
<td>IP</td>
<td>IP address of the asset on which the error was detected.</td>
</tr>
</tbody>
</table>
## Column | Description
--- | ---
Discovery status | Discovery status number.

### Active Discovery Errors report

<table>
<thead>
<tr>
<th>Created</th>
<th>Short message</th>

Actions on selected rows...
Discovery performance metrics

This Discovery enhancement collects performance metrics on probe/pattern and sensor processing times and then aggregates that data over time. You can use the roll-up data to monitor the performance of specific discoveries or to compare performance between versions after an upgrade.

Metrics

Discovery provides these individual performance metrics:

- Probe and pattern processing time.
- Sensor processing time.
- Identification and Reconciliation Engine (IRE) processing time for Discovery patterns. This processing time is already included in the sensor processing time, but is isolated here to provide more insight into the identification and reconciliation of pattern payloads.

Discovery can aggregate individual metrics for these attributes:

- Builds/versions
- Discovery status
- Target IP address

How metric aggregations are triggered

Metric roll-ups are initiated as follows:

- **Aggregated by build**: Implemented by the *Aggregate Discovery Probe And Sensor Metrics By Build* scheduled job. This job runs at 0200, local time.
- **Aggregated by status**: Implemented by the *Rollup Probe/Sensor Metrics by Status* Script Action, which is triggered by the `discovery.complete` or `discovery.cancelled` registered events.
- **Aggregated by target**: Implemented by the *Rollup Probe/Sensor Metrics by Target* Script Action that is triggered by the `discovery.device.complete` registered event.

**Note:** If Discovery execution is cancelled before it completes, Discovery cannot update the IP target metric aggregation table. This is because the `discovery.device.complete` event that triggers aggregation does not run. IP target data for an interrupted Discovery is collected when subsequent discoveries run successfully on the target. Cancelling Discovery execution does not affect the aggregation of other metrics, which are triggered differently.

Tables

Discovery performance metrics data is stored in these tables:

<table>
<thead>
<tr>
<th>Table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Probe and Sensor Metrics (Individual)</td>
<td>Stores the individual performance metrics for probes/patterns, sensors, and IRE processing times.</td>
</tr>
</tbody>
</table>

### Discovery properties

Performance metrics properties control whether or not aggregation occurs, but not what data is included in the aggregation. Status and IP target data is collected as follows:

- Rollups for status always contain new data. Discovery continuously collects data on all probes and sensors during the discovery execution for that discovery status and stores it in the Probe and Sensor Metrics (Individual) (discovery_perf_metric_probe_sensor) table. Aggregation rolls up all probe and sensor data for that particular status after `discovery.cancel` and `discovery.complete` events are fired for that status, but only if the aggregation property for status roll-ups is enabled.

- Discovery continuously collects data on IP targets and stores it in the Probe and Sensor Metrics (Individual) (discovery_perf_metric_probe_sensor) table. Aggregation rolls up all existing IP target data after the `glide.discovery.perf.metrics.rollup_by_target` property is enabled and creates records in the Probe and Sensor Metrics (Aggregated by Target) (discovery_perf_metric_probe_sensor_rollup_by_target) table.

These properties control the gathering of probe and sensor metrics:

<table>
<thead>
<tr>

**View Discovery performance metrics for probes, sensors, and patterns**

By default, Discovery tracks the performance of individual probes, sensors, and patterns by measuring the processing time. When patterns are used, Discovery measures the Identification and Reconciliation Engine (IRE) processing time.

Role required: discovery_admin, admin

1. Navigate to **Discovery > Discovery Performance Metrics > Probe/Sensor (Individual)**.
2. Sort the list by Discovery status to see the list of probes and patterns that ran in a specific Discovery.
3. You can view the metrics for each probe, sensor, or pattern in the list or open the record. All probe and sensor metrics data are read-only.
The Probe and Sensor Metrics (Individual) form provides these fields:

<table>
<thead>
<tr>
<th>Field label</th>
<th>Field name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Build/version</td>
<td>build_version</td>
<td>Build on which the Discovery was run.</td>
</tr>
<tr>
<td>Discovery status</td>
<td>discovery_status</td>
<td>ID number of the Discovery status from which the metrics were collected.</td>
</tr>
<tr>
<td>Target IP address</td>
<td>target_ip</td>
<td>IP address of the target for this Discovery.</td>
</tr>
<tr>
<td>ECC queue input</td>
<td>ecc_queue_input</td>
<td>Identifies a particular ECC input record in the ECC queue table.</td>
</tr>
<tr>
<td>ECC queue topic *</td>
<td>ecc_queue_topic</td>
<td>Identifies the Java class in the MID Server that executes the probe.</td>
</tr>
<tr>
<td>ECC queue name *</td>
<td>ecc_queue_name</td>
<td>Identifies the probe/pattern evaluated for performance in this aggregation.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field label</th>
<th>Field name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Probe *</td>
<td>probe</td>
<td>Name of the probe used for this Discovery.</td>
</tr>
<tr>
<td>Probe processing time</td>
<td>probe_time</td>
<td>Interaction time of the MID Server with the target, including construction of the payload that is sent back to the instance. The time is in milliseconds.</td>
</tr>
<tr>
<td>IRE processing time</td>
<td>ire_time</td>
<td>Time required to process the pattern payload on the instance by the Identification and Reconciliation Engine (IRE). IRE time is useful because it shows the part of the sensor time used by the pattern. The time is in milliseconds.</td>
</tr>
<tr>
<td>Sensor processing time</td>
<td>sensor_time</td>
<td>Time it took the sensor to process the payload on the instance for a Discovery. The time is in milliseconds.</td>
</tr>
</tbody>
</table>

* Used to uniquely identify a probe/pattern and accompanying sensor when gathering metrics for a Discovery.

*View Discovery performance metrics aggregated by build*

Use the roll-up by build data to ensure that the processing times for Discovery components remain consistent for discoveries in a 24 hour period. View aggregate build data before and after an upgrade to compare the performance of the old and new versions. All aggregated performance data is read-only.

Role required: discovery_admin, admin

1. Navigate to Discovery > Discovery Performance Metrics > Probe/Sensor (Rollup-By-Build).
2. Sort the list by Build/version.
3. Filter by a specific build to see the aggregated processing times for the probes and patterns that performed a Discovery on that build.

4. Open a record to see the probe/pattern statistics for the selected build.
   The form displays additional fields not visible on the list. Roll-up calculations are over a 24 hour period, beginning every night at 0200.

5. See the table of performance aggregation data for descriptions of additional metrics displayed on the form for roll-ups by build.

View Discovery performance metrics aggregated by status
Use the roll-up by status data to ensure that the processing times for probes/patterns and sensors remain consistent for a specific Discovery. All aggregated performance data is read-only.

Role required: discovery_admin, admin

1. Navigate to Discovery > Discovery Performance Metrics > Probe/Sensor (Rollup-By-Status).
2. Sort the list by **Discovery status** to see the aggregated processing times for the probes and patterns that ran during a specific Discovery.

3. Filter by a specific status to display metrics available for probes and patterns that ran in that status.

4. Open a record to see the probe/pattern statistics for the selected status.
   The form displays additional fields not visible on the list. Roll-ups are only created for a completed or cancelled status.

5. See the table of performance aggregation data for descriptions of additional metrics displayed on the form for roll-ups by status.

View Discovery performance metrics aggregated by IP address
Use the roll-up by target data to ensure that the processing times for probes/patterns and sensors remain consistent for each Discovery of a specific IP address. All aggregated performance data is read-only.

Role required: discovery_admin, admin

1. Navigate to **Discovery > Discovery Performance Metrics > Probe/Sensor (Rollup-By-Target).**
2. Sort the list by **Target IP address.**
3. Filter by a specific IP address to see the aggregated processing times for the probes and patterns that performed the Discovery of that IP address.

4. Open a record to see the statistics about the selected probe/pattern for the specific IP address.
   The form displays additional fields not visible on the list. Roll-ups are performed after IP Discovery has completed successfully.

5. See the table of performance aggregation data for descriptions of additional metrics displayed on the form for roll-ups by target.
Aggregated data for Discovery performance metrics
Discovery performance metrics can accumulate data for probes, patterns, and sensors each time Discovery runs. Discovery calculates processing times and increments the number of times a component runs for each roll-up profile: status, target, or build. All aggregated performance data is read-only.

Sample roll-up form

This is an example of an aggregation record for probe and sensor metrics. The metrics fields shown here are used for each aggregation.

## Performance Framework aggregated data

Except where noted, these fields are common to all aggregation records.

<table>
<thead>
<tr>
<th>Field label</th>
<th>Field name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Build/version</td>
<td>build_version</td>
<td>Name of the build running on the instance. This name identifies the version, patch level, and release date of the ServiceNow platform.</td>
</tr>
<tr>
<td>Discovery status</td>
<td>discovery_status</td>
<td>ID number of the Discovery status record for this aggregation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Note: This field only appears on the form for roll-ups by status.</td>
</tr>
<tr>
<td>Target IP address</td>
<td>target_ip_address</td>
<td>IP address of the target for this Discovery.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Note: This field only appears on the form for roll-ups by target.</td>
</tr>
<tr>
<td>Aggregation cutoff</td>
<td>aggregation_cutoff</td>
<td>The cutoff time varies, depending on the roll-up profile.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>By-build</strong>: Occurs daily at 02:00, by default.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>By-status</strong>: Closing time of the last aggregation for that Discovery status, which might have run the last time <code>discovery.complete</code> or <code>discovery.cancelled</code> ran for that status.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>By-target</strong>: Closing time of the last aggregation for that target IP address, which might have run the last time <code>discovery.device.complete</code> ran for that IP address.</td>
</tr>
<tr>
<td>ECC queue topic *</td>
<td>ecc_queue_topic</td>
<td>Identifies the Java class in the MID Server that executes the probe.</td>
</tr>
<tr>
<td>ECC queue name *</td>
<td>ecc_queue_name</td>
<td>Identifies the probe/pattern evaluated for performance in this aggregation.</td>
</tr>
<tr>
<td>Probe *</td>
<td>probe</td>
<td>Name of the probe used for this Discovery.</td>
</tr>
<tr>
<td>Probe time (count)</td>
<td>probe_time_count</td>
<td>Number of times a probe ran for a given roll-up profile.</td>
</tr>
<tr>
<td>Field label</td>
<td>Field name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Probe time (average)</td>
<td>probe_time_average</td>
<td>Average time a probe took to gather data on the target and format the payload for a given roll-up profile.</td>
</tr>
<tr>
<td>Probe time (minimum)</td>
<td>probe_time_min</td>
<td>Minimum time a probe took to gather data on the target and format the payload for a given roll-up profile.</td>
</tr>
<tr>
<td>Probe time (maximum)</td>
<td>probe_time_max</td>
<td>Maximum time a probe took to gather data on the target and format the payload for a given roll-up profile.</td>
</tr>
<tr>
<td>Probe time (total)</td>
<td>probe_time_total</td>
<td>Total time used by a probe to gather data on the target and format the payload for a given roll-up profile.</td>
</tr>
<tr>
<td>Sensor time (count)</td>
<td>sensor_time_count</td>
<td>Number of times a sensor processed payloads for a given roll-up profile.</td>
</tr>
<tr>
<td>Sensor time (average)</td>
<td>sensor_time_average</td>
<td>Average time a sensor took to process payloads on the instance for a given roll-up profile.</td>
</tr>
<tr>
<td>Sensor time (minimum)</td>
<td>sensor_time_min</td>
<td>Minimum time a sensor took to process a payload on the instance for a given roll-up profile.</td>
</tr>
<tr>
<td>Sensor time (maximum)</td>
<td>sensor_time_max</td>
<td>Maximum time a sensor took to process a payload on the instance for a given roll-up profile.</td>
</tr>
<tr>
<td>Sensor time (total)</td>
<td>sensor_time_total</td>
<td>Total time used by a sensor to process payloads on the instance for a given roll-up profile.</td>
</tr>
<tr>
<td>IRE time (count)</td>
<td>ire_time_count</td>
<td>Number of times a pattern's payload was processed by the Identification and Reconciliation Engine (IRE) for a given roll-up profile.</td>
</tr>
<tr>
<td>IRE time (average)</td>
<td>ire_time_average</td>
<td>Average time used for IRE processing of a pattern's payload for a given roll-up profile.</td>
</tr>
<tr>
<td>IRE time (minimum)</td>
<td>ire_time_min</td>
<td>Minimum time used for IRE processing of a pattern's payload for a given roll-up profile.</td>
</tr>
<tr>
<td>IRE time (maximum)</td>
<td>ire_time_max</td>
<td>Maximum time used for IRE processing of a pattern's payload for a given roll-up profile.</td>

<tr>
<td>Field label</td>
<td>Field name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>IRE time (total)</td>
<td>ire_time_total</td>
<td>Total time used for IRE processing of a pattern's payload for a given roll-up profile.</td>
</tr>
</tbody>
</table>

* Together, these values uniquely identify a probe/sensor pair (a "probe execution") that is used for a Discovery.

**Discovery error messages**

Error messages and warnings in the system are documented to allow users to recognize the issues they are having and to take steps to resolve their problems.

**Common error messages**

**Input/output errors**

- CONNECTION_FAILED
- CONNECTION_TIMEOUT
- CONNECTION_REFUSED
- CONNECTION_CIPHER_UNSUPPORTED
- CONNECTION_PROTOCOL_UNSUPPORTED
- CONNECTION_LOST
- INVALID_CONNECTION_PARAMETER
- FILE_NOT_FOUND
- IO_ERROR

**Authentication errors**

- NO_CREDENTIALS
- AUTHENTICATION_FAILED
- INVALID_CREDENTIALS_TYPE

**SSH errors**

- SSH_SHELL_UNSUPPORTED
- SSH_SCRIPT_TRANSFER_FAILED
- SSH_INVALID_SESSION

**Windows errors**

- POWER_SHELL_VERSION_UNSUPPORTED

**Command errors**

- COMMAND_TIMEOUT
- INVALID_COMMAND
- COMMAND_FILTER_ERROR
- COMMAND_PARSER_ERROR
- COMMAND_KEY_MAPPER_ERROR
- COMMAND_VALUE_NORMALIZER_ERROR
- TERMINAL_SESSION_LOST_ERROR
- TERMINAL_SESSION_ENVIRONMENT_MODIFICATION_ERROR

Generic component errors
- INVALID_COMPONENT
- INVALID_COMPONENT_PARAMETER
- INVALID_OPERATION

General error messages

Message: org.xml.sax.SAXParseException: The entity name must immediately follow the ' & ' in the entity reference
A version of this message occurs if you have used special characters in a password that is saved in an XML file.

Message: Identified, ignored extra IP
This message can appear during the identification phase of Discovery if a targeted IP address belongs to a device that is being discovered at the same time.

For example, a Windows server has two NIC cards with two IP addresses. Discovery targets both IP addresses within the same Discovery schedule. This message is generated to note that that second IP address is ignored because we don't want to update the same CI twice within the same Discovery run.

This message is a warning and is expected. No action is needed.

Message: Authentication failures
The discovery process could not discover the CI because the discovery application could not authenticate. To resolve, add the credentials of that machine in to the discovery credentials table.

Message: Identified, not updating CI, now finished
No match on any of the CI Identifiers.

Message: The impersonation of user failed
This message originates in the Powershell. Check that the domain is specified along with the user name in the credentials.

Message: Connection failed to WMI service. Error: Permission denied
This message originates in WMI. Check that the MID Server service is running with the correct credentials and has access to the target device.

To check this, run the following command from the command prompt on the MID Server host:

```
wmic /node:target /user:user /password:password path win32_operatingsystem
```

target = IP address of target device
user = user account used by the mid server service
password = password used by the mid server service

Message: Connection failed to WMI service. Error: The remote server machine does not exist or is unavailable
This message originates in WMI. Check that the MID Server service account has access to the targeted machine. Check if a domain admin account is used as the MID Server service
account. Check if any existing firewalls are open to the connection. To check this, run the following command from the command prompt on the MID Server host.

Execute for runner_type=WMI:

```plaintext
wmic /node:"<target>" /user:"<user>" /password:"<password>" path win32_operatingsystem
```

From within a Powershell console on the mid server host, execute for runner_type=Powershell:

```plaintext
gwmi win32_operatingsystem -computer <ip> -credential '<username>'
```

**Message: Provider is not capable of the attempted operation**

WMI repository was corrupted. After following the "WMI: Repository Corruption, or Not?" article on the Microsoft TechNet site, the problem was corrected.

**Message: The result file can't be fetched because it doesn't exist**

PRB581515 - Powershell does not work when customer has locked down write rights to admin share.

**Message: Please run sneep as root to ensure correct serial number from fserial data source**

The Oracle Sneep command line tool must be installed for the Solaris - Serial Number probe to work correctly. There is a **known limitation** with Fujitsu PRIMEPOWER devices. To work around this limitation, run the Solaris discovery with root credentials.

**Discovery sensor error messages**

**Message: The multisensor will not process because its major version = X while probe_name responding script's major version = Y**

**Message: The multisensor will not process because its responding script's major version = X while its referenced probe probe_name major version = Y**

**Message: sensor_name sensor's major version = X while its related probe's major version = Y**

The above error messages indicate that there is a major version mismatch in the probe and sensor versions and the sensor will stop processing until this condition is resolved.

**Message: sensor_name multisensor's minor version = X while probe_name responding script's minor version = Y**

**Message: sensor_name multisensor's responding script's minor version = X while its referenced probe probe_name minor version = Y**

**Message: sensor_name sensor's minor version = X while its related probe's minor version = Y**

The above error messages indicate that there is a minor version mismatch in the probe and sensor versions. Processing will continue, but you may want to resolve this condition.

**Message: Message: Sensor error when processing . . . : No sensors defined**

Every active probe looks for a corresponding sensor to process the data that is collected by the probe. The No sensors defined message indicates that the corresponding sensor for the probe is missing or inactive.

**Message: Message: Sensor error when processing . . . : typeError: . . .**

This type error message occurs to indicate the sensor has one of the core error constructors in JavaScript.
Message: Sensor error when processing Linux - Network ARP Tables: Exception while running probe post processing script: No XML data
The system displays the No XML data error when the XML sensor processor fails to find the expected XML data in the probe output. During sensor processing, Discovery attempts to retrieve the probe results but finds the probe output empty. Verify that the probe returns the correct output for the sensor to process.

Message: Sensor error when processing Shazzam: Exception while running probe post processing script: Probe not found: null
The Probe not found error occurs when the sensor processor fails to find the probe record supposedly associated with the sensor. During sensor processing, Discovery gets the probe record from the probe cache and stores it for later reference. The "Probe not found" error occurs either when the sys_id of the probe cannot be found or there is an issue with the probe cache.

See Find the cause of a "Probe not found" error for more information.

Find the cause of a sensor error message
Use this procedure to identify a Discovery sensor error.

Role required: admin

This process requires that you identify the following:

- The error.
- The name of the sensor where the error occurred.
- The datestamp of the error.
- The associated stack trace of the error.

1. Navigate to Discovery > Discovery Log.
2. To find the error, filter on the Level name of Error.
   You can also view the error and the date stamp in the Error Report on the Discovery dashboard.
3. Note the Created field of the error record.
   This timestamp is used to find the proper stack trace.
4. Note the Short Message field of the error record.
   This field shows the name of the sensor where the error has occurred. In this example, a generic sensor error occurred in the SMI – Fiber Channel Switch sensor at 4:03 on 10-24-2014.
Error message in fiber channel switch sensor

In this example, a sensor TypeError occurred in the Windows – Installed Software sensor.

Error message in installed software sensor for Windows

5. To find the stack trace, navigate to **System Logs > Errors**.

6. Search for the date and time that matches the value in the **Created** field of the error record in the discovery log.

7. The **Message** field of that entry contains the full stack trace of the error.

The stack trace contains the error message, the sys_id of the script, and the line number where the error occurred. This stack trace shows the following errors:

- **Line 1 and 2**: There was a JavaScript evaluation error on new DiscoverySmiFcSwitchSensor().
- **Line 3**: The Ci.controller variable is undefined.
- **Line 4**: This script_includes line indicates the sysid 7780111 ... d768 and the error occurred at approximately line 26 of the JavaScript file.

Stack trace

8. After determining the error details, you can fix the JavaScript file.
**Identify cause of No Sensor Defined error message**

Every active probe looks for a corresponding sensor to process the data that is collected by the probe. The No Sensors Defined message indicates that the corresponding sensor for the probe is missing or inactive.

**Role required:** admin

To find the cause of this error, identify the **Short Message** field of the error record. This field shows the name of the probe for which the sensor is missing.

1. Navigate to **Discovery > Discovery Log**.
2. Filter on the **Level name** of **Error**.
   
   You can also view the Error Report on the Discovery dashboard.
3. Note the **Short Message** field of the error record.
   
   This field shows the name of the sensor. In this example, the sensor error occurred when the Shazzam probe checked for the existence of the Shazzam sensor.

![Stack trace for No Sensor Defined error](image)

**Fix the cause of a sensor error message**

To fix a Discovery sensor error message, you must fix the JavaScript file containing the code that generated the error.

**Role required:** admin

To fix the JavaScript file:

1. Navigate to the module in Discovery in which the error occurred.
   
   In this example, navigate to **Discovery Definition > Script Includes**.
2. Fix the error.
   
   a) In this example, search for DiscoverySmiFcSwitchSensor in the **Name** field.
Discovery script includes

b) Click on the link to go to the details page for that script include.
c) Modify the JavaScript script on that page to fix the error indicated.
d) Click Update.

Find the cause of a “Probe not found” error
Verify the correct sys_id of the probe associated with the probe parameter in the payload of the ECC Queue input record.

Role required: discovery_admin, admin

1. Record the sys_id of the probe as it appears in the ECC Queue payload.

   ▼<parameters>
   <parameter name="port" value="22"/>
   <parameter name="probe" value="10e0eebd0a0a0b4f61f46a5027df7fb6"/>
   <parameter name="priority" value="0"/>
   <parameter name="use_class" value="discovery_classy_unix"/>

   ECC Queue payload sample

2. Navigate to Discovery Definition > Probes and open the record for the probe you want to inspect.
3. Right-click in the record’s header bar.
4. Select Copy sys_id from the context menu. Follow browser instructions to copy the sys_id if browser security measures restrict this function.
5. Compare this value with the sys_id of the probe from the payload.
   If the sys_id of the probe record does not match the value in the payload, try to determine the cause of the incorrect value.
Out-of-the-box Discovery Performance Analytics Solutions

Performance Analytics Solutions contain preconfigured dashboards. These dashboards contain actionable data visualizations that help you improve your business processes and practices.

Performance Analytics Solutions

Use the Performance Analytics widgets on the dashboard to visualize data over time, analyze your business processes, and identify areas of improvement. With solutions, you can get value from Performance Analytics for your application with minimal setup.

Important: Set up and test Out-of-the-box Performance Analytics Solutions on a sub-production instance before enabling them in production. You can set up and test Performance Analytics on a sub-production instance without a subscription.

Note:
- Solutions include some dashboards that are inactive by default. You can activate these dashboards to make them visible to end users according to your business needs.
- Out-of-the-box solutions and in-form analytics provide all the configuration records required to analyze default applications. Customize these records for use in your production environment.

To enable the solution plugin for Discovery, an admin can navigate to System Definitions > Plugins and activate the Performance Analytics - Content Pack - Discovery plugin.

Discovery patterns used by ITOM Visibility

Service Mapping and Discovery use patterns in their discovery process. The base system contains a wide range of patterns that cover most industry standard network devices and applications. You can customize these patterns and create new ones.

ServiceNow applications refer to devices and applications that comprise an application service as configuration items (CIs).

What discovery patterns are

A pattern is a sequence of steps whose purpose is to detect attributes of a CI and its outbound connections. Service Mapping and Discovery share a set of preconfigured patterns that cover most of the commonly used devices and applications. Patterns can be of infrastructure or application type. Infrastructure patterns are used only by Discovery for creating lists of devices. Application patterns serve both Service Mapping and Discovery that use the same application patterns for their purposes. For example, Discovery runs the horizontal discovery with the Apache Web Server pattern to find and list all Apache Web Servers in your organization. Service Mapping runs the top-down discovery using the same pattern to discover a specific Apache Web Server and place it on an application service map.

Pattern usage by Service Mapping and Discovery

<table>
<thead>
<tr>
<th>Product</th>
<th>Pattern type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discovery</td>
<td>Infrastructure pattern</td>
<td>Inventory list of devices</td>
</tr>
</tbody>
</table>
For discovering devices that act as hosts for applications, Service Mapping relies on Discovery. As part of the top-down discovery process, Service Mapping triggers Discovery to perform its horizontal discovery behind the scenes. Service Mapping then uses information on hosts provided by the horizontal discovery to create its application service maps.

Patterns of all types are stored in the Discovery Patterns (sa_pattern) table.

Discovery uses a combination of probes and patterns. For more information, see Horizontal discovery process flow with probes and sensors.

**Correlation between pattern and CI type**

Patterns are assigned to the CI types that they serve to discover. If necessary, you may assign more than one CI type per pattern. In that case, you define one main CI type and multiple related CI types. For example, a pattern for discovering BIG-IP Global Traffic Manager (GTM) F5 has BIG-IP Global Traffic Manager (GTM) F5 as its main CI type and related CI types for the DNS name, network adapter and other components.

For top-down discovery performed by Service Mapping, each application pattern serves to discover only the main CI type.

At the same time, Service Mapping usually uses more than one pattern to discover the same CI type, since a CI type can use different protocols, operating systems, entry points, and so on.

Unlike top-down discovery, the process of horizontal discovery uses each pattern to discover a main CI type with all related CI types.
Why install patterns from the ServiceNow Store

ServiceNow releases new discovery patterns on the ServiceNow Store on a monthly basis to ensure that your organization can discover the latest industry-standard devices and applications. Major ServiceNow versions incorporate patterns previously released on the ServiceNow Store.

Why customize patterns

You can customize patterns in the following cases:

- If your organization uses proprietary devices and applications, create patterns for these items to enable Discovery and Service Mapping to discover them.
- If you modify key attributes of CI types that had corresponding patterns, modify the relevant patterns to reflect the change.

Pattern versions

When you customize a pattern, you actually create a copy of the original pre-configured pattern. While Service Mapping or Discovery use the customized version, the original version is not deleted. When you upgrade your Now Platform, it updates the original pattern, not the customized copy of it.
If at some point you want to abandon the customized pattern and start using the updated original pattern, you can revert to the original pattern as described in [Choose the pattern version](#).

**Who can customize patterns**

Users must have the pd_admin role to customize patterns. In the base system, the sm_admin role contains the pd_role. Customizing patterns requires basic knowledge of programming.

**Patterns for instances using domain separation**

In instances that use domain separation, patterns may be domain-specific, covering only domains that you created them for, or global, applying to all domains.

Patterns belong to domains. By default, all preconfigured patterns are assigned to the global domain and apply to all domains of all levels.

You can create patterns for specific domains. In that case, the new pattern is used only for this domain and does not exist in any other domains. If you customize an existing pattern in the global domain and assign it to a specific domain, you create a copy of the global pattern, which is still used for all other domains except the domain that has the customized version of this pattern. Likewise, if you customize the pattern belonging to the global domain, the change effects all domains except the one that uses a customized copy of this pattern.
Pattern creation or modification flow

Typically, you maintain two ServiceNow instances in your organization: for production and for development. Create or modify patterns, test them, and verify results in the development instance. When you are satisfied with the discovery results, export relevant patterns from the development instance to create an update set. Then you retrieve and commit the update set in your production instance.

If you are creating a pattern for applications and devices that are not supported in the base system, start from creating CI types for them.
Available discovery patterns

ITOM Visibility comes with an extensive library of patterns. Learn about the discovery patterns that became available since the Kingston release.

ServiceNow releases new discovery patterns on the ServiceNow Store on a monthly basis to ensure that your organization can discover the latest industry-standard devices and applications. Major ServiceNow versions incorporate patterns previously released on the ServiceNow Store.

For a complete list of devices and applications that ITOM Visibility can discover, see Applications supported by Discovery and Service Mapping.
Apigee Edge discovery

Discovery finds Apigee Edge Enterprise edition versions 4.x.x using the APIGee pattern.

The APIGee pattern uses a built-in cache mechanism that collects data from each API service into a local cache file. Service Mapping performs top-down discovery on these cache files to find outgoing Apigee Edge connections.

You can use this pattern on the ServiceNow platform of Jakarta release or later.

Prerequisites

Linux user

Provide the Linux operating system (OS) user with elevated rights for running the cat, ls, netstat, and stat commands. For more information, refer to Service Mapping commands requiring a privileged user in Service Mapping documentation.

In addition, provide this Linux user with permissions to run the following commands on the OS user home folder:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;date +%s&quot;</td>
<td>Gets the current date.</td>
</tr>
<tr>
<td>&quot;ls -d $HOME/APIGee_Cache/cache_folder*&quot;</td>
<td>Gets the last cache folder.</td>
</tr>
<tr>
<td>&quot;mkdir-p $HOME/APIGee_Cache/cache_folder_&quot; + $today + &quot;; ls -d $HOME/APIGee_Cache/cache_folder_&quot; + $today</td>
<td>Creates the cache file if the cache file is empty.</td>
</tr>
<tr>
<td>&quot;ls -d $HOME/APIGee_Cache/cache_folder*&quot;</td>
<td>Verifies that the cache file has been created.</td>
</tr>
<tr>
<td>&quot;echo &quot;expr &quot; + $today + &quot; -&quot; + $current_date+ &quot; &quot; \geq &quot; + $week_seconds+ &quot; \; fi&quot;</td>
<td>Calculates the gap between the folder creation time and the current date.</td>
</tr>
<tr>
<td>&quot;ls -d $HOME/APIGee_Cache/cache_folder*&quot;</td>
<td>Checks if existing cache files contain the source URL that you enter as the entry point for the service.</td>
</tr>
<tr>
<td>&quot;ls + $cache_folder+ &quot;/&quot; s ort &quot; xarg sgrep -l &quot; + $entry_point.u_source_url</td>
<td>Checks if it is necessary to recreate the folder.</td>
</tr>
<tr>
<td>&quot;rm -rf $cache_folder+ &quot; s ort &quot; xarg sgrep -l &quot; + $entry_point.u_source_url</td>
<td>Removes old cache files.</td>
</tr>
<tr>
<td>&quot;curl -k -X GET &quot;URL&quot; -H &quot;&lt;ClientID&gt;: &lt;Token&gt;&quot;</td>
<td>Gets the API response for the given token.</td>
</tr>
<tr>
<td>&quot;ls + $cache_folder+ &quot;/&quot; s ort &quot; xarg sgrep -l &quot; + $entry_point.u_source_url</td>
<td>Gets the URL definition from the cache file.</td>
</tr>
</tbody>
</table>

Applicative credential

Configure the applicative credential as follows:

Applicative Credentials form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The credential name, for example Apigee token.</td>
</tr>
<tr>
<td>Active</td>
<td>Check box for enabling this credential for discovery.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>User name</td>
<td>The name of the user of this applicative credential. You can use any user for the credential for this pattern, since the information is extracted from a local cache.</td>
</tr>
<tr>
<td>Password</td>
<td>The actual user password of this applicative credential.</td>
</tr>
<tr>
<td>CI type</td>
<td>The CI type for which this credential is used: APIGee Service (u_cmdb_ci_appl_apigee_srv).</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>ServiceNow applications refer to devices and applications that comprise an application service as configuration items (CIs).</td>
</tr>
<tr>
<td>Applies to</td>
<td>Select whether to apply these credentials to All MID servers in your network, or to one or more Specific MID servers. Specify the MID Servers that should use these credentials in the MID servers field.</td>
</tr>
<tr>
<td>Order</td>
<td>Enter the order (sequence) in which the platform tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), the instance tries the credentials in a random order.</td>
</tr>
</tbody>
</table>

**curl command**

Make sure that the curl command is installed on the Linux server hosting Apigee Edge.

**Apigee URLs for discovering connections**

In the first step of the connection section of the APIGee pattern, configure URLs of the outgoing Apigee Edge connections in the following syntax:

```
"01#DVL#https://<url1>.com/dashboard/v1/targetServers/dvl### 02#QA#https://<url2>.com/dashboard/v2/targetServers/dvl###
```

Where

- ‘01’ is the URL number,
- ‘DVL’ is the environment type, like development.
Data collected by Discovery during horizontal discovery

<table>
<thead>
<tr>
<th>Table and field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Apigee Edge (cmdb_ci_appl_apigee_srv)</td>
<td>The name of the server hosting the Apigee Edge.</td>
</tr>
<tr>
<td>Name</td>
<td>The name of the server hosting the Apigee Edge.</td>
</tr>
<tr>
<td>Version</td>
<td>The version of the Apigee Edge.</td>
</tr>
<tr>
<td>Installation directory</td>
<td>The folder containing all the Apigee Edge libraries and executable files.</td>
</tr>
<tr>
<td>Configuration directory</td>
<td>The folder containing all the Apigee Edge configuration files.</td>
</tr>
</tbody>
</table>

CI relationships

The APIGee pattern does not create any CI relationships.

Data collected by Service Mapping during top-down discovery

The APIGee pattern identifies connections from the Apigee Edge to other CIs based on the URL you configure in the connection section of the pattern.

Amazon AWS application ELB Service discovery

Discovery uses the Amazon AWS application ELB Service discovery pattern to show all load balancers in your environment in a map.

Elastic Load Balancing (ELB) automatically distributes incoming application traffic across multiple targets.

The Amazon AWS application ELB Service discovery pattern supports top-down discovery. This pattern discovers all load balancers with these characteristics:

- Use ultra-high performance, TLS offloading at scale, and centralized certificate deployment
- Support UDP and static IP addresses for your application

For top-down discovery, the entry point is HTTP(s) Endpoint. Outgoing relations are to Amazon EC2 instances.

You can use this pattern on the ServiceNow platform using Kingston or later releases.
Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store.

**Prerequisites**

- Run a horizontal discovery, using Cloud API (CAPI). This is necessary because this discovery pattern supports top-down discovery only. For cloud discovery, you can run the horizontal discovery as usual.
- When the load balancers data has been stored in the CMDB, create an application service for each load balancer.
- Set read-only permissions for these REST APIs:

**Data collected by Discovery during horizontal discovery**

The discovered data includes the following tables and fields.

<table>
<thead>
<tr>
<th>Table and field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Load Balancer Services (cmdb_ci_lb_service)</td>
<td>Fully Qualified Domain Name (FQDN) of the load balancer. The DNS name.</td>
</tr>
<tr>
<td>Fully qualified domain name (fqdn)</td>
<td>Name of the load balancer, in the following format: &lt;LB name&gt;:&lt;LB port&gt;.</td>
</tr>
<tr>
<td>Name (name)</td>
<td>Serial number of the load balancer, in the following format: #Object_ID=&lt;LB_ARN&gt;.</td>
</tr>
<tr>
<td>Serial Number (serial_number)</td>
<td>Port of the load balancer.</td>
</tr>
<tr>
<td>Port (port)</td>
<td>Object ID (object_id)</td>
</tr>
<tr>
<td>Object ID (object_id)</td>
<td>IP Address (ip_address)</td>
</tr>
<tr>
<td>IP Address (ip_address)</td>
<td>Unique identifier of the load balancer.</td>
</tr>
</tbody>
</table>

**Amazon AWS classic ELB Service discovery**

Discovery uses the Amazon AWS classic ELB Service discovery pattern to find all load balancers that use HTTP and HTTPS traffic.

Elastic Load Balancing (ELB) automatically distributes incoming application traffic across multiple targets.
The Amazon AWS classic ELB Service discovery pattern supports top-down discovery. The two possible entry points for top-down discovery are the HTTP(s) Endpoint and TCP Endpoint. Outgoing relations are to Amazon EC2 instances.

You can use this pattern on the ServiceNow platform using Jakarta or later releases.

Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store.

**Prerequisites**

- Run a horizontal discovery, using Cloud API (CAPI). This is necessary because this discovery pattern supports top-down discovery only. For cloud discovery, you can run the horizontal discovery as usual.
- When the load balancers data has been stored in the CMDB, create an application service for each load balancer.
- Set read-only permissions for these REST APIs:

**Data collected by Discovery during horizontal discovery**

The discovered data includes the following tables and fields.

<table>
<thead>
<tr>
<th>Table and field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Load Balancer Services (cmdb_ci_lb_service)</td>
<td>Fully Qualified Domain Name (FQDN) of the load balancer. The DNS name.</td>
</tr>
<tr>
<td>Fully qualified domain name (fqdn)</td>
<td>Name of the load balancer, in the following format: &lt;LB name&gt;:&lt;LB port&gt;.</td>
</tr>
<tr>
<td>Name (name)</td>
<td>Port of the instance.</td>
</tr>
<tr>
<td>Back End Port (back_end_port)</td>
<td>Port of the instance.</td>
</tr>
<tr>
<td>Server Port (server_port)</td>
<td>Port of the instance.</td>
</tr>
<tr>
<td>Port (port)</td>
<td>Port of the load balancer.</td>
</tr>
<tr>
<td>Front End Port (front_end_port)</td>
<td>Port of the load balancer.</td>
</tr>
<tr>
<td>Object ID (object_id)</td>
<td>LB port.</td>
</tr>
<tr>
<td>IP Address (ip_address)</td>
<td>IP address of the FQDN.</td>
</tr>
<tr>
<td>IP Address (cmdb_ci_ip_address)</td>
<td></td>
</tr>
<tr>
<td>Name (name)</td>
<td>Name of the load balancer, in the following format: &lt;LB name&gt;:&lt;LB port&gt;.</td>
</tr>
<tr>
<td>Netmask (netmask)</td>
<td>0.0.0.0</td>
</tr>
</tbody>
</table>
Amazon AWS Relational Database Service discovery

The ServiceNow® Discovery application uses the Amazon AWS Relational Database Service discovery pattern to find AWS RDS components.

Amazon Relational Database Service (RDS) is a managed relational database service by Amazon Web Services (AWS). It enables users to easily create and manage relational database instances in the cloud.

Discovery uses the discovery pattern to run horizontal discovery, events discovery, and tags discovery. The pattern uses a set of Amazon REST APIs to find the RDS components.

Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store.

Prerequisites

- Install the Discovery and Service Mapping Patterns application from the ServiceNow Store.
- On the Now Platform, configure AWS credentials, using a secret key and an access key.
- Create a service account. Set the Account ID to the Amazon account ID to which RDS belongs. Use the Account ID as it appears in the AWS Management Console.
- Set read-only permissions for these REST APIs:
  - https://rds.<REGION>.amazonaws.com/?Action=DescribeDBInstances
  - https://rds.<REGION>.amazonaws.com/?Action=DescribeDBInstances&DBInstanceIdentifier=<input_object_id> for events discovery
  - https://tagging.<REGION>.amazonaws.com/ for tags discovery
- Ensure to place the MID Server inside the Amazon cloud.

Data collected by Discovery during horizontal discovery

The discovered data includes the following tables and fields.

<table>
<thead>
<tr>
<th>Table and field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud Database (cmdb_ci_cloud_database)</td>
<td>Class of the database. Includes templates for CPU and memory.</td>
</tr>
<tr>
<td>Category (category)</td>
<td>Class of the database.</td>
</tr>
<tr>
<td>Object ID (object_id)</td>
<td>Unique resource ID that identifies each logical datacenter (LDC).</td>
</tr>
<tr>
<td>Fully qualified domain name (fqdn)</td>
<td>Address of the database endpoint. The DNS name.</td>
</tr>
<tr>
<td>TCP Port (tcp_port)</td>
<td>Port of the database endpoint.</td>
</tr>
<tr>
<td>Name (name)</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Version (version)</td>
<td>Version of the database.</td>
</tr>
<tr>
<td>Type (type)</td>
<td>Type of the database. Can be one of the following: Amazon Aurora, PostgreSQL, MySQL, MariaDB, Oracle Database, SQL Server.</td>
</tr>
<tr>
<td>Operational Status (operational_status)</td>
<td>Status of the database.</td>
</tr>
</tbody>
</table>
Amazon DynamoDB discovery

Discovery and Service Mapping use the Amazon AWS DynamoDB pattern to find components of DynamoDB.

The Amazon AWS DynamoDB pattern deploys Amazon REST APIs for fetching information about DynamoDB. You can also configure Service Mapping and Discovery to discover AWS DynamoDB components using AWS events.

You can use this pattern on the Now Platform® using Jakarta Patch 10, Kingston Patch 8, or London Patch 2.

Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store.

Prerequisites

User access

On the AWS Console, provide a user with the following permissions: AmazonDynamoDBReadOnly Access and AWSLambdaInvocation-DynamoDB.

Cloud Service Account

On the Now Platform®, set up the service account with these properties:

- An Account ID, which is the Amazon account ID to which DynamoDB belongs. Use the Account ID as it appears in the AWS Management Console.
- The appropriate AWS credentials required for the account ID to reach the AWS cloud.

AWS Credentials

On the Now Platform®, configure AWS credentials, using a secret key and an access key.

Entry point for service containing DynamoDB

Use AWS Resource Name Endpoint as the Entry Point Type when creating a service containing DynamoDB. Provide the Amazon Resource Name (ARN) and host for the entry point.

(For top-down discovery by Service Mapping) Run horizontal discovery of the Logical Datacenters
Discover Logical Datacenters hosting DynamoDBs as described in Run Discovery on an AWS cloud service account in the ServiceNow Cloud Management documentation.

**Discovery schedule**

Create a schedule for the relevant AWS service account as described in Schedule Discovery on a service account in the ServiceNow Cloud Management documentation.

**Configure AWS event service**

To enable alert-based discovery, configure the AWS event service as described in Set up AWS event processing for Discovery and Service Mapping in the ServiceNow Cloud Management documentation.

**Data collected by Discovery during horizontal discovery**

</tr>
</tbody>
</table>

The graphic illustrates CIs that are part of DynamoDB discovery.
CI relationships

The Amazon AWS DynamoDB pattern creates the following CI relationships:

<table>
<thead>
<tr>
<th>CI</th>
<th>Relationship</th>
<th>CI</th>
</tr>
</thead>
<tbody>
<tr>
<td>DynamoDB Global Table</td>
<td>Cluster of::Cluster</td>
<td>DynamoDB Table</td>
</tr>
<tr>
<td>(cmdb_ci_dynamodb_global_table)</td>
<td></td>
<td>(cmdb_ci_dynamodb_table)</td>
</tr>
</tbody>
</table>

Data collected by Service Mapping during top-down discovery

The Amazon AWS DynamoDB pattern identifies connections from the DynamoDB to AWS Lambda functions.
Troubleshooting

If the mapping result is not as you expected, perform basic troubleshooting.

<table>
<thead>
<tr>
<th>Symptom</th>
<th>Cause</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discovery fails. The discovery message contains the information about an error caused by the REST timeout.</td>
<td>There are many CIs sending the REST call response in the deployment. The MID Server cannot process the REST call response without exceeding the time limit controlled by the mid.sa.cloud.request_timeout parameter.</td>
<td>By default, the mid.sa.cloud.request_timeout parameter is set to 30000 milliseconds. Increase the value of this parameter on the relevant MID Server and run discovery again.</td>
</tr>
<tr>
<td>Pattern designer fails during a debug session. The pattern designer message contains information about an error caused by a timeout.</td>
<td>The pattern designer fails because of a timeout during pattern debugging (and not during discovery).</td>
<td>By default, the sa.debugger.max_timeout parameter is set to 240 seconds. Increase the value of this parameter on the relevant MID Server.</td>
</tr>
</tbody>
</table>

**Define a Cloud REST Query for cloud computing devices**

As part of creating or modifying a discovery pattern, you can use the Cloud REST Query operation to extract information from configuration items (CIs) of the PaaS (Platform as a Service) type, such as Microsoft Azure or Amazon Web Services.

- Verify that the operating system of the CIs for which you want to use the Cloud REST Query operation extends the Logical Data Center OS type (cmdb_ci_logical_datacenter):
  1. Navigate to Pattern Designer > Discovery Patterns.
  2. Double-click the relevant pattern to open it in the Pattern Designer.
  3. Click the Basic tab.
  4. Note the operating system for this CI.
  5. Navigate to System Definition > Tables.
  6. Set the search field to Label and enter the name of the operating system as stated on the Basic tab of the pattern.
  7. Find the operating system in the list and verify that Logical Datacenter appears in the Extends table column.

- Navigate to the relevant pattern step:
  1. On the pattern form, select the relevant identification section for Discovery. Alternatively, select the relevant identification or connection section for Service Mapping.
  2. Select the relevant pattern step or click the Add a step above icon to add a step.
Basic knowledge of programming is desirable.

Role required: pd_admin

Deploy the Cloud REST Query operation in patterns used for discovery of PaaS CIs. This Java-script based custom operation is available only after downloading patterns version 1.0.24 or later from ServiceNow Store. Use this operation instead of the Cloud REST Call operation available in the base system.

Refer to the official API-related documentation provided by manufacturers to obtain the query syntax for the device you want to query using the Cloud REST Query operation. For example:

- https://docs.microsoft.com/en-us/rest/api/apimanagement/

1. Select **Cloud REST Query** from the **Operation** list.
2. Define query parameters as necessary:

   **Note:** If you customized this operation, the query parameters may be different.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>URL</td>
<td>Specify the URL as described in the official Microsoft Azure or Amazon Web Services documentation. You can use variables. You can also enter a value from the specific field in a tabular variable.</td>
</tr>
</tbody>
</table>
   | Method    | Enter the method value as a string using all capital letters, for example “GET”. Supported methods are:
   |           | - GET
   |           | - POST
   |           | - PUT
   |           | Refer to the relevant API guide for information. If the API documentation does not specifically mention the HTTP query method, use the GET method. |
   | Body      | (Optional) Enter a request body as a string. If the string contains quotation marks, use the backslash mark in front of the quotation marks to indicate that the string does not end at the quotation marks. |
   | Headers   | (Optional) If the relevant API documentation states that HTTP headers must be sent, enter these headers in the following format:
   |           | Header_name1:header_value1,header_name2:header_value2
   |           | For example, Content-Type:xml. |
   | Formatted | Formatted JSON or not |

3. To save the command output in its entirety as a variable, select **NONE** from the **Define Parsing** list and define the variable.
4. Select the parsing strategy from the **Define Parsing** list.
5. If working in the Debug Mode, define the parsing criteria as follows:
   a) Click Run Operation to see the result in the Output pane.
   b) In the Output pane, mark text or symbols that you want a variable to contain.
   c) In the variable name box, enter the name for the new variable, for example ‘process_name’.
   
   ![Screenshot of parsing criteria]

   d) Press Enter.
   
   The new variable is added in the Variables pane.

6. If you are not working in Debug Mode, define the parsing criteria as follows:
   a) In the Variables pane, click Add Variable and enter the name for the new variable.
   b) Click the Advanced icon.
c) Click **Add Column Label**.

d) Enter the parsing query.

e) Enter a value for the delimiter.

f) Enter a value for the position.

7. Select **Terminate** to stop discovery if no results are found.

<table>
<thead>
<tr>
<th>This operation is used in</th>
<th>This item</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hierarchy</td>
<td>Application</td>
</tr>
<tr>
<td>CI Type</td>

<td>Identification of AWS S3</td>
</tr>
<tr>
<td>Step number and Name</td>
<td>3. List buckets</td>
</tr>
</tbody>
</table>
Use the Cloud REST Query operation to extract information about AWS buckets, their names and creation dates.

Amazon Web Services (AWS) Resource Inventory

Discovery and Service Mapping can find and map the AWS resources available by AWS Config service.

Request apps on the Store

Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store. For cumulative release notes information for all released apps, refer to the ServiceNow Store version history release notes.
About this pattern

Discovery uses the AWS Resource Inventory pattern to discover the resources available through AWS. Use this pattern for AWS resources which do not have a dedicated pattern, such as AWS Lambda or EC2. This pattern is limited to resources that are available from AWS Config Service, as described in the AWS Config Developer Guide.

You can use this pattern on the ServiceNow platform using London (Patch 8), Madrid (Patch 2), or later releases.

Prerequisites

- Create AWS credentials.
- Create an AWS cloud service account.
  You can use only the AWS master service account for discovery, not its sub-accounts.

  Note: The Cloud Discovery user interface refers to member accounts as sub-accounts.

- Discover AWS Datacenters (LDC)
- Schedule a full AWS discovery or use a specific inventory pattern

- To discover the resources that support the AWS Config service, use API 'https://config.[AWS region].amazonaws.com.' Also, specify the resource type in the API request using the following format: {'resourceType': 'AWS::[RESOURCE]::[TYPE]'}
  The POST method requires the following headers:
  - X-Amz-Target - StarlingDoveService.ListDiscoveredResources
  - Accept - application/json
  - Content-Type - application/x-amz-json-1.1

- Modify the ServiceNow identification rules. Be sure to switch to the Cloud Management Platform application scope before you begin the following procedure.
  1. Navigate to CI Class Manager > Hierarchy > Cloud Resource > Identification Rule.
  2. Delete and add the appropriate identification rule.
     The new identification rule should include only the Object ID attribute.
Modify the ServiceNow related entries

1. Navigate to **Related Entries**.
2. Click **New**.
3. For the identifier, enter `cmdb_ci_cmp_resource`.
4. For the related table, select **Key Value (cmdb_key_value)**.
5. For the referenced field, select **Configuration Item**.
6. For the criterion attributes, add **Key** and **Value**.

You may need to click the lock icon to view and change the criterion attributes.

If your deployment has custom patterns for AWS discovery, ensure that you do not discover AWS resources twice.

1. Ensure that the application scope is Discovery and Service Mapping Patterns:
   a. Navigate to Settings > Developer.
   b. Select Discovery and Service Mapping Patterns from the Application list.

2. Navigate to System Definitions > Tables.
3. Open the Cloud Inventory Resource Whitelist (sa_cloud_inventory_resource_whitelist) table.
4. Under Related Links, click Show List.
5. Select resource types for which you have custom patterns, and select Delete from the Actions on selected rows list.

The Cloud Inventory Resource Whitelist is predefined with common services. You can expand the whitelist with additional resource types that you want the pattern to discover. The names of these resource types must conform to the appropriate vendor naming conventions.

**Note:** When you modify the out-of-the-box whitelist, it is no longer updated automatically in application updates. You need to maintain the customized list on your own.

1. Open the Cloud Inventory Resource Whitelist (sa_cloud_inventory_resource_whitelist) table.
2. Click New.
3. Fill in the form, and then click Submit.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud Vendor</td>
<td>The vendor of the resource type: AWS.</td>
</tr>
<tr>
<td>Resource Type</td>
<td>The AWS resource type value. For example, AWS::CloudWatch::Alarm.</td>
</tr>
</tbody>
</table>
The changes are applied the next time you run the pattern.

- To discover the resources that support the AWS Config service, use API `https://config.(AWS region).amazonaws.com` Also, specify the resource type in the API request using the following format: `{"resourceType":"AWS::(RESOURCE)::(TYPE)"}`

The POST method requires the following headers:
- X-Amz-Target - StarlingDoveService.ListDiscoveredResources
- Accept - application/json
- Content-Type - application/x-amz-json-1.1

- To discover the resource tags for those resources that support tags, use API `https://tagging.(AWS region).amazonaws.com` Also, specify the resource type filter in the API request using the following format: `{"ResourceTypeFilters": [{"resource"}:"(type)"]}`

The POST method requires the following headers:
- X-Amz-Target - ResourceGroupsTaggingAPI_20170126.GetResources
- Accept - application/json
- Content-Type - application/x-amz-json-1.1

### Data collected by Discovery during horizontal discovery

<table>
<thead>
<tr>
<th>Table and field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Main CI (cmdb_ci_cmp_resource)</td>
<td>The ID of the item. This is typically the Amazon Resource Name (ARN).</td>
</tr>
<tr>
<td>object_id</td>
<td>Name of the resource.</td>
</tr>
<tr>
<td>resource_type</td>
<td>The asset resource type, based on the contents of the JSON file.</td>
</tr>
<tr>
<td>description</td>
<td>Short description of how the CI is populated.</td>
</tr>
</tbody>
</table>

This pattern extends the cmdb_ci_vm_object as shown below:

- Identifier: None. Inherits identifier from cmdb_ci_vm_object.
- Hosting rules:
  - Hosted on Cloud Service Account
  - Hosted on Logical Datacenter
- Deletion strategy: Marks the CIs as absent.

This pattern populates the cmdb_key_value table with the following data:

- object_id: The ID of the item.
- key: Key in the key-value pair.
• value: Value in the key-value pair.

• The identifier for the related entry of the cmdb_key_value table is inherited from cmdb_ci_vm_object (the parent). The attributes are "key" and "value."

• The deletion strategy can't be applied to the cmdb_key_value table.

CI relationships

The AWS Resource Inventory pattern creates the following CI relationship:

<table>
<thead>
<tr>
<th>CI</th>
<th>Relationship</th>
<th>CI</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud Resource</td>
<td>Hosted on :: Hosts</td>
<td>Logical Datacenter</td>
</tr>
<tr>
<td>(cmdb_ci_cmp_resource)</td>
<td></td>
<td>(cmdb_ci_logical_datacenter)</td>
</tr>
</tbody>
</table>

The following is a dependency view of the collected data flow.
AWS Resource Inventory dependency view

**AWS API gateway discovery**

Discovery and Service Mapping can find AWS API gateways and connections to other entities. Discovery and Service Mapping use the **Amazon AWS API Gateway** pattern to run horizontal and top-down discovery.

You can use this pattern on the ServiceNow platform using the Kingston release or later.

**Prerequisites**

**AWS service account with credentials**

On the Now Platform®, set up the service account with the following:
- An **Account ID**, which is the Amazon account ID to which API Gateway belongs. Use the Account ID as it appears in the AWS Management Console. You can run discovery from the service account form.
- The appropriate AWS credentials required for the account ID to reach the AWS cloud.

Refer to Service accounts for Discovery and Service Mapping in product documentation.

**Update set**

If your instance is on the Jakarta or Istanbul versions, import the update set provided in KB0679927: AWS Lambda top-down discovery update set. This update set is required for Service Mapping.

**User access**

On the AWS Console, provide a user with permissions to run the `apigateway:GET` function for just the GET action in API Gateway.

**Data collected by Discovery during horizontal discovery**

<table>
<thead>
<tr>
<th>Table and field</th>
<th>Additional information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud Gateway (cmdb_ci_cloud_gateway)</td>
<td>The ID of the gateway.</td>
</tr>
<tr>
<td>Object ID</td>
<td>The ID of the gateway.</td>
</tr>
<tr>
<td>Short description</td>
<td>The short description of the gateway.</td>
</tr>
<tr>
<td>DNS Name (cmdb_ci_dns_name)</td>
<td>The unique name or IP address of the DNS host.</td>
</tr>
<tr>
<td>Name</td>
<td>The IP address of the DNS host.</td>
</tr>
<tr>
<td>IP address</td>
<td>The hostname or IP address of the endpoint.</td>
</tr>
<tr>
<td>AWS Resource Name Endpoint (cmdb_ci_endpoint_arn)</td>
<td>The ID (Amazon Resource Name) of other AWS entities to which the gateway connects.</td>
</tr>
</tbody>
</table>

**Configuration item (CI) Relationships**

These relationships are created to support AWS API Gateway discovery:

<table>
<thead>
<tr>
<th>CI</th>
<th>Relationship</th>
<th>CI</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud Gateway (cmdb_ci_cloud_gateway)</td>
<td>Uses:Used by</td>
<td>DNS Name (cmdb_ci_dns_name)</td>
</tr>
</tbody>
</table>
Connections discovered by Service Mapping during the top-down discovery

Service Mapping performs the top-down discovery of the AWS API Gateways in the context of application services. It discovers outgoing connections of the AWS API Gateways:

- AWS Lambda
- VPC Link for Virtual Private Cloud
- HTTP endpoint defined as the configured URL on the API Gateway

Troubleshooting

If the mapping result is not as you expected, perform basic troubleshooting.

<table>
<thead>
<tr>
<th>Symptom</th>
<th>Cause</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discovery fails. The discovery message contains the information about</td>
<td>There are many CIs sending the REST call response in the deployment. The MID Server cannot process the REST</td>
<td>By default, the mid.sa.cloud.request_timeout parameter is set to 30000</td>
</tr>
<tr>
<td>an error caused by the REST timeout.</td>
<td>call response without exceeding the time limit controlled by the mid.sa.cloud.request_timeout parameter.</td>
<td>milliseconds. Increase the value of this parameter on the relevant MID</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Server and run discovery again.</td>
</tr>
<tr>
<td>Pattern designer fails during a debug session. The pattern designer</td>
<td>The pattern designer fails because of a timeout during pattern debugging (and not during discovery).</td>
<td>By default, the sa.debugger.max_timeout parameter is set to 240 seconds.</td>
</tr>
<tr>
<td>message contains information about an error caused by a timeout.</td>
<td></td>
<td>Increase the value of this parameter on the relevant MID Server.</td>
</tr>
</tbody>
</table>

Note: If the Configuration Parameters related list for the relevant MID Server does not show this parameter, you may need to add it.
Test patterns for discovering AWS API Gateway and AWS Lambda

Run the horizontal and top-down discovery using Amazon AWS API Gateway (cmdb_ci_cloud_gateway) and Amazon AWS Lambda (cmdb_ci_cloud_function) patterns. Verify that the result is as expected.

Make sure that your deployment complies with all the prerequisites for AWS API gateway discovery and AWS Lambda discovery.

Role required: admin

1. Create a business service using the following properties for its entry point.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CI type</td>
<td>HTTPS</td>
</tr>
<tr>
<td>URL</td>
<td>The URL for invoking the API Gateway. Typically, the API GW has the following format: https://{restapi_id}.execute-api.{region}.amazonaws.com/{stage_name}/ For example, <a href="https://k40o0l3af6.execute-api.us-east-1.amazonaws.com/prod/">https://k40o0l3af6.execute-api.us-east-1.amazonaws.com/prod/</a>. For information about the URL format, see <a href="https://docs.aws.amazon.com/apigateway/latest/developerguide/how-to-call-api.html">https://docs.aws.amazon.com/apigateway/latest/developerguide/how-to-call-api.html</a>.</td>
</tr>
</tbody>
</table>

Note: The default stage_name parameter is prod.

2. Click Discover.

Service Mapping runs the top-down discovery using the Amazon AWS API Gateway (cmdb_ci_cloud_gateway) pattern.

After Service Mapping completes identifying the API Gateway configuration item (CI), it runs the Connection to APIs connection section and discovers connection to the AWS Lambda. It then runs the Amazon AWS Lambda (cmdb_ci_cloud_function) pattern and identifies the AWS Lambda CI.

3. After Service Mapping finishes to discover this business service, verify that it discovered and identified AWS components correctly. Check that

- Service Mapping correctly resolves the URL, finds all IP addresses behind it and creates an entry point for each IP address.
Service Mapping identifies the AWS API Gateway and creates an application cluster for IP address.

- The Properties pane shows the properties for the AWS API Gateway: Cloud Gateway (cmdb_ci_cloud_gateway).
- Service Mapping discovers the AWS Lambda connected to the application cluster for API Gateway.
- Service Mapping discovers the databases connected to AWS Lambda.

**AWS Cognito discovery**

Discovery and Service Mapping use the Amazon AWS Cognito pattern to provide authentication, authorization, and user management functions for AWS customers.

You can use this pattern on the Now Platform using London Patch 8, Madrid Patch 2, or later releases.

**Prerequisites**

**User permissions**

Provide user with read-only permission to run the following API:

- `https://cognito-idp.<region>.amazonaws.com`
- Method: POST
- Body: `{"MaxResults": 10}`
- Headers: X-Amz-Target:AWSCognitoIdentityProviderService.ListUserPools,Content-Type:application/x-amz-json-1.0

**AWS Credentials**

On your instance, configure credentials of type AWS Credentials and set to Active.

**Cloud service account**

On your instance, configure the cloud service account of type AWS Datacenter and set to AWS account ID. Use the credentials defined in the preceding AWS Credentials.

**Discovery schedule**

Create a cloud application schedule for discovering AWS Cognito and configure the attributes. Set Discovery to Cloud application.

**Execution pattern**

Create and define the serverless execution pattern for cloud application discovery.

1. Create new Cloud Execution Patterns.
2. Define Name.
3. Verify that Active is true.
4. Verify that Domain is global.
5. Choose the AWS pattern you want to run.
6. Create multiple records if you want to run more than one pattern.

**Discovery schedule for full AWS discovery**

Create a discovery schedule from your Cloud service account created in the earlier procedure.

1. Click on Discover Datacenter and wait for it to finish.
2. Click Create Discovery Schedule.
3. This new schedule is created under the Discovery Schedule and runs all AWS patterns.

**Data collected by Discovery and Service Mapping during horizontal and top-down discovery**

The AWS Cognito pattern collects data.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Main C1: cmdb_ci_cloud_authentication</td>
<td></td>
</tr>
<tr>
<td>name</td>
<td>A descriptive name used to identify the user pool.</td>
</tr>
<tr>
<td>object_id</td>
<td>This is equal to the account_id and used by IRE identification rules.</td>
</tr>
<tr>
<td>Fqdn</td>
<td>Example of an ARN: arn:aws:cognito-idp:eu-west-1:1751200741520:userpool/eu-west-1_fim5E2mix</td>
</tr>
</tbody>
</table>
Tags are also being collected by an extension section that runs following the pattern. The tagging API for AWS specifies the resource type Cognito.

**Collected information from the AWS Cognito tags**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmdb_key_value</td>
<td></td>
</tr>
<tr>
<td>key</td>
<td>The actual tag key.</td>
</tr>
<tr>
<td>value</td>
<td>The tag value.</td>
</tr>
<tr>
<td>configuration_item</td>
<td>The unique resource ID (ARN) that identifies the resource in the AWS console.</td>
</tr>
</tbody>
</table>

**CI relationships**

The AWS Cognito pattern creates the following CI relationship.

<table>
<thead>
<tr>
<th>CI</th>
<th>Relationship</th>
<th>CI</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud authentication</td>
<td>Hosts:Hosted on</td>
<td>Logical datacenter</td>
</tr>
<tr>
<td>(cmdb_ci_cloud_authentication)</td>
<td></td>
<td>(cmdb_ci_logical_datacenter)</td>
</tr>
</tbody>
</table>

**Troubleshooting**

If the mapping result is not as you expected, perform basic troubleshooting.

<table>
<thead>
<tr>
<th>Symptom</th>
<th>Cause</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discovery fails. The discovery message contains the information about an error caused by the REST timeout.</td>
<td>There are many CIs sending the REST call response in the deployment. The MID Server cannot process the REST call response without exceeding the time limit controlled by the <code>mid.sa.cloud.request_timeout</code> parameter.</td>
<td>By default, the <code>mid.sa.cloud.request_timeout</code> parameter is set to 30000 milliseconds. Increase the value of this parameter on the relevant MID Server and run discovery again.</td>
</tr>
<tr>
<td>Pattern designer fails during a debug session. The pattern designer message contains information about an error caused by a timeout.</td>
<td>The pattern designer fails because of a timeout during pattern debugging (and not during discovery).</td>
<td>By default, the <code>sa.debugger.max_timeout</code> parameter is set to 240 seconds. Increase the value of this parameter on the relevant MID Server.</td>
</tr>
</tbody>
</table>

*Note: If the Configuration Parameters related list for the relevant MID Server does not show this parameter, you may need to add it.*
AWS ECS-Fargate resource discovery

Discovery uses the AWS ECS-Fargate pattern to find resources that are managed by the AWS Elastic Container Service (ECS). This includes resources that are run on the Fargate launch type.

AWS ECS is a highly scalable, fast, container management service that makes it easy to run, stop, and manage Docker containers. AWS Fargate is a compute engine for AWS ECS that allows AWS customers to run containers without having to manage servers or clusters.

Discovery uses the AWS ECS-Fargate pattern to run horizontal discovery. You can use this pattern on the ServiceNow platform using Madrid release patch 10 or later.

Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store.

Prerequisites

- In the AWS console, create AWS credentials with privileges to view ECS resources. For more information, see: https://docs.aws.amazon.com/en_pv/AmazonECS/latest/userguide/get-set-up-for-amazon-ecs.html.

  Note: The API requests use AWS Signature Version 4 to authenticate. When the correct credentials are provided, authentication is done internally for the Cloud API Call pattern steps.

- In Now Platform, create AWS Cloud Service account and credential records. For more information, see Cloud credentials.
- In the Cloud Service Account record, click Discover Datacenters to find AWS Datacenters (LDCs) for the configured AWS Cloud Service account.
- Schedule for either full AWS discovery or only ECS pattern discovery. For more information, see Schedule a horizontal discovery.
- To enable the pattern to find the resource Tags, the parent ECS table (VM Object) must have a related entry for the cmdb_key_value table:
  1. In the Now Platform navigation bar, navigate to Configuration > Identification/Reconciliation, and click CI Identifiers.
  2. Search for and open the VM Object record.
  3. Click the Related Entries tab and make sure it is configured as shown in the VM Object Related Entry figure. If it is not, specify a new related entry: In the Related Entries related list, click New, fill out the form, and then click Submit.
**Data collected by Discovery during horizontal discovery**

This pattern discovers data that provides visibility for ECS clusters, ECS services, ECS task definitions, ECS tasks, Docker containers, and ECS container instances in your organization. The discovered data includes the following tables and fields.

<table>
<thead>
<tr>
<th>Table and field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AWS Cloud ECS Cluster (cmdb_ci_cloud_ecs_cluster)</strong></td>
<td></td>
</tr>
<tr>
<td>object_id</td>
<td>The ARN that identifies the cluster.</td>
</tr>
<tr>
<td>name</td>
<td>A user-generated string used to identify the cluster.</td>
</tr>
<tr>
<td>status</td>
<td>The status of the cluster. Valid values: ACTIVE, INACTIVE.</td>
</tr>
<tr>
<td>registered_container_instances</td>
<td>The number of container instances registered to the cluster. The status of these container instances can be either ACTIVE or DRAINING.</td>
</tr>
<tr>
<td><strong>AWS Cloud ECS TaskDefinition (cmdb_ci_cloud_ecs_task_definition)</strong></td>
<td></td>
</tr>
<tr>
<td>object_id</td>
<td>The full ARN of the task definition.</td>
</tr>
<tr>
<td>name</td>
<td>The name of the family to which this task definition is registered.</td>
</tr>
<tr>
<td>status</td>
<td>The status of the task definition.</td>
</tr>
<tr>
<td>Table and field</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>revision</td>
<td>The revision of the task in a particular family. This is the version number of the task definition in a family.</td>
</tr>
<tr>
<td>network_mode</td>
<td>The Docker networking mode to use for the containers in the task. Valid values: None, bridge, awsvpc, host.</td>
</tr>
<tr>
<td>cpu</td>
<td>The number of CPU units used by the task.</td>
</tr>
<tr>
<td>memory</td>
<td>The amount of memory, in MiB, used by the task.</td>
</tr>
</tbody>
</table>

AWS Cloud ECS Task (cmdb_ci_cloud_ecs_task)

| object_id            | The ARN that identifies the task.                                           |
| name                 | A user-generated string used to identify the task.                           |
| status               | The last-known status of the task.                                           |
| launch_type          | The launch type on which the task runs.                                      |
| operation_status     | The health status of the task, determined by the health of the essential containers in it. |
| cpu                  | The number of CPU units used by the task, as stated in the task definition. |
| memory               | The amount of memory, in MiB, used by the task, as stated in the task definition. |

AWS Cloud ECS Service (cmdb_ci_cloud_ecs_service)

| object_id            | The ARN that identifies the service.                                         |
| name                 | The name of the service.                                                     |
| status               | The status of the service.                                                   |
| launch_type          | The launch type on which the service runs.                                    |
| scheduling_strategy  | The scheduling strategy to use for the service.                              |

Docker Container (cmdb_ci_docker_container)

| container_id         | The ARN of the container.                                                    |
| name                 | The name of the container.                                                   |
| status               | The last-known status of the container.                                      |
| operational_status   | The health status of the container.                                          |
| cpu                  | The number of CPU units set for the container.                               |
| memory               | The hard limit of memory, in MiB, set for the container.                     |

Virtual Machine Instance (cmdb_ci_vm_instance)

| object_id            | The ARN that identifies the VM instance.                                     |

**Note:** Complete Virtual Machine Instance information is discovered in a different EC2 cloud pattern. In AWS ECS-Fargate resource discovery, only the object_id is parsed to aid with the unique identification of the CI.

<table>
<thead>
<tr>
<th>Key Value (cmdb_key_value)</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>The Tag key.</td>
</tr>
</tbody>

On the Dependency Views map you can see all discovered resources in your organization that are managed by AWS EWS, and the relationships between them.

In this example, the AWS Cloud ECS Cluster CI is hosted on an AWS Datacenter. It runs two AWS Cloud ECS Tasks and two AWS Cloud ECS Services, and uses three Docker Containers.

**Dependency Views sample map**

**CI relationships**

These relationships are created to support AWS ECS-Fargate discovery:
<table>
<thead>
<tr>
<th>CI</th>
<th>Relationship</th>
<th>CI</th>

</table>
AWS Lambda discovery

Discovery and Service Mapping can find and map Lambda functions that run in your AWS cloud. Discovery and Service Mapping use the Amazon AWS Lambda pattern to run horizontal and top-down discovery. When you run cloud discovery, your instance queries your AWS service account using the necessary credentials, and then runs a query to obtain Lambda information. The pattern parses this information and then it is saved in the CMDB.

You can use this pattern on the ServiceNow platform using Jakarta Patch 10, Kingston Patch 8, or London Patch 1.

Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store.

Prerequisites

Update set

If your instance is on the Jakarta or Istanbul versions, import the update set provided in KB0679927: AWS Lambda top-down discovery update set. This update set is required for Service Mapping.

User policy for AWS user

If you use Identity and Access Management (IAM) to manage users in Amazon Web Services (AWS) platform, ensure that you created a user policy for the AWS user. For more information, refer to Create an IAM user policy for Cloud Management in the ServiceNow Cloud Management documentation.

AWS service account with credentials

You must set up your service account with the appropriate AWS credentials. You run discovery from the service account form.

Refer to Service accounts for Discovery and Service Mapping in product documentation.

Service account

On the ServiceNow platform, create a service account. Set the Account ID to the Amazon account IT to which AWS Lambda belongs. Use the Account ID as it appears in the AWS Management Console. Ensure to place the MID Server on the virtual machine that is part of the service account that you are planning to discover.

Discover logical datacenters using horizontal discovery

Click Discover datacenters under Related Links on the Cloud Service Account form.

User permissions

Provide a user with permissions to run the ListFunctions API with the Resource: arn:aws:lambda:region:account-id: function:function-name. Provide a user with permissions to run the GetFunction API with the Resource: `*`.

Amazon Resource Name (ARN)

(Optional for application services using ARN as an entry point) Ensure that you know the ARN for the AWS Lambda you need to discover. ARNs serve as the resource identifiers for Amazon Web Services.

Host

If your instance is on the Jakarta or Istanbul versions, use the following host: 127.0.0.1.
Data collected by Discovery during horizontal discovery

Horizontal discovery populates this data in the CMDB:

<table>
<thead>
<tr>
<th>Table and field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud Function (cmdb_ci_cloud_function)</td>
<td></td>
</tr>
<tr>
<td>Name (name)</td>
<td>The name of the function.</td>
</tr>
<tr>
<td>Object ID (object_id)</td>
<td>The ID (Amazon Resource Name) of the AWS Lambda function, for example: arn:aws:lambda: {datacenter}1:751200741520:function: {function-name}</td>
</tr>
<tr>
<td>Version (version)</td>
<td>The version of the function. For example, $Latest represents the most recent published version.</td>
</tr>
<tr>
<td>Language (language)</td>
<td>The runtime environment, or language and version, that the function is written in, for example: Node.js6.10 for JavaScript version 6.10.</td>
</tr>
<tr>
<td>Code Location URL (code_location_url)</td>
<td>The URL of the function that you built from the API Gateway console.</td>
</tr>
<tr>
<td>CodeSha256 (codesha256)</td>
<td>The cryptographic hash signature for the function.</td>
</tr>
<tr>
<td>Code Size (code_size)</td>
<td>The size of the function code in MB.</td>
</tr>
<tr>
<td>Function Last Modified (function_last_modified)</td>
<td>The date the function last changed in your AWS Lambda environment.</td>
</tr>
</tbody>
</table>

Note: To see all of these fields, you need to configure the form layout as described in product documentation.

CI relationships

These relationships are created to support AWS Lambda discovery:

<table>
<thead>
<tr>
<th>CI</th>
<th>Relationship</th>
<th>CI</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud Function (cmdb_ci_cloud_function)</td>
<td>Uses:Used by</td>
<td>Cloud Database (cmdb_ci_cloud_database)</td>
</tr>
<tr>
<td></td>
<td>Hosted on:Hosts</td>
<td>AWS Datacenter (cmdb_ci_aws_datacenter)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The AWS datacenter has relationships to other AWS CIs, such as availability zones, service accounts, and so on. Refer to AWS and Azure cloud discovery in product documentation.</td>
</tr>
</tbody>
</table>
### Connections discovered by Service Mapping during the top-down discovery

Service Mapping performs the top-down discovery of the AWS Lambda in the context of application services. It discovers outgoing connections of the AWS Lambda:

- AWS API Gateway
- Amazon Relational Database Service (RDS)
- Other instance of AWS Lambda inside or outside the current region using ARN

### Troubleshooting

If the mapping result is not as you expected, perform basic troubleshooting.

<table>
<thead>
<tr>
<th>Symptom</th>
<th>Cause</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discovery fails. The discovery message contains the information about an error caused by the REST timeout.</td>
<td>There are many CIs sending the REST call response in the deployment. The MID Server cannot process the REST call response without exceeding the time limit controlled by the mid.sa.cloud.request_timeout parameter.</td>
<td>By default, the mid.sa.cloud.request_timeout parameter is set to 30000 milliseconds. Increase the value of this parameter on the relevant MID Server and run discovery again.</td>
</tr>
</tbody>
</table>

**Note:** If the Configuration Parameters related list for the relevant MID Server does not show this parameter, you may need to add it.

| Pattern designer fails during a debug session. The pattern designer message contains information about an error caused by a timeout. | The pattern designer fails because of a timeout during pattern debugging (and not during discovery). | By default, the sa.debugger.max_timeout parameter is set to 240 seconds. Increase the value of this parameter on the relevant MID Server. |

### AWS S3 discovery

The Amazon AWS S3 pattern uses a set of REST API calls to find public and non-public storage buckets of Amazon Simple Storage Service.

In addition to the discovery schedule, the ServiceNow instance triggers the Amazon AWS S3 pattern when AWS Config sends an event to the ServiceNow instance. Config is a service that
ServiceNow continuously monitors AWS resources and sends events to the ServiceNow every time it senses that a resource configuration has changed.

Amazon AWS S3 pattern can also discover AWS S3 buckets located in the AWS GovCloud (US) region. For AWS S3 located in the AWS GovCloud (SU), the pattern cannot discover AWS S3 outgoing connections to other cloud resources like Lambda function. Discovery of outgoing connections for AWS S3 will be supported in future releases.

You can use this pattern on the ServiceNow platform using Jakarta Patch 10, Kingston Patch 8, or London Patch 1.

Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store.

Prerequisites

- If you use Identity and Access Management (IAM) to manage users in Amazon Web Services (AWS) platform, ensure that you created a user policy for the AWS user. For more information, refer to Create an IAM user policy for Cloud Management in the ServiceNow Cloud Management documentation.
- Configure the AWS service account.
- Configure AWS credentials, using a secret key and an access key.
- AmazonS3ReadOnlyAccess policy user permissions.
- Discover Logical Datacenters hosting S3 buckets as described in Run Discovery on an AWS cloud service account in the ServiceNow Cloud Management documentation.
- Create a schedule for the relevant AWS service account as described in Schedule Discovery on a service account in the ServiceNow Cloud Management documentation.
- To enable alert-based discovery, configure the AWS event service as described in Set up AWS event processing for Discovery and Service Mapping in the ServiceNow Cloud Management documentation.

Data collected by Discovery during horizontal discovery

<table>
<thead>
<tr>
<th>Table and field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud Object Storage (cmdb_ci_cloud_object_storage)</td>
<td></td>
</tr>
<tr>
<td>Bucket name (bucket_name)</td>
<td>The name of the AWS S3 bucket. You can discover all buckets hosted on a Logical Datacenter during one discovery process.</td>
</tr>
<tr>
<td>Creation date (creation date)</td>
<td>Creation date of the AWS S3 bucket.</td>
</tr>
<tr>
<td>Cloud provider (cloud_provider)</td>
<td>Amazon AWS</td>
</tr>
<tr>
<td>Object ID (object_id)</td>
<td>The Amazon Resource Name (ARN), expressed in this format: arn:aws:s3:::&lt;bucket name&gt;</td>
</tr>
<tr>
<td>Service name (service_name)</td>
<td>Set to S3 by default.</td>
</tr>
<tr>
<td>Owner (owner)</td>
<td>Name of the AWS S3 bucket owner.</td>
</tr>
<tr>
<td>Encryption type (encryption_type)</td>
<td>Type of encryption for this bucket. The choices are:</td>
</tr>
<tr>
<td></td>
<td>• None</td>
</tr>
<tr>
<td></td>
<td>• AES-256</td>
</tr>
<tr>
<td></td>
<td>• AWS-KMS</td>
</tr>
<tr>
<td>Table and field</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ACL access type (acl_access_type)</td>
<td>The choices for access control types are:</td>
</tr>
<tr>
<td></td>
<td>• Public</td>
</tr>
<tr>
<td></td>
<td>• Not Public</td>
</tr>
<tr>
<td>Policy access type (policy_access_type)</td>
<td>The choices for policy access types are:</td>
</tr>
<tr>
<td></td>
<td>• Public</td>
</tr>
<tr>
<td></td>
<td>• Not Public</td>
</tr>
<tr>
<td>Replication destination (replication_destination)</td>
<td>Bucket ARN of the Replication Destination bucket.</td>
</tr>
</tbody>
</table>

On the Dependency Views map you can see all discovered S3 buckets in your organization, including S3 buckets that you configured as replicas. In this example, Cloud Object Storage 1, Cloud Object Storage 2, and Cloud Object Storage 3 replicate Cloud Object Storage 2. In its turn, Cloud Object Storage 2 replicates Cloud Object Storage 1.
**CI relationships**

These relationships are created to support AWS S3 discovery:

<table>
<thead>
<tr>
<th>CI</th>
<th>Relationship</th>
<th>CI</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmdb_ci_cloud_object_storage</td>
<td>Replicates to::Replicated By</td>
<td>cmdb_ci_cloud_object_storage</td>
</tr>
<tr>
<td>cmdb_ci_cloud_object_storage</td>
<td>Hosted on::Hosts</td>
<td>cmdb_ci_logical_datacenter</td>
</tr>
</tbody>
</table>

**Data discovered by Service Mapping during top-down discovery**

Service Mapping can discover AWS S3 outgoing connections to cloud resources, for example Lambda function.
**Troubleshooting**

If the mapping result is not as you expected, perform basic troubleshooting.

<table>
<thead>
<tr>
<th>Symptom</th>
<th>Cause</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discovery fails. The discovery message contains the information about an error caused by the REST timeout.</td>
<td>There are many CIs sending the REST call response in the deployment. The MID Server cannot process the REST call response without exceeding the time limit controlled by the mid.sa.cloud.request_timeout parameter.</td>
<td>By default, the mid.sa.cloud.request_timeout parameter is set to 30000 milliseconds. Increase the value of this parameter on the relevant MID Server and run discovery again.</td>
</tr>
</tbody>
</table>

*Note:* If the Configuration Parameters related list for the relevant MID Server does not show this parameter, you may need to add it.
<table>
<thead>
<tr>
<th>Symptom</th>
<th>Cause</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pattern designer fails during a debug session. The pattern designer message contains information about an error caused by a timeout.</td>
<td>The pattern designer fails because of a timeout during pattern debugging (and not during discovery).</td>
<td>By default, the <code>sa.debugger.max_timeout</code> parameter is set to 240 seconds. Increase the value of this parameter on the relevant MID Server.</td>
</tr>
</tbody>
</table>

**AWS tag discovery**

Discovery and Service Mapping can use patterns to discover the tags for AWS resources and configuration item (CI) types, and then populate the CMDB with these discoveries.

This tag-specific discovery pattern is in addition to the other AWS patterns available on the ServiceNow Store. This pattern extends the ones used for discovering the respective AWS resources.

You can use this pattern to discover tags on the Now Platform® using New York. Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store.

**Prerequisites**

**AWS Credentials**

- On the Now Platform, configure AWS credentials, using a secret key and an access key.
- Have an Amazon **Account ID**. Use the Account ID as it appears in the AWS Management Console. You can run Discovery from the service account form.
- Set read-only permissions for the following URL: `https://tagging.<region>.amazonaws.com`.

**Discovery schedule**

Create a schedule for the relevant AWS service account as described in Schedule Discovery on a service account in the ServiceNow® Cloud Management documentation.

The CMDB is populated with tags for the following AWS resources and configuration item (CI) types:

- **API Gateway** (`cmdb_ci_cloud_gateway`)
- **Cognito** (`cmdb_ci_cloud_authentication`)
- **DynamoDB** (`cmdb_ci_dynamodb_table`)
- **Lambda** (`cmdb_ci_cloud_function`)
- **RDS** (Relational Database Service) (`cmdb_ci_cloud_database`)
- **S3** (`cmdb_ci_cloud_object_storage`)

**Note:** For more information about the tags and patterns for each of these resources, see the documentation for the specific AWS resource.

When discovering AWS tags, the pattern completes the following high-level tasks:

- Sets the Resource Type filter: Filters the tags to only those tags related to the pattern CI type.
- Initiates the Cloud API call: The API call to the cloud environment that collects the tags and parses their attributes in the Tags table.
- Parses the resource name from the Amazon Resource Name (ARN). Each Amazon resource is assigned a name and a unique identifier.
Note: Parsing the resource name is needed only for patterns where the main identification section does not work with the ARN of the AWS resource. When that is the case, a relation attribute has to be parsed from the AWS ARN.

- Includes references to cloud resource type. Establishes the relationship between the tag and the cloud resource type.

The pattern includes an API called “Cloud Rest Call” Post Call used to collect the following data:

- API URL used to retrieve the data — “https://tagging.” + $ldc(1).object_id + “.amazonaws.com/”
- API Body — “{"ResourceTypeFilters": ["" + $resource_type + "]}“
- Headers — “Content-Type: application/x-amz-json-1.1,X-Amz-Target:ResourceGroupsTaggingAPI_20170126.GetResources”

This data displays as shown in the following window.
2.1. Get tags

<table>
<thead>
<tr>
<th>Operation</th>
<th>Cloud REST Call</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>URL</strong></td>
<td>&quot;<a href="https://tagging.+$%7Bdc%5B1%5D.object_id%7D+amazonaws.com/">https://tagging.+${dc[1].object_id}+amazonaws.com/</a>&quot;</td>
</tr>
<tr>
<td><strong>Method</strong></td>
<td>&quot;POST&quot;</td>
</tr>
<tr>
<td><strong>Body</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Headers</strong></td>
<td>&quot;Content-Type:application/x-amz-json-1.1,X-Amz-Target:ResourceGroupsTaggingService.GetTags&quot;</td>
</tr>
<tr>
<td><strong>Formatted</strong></td>
<td>&quot;true&quot;</td>
</tr>
</tbody>
</table>

**Define Parsing**

- JSON File

**Output**

Data from Cloud Rest Call

This pattern collects the following data during horizontal discovery:

<table>
<thead>
<tr>
<th>Table and field</th>
<th>Additional information</th>
</tr>
</thead>
<tbody>
<tr>
<td>CI type (cmdb_key_value)</td>
<td></td>
</tr>
<tr>
<td>Key</td>
<td>Tag key</td>
</tr>
<tr>
<td>Value</td>
<td>Tag value</td>
</tr>
<tr>
<td>Table and field</td>
<td>Additional information</td>
</tr>
<tr>
<td>-----------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Object_id</td>
<td>Unique resource ID that identifies the resource in the AWS console.</td>
</tr>
<tr>
<td>Class model (cmdb_key_value)</td>
<td></td>
</tr>
<tr>
<td>Extends table</td>
<td>Not applicable</td>
</tr>
<tr>
<td>Identifier - Object_id</td>
<td>Related entries to cloud resources</td>
</tr>
<tr>
<td>Metadata rules</td>
<td>Not applicable</td>
</tr>
</tbody>
</table>

This data is displayed as shown in the following window:

![Image of Key Value window]

Data collected during horizontal discovery

AWS discovery pattern uses the following EVAL:

```javascript
var rtrn;
var name = ${cmdb_key_value[].object_id} 
name = name.substring(name.lastIndexOf("restapis/")+9,name.lastIndexOf); 
name = name.substring(0,name.indexOf("/")); 
rtrn = name;
```

Similar EVALS are available for patterns where the main identification section does not include ARN information in the main CI type table. When this information is not available, the Tag
Extension section must parse a unique ARN used to establish the relationship to the related cloud resource.

**ColdFusion discovery**

Discovery finds Adobe ColdFusion servers and the instances of ColdFusion applications running on them. Only the 2016 version of ColdFusion is supported.

**Components**

Discovery and Service Mapping use the **ColdFusion Application** and **ColdFusion Application Server** patterns to run horizontal and top-down discovery. The **ColdFusion Application Server** pattern is triggered from the ColdFusion Application Server process classifier for horizontal discovery.

**Prerequisites**

**Credentials**

Configure the following credentials, depending on what type of host machine the ColdFusion server is installed on:

- Windows credentials
- SSH credentials (for Linux machines)

**File access**

The pattern must be able to access these ColdFusion files:

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>neo-runtime.xml</td>
<td>This file provides the mapping between the URL and the working directory path of the application.</td>
</tr>
<tr>
<td>application.cfc and application.cfm</td>
<td>These files provide application names.</td>
</tr>
<tr>
<td>neo-datasource.xml</td>
<td>This file provides the name of the datasource that is used in the configuration of the ColdFusion application. The datasource reference is configured in the application.cfc and application.cfm files.</td>
</tr>
</tbody>
</table>

*Note:* The datasource is used for top-down discovery only.

**Entry point**

For top-down discovery, use the full URL or IP address of the web application as the HTTP(S) endpoint. For example: [https://my-website-on-coldfusion/path](https://my-website-on-coldfusion/path) or [https:10.120.255.255:8500/path](https:10.120.255.255:8500/path)
Data collected during horizontal discovery

<table>
<thead>
<tr>
<th>Table and Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cold Fusion Server (cmdb_ci_coldfusion_server)</td>
<td>The name and version of the ColdFusion server, and the directory where it is installed.</td>
</tr>
<tr>
<td>Installation directory (installation_directory)</td>
<td>The name of the application and the directory where it is installed.</td>
</tr>
<tr>
<td>Name (name)</td>
<td></td>
</tr>
<tr>
<td>Version (version)</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** Cold Fusion applications (cmdb_ci_cf_application) are custom applications that this pattern does not discover.

CI relationships

<table>
<thead>
<tr>
<th>CI</th>
<th>Relationship</th>
<th>CI</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmdb_ci_cf_application</td>
<td>Contains::Contained by</td>
<td>cmdb_ci_coldfusion_server</td>
</tr>
<tr>

<td>Runs on::Runs</td>
<td>cmdb_ci_linux_server</td>
</tr>
<tr>
<td></td>
<td></td>
<td>cmdb_ci_win_server</td>
</tr>
<tr>
<td></td>
<td></td>
<td>cmdb_ci_osx_server</td>
</tr>
</tbody>
</table>

Connections discovered by Service Mapping during the top-down discovery

Service Mapping performs the top-down discovery of the Adobe ColdFusion in the context of application services. Service Mapping discovers the outgoing datasource connections from ColdFusion servers to instances of database.

**Example**

In this example, the application service map shows the results of a top-down discovery of the ColdFusion Web application service. The application service is comprised of three CIs:

- The ColdFusion application server is named `cfusion`.
- The ColdFusion application `hdStreetOracle`.
- A database named `XE`, which the ColdFusion application connects to.
**EMC Isilon discovery**

Discovery uses the EMC Isilon pattern to find components of Dell EMC Isilon. Discovery can find EMC Isilon running OneFS OS version 8.0 and later. The EMC Isilon pattern is triggered by the EMC Isilon classifier that is part of the update set you download from Store.

**Prerequisites**

**SNMP Community**

Create a SNMP Community credential for the Isilon cluster. The discovery process begins with using SNMP-based queries to classify an application as an Isilon cluster.

**EMC Isilon user**

Once the application is classified as an Isilon cluster, the discovery process uses REST queries to find information about it. Provide the EMC Isilon user with the following REST capabilities:

- "https://" + $host + ":8080/platform/3/cluster/config"
In addition to these capabilities, this EMC Isilon user must have the following privileges:

- ISI_PRIV_LOGIN_PAPI
- ISI_PRIV_AUTH
- ISI_PRIV_DEVICES
- ISI_PRIV_NETWORK
- ISI_PRIV_NFS
- ISI_PRIV_SMARTPOOLS
- ISI_PRIV_SMB

**Basic authentication**

In the Credentials module of the ServiceNow platform, create a basic authentication credential for the same EMC Isilon user.

**Upgrade the ServiceNow platform**

Upgrade the ServiceNow platform to the relevant patch: Jakarta Patch 10, Kingston Patch 8, or London Patch 1.

⚠️ **Note:** The latest patches contain metadata rules for Isilon and its components.

### Data collected by Discovery during horizontal discovery

<table>
<thead>
<tr>
<th>Table and Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</table>

**Google Cloud Platform (GCP) asset inventory discovery**

Discovery uses the Google Cloud Platform (GCP) asset inventory pattern to find GCP resources and policies.

GCP provides container resources, such as organizations and projects, that allow other GCP resources to be grouped and organized hierarchically. The GCP Resource Manager API enables you to manage these container resources.

The pattern provides visibility for services supported by the Asset Inventory API. It collects inventory data on the deployed GCP services and updates the CMDB.

The pattern collects inventory data either for all GCP-supported resources or for a preconfigured whitelist of resources. The whitelist resides in the Cloud Inventory Resource Whitelist (sa_cloud_inventory_resource_whitelist) table. It contains the resource types supported by GCP Cloud Asset Inventory, except for Compute Engine resources and IAM policies. For more information, see [https://cloud.google.com/resource-manager/docs/cloud-asset-inventory/overview](https://cloud.google.com/resource-manager/docs/cloud-asset-inventory/overview).

Visit the [ServiceNow Store](https://servicenow.com/store) website to view all the available apps and for information about submitting requests to the store.

**Prerequisites**

- GCP authorization to use the API [https://cloudasset.googleapis.com/v1/projects/deductive-reach-207607:exportAssets](https://cloudasset.googleapis.com/v1/projects/deductive-reach-207607:exportAssets), and one or more of the following Google IAM permissions on the specified resource parent:
  - cloudasset.assets.exportResource
  - cloudasset.assets.exportIamPolicy
- A storage bucket for storing the collected data. This bucket is used as input parameter in the pattern.
  - If a bucket must be created for this purpose, the same GCP user must have both Create and Edit access for it.
  - The Retention Policy for the storage bucket must not be active. Otherwise, the pattern does not delete the auto-generated inventory data file.

- A read-only GCP user for using the API https://www.googleapis.com/storage/v1.

  **Note:** You can use the headers on the Encryption page in your request to do the following:
  - Download an object that is encrypted by a customer-supplied encryption key.
  - Get object metadata with content hashes.

- To collect inventory data for GCP-supported resources, in Now Platform navigate to **Cloud Inventory Resource Whitelist** and clear all GCP table records.

  ![Cloud Inventory Resource Whitelist](image)

Cloud Inventory Resource Whitelist

- Fine-tune the GCP resource discovery using the Resource Whitelist.
  If your deployment has custom patterns for GCP discovery, ensure that you do not discover GCP resources twice.

  1. Ensure that the application scope is Discovery and Service Mapping Patterns:
     a. Navigate to **Settings > Developer**.
     b. Select **Discovery and Service Mapping Patterns** from the **Application** list.

  2. Navigate to **System Definitions > Tables**.

  3. Open the Cloud Inventory Resource Whitelist (sa_cloud_inventory_resource_whitelist) table.
4. Under Related Links, click Show List.

5. Select resource types for which you have custom patterns, and select Delete from the Actions on selected rows list.

The Cloud Inventory Resource Whitelist is predefined with common services. You can expand the whitelist with additional resource types that you want the pattern to discover. The names of these resource types must conform to the appropriate vendor naming conventions.

**Note:** When you modify the out-of-the-box whitelist, it is no longer updated automatically in application updates. You need to maintain the customized list on your own.

a. Open the Cloud Inventory Resource Whitelist (sa_cloud_inventory_resource_whitelist) table.

b. Click New.

c. Fill in the form, and then click Submit.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud Vendor</td>
<td>The vendor of the resource type: GCP.</td>
</tr>
<tr>
<td>Resource Type</td>
<td>The AWS resource type value.</td>
</tr>
<tr>
<td>Application</td>
<td>The application scope: Discovery and Service Mapping Patterns.</td>
</tr>
</tbody>
</table>

The changes are applied the next time you run the pattern.

- Modify the ServiceNow identification rules. Be sure to switch to the Cloud Management Platform application scope before you begin the following procedure.
  1. Navigate to CI Class Manager.
  2. Navigate to and select Hierarchy.
  5. Delete and add the appropriate identification rule.

     The new identification rule should include only the Object ID attribute.
Schedule for all serverless discovery and pass the path of the storage bucket as a pattern variable. For more information, see Create a schedule for standard serverless Discovery.

Data collected by Discovery during horizontal discovery

This pattern discovers data that provides visibility for all GCP services in your organization. The discovered data includes the following tables and fields.

<table>
<thead>
<tr>
<th>Table and field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Main CI (cmdb_ci_cmp_resource)</td>
<td>The ID of the item. The item is accessed with this URL.</td>
</tr>
<tr>
<td>object_id</td>
<td>The name of the resource.</td>
</tr>
<tr>
<td>name</td>
<td>The asset resource type, according to the data in the JSON file.</td>
</tr>
</tbody>
</table>

The Dependency Views map shows the discovered CIs in your organization and the relationships between them. Here, the only meaningful relationship between the CIs is the one that helps Discovery identify them.

Each GCP Inventory CI is related either to a Logical Datacenter (LDC) CI or to a Cloud Service Account CI. In this example, the Inventory CI is related to a Cloud Service Account CI.
CI relationships

These relationships are created to support GCP asset inventory discovery:

<table>
<thead>
<tr>
<th>CI</th>
<th>Relationship</th>
<th>CI</th>
</tr>
</thead>
<tbody>
<tr>
<td>For Global Resources:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Main CI</td>
<td>Contained by::Contains</td>
<td>Cloud Service Accounts</td>
</tr>
<tr>
<td>(cmdb_ci_cmp_resource)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>For Regional Resources:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Main CI</td>
<td>HostedOn::Hosts</td>
<td>Logical Datacenter (LDC)</td>
</tr>
<tr>
<td>(cmdb_ci_cmp_resource)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Google Cloud Platform discovery

ServiceNow® Discovery finds Google Cloud Platform (GCP) GCP API v1 components using the Google Cloud Platform pattern. The Google Cloud Platform pattern is a ServiceNow Store app.

Get the app on the ServiceNow Store

Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store.
Prerequisites
For details on system requirements, view the application listing on the ServiceNow Store website.

Cloud Management
Google Cloud Platform patterns work with Cloud Management. The Cloud Management application is available as a separate subscription and requires the Cloud Management plugin (com.snc.cloud.mgmt). Use your current Cloud Management instance or request a subscription from your sales representative.

MID Server requirements
Use a dedicated MID Server for cloud discovery. The MID Server must have 16 Cores, 8 GB with 4 GB Java Memory Model (JVM) memory allocation. Deploy and connect the dedicated MID Server with internet access.

User role settings
Set the user permission for the Google Cloud Platform member to Viewer:
1. In the Google Cloud Platform console, navigate to AIM.
2. Select the relevant member from the list and click the Edit icon.
3. In the Edit permissions window, select Viewer from the Role list.
4. Click Save.

Credentials
Configure the following credentials:
1. Navigate to Discovery > Credentials.
2. Click New.
3. Click Google API Credentials, fill in the form, and then click Submit.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Credential name. An example is gcp-cred</td>
<td></td>
</tr>
<tr>
<td>Active</td>
<td>Option for enabling this credential for discovery. Select this check box to enable discovery.</td>
<td></td>
</tr>
<tr>
<td>Applies to</td>
<td>MID Server to which you must apply the credentials. Select All MID servers.</td>
<td></td>
</tr>
<tr>
<td>Order</td>
<td>Order in which the platform tries this credential as it attempts to log on to devices. A smaller number indicates that the credential appears higher in the list. Establish the credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number, or none, the instance tries the credentials in a random order. The default value is 100.</td>
<td></td>
</tr>
<tr>
<td>EMail</td>
<td>GCP client email.</td>
<td></td>
</tr>
</tbody>
</table>
Create a Google Cloud Platform service account

Use the credentials defined in the preceding procedure for the service account.

1. Navigate to Cloud Management > Service Accounts.
2. Click New, fill in the form, and then click Submit.

Service account form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Secret Key</td>
<td>Secret key for these credentials.</td>
</tr>
<tr>
<td>Credential alias</td>
<td>Credential alias that is used by the credentials to authorize actions.</td>
</tr>
</tbody>
</table>

Create a discovery schedule

1. Navigate to Discovery > Discovery Schedules.
2. Click New and then fill in the form.

Discovery Schedule form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name for the Discovery schedule. For example, gcp</td>
</tr>
<tr>
<td>Discover</td>
<td>Discover type. For the London release only, select Serverless.</td>
</tr>
<tr>
<td>MID Server</td>
<td>Name of the MID Server. For example, Discovery_Server</td>
</tr>
<tr>
<td>Active</td>
<td>Option for enabling this schedule for discovery. Select this check box to enable discovery.</td>
</tr>
</tbody>
</table>

3. Right-click the header of the Discovery Schedule form and select Save.
4. For the London release only, click the **Serverless Execution Patterns** tab, click **New**, and then fill in the

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name for this Serverless Execution Pattern. For example, gcp1</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Pattern</td>
<td>Name of the GCP pattern to run. Select the pattern to run.</td>
</tr>
<tr>
<td>Proxy Host</td>
<td>Fully qualified domain name of the machine on which you are installing the proxy server. Specify <strong>Global</strong>.</td>
</tr>
<tr>
<td>Active</td>
<td>Option for enabling this schedule for discovery. Select this check box to enable discovery.</td>
</tr>
</tbody>
</table>

The following parameters are required to run specific patterns:

**Discovery schedule configuration for specific patterns**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cloud_account_id</td>
<td>Name of the GCP project.</td>
</tr>
<tr>
<td>cloud_cred_id</td>
<td>Sysid of the credentials that you created for the service account.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>cloud_datacenter_type</td>
<td>CI’s name that holds the datacenters for GCP. Specify cmdb_ci_google_datacenter</td>
</tr>
</tbody>
</table>

**Discovery schedule configuration for full Google Cloud Platform discovery**

1. Navigate to **Cloud Management** > **Service Accounts**.
2. Click the required service account.
3. Click **Create Discovery Schedule**.
4. Create and define the Discovery Schedule as described in the product documentation.
   This discovery schedule runs all GCP patterns.

**Credentials for API elements**

Provide a read-only user with permission to use the following API elements:

- https://www.googleapis.com/compute/<api_version>/projects/<project_id>/regions
- https://www.googleapis.com/compute/<api_version>/projects/<project_id>/aggregated/subnetworks
- https://www.googleapis.com/compute/<api_version>/projects/<project_id>/global/firewalls
- https://www.googleapis.com/compute/<api_version>/projects/<project_id>/zones
   (For HTTP Load Balancer)
  (For TCP/UDP Load Balancer)
- https://www.googleapis.com/compute/<api_version>/projects/<project_id>/aggregated/backendServices
- https://www.googleapis.com/compute/<api_version>/projects/<project_id>/aggregated/instanceGroups
- https://www.googleapis.com/compute/<api_version>/projects/<project_id>/aggregated/instanceGroupManagers
- https://www.googleapis.com/compute/<api_version>/projects/<project_id>/zones/<ZONE>/instanceGroups/<instance group>/listInstances
- https://www.googleapis.com/compute/<api_version>/projects/<project_id>/regions/<REGION>/instanceGroups/<instance group>/listInstances
- https://www.googleapis.com/compute/<api_version>/projects/<project_id>/aggregated/instances
- https://www.googleapis.com/compute/<api_version>/projects/<project_id>/aggregated/machineTypes
- https://www.googleapis.com/compute/<api_version>/projects/<project_id>/global/instanceTemplates
- https://www.googleapis.com/compute/<api_version>/projects/<project_id>/aggregated/disks
- https://www.googleapis.com/compute/<api_version>/projects/<project_id>/aggregated/diskTypes
- https://www.googleapis.com/compute/<api_version>/projects/<project_id>/global/healthChecks
- https://www.googleapis.com/compute/<api_version>/projects/<project_id>/aggregated/addresses

**GCP flow - horizontal discovery**

Where discovery is performed using a serverless schedule, the GCP patterns that were selected run and discover GCP resources.

Where discovery is performed using a service account, a full GCP discovery schedule is run, discovering all supported GCP resources.

**Methods to retrieve data**

Cloud REST – Add Response To Context

The operation to run a REST call against supported clouds. This operation supports pagination by automatically concatenating pages returned by the Cloud provider, Google, into one response, and saves the outcome as a list for fast parsing.

Use **Body** and **Headers** when requested by Google. Credentials are automatically inserted into the required field of the request form.

You can use:

- GCP Compute Pillar – Class Model – Service Account
- GCP Compute Pillar – Class Model – Google Datacenter
- GCP Compute Pillar – Class Model – Availability Zone
- GCP Network Pillar – Class Model – VM instance
- GCP Compute Pillar – Class Model – Storage Volume
- GCP Compute Pillar – Class Model – Image
- GCP Compute Pillar – Class Model – instance template
- GCP Compute Pillar – Class Model – NIC

(Optional) Use GCP labels

You can use GCP labels (set up as key-value pairs) to find and group resources, such as the following:

- Virtual machine instances
- Forwarding rules (Alpha)
- Images
- Persistent disks
- Persistent disk snapshots
- Static external IP addresses (Alpha)
- VPN tunnels (Alpha)

**Note:** Resources listed as Alpha are not currently supported on either the GCloud or the GCP Console.

**Limitations**

The GCP Load Balancer pattern works with these load balancer models:

- HTTP/s Load Balancer
- TCP/UDP Load Balancer

**GCP Load Balancer models**

**GCP Load Balancer – HTTP Model**

- In the HTTP LB, there are load balancer services of the frontend and backend type.
- In the HTTP LB, the health service has a relationship to the Load Balancer service (only Backend Service).
- The load balancer does not have a direct relationship to the Load balancer pool.
- Pools are groups of instances.

The following image depicts the HTTP Load Balancer
The TCP/UDP LB has the load balancer service of the front-end type only.
- In the TCP/UDP LB, the health service has a relationship to the Load Balancer pools.
- In case the TCP/UDP LB does not have instance groups (pools), a virtual pool is created with a name that includes the name of the LB + “-Pool”.
- Pools are groups of instances.

The following image depicts the TCP/UDP Load Balancer
About the event-driven GCP load balancer

Event-driven discovery is triggered only when Cloud Load Balancing receives the optional input_object_id. Note the following points:

- **For Cloud Load Balancing (HTTP(s))**: The event-driven pattern is triggered when an event is received, when a new HTTP type load balancer (url_map) is added, or when a new backend service is added for a specific load balancer.

- **For Cloud Load Balancing (TCP/UDP)**: The event-driven pattern is triggered when an event is received, when a new TCP/UDP type load balancer (target_pool) is added, or when an instance is added or removed from an instance_group (pool) belonging to a TCP/UDP load balancer.
Create a filter to use for event-driven discovery, as shown below. The filter is used in the REST API calls to retrieve the GCP data.

```
Operation: Set Parameter Value

Meet: Any

If Condition Is: true

Do:

Value: "?filter=id%3D%20" + $input_object_id

Name: $filter
```

- **For Cloud Load Balancing (HTTP):** `https://www.googleapis.com/compute/" + $API_version + "/projects/" + $service_account[1].account_id + "/global/urlMaps" + $filter

### Data collected by Discovery during horizontal discovery

Data is collected using these patterns:

- Google Cloud Platform Discovery Compute Pillar.
- Google Cloud Platform Discovery External IP Pillar.
- Google Cloud Platform Discovery Load Balancer.
- Google Cloud Platform Discovery Labels.
- Google Cloud Platform Discovery Network Pillar.
- Google Cloud Platform Discovery Storage Pillar.

### Resources discovered by the Google Cloud Platform Discovery Compute Pillar

<table>
<thead>

</tbody>
</table>

**Resources discovered by Google Cloud Platform Discovery using labels**

When Google Cloud Platform Discovery uses labels during discovery, the following data is collected from the Key Value form:

- Key
- Value
- Configuration item
Key Value form

This data is identified in the Related Entry form for the following CMDB tables:

- Virtual Machine Instance table (cmdb_ci_vm_instance) as shown below
- Image table (cmdb_ci_os_template)
- Storage Volume table (cmdb_ci_storage_volume)
- Storage Snapshot table (cmdb_ci_storage_vol_snapshot as inherited from the parent)
### Resources discovered by the Google Cloud Platform Discovery Network Pillar

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Main CI: cmdb_ci_cloud_service_account</td>
<td>Name of the project that is used for the discovery.</td>

<tr>
<td>object_id</td>
<td>Unique identifier allocated by Google Cloud for this resource.</td>
</tr>
<tr>
<td>short_description</td>
<td>Datacenter or region description that you provide for easy identification.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| status | Datacenter or region status. One of the following:  
- Up  
- Down |
| state | Field with the same value as the status field. |
| name | Name of the availability zone. |
| object_id | Unique identifier, allocated by Google Cloud for this resource. |
| short_description | Availability zone that you provide. |

**Related CI:** cmdb_ci_availability_zone

| name | Name of the Virtual Private Cloud (VPC) network. |
| object_id | Unique identifier, allocated by Google Cloud for this resource. |
| default_gateway | Gateway address for default routing out of the network. |
| state | State of the network. The state is always “available”, since it was returned on discovery. |

**Related CI:** cmdb_ci_network

| name | Name of the instance template. |
| object_id | Unique identifier, allocated by Google Cloud for this resource. |
| cidr | CIDR representation of the subnet. For example, 10.0.0.0/24 |
| subnet_mask | Dotted representation of the subnet mask. For example, 255.255.255.0 |
| gateway | Gateway address for default routing out of the network. |
| broadcast_address | Broadcast address of the subnet. |
| available_ip_count | Number of IPs that are available in the subnet. This amount does not include network and broadcast addresses. |

**Related CI:** cmdb_ci_cloud_subnet

| name | Name of the access control list (ACL). |
| object_id | Unique identifier, allocated by Google Cloud for this resource. |
| short_description | ACL description that you provide. |

**Related CI:** cmdb_ci_network_acl

<p>| name | ACL rule name. This name is the same as the name of the cmdb_ci_network_acl. |</p>
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| allow_deny            | ACL rule behavior. One of:  
• Allowed  
• Denied                                                                                                                                  |
| is_outbound           | Rule for outbound traffic. Use one of the following:  
• True if the rule is for outbound traffic  
• False if the rule is for inbound traffic                                                                                      |
| source_ranges         | JSON blob service that contains sources that are Classless Inter-Domain Routing (CIDR) representations that the rule either allows or blocks the traffic from the service.                                           |
| destination_ranges    | JSON blob service that contains destinations that are CIDR representations that the rule either allows or blocks the traffic from the service.                                                             |
| target_tags           | JSON blob service that represents a list of tags that controls which instances the firewall rule applies to.                                                                                                    |
| allowed_deny_traffic  | JSON blob service that contains the rules that are either allowed or denied by this ACL rule.                                                                                                               |

**Related CI:** cmdb_ci_os_template

<table>
<thead>
<tr>

### IBM Cloud Platform discovery

Discovery finds IBM Cloud Platform components (Softlayer API v3 and v3.1 and Bluemix API v2) using the IBM Cloud Platform patterns. You can use the patterns on the Now Platform using London Patch 7, Madrid Patch 2, or later releases.
Prerequisites

Cloud Management Platform plugin
IBM Cloud Platform patterns work with the Cloud Management Platform. The Cloud Management Platform application is available as a separate subscription and requires the Cloud Management Platform plugin (com.snc.cloud.mgmt). Use your current Cloud Management Platform instance or request a subscription from your sales representative.

MID Server
Use a dedicated MID Server for cloud discovery. The MID Server must have 16 Cores, 8 GB with 4 GB Java Memory Model (JVM) memory allocation. Deploy and connect the dedicated MID Server with internet access.

Credentials
The cloud resources are in an IBM cloud. Create the following credentials that can access your IBM account.
1. Navigate to Discovery > Credentials.
2. Click New.
3. Click IBM Credentials and then fill in the form:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Credential name. An example is ibm-cred</td>
</tr>
<tr>
<td>Order</td>
<td>Order in which the platform tries this credential as it attempts to log on to devices. A smaller number indicates that the credential appears higher in the list. Establish the credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number, or none, the instance tries the credentials in a random order. The default value is 100.</td>
</tr>
<tr>
<td>Softlayer API User</td>
<td>Username for the Softlayer API. Use the Softlayer API Username defined in the Softlayer console.</td>
</tr>
<tr>
<td>Softlayer API Key</td>
<td>Key for the Softlayer API. Use the Softlayer API Key that is defined in the Softlayer console.</td>
</tr>
<tr>
<td>Bluemix API Key</td>
<td>Key for the Bluemix API. Use the Bluemix API Key defined in the IBM Cloud console.</td>
</tr>
</tbody>
</table>

4. Click Submit.

Create an IBM cloud service account
Use the credentials defined in the preceding procedure to create the IBM cloud service account.
1. Navigate to Cloud Management > Service Accounts.
2. Click New.
3. On the form, fill in the fields:

Cloud Service Account form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Credential name. An example is ibm-snow</td>
</tr>
<tr>
<td>Account Id</td>
<td>IBM account ID name. Enter the IBM Account ID.</td>
</tr>
<tr>
<td>Discovery credentials</td>
<td>Discovery credentials that you defined earlier.</td>
</tr>
<tr>
<td>Datacenter Type</td>
<td>Datacenter type. As an example, IBM Datacenter [cmdb_ci_ibm_datacenter]</td>
</tr>
</tbody>
</table>

4. Click Submit.

Create a serverless Discovery schedule

For the London release, configure a serverless Discovery.

1. On the Now Platform, navigate to Discovery > Discovery Schedules.
2. Click New.
3. On the form, fill in the fields:

Discovery Schedule form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name for this Discovery schedule. As an example, Serverless Pattern</td>
</tr>
<tr>
<td>Discover</td>
<td>Discover type. Select Serverless</td>
</tr>
<tr>
<td>MID Server</td>
<td>Name of the MID Server. As an example, Discovery_Server</td>
</tr>
<tr>
<td>Active</td>
<td>Option for enabling this schedule for Discovery. Select this check box to enable Discovery.</td>
</tr>
<tr>
<td>Run</td>
<td>Specifies how frequently to run the Discovery schedule.</td>
</tr>
</tbody>
</table>

4. Right-click the header of the Discovery Schedule form and select Save.
5. Click the **Serverless Execution Patterns** tab.
6. Click **New**.
7. On the form, fill in the fields:

**Serverless Execution Pattern form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name for this Serverless Execution Pattern. As an example, IBM1</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Pattern</td>
<td>Name of the pattern that you want to run.</td>
</tr>
<tr>
<td>Proxy Host</td>
<td>Fully qualified domain name of the machine on which you are installing the proxy server. Specify Global.</td>
</tr>
<tr>
<td>Active</td>
<td>Option for enabling this schedule for Discovery. Select this check box to enable Discovery.</td>
</tr>
</tbody>
</table>

8. Configure the parameters required by the IBM Cloud Platform pattern as follows:

**Discovery Pattern Launcher parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cloud_cred_id</td>
<td>The sys_id of the IBM credentials specified into the configuration.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------</td>
</tr>
<tr>
<td>cloud_account_id</td>
<td>The IBM account ID.</td>
</tr>
<tr>
<td>cloud_datacenter_type</td>
<td>cmdb_ci_ibm_datacenter</td>
</tr>
</tbody>
</table>

9. **Update.**

10. To start Discovery, navigate to the Serverless Discovery definition and click **Discover Now**.

**IBM flow - horizontal discovery**

- To perform a discovery using a serverless schedule, the IBM Cloud Platform patterns that were selected run and discover IBM Cloud Platform resources.
- To perform a discovery using a service account, a full IBM Cloud Platform discovery schedule runs, discovering all supported IBM Cloud Platform resources.

**Cloud custom operation**

Cloud REST – Add Response to Context

Operation for Cloud REST queries that supports large-scale responses and better memory usage.

- Specify all the fields with the same values as in the Cloud REST Query custom operation, except to specify the table for the response, which is set in the **Response Variable Name** field.

- Set **Define parsing** to None.
Methods to retrieve data for the IBM account

1. Navigate to **Pattern Designer > Custom Operations**.

2. Click **Cloud REST – add response to context**.

Method: Get Call

API URLs used to retrieve the data:

- **Load Balancer**
  ```
  https://api.softlayer.com/rest<api_version>/
  SoftLayer_Network_LBaaS_LoadBalancer/getAllObjects?
  objectMask=mask[listeners[defaultPool],members,healthMonitors]
  ```

- **Network**
  ```
  https://api.softlayer.com/rest/<API_VERSION>/SoftLayer_Account/
  getNetworkVlans?
  objectMask=mask[primaryRouter.datacenter,name,id,vlanNumber,networkSpace]
  ```

- **Virtual Server**
  ```
  https://api.softlayer.com/rest/v3.1/SoftLayer_Account/
  getSecurityGroups
  ```

- **Virtual Server**
  ```
  http://api.softlayer.com/rest/v3.1/SoftLayer_Account/getSecurityGroups?
  objectMask=mask[id,name,networkComponentBindings[networkComponentId,networkComponent
  ```

- **Virtual Server**
  ```
  https://api.softlayer.com/rest/v3.1/SoftLayer_Account/getVirtualGuests?
  objectMask=mask[hostname,domain,powerState,fullyQualifiedDomainName,notes,id,statusId,
  ```

**EVAL functions**
Use the following EVAL function to transform the Load Balancer API response into a full JSON format. The default response is formatted as "[<resource objects>]".

```javascript
var cloud_lb_response = ${cloud_lb_response};
for (var i = 0; i < cloud_lb_response.size(); i++){
    cloud_lb_response.set(i, '{"result":[' + cloud_lb_response.get(i) + ']}');
}CTX.setAttribute("cloud_lb_response", cloud_lb_response);
```

Use the following EVAL function to transform the Network API response into a full JSON format. The default response is formatted as "[<resource objects>]".

```javascript
var network_response = ${network_response};
for (var i = 0; i < network_response.size(); i++){
    network_response.set(i, '{"result":[' + network_response.get(i) + ']}');
}CTX.setAttribute("network_response", network_response);
```

Use the following EVAL function to get the IBM region from the LB availability zone (datacenter). The same function is used for other resources inside the pattern.

```javascript
var res = "";
res = IbmCloudDcToRegion.convertDctoRegion(${cloud_lb[].cloud_lb_az_short_name});
```

Use the following EVAL function to select the required algorithm in the pattern.

```javascript
var rtrn
var lb_algorithm = ${cloud_lb_pools[].lb_algorithm}.toString();
switch (lb_algorithm){
    case "ROUNDROBIN":
        lb_algorithm = "round-robin";
        break;
    case "WEIGHTED_RR":
        lb_algorithm = "round-robin";
        break;
    case "LEASTCONNECTION":
        lb_algorithm = "least-connections";
        break;
    default: break;
}
```

Use the following EVAL function to parse the unique region to the account that hosts the Organizations and the corresponding spaces.

```javascript
var tableWithoutDuplicates = "";
tableWithoutDuplicates =  
    DuplicateRemover.removeDuplicates(${account_region},["region_name"]);
CTX.setAttribute("account_region_unique", tableWithoutDuplicates);
```

Use the following EVAL function to get information for all the organizations that are assigned to the IBM cloud account, where iteration for getting the unique region is performed.

```javascript
var cloudcall = new CloudRestAPIClient();
var resourceTable = ${account_region_unique[*].region_name};
var tableSize = resourceTable.size();
var tmp_response = new Packages.java.util.ArrayList();
var all_organizations_response = new Packages.java.util.ArrayList();
```
Use the following EVAL function to get information for all the IBM cloud account assigned spaces, where the iteration for getting the unique region is performed.

```javascript
var rtrn = ''; var cloudcall = new CloudRestAPIClient(); var resultList = new Packages.java.util.ArrayList(); var rest = ''; var resourceTable = ${account_region_unique[*].region_name}; var result = new Packages.java.util.ArrayList(); var all_organizations_response = ${all_organizations_response}
for (var i = 0; i < resourceTable.size(); i++){
    var url = "https://api."+resourceTable.get(i)+".bluemix.net/v2/spaces";
    result = cloudcall.arrayListExecute(${service_account}, null, url, null, 'GET', null, 'true', CTX);
    for (var j = 0; j < result.size(); j++){
        var jsonObj = JSON.parse(result.get(j));
        ms.log("length " + jsonObj.resources.length);
        for(var k=0;k<jsonObj.resources.length;k++){
            var gui = jsonObj.resources[k].metadata.guid;
            var url = jsonObj.resources[k].metadata.url;
            var name = jsonObj.resources[k].entity.name;
            var organization_guid = jsonObj.resources[k].entity.organization_guid;
            var allow_ssh = jsonObj.resources[k].entity.allow_ssh ? "true" : "false";
            var row = new Packages.java.util.HashMap();
            Packages.com.snc.sw.log.DiscoLog.getLogger("IBM Cloud Space and Org").debug(">>>>>>>>>>>>> region alias=" + resourceTable.get(i));
            Packages.com.snc.sw.log.DiscoLog.getLogger("IBM Cloud Space and Org").debug(">>>>>>>>>>>>> region full name=" + IbmCloudDcToRegion.regionNamebyAlias(resourceTable.get(i)));
            row.put("region", IbmCloudDcToRegion.regionNamebyAlias(resourceTable.get(i)));
            row.put("space_guid", gui);
            row.put("space_url", url);
            row.put("space_name", name);
            row.put("space_organization_guid", organization_guid);
            row.put("space_allow_ssh", allow_ssh);
            row.put("rest", rest);
            resultList.add(row);
        }
    }
}
CTX.setAttribute('spaces_table', resultList);
```
Use the following EVAL function to filter all the spaces by unique region.

```javascript
var space_region = ${spaces_table[].region};

Packages.com.snc.sw.log.DiscoLog.getLogger("IBM Cloud Space and Org").debug("filtering space according to LDC. space_region=" + space_region);
var regions = ${cmdb_ci_ibm_datacenter[*].region};
Packages.com.snc.sw.log.DiscoLog.getLogger("IBM Cloud Space and Org").debug("input regions list=" + regions.toString());

var rtrn = "false";
if(regions.contains(space_region)) {
    rtrn = "true";
}

rtrn;
```

Use the following EVAL function to filter all the spaces by storage discovery.

```javascript
var storage_response = ${storage_response};
for (var i = 0; i < storage_response.size(); i++){
    storage_response.set(i, '{"result":' + storage_response.get(i) + '}');
}
CTX.setAttribute("storage_response", storage_response);
```

Use the following EVAL function to transform the API response into full JSON format, as the untouched response is formatted as "<resource objects>".

```javascript
var ssh_key = ${ssh_key_json};
for(var i = 0; i < ssh_key.size(); i++){
    ssh_key.set(i,'"result" : ' + ssh_key.get(i) + ");
}
CTX.setAttribute("ssh_key_json", ssh_key);
```

Use the following EVAL function to populate the availability zone into the storage volume table.

```javascript
var rtrn;
var resource_group = ${network_storage[].resource_name};
var regex = /.*-(\w{3}\d{2}).*/;
var az_name = regex.exec(resource_group);
if (az_name) {
    rtrn = az_name[1];
} else {
    rtrn;
}
```

Use the following EVAL function to populate the region into the storage volume table.

```javascript
var res = ""
res = IbmCloudDcToRegion.convertDctoRegion(${network_storage[].availability_zone});
```

Use the following EVAL function to transform the size of the storages to bytes from gigabytes.

```javascript
var rtrn = ""
var size = ${network_storage[].size};
```
rtrn = (parseInt(size) * 1073741824) + '';

Use the following EVAL function to transform the size of the storages to bytes from gigabytes.

```javascript
var cloudcall = new CloudRestAPIClient();
var resourceTable = ${network_storage[*].storage_object_id};
var tableSize = resourceTable.size();
var allResources = new Packages.java.util.ArrayList();
var response = new Packages.java.util.ArrayList();
for (var i = 0; i < tableSize ; i++){
    if  (!resourceTable.get(i)) continue;
    var url = "https://api.softlayer.com/rest/"+${api_version}="/SoftLayer_Network_Storage/"+resourceTable.get(i)+"/getObject?objectMask=mask[snapshots];";
    // the commented out code is to call the "Cloud Rest Call" API
    allResources = cloudcall.arrayListExecute(${service_account}, null, url, null, 'GET', null, 'true', CTX);
    for (var j = 0; j < allResources.size(); j++){
        response.add('"result":[' + allResources.get(j) + ']}');
    }
}
CTX.setAttribute("all_snapshots_response", response);
```

Use the following EVAL closure that transforms the JSON that is received from the API to a format that the JSON parser can work with. The default JSON is saved in `vm_json_array`, the new JSON is in `vm_json`.

```javascript
var vm_json = new Packages.java.util.ArrayList();
vm_json.addAll(${vm_json_array});
for (var i = 0 ; i < vm_json.size(); i++){
    vm_json.set(i, '{"result":[' + vm_json.get(i) + ']}');
}
CTX.setAttribute("vm_json", vm_json);
```

Use the following EVAL closure that returns `on` if the power status is running. The value `off` is returned if the power status is off.

```javascript
var power = ${cmdb_ci_vm_instance[].state};
var rtrn = '';
if (power == 'Running'){
    rtrn = "on";
} else {
    rtrn = "off"
}
```

Use the following EVAL closure that returns the region of the CI, based on provided availability zone name.

```javascript
var az = ${cmdb_ci_vm_instance[].avail_zone};
var rtrn = '';
rtrn = IbmCloudDcToRegion.convertDctoRegion(az);
```

Use the following EVAL closure that builds a HashMap of HashSets, Connecting VMs with their network storages. The following key is used:

- P = page
\* V = VM \\
\* N = network storage

```javascript
var rtrn = ''; 
var vmJson = $(vm_json_array);
var VMtoStorageHashMap = new Packages.java.util.HashMap();

for (var p = 0 ; p < vmJson.size(); p++){
    var page = JSON.parse(vmJson.get(p));
    for (var v in page){
        if (page[v].allowedNetworkStorage.length > 0){
            var vm_id = page[v].id + '';
            var storageSet = new Packages.java.util.HashSet();
            for (var n in page[v].allowedNetworkStorage){
                storageSet.add(page[v].allowedNetworkStorage[n].id + '');
            }
            VMtoStorageHashMap.put(vm_id,storageSet);
        }
    }
}
CTX.setAttribute("VMStorageCache", VMtoStorageHashMap);
```

**Use the following EVAL closure to remove duplicate entries from tables.**

```javascript
var tableWithoutDuplicates = '';
tableWithoutDuplicates = DuplicateRemover.removeDuplicates($(cmdb_ci_os_template),['object_id']);
CTX.setAttribute("cmdb_ci_os_template", tableWithoutDuplicates);
```

**Use the following EVAL closure that builds a list of VM IDs that are related to the current security group ID.**

```javascript
var rtrn = '';
//get the Security Group ID of the current record in the table for comparison
var current_table_id = $(security_groups[].sec_group_id);
var current_table_id_string = current_table_id + '';

// get the list of instance's ID that will be then added to Security Group table
var needed_value_id_list = $(sec_group_network_components[*].vm_instance_id);
//get the list of Security Group IDs in the Network Component table, which will then be compared one by one to the current record of the security_groups table
var compare_id_list = $(sec_group_network_components[*].sec_group_id);

var beforeReturn = '';
var separator = '';
for (var i = 0; i < compare_id_list.size(); i++) {
    if   (current_table_id_string == compare_id_list.get(i)){
        beforeReturn += separator + needed_value_id_list.get(i);
        separator = ',';
    }
}
rtrn = beforeReturn;
```
Use the following EVAL closure that builds a HashMap of HashSet between security groups and the VMs that are configured to use them.

```javascript
rtrn = ''; 
var secGroupTable = ${cmdb_ci_endpoint_comp_security};
var secToVMHashSet = new Packages.java.util.HashMap();

// this loop worst case O(N*M) M = security groups, N = VMs
for(var i=0; i<secGroupTable.size(); i++){
    var securityTableId = secGroupTable.get(i).get('object_id');
    var vmListStr = secGroupTable.get(i).get('instance_list');
    var vmList = vmListStr.split(',');
    var vmSet = new Packages.java.util.HashSet();
    for (var j in vmList){
        vmSet.add(vmList[j]);
    }
    secToVMHashSet.put(securityTableId,vmSet);
}
CTX.setAttribute("securityVMCache", secToVMHashSet);
```

Use the following EVAL closure that returns ‘true’ if the current VM is using the current security group ID.

```javascript
var rtrn = ''; 
var vm_id = ${cmdb_ci_vm_instance[].object_id};
var vmHashSet = ${securityVMCache}.get(${cmdb_ci_endpoint_comp_security[].object_id});
rtrn = vmHashSet.contains(vm_id);
```

Use the following EVAL closure that returns ‘true’ if the current VM is using the current storage volume.

```javascript
var rtrn = ''; 
var vm_id = ${cmdb_ci_vm_instance[].object_id};
var vol_id = ${cmdb_ci_endpoint_iscsi[].object_id};
var vmHashSet = ${VMStorageCache}.get(vm_id);
if (vmHashSet){
    rtrn = vmHashSet.contains(vol_id);
} else {
    rtrn = 'false'
}
```

Use the following EVAL function to transform the API response into full JSON format, as the untouched response is formatted as "<resource objects>".

```javascript
var cloud_response = ${location_groups_response}
for (var i = 0; i < cloud_response.size(); i++){
    cloud_response.set(I, '"result":[' + cloud_response.get(i) + ']')
}
CTX.setAttribute("location_groups_response", cloud_response);
```

 Parses the unique Location Groups in the “location_groups_az” table basdon the column “lg_id” and creates a new table “location_groups_az_unique” that contains the result.

```javascript
var tableWithoutDuplicates= '';
tableWithoutDuplicates = 
    DuplicateRemover.removeDuplicates(${location_groups_az},${"lg_id"});
```
Creates a list of Availability Zones per Location Group, that is stored in a column new column in the location_groups_az_unique table. The list records are divided by commas purposely, so that unique relations could be made in consecutive step.

```javascript
CTX.setAttribute("location_groups_az_unique", tableWithoutDuplicates);

var current_table_id = ${location_groups_az_unique[].lg_id};
var current_table_id_string = current_table_id + "";
var needed_value_id_list = ${location_groups_az[*].lg_az_id};
var compare_id_list = ${location_groups_az[*].lg_id};
var beforeReturn = "";
var separator = ",";
for (var i = 0; i < compare_id_list.size(); i++) {
  if (current_table_id_string == compare_id_list.get(i)) {
    beforeReturn += separator + needed_value_id_list.get(i) + separator;
  }
}
return = beforeReturn;
```

**Data collected by Discovery during horizontal discovery**

Data is collected using these patterns:
- IBM Cloud Load Balancer
- IBM Cloud Location Groups
- IBM Cloud Network
- IBM Cloud Organizations and Spaces
- IBM Cloud Resource Groups
- IBM Cloud SSH Key
- IBM Cloud Storage
- IBM Cloud Virtual Server

**IBM Cloud Load Balancer discovered resources**

**Troubleshooting**

If the mapping result is not as you expected, perform basic troubleshooting.
<table>
<thead>
<tr>
<th>Symptom</th>
<th>Cause</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discovery fails. The discovery message contains the information about an error caused by the REST timeout.</td>
<td>There are many CIs sending the REST call response in the deployment. The MID Server cannot process the REST call response without exceeding the time limit controlled by the mid.sa.cloud.request_timeout parameter.</td>
<td>By default, the mid.sa.cloud.request_timeout parameter is set to 30000 milliseconds. Increase the value of this parameter on the relevant MID Server and run discovery again.</td>
</tr>
</tbody>
</table>

**Note:** If the Configuration Parameters related list for the relevant MID Server does not show this parameter, you may need to add it.

<table>
<thead>
<tr>
<th>Symptom</th>
<th>Cause</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pattern designer fails during a debug session. The pattern designer message contains information about an error caused by a timeout.</td>
<td>The pattern designer fails because of a timeout during pattern debugging (and not during discovery).</td>
<td>By default, the sa.debugger.max_timeout parameter is set to 240 seconds. Increase the value of this parameter on the relevant MID Server.</td>
</tr>
</tbody>
</table>

**IBM Informix Dynamic Server discovery**

Discovery and Service Mapping can find and map the Informix Dynamic Server.

**Prerequisites**

**User**

Provide a user with permissions to run the following commands without elevated rights:

- `install_directory/bin/onstat -g dis`
  This command gets the status and configuration of Informix Dynamic server.
- `install_directory/bin/dbaccess sysmaster`
  This command runs an sql query against the master schema.

The same user must have read permission for the following directories:

- `install_directory + */etc/sqlhosts`
  Access to this directory is necessary to get information about the port, host, and service definition of the Informix Dynamic server.
- `/etc/services`
  Access to this directory is required to get information about the host service definition.

**Credentials**

Configure SSH credentials in the Credentials module of the ServiceNow platform for accessing the server hosting the Informix Dynamic server.
Data collected by Discovery during horizontal discovery

</tr>
</tbody>
</table>

Top-down

During top-down discovery, Service Mapping discovers connections between the Informix Instance and the Informix Catalogs that the instance contains and displays them as an inclusion on the application service map.

IBM PowerHA Cluster (HACMP) discovery

Discovery uses the IBM PowerHA Cluster (HACMP) pattern to find IBM PowerHA SystemMirror for AIX (formerly HACMP) high-availability clusters on the AIX UNIX and Linux for IBM System p platforms.

Discovery uses this pattern to run horizontal discovery.

You can use this pattern on the ServiceNow platform using the London release or later.

Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store.

Prerequisites

- In UNIX Classification (AIX), the Triggers probes related list, configure this pattern as an exploration that runs after the OS pattern. It can also run after the probes.
Pattern configuration in Triggers probes

- Make sure that the MID Server has access to the target host and can execute all the commands that are implemented in the pattern.
- Verify that the pattern is set to run against the server IP address or hostname.
- Configure a UNIX user with permissions to run all commands defined in the official IBM documentation, and the following commands on AIX:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lssrc -s clstrmgrES</td>
<td>Verify that the clstrmgrES process is running.</td>
</tr>
<tr>
<td>lslpp -l cluster.license</td>
<td>Get the license and version data of the cluster.</td>
</tr>
<tr>
<td>lslpp -l cluster.license</td>
<td>Get the software label version data of the cluster.</td>
</tr>
<tr>
<td>awk '{$1=$2=$3=&quot;&quot;; print $0)</td>
<td>Get the name and state of the resource group.</td>
</tr>
<tr>
<td>/usr/es/sbin/cluster/utilities/</td>
<td>Set the path to variable - '$util'</td>
</tr>
<tr>
<td>cltopinfo -c</td>
<td>Get the current state of the cluster.</td>
</tr>
<tr>
<td>/usr/es/sbin/cluster/utilities/</td>

<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>/usr/es/sbin/cluster/clstat -o</td>
<td>Get the state of the nodes participating in the cluster.</td>
</tr>
<tr>
<td>/usr/es/sbin/cluster/utilities/cllsif</td>
<td>Get network IP/Non-IP interface data.</td>
</tr>
<tr>
<td>lsvg</td>
<td>Get information about the physical volumes of the cluster.</td>
</tr>
<tr>
<td>lsvg -o</td>
<td>Get information about the volume groups of the cluster.</td>
</tr>
<tr>
<td>lsattr -E -l inet0 -a hostname</td>
<td>awk '{print $2}'</td>
</tr>
<tr>
<td>/usr/es/sbin/cluster/utilities/clshowres</td>
<td>grep 'Concurrent Volume Group'</td>
</tr>
</tbody>
</table>

**Data collected by Discovery during horizontal discovery**

The pattern discovers data that helps you understand the cluster topology of your organization and the relationships between its components. The discovered data includes the following tables and fields.

<table>
<thead>
<tr>
<th>Table and field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Cluster Resource Group</strong> (cmdb_ci_cluster_resource_group)**</td>
<td></td>
</tr>
<tr>
<td>name</td>
<td>The name of the resource group of the cluster.</td>
</tr>
<tr>
<td>server</td>
<td>The server on which the resource group resides. Example: HOST_NAME of the server.</td>
</tr>
<tr>
<td>resource_group_status</td>
<td>The status of the resource group of the cluster. Example: Online.</td>
</tr>
<tr>
<td>resource_group_type</td>
<td>The type of the resource group. Examples: Concurrent, non-concurrent.</td>
</tr>
<tr>
<td>cluster</td>
<td>The name of the cluster to which the resource group belongs.</td>
</tr>
<tr>
<td><strong>UNIX Cluster Resource</strong> (cmdb_ci_unix_cluster_resource)**</td>
<td></td>
</tr>
<tr>
<td>name</td>
<td>The name of the volume group of the cluster.</td>
</tr>
<tr>
<td>resource_type</td>
<td>The resource type (volume group).</td>
</tr>
<tr>
<td>resource_status</td>
<td>The status of the volume group. Examples: Online, Offline.</td>
</tr>
<tr>
<td>cluster</td>
<td>The name of the cluster to which the resource belongs.</td>
</tr>
<tr>
<td><strong>UNIX Cluster Node</strong> (cmdb_ci_unix_cluster_node)**</td>
<td></td>
</tr>
<tr>
<td>name</td>
<td>The name of the node that participates in the cluster.</td>
</tr>
<tr>
<td>node_state</td>
<td>The state of the node in the context of the CI state.</td>
</tr>
<tr>
<td>ip_address</td>
<td>The IP addresses assigned to the node.</td>
</tr>
<tr>
<td>Table and field</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>node_status</td>
<td>The status of the node in the context of the resource group to which it belongs.</td>
</tr>
<tr>
<td>cluster</td>
<td>The name of the cluster to which the node belongs.</td>
</tr>
</tbody>
</table>

AIX Server (cmdb_ci_aix_server)

| serial_number  | The serial number of the AIX server host. |
| model_number   | The model number of the AIX host. |
| memory         | The memory size installed on the AIX host. |
| fqdn           | The fully qualified domain name of the AIX host. |
| os             | The type of the operating system of the AIX host. |
| os_version     | The version of the operating system. |
| start_date     | The start date of the machine. |
| cpu_vendor     | The manufacturer of the CPU. |

UNIX Cluster (cmdb_ci_unix_cluster)

| name           | The name of the cluster. |
| cluster_id     | The ID of the cluster. Example: 0123456789. |
| cluster_status | The current state of the cluster. Examples: ST_STABLE, NOT_CONFIGURED. |
| cluster_version| The version of the cluster. Examples: 5.5; 6.1; 7.2. |
| cluster_type   | The type of the cluster. Relevant only for versions 7.2 and above. Example: Stretched. |
| short_description | Description of the cluster (version, ID). |

Cluster Virtual IP (cmdb_ci_cluster_vip)

| ip_address     | Hostname/IP address of the server on which the cluster resides. (The IBM PowerHA SystemMirror/HACMP cluster almost never has a dedicated virtual IP address configured.) |
| cluster        | The name of the cluster. |

On the Dependency Views map you can see all discovered cluster CIs in your organization and the relationships between them.

In this example, UNIX Cluster Node represents a cluster of UNIX Clusters. UNIX Cluster Node gets resources from UNIX Cluster Resource and uses Cluster Virtual IP. UNIX Cluster Node contains three Cluster Resource Groups.
Dependency Views sample map

CI relationships

</table>
IBM Virtualization and Hardware Management Console discovery

ServiceNow® Discovery can use the Hardware Management Console (HMC) to find and manage virtual IBM systems, such as IBM System i, IBM System p, IBM System z, and IBM Power Systems.

Discovery supports the following CIs:

- HMC server
- IBM frame
- Logical partition (LPAR) instance
  
  An LPAR is virtual machine equivalent of IBM.
- LPAR resource

Discovery is used on the HMC server and the individual AIX machines (LPARs).

Prerequisites

- Configure SSH credentials on a ServiceNow instance to allow using the following HMC commands:
  
  - Issyscfg
  - Lshmc
  - Lshwres

- Configure the SSH credentials on a ServiceNow instance to allow using the lparstat -i command on the AIX logical partition (LPAR).

  **Note:** The lparstat -i command is in addition to the commands required for AIX host discovery.

- Install the CMDB application.

Configure a discovery

To configure a discovery, do the following tasks:

1. Complete a discovery on the HMC IP address. Make sure this discovery completes successfully before you continue.
2. Complete a discovery on the LPARs (the AIX machines).

Data collected during horizontal discovery

<table>
<thead>
<tr>

<tr>
<td>lpar_names</td>
<td>LPAR name in the discovered pool.</td>
</tr>
<tr>
<td>frame_name</td>
<td>The name of the frame to which the pools belongs.</td>
</tr>
</tbody>
</table>

The following is a dependency view of the relationships between the IBM frames, the LPAR instances, and the AIX servers.
Kubernetes discovery

Discovery Kubernetes and OpenShift components of the Kubernetes deployment using the Kubernetes pattern.

Discovery finds Kubernetes versions 1.5, 1.6, 1.7, 1.8, 1.9, and 1.10 using the Kubernetes pattern.

You can use this pattern on the Now Platform using Jakarta P9, Kingston P5, London P8, Madrid P2 or New York.
The Collect OpenShift info extension section of the Kubernetes pattern discovers the OpenShift components of the Kubernetes deployment. The OpenShift Build Config extension section is available from the October 2019 release, Store version 1.0.53. The OpenShift Build Config extension section is supported on the London patch 10, Madrid patch 5, and New York.

Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store.

Prerequisites

Perform the following steps to ensure that Discovery can use the new pattern to successfully find Kubernetes.

1. On the Kubernetes platform, find the parameters to set up Kubernetes discovery:
   - Find the url of the kubeapi server:
     1. On the Kubernetes platform, run the following command:
     
        ```bash
        kubectl cluster-info
        ```
     2. In the output, find the line that states the url of the kubeapi server. For example,

        ```text
        https://10.154.144.146:443
        ```
   - Find the namespaces of the kubeapi server:
     1. On the Kubernetes platform, run this command:

        ```bash
        kubectl get namespaces
        ```
     2. In the output, find the line that states the namespaces. For example, `kube-system`.
   - Find out the Kubernetes username and password:
     1. On the Kubernetes platform, run this command:

        ```bash
        kubectl config view
        ```
     2. In the output, find the username and password.

```text
contexts:
- context:
  cluster: juju-cluster
  user: admin
  name: juju-context
  current-context: juju-context
kind: Config
preferences: {}
users:
- name: admin
  user:
    password: X3w8ZS1kSeFnbQI3i90Z67G
  username: admin
ruty@kube1:~$ Kubernetes password and username
```

- If you are planning to use advance authentication using a bearer token, find the bearer token:
1. On the Kubernetes platform, use the following command: `kubectl describe secret [default-token-g6pwc parameter]`,

   Where `kubectl` is the generic Kubernetes client,
   `describe` is the generic `kubectl` method,
   `secret` parameter reflects that in your Kubernetes cluster the default token is protected by containing it inside the object of type `secret`,
   `default-token-g6pwc` is the parameter value of the default token for `g6pwc`.

   The output shows all existing tokens for this Kubernetes account.

2. Choose one token to use for configuring Kubernetes credentials on the ServiceNow platform.

   2. Create the Kubernetes credentials:
      a. On the ServiceNow platform, navigate to **Discovery > Credentials**.
      b. Click **New**.
      c. Click **Kubernetes credentials**.
      d. Configure the form fields (see table):

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a unique and descriptive name for this credential.</td>
</tr>
<tr>
<td>User name</td>
<td>Enter the user name to create in the Credentials table. Avoid leading or</td>
</tr>
<tr>
<td></td>
<td>trailing spaces in user names. A warning appears if the platform detects</td>
</tr>
<tr>
<td></td>
<td>leading or trailing spaces in the user name.</td>
</tr>
<tr>
<td>Password</td>
<td>Enter the password for this credential.</td>
</tr>
<tr>
<td>Bearer Token</td>
<td><em>(Optional)</em> For advanced authentication using a bearer token, enter the</td>
</tr>
<tr>
<td></td>
<td>bearer token that Discovery use for authentication when accessing</td>
</tr>
<tr>
<td></td>
<td>Kubernetes. Use the character sequence as the token, for example, <code>31ada4fd-</code></td>
</tr>
<tr>
<td></td>
<td><code>adec-460c-809a-9e56ceb75269</code>.</td>
</tr>
<tr>
<td>Bearer Token Authentication</td>
<td><em>(Optional)</em> For advanced authentication using a bearer token, select this check box.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| Credential alias      | 1. Click the padlock icon, and then click the search icon.  
2. On the Connection & Credential Aliases form, click New.  
3. Define attributes for the alias. Set the Type to Credential.  
4. Right-click the form header and click Save, then click Update.  
5. On the Connection & Credential Aliases form, click the newly added alias. The alias appears in the Credential alias field. |

**Note:** The alias allows you to use the Kubernetes credential for devices and applications other than Kubernetes.

e. On the Kubernetes credentials form, click **Update**.

3. Provide a user with the permissions to the following /api/v1 elements:
   - https://<url>/api/v1/namespaces/
   - https://<url>/api/v1/namespaces/<namespace>
   - https://<url>/api/v1/namespaces/kube-system/endpoints/kube-controller-manager
   - https://<url>/api/v1/services
   - https://<url>/api/v1/pods
   - https://<url>/api/v1/nodes

4. To discover the OpenShift components of the Kubernetes deployment, provide a user with the permissions to run the following /api/v1 elements:
   - /apis/apps.openshift.io/v1/deploymentconfigs
   - /apis/build.openshift.io/v1/buildconfigs
   - /apis/route.openshift.io/v1/routes
   - /apis/user.openshift.io/v1/groups
   - /apis/user.openshift.io/v1/users
   - /apis/project.openshift.io/v1/projects
   - /apis/image.openshift.io/v1/images
   - /apis/image.openshift.io/v1/imagestream

5. Create a serverless discovery schedule using the IP address and the port of the kubeapi server. Set the **Pattern** parameter to Kubernetes.

6. Create and define the serverless execution pattern as described in the product documentation. Configure the parameters required by the Kubernetes pattern as follows:
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>host_ip</td>
<td>The identifier for the host_ip of the kubernetes apiserver.</td>
</tr>
<tr>
<td>port</td>
<td>The identifier for the kubernetes apiserver port.</td>
</tr>
</tbody>
</table>
| namespace   | Namespaces the system passed in the Kubernetes Discovery Configuration. Enter one of the following values:  
  - The actual namespace you found on the kubernetes platform. If there are more than one namespace, use comma (,) to separate values.  
  - Asterisk (*) for all namespaces.  
  - default" as the default value for namespaces. |
| credentialAlias | The alias associated with the previously created kubernetes credentials you created earlier. |

</tbody>
</table>

OpenShift User (cmdb_ci_openshift_user)

| name            | The name of the OpenShift user. |
| k8s_uid         | The Kubernetes volume UUID. |
| url             | The URL of the OpenShift user. |
| full_name       | The full name of the OpenShift user. |

OpenShift Project (cmdb_ci_openshift_project)

| name            | The name of the OpenShift project. |
| k8s_uid         | The Kubernetes volume UUID. |
| url             | The URL of the OpenShift Project. |

OpenShift Image (cmdb_ci_openshift_images)

| name            | The name of the OpenShift Image. |
| k8s_uid         | The Kubernetes volume UUID. |
| url             | The URL of the OpenShift Image. |
| docker_image_metadata_id | The ID of the docker image. |
| docker_image_metadata_parent_id | The ID of the image parent ID. |
| arch            | Architecture of the image. |
| size            | The image size. |
| hostname        | The hostname related to the image. |

OpenShift Image Stream (cmdb_ci_openshift_images_stream)

| name            | The name of the OpenShift Image Stream. |
| k8s_uid         | The Kubernetes volume UID. |
| url             | The URL of the OpenShift Image Stream |
| namespace       | The name of the namespace containing the OpenShift image stream. |

OpenShift Docker Image Repository (cmdb_ci_openshift_docker_images_repository)

| name            | The name of the OpenShift docker image repository. |
| parent_ID       | The ID of the parent system. |

The graphic illustrates CIs that are part of Kubernetes discovery.

**Note:** This Dependency Views map was simplified for clarity. Your Kubernetes deployments can contain many more CIs.
CI relationships

These relationships are created to support Kubernetes discovery:

<table>
<thead>
<tr>
<th>CI</th>
<th>Relationship</th>
<th>CI</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes Cluster (cmdb_ci_kubernetes_cluster)</td>
<td>Contains::Contained By Kubernetes Service (cmdb_ci_kubernetes_service)</td>
<td></td>
</tr>
<tr>
<td>Contains::Contained By Kubernetes Pod (cmdb_ci_kubernetes_pod)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Contains::Contained By (cmdb_ci_openshift_source_2_image)</td>
<td></td>

<td></td>
</tr>
<tr>
<td>Contains::Contained By OpenShift Image (cmdb_ci_openshift_images)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
## Kubernetes event discovery

Discovery finds Kubernetes events and frequently updates the CMDB to reflect the dynamic Kubernetes environment. Discovery finds Kubernetes events for versions 1.5, 1.6, 1.7, 1.8, 1.9, and 1.10 using the Kubernetes Event pattern.

You can use this pattern on the ServiceNow platform using Jakarta P9, Kingston P5, London P8, or Madrid P2.

### Prerequisites

Perform the following steps to ensure that Discovery can use the new pattern to successfully find Kubernetes.

---

<table>
<thead>
<tr>

</tbody>
</table>
1. Discover Kubernetes in your organization using the Kubernetes pattern.

2. On the Kubernetes platform, find the parameters to set up Kubernetes discovery:
   - Find the url of the kubeapi server:
     1. On the Kubernetes platform, run the following command:
        ```bash
        kubectl cluster-info
        ```
     2. In the output, find the line that states the url of the kubeapi server. For example,
        ```bash
        https://10.154.144.146:443
        ```
   - Find the namespaces of the kubeapi server:
     1. On the Kubernetes platform, run this command:
        ```bash
        kubectl get namespaces
        ```
     2. In the output, find the line that states the namespaces. For example, `kube-system`.
   - If you are planning to use advance authentication using a bearer token, find the bearer token:
     1. On the Kubernetes platform, use the following command:
        ```bash
        kubectl describe secret [default-token-g6pwc parameter],
        ```
        Where `kubectl` is the generic Kubernetes client,
        `describe` is the generic `kubectl` method,
        `secret` parameter reflects that in your Kubernetes cluster the default token is protected by containing it inside the object of type `secret`,
        `default-token-g6pwc` is the parameter value of the default token for g6pwc.
        The output shows all existing tokens for this Kubernetes account.
     2. Choose one token to use for configuring Kubernetes credentials on the ServiceNow platform.

3. Create a serverless discovery schedule to run every 5 or 10 minutes.

   **Note:** When the pattern is run for the first time, it stores an event_timestamp. Later on it collects only the delta events based on the timestamp. The more often the pattern is run, the fewer updates to the CMDB IRE are needed.

4. Create a serverless execution pattern for the discovery schedule and assign it to the Kubernetes Events pattern. Configure the discovery pattern launcher the parameters required by the Kubernetes pattern as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>url</strong></td>
<td>The identifier for the hostname, IP or FQDN and the port of the Kubernetes api server. Use the following format: <code>example_hostname:example_port</code> or <code>example_ip:example_port</code>.</td>
</tr>
</tbody>
</table>
## Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| namespace      | Namespaces the system passed in the Kubernetes Discovery Configuration. Enter one of the following values:  
- The actual namespace you found on the Kubernetes platform. If there is more than one namespace, use comma (,) to separate values.  
- Asterisk (*) for all namespaces.  
- default" as the default value for namespaces. |
| credentialsAlias | The alias associated with the previously created Kubernetes credentials. |

<tr>
<td>Key Value (cmdb_key_value)</td>
<td>This configuration item contains Kubernetes labels. Labels are key/value pairs that are attached to objects, such as pods.</td>
</tr>
<tr>
<td>key</td>
<td>The key of the kubernetes pod or Kubernetes service Key Value parameter.</td>
</tr>
<tr>
<td>Table and field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>value</td>
<td>The value of the kubernetes pod or Kubernetes service Key Value parameter.</td>
</tr>
<tr>
<td>Kubernetes Volume (cmdb_ci_kubernetes_volume)</td>
<td></td>
</tr>
<tr>
<td>k8s_uid</td>
<td>The Kubernetes volume UUID.</td>
</tr>
<tr>
<td>mount_path</td>
<td>The path for accessing this Kubernetes volume.</td>
</tr>
<tr>
<td>name</td>
<td>The name of the Kubernetes volume.</td>
</tr>
<tr>
<td>namespace</td>
<td>The Kubernetes namespace to which this Kubernetes volume belongs.</td>
</tr>
<tr>
<td>volume_id</td>
<td>The ID of the Kubernetes volume.</td>
</tr>
</tbody>
</table>

The graphic illustrates CIs that are part of Kubernetes discovery.

**Note:** This Dependency Views map was simplified for clarity. Your Kubernetes deployments can contain many more CIs.
CI relationships

These relationships are created to support Kubernetes event discovery:

<table>
<thead>
<tr>
<th>CI</th>
<th>Relationship</th>
<th>CI</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes Cluster (cmdb_ci_kubernetes_cluster)</td>
<td>Contains::Contained By</td>
<td>Kubernetes Service (cmdb_ci_kubernetes_service)</td>
</tr>
<tr>
<td>Contains::Contained By</td>
<td></td>
<td>Kubernetes Pod (cmdb_ci_kubernetes_pod)</td>
</tr>
</tbody>
</table>
Microsoft Azure Application Gateway discovery

Discovery uses the Azure Application Gateway HD pattern for discovering this product, while Service Mapping discovers Application Gateway using Azure Application Gateway TD (LBS) pattern.

Discovery and Service Mapping discover the 2017-03-01 version of Azure Application Gateway. You can use this pattern on the ServiceNow platform using Jakarta Patch 10, Kingston Patch 8, or London Patch 1.
