
Prerequisites

Azure Principal credentials

On the ServiceNow platform, create a service account for cloud discovery. Set the account Id to the Azure Service Principal as it appears at the Microsoft Azure Console.

Privileges

On the Microsoft Azure Console, provide a user a user with the reader role.

Data collected by Discovery during horizontal discovery

Connections discovered by Service Mapping during the top-down discovery

Service Mapping performs the top-down discovery of the Azure Application Gateway in the context of application services. Service Mapping discovers the outgoing http connections from Azure Application Gateway service to pool members, such as virtual machines.

Microsoft Azure Inventory discovery

Discovery uses the Azure Inventory pattern for discovering resources available through Azure. Use this pattern for Azure resources, which do not have a dedicated pattern like Azure Functions or Azure Application Gateway.

You can discover up to 10 thousand resources using the Azure Inventory pattern.

You can use this pattern on the ServiceNow platform using London (Patch 8) or later releases.

Request apps on the Store

Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store. For cumulative release notes information for all released apps, refer to the ServiceNow Store version history release notes.

Prerequisites

Azure service account
 Configure the Azure service account.

Azure Principal credentials
 On the Now Platform, create a service account for cloud discovery. Set the account Id to the Azure Service Principal as it appears at the Microsoft Azure Console.

Privileges
 On the Microsoft Azure Console, provide a user with the API Management Service Reader role with permissions to run the following REST request:

```
href="https://management.azure.com/subscriptions/<subscription id>/resources"
format="html" scope="external"/>
```

Upgrade the Now Platform
 Upgrade the Now Platform to the Kingston release or later.

Logical Datacenters
 Discover Logical Datacenters hosting Azure Functions as described in Run Discovery on an Azure cloud service account in the ServiceNow Cloud Management documentation.

Create discovery schedule
 Create a schedule for the relevant Azure service account as described in Schedule Discovery on a service account in the ServiceNow Cloud Management documentation. Alternatively, create a schedule for running the Azure Resource Inventory pattern as described in Run cloud application discovery in the ServiceNow Discovery documentation.

Fine-tune Azure inventory discovery using the Resource Whitelist
 If your deployment has custom patterns for Azure discovery, ensure that you do not discover Azure resources twice.
1. Ensure that the application scope is Discovery and Service Mapping Patterns:
   a. Navigate to Settings > Developer.
   b. Select Discovery and Service Mapping Patterns from the Application list.

2. Navigate to System Definitions > Tables.
3. Open the Cloud Inventory Resource Whitelist (sa_cloud_inventory_resource_whitelist) table.
4. Under Related Links, click Show List.
5. Select resource types for which you have custom patterns, and select Delete from the Actions on selected rows list.

   The Cloud Inventory Resource Whitelist is predefined with common services. You can expand the whitelist with additional resource types that you want the pattern to discover. The names of these resource types must conform to the appropriate vendor naming conventions.

   **Note:** When you modify the out-of-the-box whitelist, it is no longer updated automatically in application updates. You need to maintain the customized list on your own.

1. Open the Cloud Inventory Resource Whitelist (sa_cloud_inventory_resource_whitelist) table.
2. Click New.
3. Fill in the form, and then click Submit.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud Vendor</td>
<td>The vendor of the resource type: Azure.</td>
</tr>
<tr>
<td>Resource Type</td>
<td>The AWS resource type value.</td>
</tr>
<tr>
<td>Application</td>
<td>The application scope: Discovery and Service Mapping Patterns.</td>
</tr>
</tbody>
</table>

The changes are applied the next time you run the pattern.

**Modify the ServiceNow identification rules.**

Be sure to switch to the Cloud Management Platform application scope before you begin the following procedure.

1. Navigate to CI Class Manager > Hierarchy > Cloud Resource > Identification Rule.
2. Delete and add the appropriate identification rule.

   The new identification rule should include only the Object ID attribute.
Modify the ServiceNow related entries

1. Navigate to Related Entries.
2. Click New.
3. For the identifier, enter `cmdb_ci_cmp_resource`.
4. For the related table, select Key Value (cmdb_key_value).
5. For the referenced field, select Configuration Item.
6. For the criterion attributes, add Key and Value.

You may need to click the lock icon to view and change the criterion attributes.
Data collected by Discovery during horizontal discovery

<table>
<thead>
<tr>
<th>Table and field</th>
<th>Additional information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud Resource (cmdb_ci_cmp_resource)</td>
<td>A descriptive name used to identify the Azure resource.</td>
</tr>
<tr>
<td>name</td>

<tr>
<td>tag</td>
<td>The tag value that Discovery collects from the Azure resource.</td>
</tr>
</tbody>
</table>

CI relationships

These relationships are created to support Azure Functions discovery:

| CI | Relationship | CI |
|----------------|--------------|-----------------|-----------------|-----------------|
| Azure Resource (cmdb_ci_cmp_resource) | Hosted on:Hosts | Logical Datacenter (cmdb_ci_logical_datacenter) |

Troubleshooting

If the mapping result is not as you expected, perform basic troubleshooting.
### Microsoft Azure Functions discovery

Discovery and Service Mapping uses the Microsoft Azure Functions pattern for discovering Azure Functions service and mapping this service in the context of application services.

You can use this pattern on the Now Platform® using Jakarta Patch 10, Kingston Patch 8, or London Patch 1.

### Prerequisites

**Azure service account**

Configure the Azure service account.

**Azure Principal credentials**

On the Now Platform, create a service account for cloud discovery. Set the account Id to the Azure Service Principal as it appears at the Microsoft Azure Console.

**Privileges**

On the Microsoft Azure Console, provide a user with the API Management Service Reader role.

**Upgrade the Now Platform**

Upgrade the Now Platform to the relevant patch: Kingston Patch 8 or later.

**Note:** Patterns in the earlier patches do not support top-down discovery performed by Service Mapping.

**Logical Datacenters**

Discover Logical Datacenters hosting Azure Functions as described in Run Discovery on an Azure cloud service account in the ServiceNow Cloud Management documentation.
Create discovery schedule

Create a schedule for the relevant Azure service account for running the as described in Schedule Discovery on a service account in the ServiceNow Cloud Management documentation.

Configure Azure Alert service

To enable alert-based discovery, configure Discovery and Service Mapping to trigger the pattern to discover Azure Functions based on Azure alerts:

1. In the Cloud Resource Types (sn_capi_resource_type) table, associate the Microsoft Azure Functions pattern with the Microsoft.Web/sites cloud resource type.
2. Configure the Azure Alert service as described in Set up Azure alert processing for Discovery and Service Mapping in the ServiceNow Cloud Management documentation.

Commands

The Azure Functions pattern contains the following commands that do not require elevated rights:

- (On Linux) egrep — This command searches text in the previous command output.
- (On Windows) findstr — Finds a string in the previous command output.

Data collected by Discovery during horizontal discovery

<table>
<thead>
<tr>
<th>Table and field</th>
<th>Additional information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Azure Function (cmdb_ci_cloud_function)</td>
<td></td>
</tr>
<tr>
<td>name</td>
<td>The name of Azure Functions.</td>
</tr>
<tr>
<td>short_description</td>
<td>The description that distinguishes the Azure Function from other cloud functions. The value is Azure Function.</td>
</tr>
<tr>
<td>Object_id</td>
<td>The ID of Azure Functions.</td>
</tr>
<tr>
<td>state</td>
<td>The state of Azure Functions.</td>
</tr>
<tr>
<td>version</td>

<td>The URL of the Azure Functions source code.</td>
</tr>
<tr>
<td>FQDN</td>
<td>The FQDN of the Azure Functions application.</td>
</tr>
</tbody>
</table>

CI relationships

These relationships are created to support Azure Functions discovery:

<table>
<thead>
<tr>
<th>CI</th>
<th>Relationship</th>
<th>CI</th>
</tr>
</thead>
<tbody>
<tr>
<td>Azure Functions (cmdb_ci_cloud_function)</td>
<td>Hosted on:Hosts</td>
<td>Logical Datacenter (cmdb_ci_logical_datacenter)</td>
</tr>
<tr>
<td></td>
<td>Uses:Used by</td>
<td>Cloud Database (cmdb_ci_cloud_database)</td>
</tr>
</tbody>
</table>
Connections found by Service Mapping during top-down discovery

Service Mapping can discover the following connections:

- Connections to the following databases: MSSql, MySql, MongoDB, and Documentum.
- HTTP connections belonging to Azure Functions environment, for example, https://scenario4-hop1-azure-function.azurewebsites.net.

**Note:** Service Mapping does not scan java classes/jars and binary files for possible information about outgoing HTTP connections of Azure Functions. If java classes/jars and binary files are the only source of information about some outgoing HTTP connections, Service Mapping does not find such HTTP connections.

Troubleshooting

If the mapping result is not as you expected, perform basic troubleshooting.

<table>
<thead>
<tr>
<th>Symptom</th>
<th>Cause</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discovery fails. The discovery message contains the information about an error caused by the REST timeout.</td>
<td>There are many CIs sending the REST call response in the deployment. The MID Server cannot process the REST call response without exceeding the time limit controlled by the mid.sa.cloud.request_timeout parameter.</td>
<td>By default, the mid.sa.cloud.request_timeout parameter is set to 30000 milliseconds. Increase the value of this parameter on the relevant MID Server and run discovery again.</td>
</tr>
<tr>
<td>Pattern designer fails during a debug session. The pattern designer message contains information about an error caused by a timeout.</td>
<td>The pattern designer fails because of a timeout during pattern debugging (and not during discovery).</td>
<td>By default, the sa.debugger.max_timeout parameter is set to 240 seconds. Increase the value of this parameter on the relevant MID Server.</td>
</tr>
</tbody>
</table>

Nutanix Acropolis discovery

Discovery uses the Nutanix Components pattern to find components of the Nutanix Acropolis solution containing Nutanix Prism Central version 5.10 or Nutanix Prism Element 5.9.
You can use this pattern on the Now Platform using Madrid Patch 5 and London Patch 9. The Nutanix Components pattern uses REST APIs to collect information about the Acropolis deployment components.

Prerequisites

MID Server requirements
Deploy and connect the dedicated MID Server for accessing the Nutanix deployment.

Credentials
Configure the following credentials:
1. Navigate to Discovery > Credentials.
2. Click New.
3. Click Basic Auth Credentials, fill in the form, and then click Submit.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Credential name. An example is Acropolis</td>
</tr>
<tr>
<td>Active</td>
<td>Option for enabling this credential for discovery. Select this check box to enable discovery.</td>
</tr>
<tr>
<td>Applies to</td>
<td>Select All MID servers.</td>
</tr>
<tr>
<td>Order</td>
<td>Order in which the platform tries this credential as it attempts to log on to devices. A smaller number indicates that the credential appears higher in the list. Establish the credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number, or none, the instance tries the credentials in a random order. The default value is 100.</td>
</tr>
<tr>
<td>User name</td>
<td>Name of the user for performing Acropolis discovery.</td>
</tr>
<tr>
<td>Password</td>
<td>Password for this user.</td>
</tr>
<tr>
<td>Credential alias</td>
<td>Credential alias for this credential to authorize actions.</td>
</tr>
</tbody>
</table>

Credentials for API elements
During the discovery, the pattern uses the following API elements. The user that was added to the credentials in the instance must have permissions to send these queries.

- /PrismGateway/services/rest/v2.0/tasks/list
- /api/nutanix/v3/clusters/list
- /PrismGateway/services/rest/v2.0/hosts
- /PrismGateway/services/rest/v2.0/clusters
- /PrismGateway/services/rest/v2.0/vms

(Optional) Create a discovery schedule

Create a discovery schedule to perform targeted discovery of Nutanix components. An alternative is to perform discovery using the HTTP classification, which queries all servers with open HTTP ports and may lead to overloading the network.

1. Navigate to Discovery > Discovery Schedules.
2. Click New and then fill in the form.

**Discovery Schedule form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name for the Discovery schedule. For example, Acropolis.</td>
</tr>
<tr>
<td>Discover</td>
<td>Discover type. Select <strong>Serverless</strong>.</td>
</tr>
<tr>
<td>MID Server</td>
<td>Name of the MID Server that can access Nutanix PRISM Central.</td>
</tr>
<tr>
<td>Active</td>
<td>Option for enabling this schedule for discovery. Select this check box to enable discovery.</td>
</tr>
</tbody>
</table>

3. Right-click the header of the Discovery Schedule form and select **Save**.
4. Click the **Serverless Execution Patterns** tab, click **New**, and then fill in the form.

**Related Links**

**Serverless Execution Pattern form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name for this Serverless Execution Pattern. For example, Acropolis.</td>
</tr>
</tbody>
</table>
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pattern</td>
<td>Name of the pattern to run: Nutanix Components.</td>
</tr>
<tr>
<td>Proxy Host</td>
<td>Fully qualified domain name of the machine on which you are installing the proxy server. Specify Global.</td>
</tr>
<tr>
<td>Active</td>
<td>Option for enabling this schedule for discovery. Select this check box to enable discovery.</td>
</tr>
</tbody>
</table>

5. Under **Discovery Pattern Launcher Parameters**, configure the IP address of the Prism Central.

**Optional** Enable the HTTP classification for using Quick Discovery

If you don’t want to create a serverless discovery schedule, you can trigger discovery of the Nutanix components with the HTTP classification. This classification enables you to run the discovery using Quick Discovery. In this case, the discovery runs on a single IP address without requiring a schedule.

To enable HTTP classification, ensure that the application scope is Discovery and Service Mapping Patterns:

1. Navigate to **Settings > Developer**.
2. Select **Discovery and Service Mapping Patterns** from the **Application** list.

Since the HTTP classification triggers queries of all servers with the open HTTP ports, it may lead to overloading the network and slowing down the discovery process.

1. Navigate to **Discovery > Discovery Definition > CI Classification > HTTP**.
2. Modify the filter to display all classifications including classifications that are not active.
3. Locate the **Nutanix HTTP** classification and set the **Active** attribute to **true**.

**CMDB CI Class Models store app**

Ensure that your instance supports the Nutanix CI class models by deploying the latest version of the CMDB CI Class Models store app from the ServiceNow Store.

**Optional** Discover VMware components

To enable viewing relations between Nutanix Acropolis and VMware, run VMware discovery before Nutanix Acropolis discovery. Run the horizontal discovery for the VMware Vcenter using the VMware - vCenter Datacenters probe.

**Optional** Disable CI tag discovery

The Nutanix Components pattern discovers tags for Nutanix hosts and virtual machines. If you have dozens of tags in your deployment, it may slow down the discovery causing performance issues. You can disable the CI tag discovery by performing the following steps:

1. Navigate to **Pattern Designer > Discovery Patterns**.
2. Select the **Nutanix Components** pattern.
3. Under **Extension Section**, select the check box for **Categories (Tags)** and click **Remove**.
4. Click **Save**.

<tr>
<td>4 Nutanix Storage Container Distro</td>
<td>The distribution of Nutanix storage containers free space and capacity, in bytes.</td>
</tr>
<tr>
<td>5 Nutanix Storage Pool Capacity</td>
<td>The capacity of the Nutanix storage pool, in bytes.</td>
</tr>
<tr>
<td>6 Nutanix VM Summary</td>
<td>The Nutanix VMs grouped by state: On, off, terminated.</td>
</tr>
<tr>
<td>7 Nutanix Controller VMs</td>
<td>The Nutanix Controller VMs grouped by hypervisor type.</td>
</tr>
</tbody>
</table>

**Troubleshooting**

If the mapping result is not as you expected, perform basic troubleshooting.

<table>
<thead>
<tr>
<th>Symptom</th>
<th>Cause</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discovery fails. The discovery message contains the information about an error caused by the REST timeout.</td>
<td>There are many CIs sending the REST call response in the deployment. The MID Server cannot process the REST call response without exceeding the time limit controlled by the mid.sa.cloud.request_timeout parameter.</td>
<td>By default, the mid.sa.cloud.request_timeout parameter is set to 30000 milliseconds. Increase the value of this parameter on the relevant MID Server and run discovery again.</td>
</tr>
<tr>
<td>Pattern designer fails during a debug session. The pattern designer message contains information about an error caused by a timeout.</td>
<td>The pattern designer fails because of a timeout during pattern debugging (and not during discovery).</td>
<td>By default, the sa.debugger.max_timeout parameter is set to 240 seconds. Increase the value of this parameter on the relevant MID Server.</td>
</tr>
</tbody>
</table>

**Oracle Database 12c discovery**

ServiceNow® Discovery can discover pluggable databases (PDBs) and container databases (CDBs), which are features of Oracle Database 12c.
Request apps on the Store

Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store. For cumulative release notes information for all released apps, refer to the ServiceNow Store version history release notes.

About this pattern

A PDB is a portable collection of schemas, schema objects, and non-schema objects that appear to an Oracle Net client as a separate database. A collection of PDBs is called a container database (CDB).

For more information about PDBs and CDBs, see What are CDBs, PDBs and Containers?

Prerequisites

Set the user credentials and grant permissions:

- For Windows, see Windows credentials
- For Unix, see SSH credentials
- For the Oracle database, see Oracle database discovery

Set the Applicative credentials. See Applicative credentials

Allow the user to run queries on the following tables:

- V$DATAFILE
- V$TEMPFILE
- V$LOG
- DBA_FREE_SPACE
- V$DATABASE
- V$PDBS

Data collected during Discovery

Discovery collects the following data:

<table>
<thead>
<tr>
<th>Table and field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmdb_ci_db_ora_pdb_instance: Relation Type : Managed By</td>
<td></td>
</tr>
<tr>
<td>sid</td>
<td>Name of the PDB instance</td>
</tr>
<tr>
<td>name</td>
<td>Name of the CI in CMDB. This is a combination of sid and the hostname.</td>
</tr>
<tr>
<td>version</td>
<td>Version of the PDB as taken from the CDB instance</td>
</tr>
<tr>
<td>edition</td>
<td>Edition of the PDB as taken from the CDB instance</td>
</tr>
<tr>
<td>install_directory</td>
<td>Install directory of the PDB as taken from the CDB instance</td>
</tr>
<tr>
<td>oracle_home</td>
<td>Oracle home of the PDB as taken from the CDB instance</td>
</tr>
<tr>
<td>Table and field</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>cdb_name</td>
<td>Name of the cdb sid that contains the PDB. This refers to the Oracle database instance configuration item (CI)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>cmdadb_ci_db_instance_size: Relation Type : Contained By</th>
</tr>
</thead>
<tbody>
<tr>
<td>sid</td>
</tr>
<tr>
<td>name</td>
</tr>
<tr>
<td>db_size</td>
</tr>
<tr>
<td>used_size</td>
</tr>
<tr>
<td>free_size</td>
</tr>
</tbody>
</table>

The following is a dependency view of the relationship between PDBs, CDBs, and containers.
Oracle GoldenGate discovery

Discovery and Service Mapping find Oracle GoldenGate version 12c components using the Oracle GoldenGate pattern.

You can use this pattern on the Now Platform using Kingston, London, or Madrid.

Discovery uses the Oracle GoldenGate pattern to perform horizontal discovery to collect data into the $report_file file. Service Mapping performs top-down discovery on the $report_file file to find outgoing Oracle GoldenGate connections.

Prerequisites

Credentials

Configure the following credentials, depending on what type of host machine that the Oracle GoldenGate Server is installed on:

- Windows credentials
- SSH credentials for UNIX (IBM AIX, Hewlett-Packard HP-UX, or Oracle Solaris) and Linux operating systems

User access

Give the UNIX OS user permissions to read the $report_file. The $report_file is the report file that is extracted from the Oracle GoldenGate manager/replicat/extract process, with the extension .rpt. For example:

Configuration file:

```
/base/ggs_beta/oracle/bt01pims/ggs/dirprm/mgr.prm REPORTFILE
```

Report file:

```
/base/ggs_beta/oracle/bt01pims/ggs/dirrpt/MGR.rpt PROCESSID MGR
```

Permissions to run commands

Give the UNIX OS user permissions to run the following commands against the Oracle GoldenGate Server:

```
<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;privilege command&quot; + &quot;is -d &quot; + $rpt_base_dir + &quot;*.rpt</td>
<td>sort &quot;</td>
<td>Mandatory</td>
<td>List all report files under the Oracle GoldenGate report base directory.</td>
</tr>
<tr>
<td>&quot;privilege command&quot; + &quot;is -d &quot; + $prm_base_dir + &quot;*.prm</td>
<td>sort &quot;</td>
<td>Mandatory</td>
<td>List all parameter files under the Oracle GoldenGate parameter base directory.</td>
</tr>
</tbody>
</table>
```

Give the Windows OS user permissions to run the following commands against the Oracle GoldenGate Server:
## Retrieve data

Retrieve data by parsing:

- The Oracle GoldenGate manager report file (report_file) to retrieve related configuration item (CI) names and counter information.
- Variables in the process command line to retrieve the install folder, manager process name, configuration file, and parameters file.
- Variables in the Oracle GoldenGate installation folder to retrieve a list of parameter and configuration files.

### EVAL closure functions

Use the following EVAL closure functions to remove duplicate entries from the extract process and the replicat process.

- var tableWithoutDuplicates = ";tableWithoutDuplicates = DuplicateRemover.removeDuplicates(${extracts},("name");CTX.setAttribute("extracts", tableWithoutDuplicates);
- var tableWithoutDuplicates = ";tableWithoutDuplicates = DuplicateRemover.removeDuplicates(${replicats},("name");CTX.setAttribute("replicats", tableWithoutDuplicates);

Use the following EVAL closure functions to count the number of extract processes and replicat processes.

- return ${cmdb_ci_appl_ora_gg_replicat(*).config_file}.size()
- return ${cmdb_ci_appl_ora_gg_extract(*).config_file}.size()

Use the following EVAL closure function to return the privileged command.

- return $(ctx).getDiscoveryProvider(com.snc.sw.dto.ProviderType.SSH).getPrivilegedCommand();

Use the following EVAL closure function to return the discovery type.

- ctx.getWork().getDiscoveryType();

Use the following EVAL closure function to extract the version from the installation directory path if it is empty.

- inst_dir = ${install_directory}if(inst_dir.isEmpty()){return ${version}}if(inst_dir.startsWith(©/©)){return inst_dir.replaceAll(©/.*/©,'')}if(!inst_dir.startsWith(©/©) && !inst_dir.isEmpty()){return inst_dir.replaceAll(©.*\\©,'')}  

### Applicative credentials

© 2020 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
1. Navigate to Discovery > Credentials.
2. Click New.
3. Click Applicative Credentials.
4. On the form, fill in the fields.

**Applicative Credentials form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Credential name. An example is oracle_db_user.</td>
</tr>
<tr>
<td>Active</td>
<td>Option for enabling this credential for discovery. Select this check box to enable discovery.</td>
</tr>
<tr>
<td>Applies to</td>
<td>Credentials that you may or may not want to apply to All MID servers in your network, or to one or more Specific MID servers. Select Specific MID servers.</td>
</tr>
<tr>
<td>MID Servers</td>
<td>MID Servers that the credentials apply to. Select the required MID Server. This field appears when Specific MID servers is selected from the Applies to field.</td>
</tr>
<tr>
<td>Order</td>
<td>Order in which the platform tries this credential as it attempts to log on to devices. A smaller number indicates that the credential appears higher in the list. Establish the credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number, or none, the instance tries the credentials in a random order. The default value is 100.</td>
</tr>
<tr>
<td>User name</td>
<td>Name of the user of this applicative credential. An example is oracle_db_user. You can use any user for the credential for this pattern, because the information is extracted from a local cache.</td>
</tr>
<tr>
<td>Password</td>
<td>Not required. You can leave this field blank or enter any value.</td>
</tr>
<tr>
<td>CI type</td>
<td>CI type for which this credential is used: Storage Server (cmdb_ci_storage_server).</td>
</tr>
</tbody>
</table>

**Note:** ServiceNow applications refer to devices and applications that comprise an application service as configuration items (CIs).

5. Click Submit.

**Entry point**

For top-down discovery, use the Oracle GoldenGate IP address and specify the MID Server.
Data collected by Discovery during horizontal discovery

Discovery uses the Oracle GoldenGate pattern to collect the data described in the following table.

<table>
<thead>
<tr>
<th>Table and field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Main CI cmdb_ci_appl_oracle_golden_gate</td>
<td>Name (name) Name of the CI in the CMDB (&lt;process name&gt;@&lt;source db&gt;).</td>
</tr>
<tr>
<td></td>
<td>Version (version) Version of the Oracle GoldenGate installation.</td>
</tr>
<tr>
<td></td>
<td>Source DB (source_db) Manager process source database system identifier (SID).</td>
</tr>
<tr>
<td></td>
<td>Replicats count (count_replicat) Counter of replicat processes that are managed by the Oracle GoldenGate manager instance.</td>
</tr>
<tr>
<td></td>
<td>Extracts count (count_extract) Counter of extract processes that are managed by the Oracle GoldenGate manager instance.</td>
</tr>
<tr>
<td></td>
<td>Configuration file (config_file) Parameter file of the Oracle GoldenGate process. Specify the path to the configuration file and the file name, &lt;name&gt;.prm</td>
</tr>
<tr>
<td></td>
<td>Replicat File (report_file) Report file of the Oracle GoldenGate replicat process. Specify the path to the report file and the file name, &lt;name&gt;.rpt</td>
</tr>
<tr>
<td></td>
<td>Type (type) Type of the Oracle GoldenGate installation. Specify the Oracle GoldenGate for Oracle technologies.</td>
</tr>
<tr>
<td></td>
<td>Installation directory (install_directory) Folder that contains all the Oracle GoldenGate setup, configuration, libraries, and executable files.</td>
</tr>
<tr>
<td>Related CI cmdb_ci_appl_ora_gg_replicat</td>
<td>Name (name) Name of the CI in the CMDB (&lt;process name&gt;@&lt;source db&gt;).</td>
</tr>
<tr>
<td></td>
<td>Replicat file (report_file) Replicat process report file. Specify the path to the report file and the file name &lt;name&gt;.rpt</td>

Pivotal Cloud Foundry discovery

Discovery finds Pivotal Cloud Foundry (PCF) version 2.4 components using the Pivotal Cloud Foundry pattern.

You can use this pattern on the Now Platform using Kingston, London, or Madrid.

Prerequisites

Cloud Foundry credentials

Create the Cloud Foundry credentials.

1. Navigate to Discovery > Credentials.
2. Click New.
3. Click CloudFoundry Credentials.
4. On the form, fill in the fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Credential name. As an example, pcf_user credentials</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Active</td>
<td>Option for enabling this credential for discovery. Select this check box to enable discovery.</td>
</tr>
<tr>
<td>Applies to</td>
<td>Credentials that you may or may not want to apply to All MID servers in your network, or to one or more Specific MID servers. Select Specific MID servers.</td>
</tr>
<tr>
<td>Order</td>
<td>Order in which the platform tries this credential as it attempts to log on to devices. A smaller number indicates that the credential appears higher in the list. Establish the credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number, or none, the instance tries the credentials in a random order. The default value is 100.</td>
</tr>
<tr>
<td>User name</td>
<td>Name of the user of these credentials. Avoid leading or trailing spaces in user names. A warning appears if the platform detects leading or trailing spaces in the user name. An example is pcf_user. Use the client_id that is used to generate the JWT token.</td>
</tr>
<tr>
<td>Password</td>
<td>Password for the user of these credentials. Use the client_secret that is used to generate the JWT token.</td>
</tr>
<tr>
<td>Credential alias</td>
<td>Alternate name for these credentials. As an example, cf If this field is closed, click the unlock icon to unlock the field.</td>
</tr>
</tbody>
</table>

5. Click Update.

### JSON web token credentials

To verify the JSON web token (JWT), perform the following token validation steps.

The format of the JWT token is: [https://docs.cloudfoundry.org/api/uaa/version/4.27.0/index.html#jwt-bearer-token-grant](https://docs.cloudfoundry.org/api/uaa/version/4.27.0/index.html#jwt-bearer-token-grant)

1. Run the following cURL script against the User Account and Authentication (UAA) server API and verify the results:

   ```bash
   ```

   - If this command does not generate a token, verify that the credentials in the ServiceNow repository are correct, otherwise go to step 2.

2. Run the following cURL script against Pivotal Cloud Foundry API:

   ```bash
   ```
If this command does not retrieve the PCF spaces information, verify the credentials on the ServiceNow credentials repository.

**Credentials for V2 API elements**

Provide a read only user with permission to use the following API elements:

- `~/v2/organizations`
- `~/v2/info`
- `~/v2/spaces`
- `~/v2/domains`
- `~/v2/routes`
- `~/v2/quota_definitions`
- `~/v2/space_quota_definitions`
- `~/v2/apps`

**Create a serverless Discovery schedule**

1. Navigate to **Discovery > Discovery Schedules**.
2. Click **New**.
3. On the form, fill in the fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a unique and descriptive name for this Discovery schedule, for example, pcf</td>
</tr>
<tr>
<td>Discover</td>
<td>For the Discover type, select <strong>Serverless</strong></td>
</tr>
<tr>
<td>MID Server</td>
<td>MID Servers that the credentials apply to. Specify the required MID Server, for example, Discovery_Server</td>
</tr>
<tr>
<td>Active</td>
<td>Option for enabling this credential for discovery. Select this check box to enable discovery.</td>
</tr>
<tr>
<td>Credential alias</td>
<td>Alternate name for these credentials. Use the alias associated with the Pivotal Cloud Foundry credentials you created earlier.</td>
</tr>
</tbody>
</table>

4. Right-click the header of the Discovery Schedule form and select **Save**.
5. Click the Serverless Execution Patterns tab.
6. Click New.
7. On the form, fill in the fields:

   **Serverless Execution Pattern form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a unique and descriptive name for this Serverless Execution Pattern, for example, pcf1</td>
</tr>
<tr>
<td>Pattern</td>
<td>Select CloudFoundry</td>
</tr>
<tr>
<td>Proxy Host</td>
<td>Fully qualified domain name of the machine on which you are installing the proxy server. Specify Global.</td>
</tr>
<tr>
<td>Active</td>
<td>Check box to enable this schedule for discovery. Select this check box.</td>
</tr>
</tbody>
</table>

8. Right-click the header of the Serverless Execution Patterns form and select Save.
9. Click the Serverless Execution Patterns tab
10. Create and define the serverless execution pattern as described in the product documentation.
    Configure the parameters required by the Cloud Foundry pattern as follows:

   **Discovery Pattern Launcher parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Organization</td>
<td>Name of the organization that is required to be discovered, or all where the input is &quot;*&quot;.</td>
</tr>
<tr>
<td>CredentialAlias</td>
<td>Alternate name for these credentials. Use the alias associated with the Cloud Foundry credentials you created earlier.</td>
</tr>
<tr>
<td>URL_CF</td>
<td>API URL of the Cloud Controller that is used to retrieve the information from Cloud Foundry.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>URL_CF_AUTH</td>
<td>UAA server API that is used to generate the token. Enter the value in the format: <a href="https://uaa.sys.dev.phx.pcf.example.com/oauth/token">https://uaa.sys.dev.phx.pcf.example.com/oauth/token</a></td>
</tr>
</tbody>
</table>

### 11. Update

To start discovery, navigate to the Serverless Discovery definition and click **Discover Now**.

### EVAL closure functions

Use the following EVAL closure functions to concatenate all organizations with “,” as a separator.

```javascript
var rtrn = ''; 
var organizations = ${organizations[*].name};
var beforeReturn = ''; 
var separator = ''; 
for (var i = 0; i < organizations.size(); i++)
{
    beforeReturn += separator + organizations.get(i);
    separator = ',';
} 
rtrn = beforeReturn;
```

Use the following EVAL closure functions to return 1 if the operational status is active and 2 if it is not active.

```javascript
var rtrn = ''; 
var currentOrgStatus = ${organizations[*].operational_status};
var status = currentOrgStatus.toLowerCase();
if(status == "active")
{
    rtrn = "1";
}
else {
    rtrn = "2";
}
```

Use the following EVAL closure function to return 1 if the operational status is started and 2 if it is not started.

```javascript
var rtrn = ''; 
var currentAppStatus = ${apps[*].state};
var status = currentAppStatus.toLowerCase();
if(status == "started")
{
    rtrn = "1";
}
else {
    rtrn = "2";
}
```

### CloudFoundry Get Call

The CloudFoundry Get Call custom operation handles the generation of tokens. It uses the credentials and URL_CF_AUTH context variable to generate a token that is used to create API calls.
When a token is generated, the URL_CF is used to create the API calls defined in the **Resource** field. The custom operation also handles pagination where the response has more than one page.

CloudFoundry Get Call parses the input JSON to populate the tables and variables.

**Data collected by Discovery during horizontal discovery**

**Entry point**

For top-down discovery, use the Cloud Foundry IP address of the Cloud Foundry host and specify the MID Server.

**Pure Storage FlashBlade discovery**

Discovery uses the FlashBlade Pure Storage pattern to find FlashBlade components.

Discovery can find Pure Storage FlashBlade version 4.

You can use this pattern on the Now Platform using Jakarta Patch 9, Kingston Patch 5, London, or Madrid.

**Prerequisites**

**SSH credentials**

On the Now Platform®, configure a user for accessing the Unix OS.

**Applicative credentials**
On the Now Platform®, configure applicative credentials as follows:

- Define the OS use with permissions to run the following commands:

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pureman</td>
<td>-</td>
<td>Mandatory</td>
<td>Accesses the list of pure storage commands and uses them for classification.</td>
</tr>
<tr>
<td>Echo</td>
<td>$username$</td>
<td>Mandatory</td>
<td>Fills in the username for the temporary variable.</td>
</tr>
<tr>
<td>&quot;pureadmin list&quot;</td>
<td>+ $usr + ' --api-token --expose --csv&quot;</td>
<td>Mandatory</td>
<td>Gets the user API token to generate the x-auth for the REST call commands.</td>
</tr>
</tbody>
</table>

This OS user must also have permissions to run the following REST API calls:

- `/api/login` – Gets the x-auth token reader from the response in Groovy.
- `/api/1.2/file-systems` – Retrieves information about the file systems.
- `/api/1.2/blades` – Retrieves information about blades.
- `/api/1.2/dns` – Retrieves information about DNS.
- `/api/1.2/hardware` – Retrieves information about the storage hardware.
- `/api/1.4/network-interfaces` – Retrieves information about network interfaces.

- Enter any value for the password or leave it empty. This password is not relevant.

**Access to the port used for REST calls**

On relevant MID Servers, provide a user with access to the port used for REST calls.

**Data collected by Discovery during horizontal discovery**

<table>

</tr>
<tr>
<td>Storage server (cmdb_ci_storage_server)</td>
<td>Contains: Contained by</td>
<td>Pure Storage Processor (cmdb_ci_storage_processor_pure)</td>
</tr>
</tbody>
</table>

Red Hat JBoss Fuse discovery

Discovery and Service Mapping can find and map the Fuse application server using the JBoss Fuse pattern.

Prerequisites

Credentials
Configure SSH credentials in the Credentials module of the ServiceNow platform for accessing the server hosting the Fuse server.

**User**

Provide a user with the read rights for accessing the following directories:

- `$install_directory + "/readme.txt"
  
  Access to this directory allows getting version information.
- `/etc/services`
  
  Access to this directory allows reading the hosts service definition.

**Data collected by Discovery during horizontal discovery**

<table>
<thead>
<tr>
<th>Table and Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Jboss Fuse (cmdb_ci_appl_jboss_fuse)</td>
<td>The configuration directory of the Fuse server.</td>
</tr>
<tr>
<td>config_directory</td>
<td>The configuration file of the Fuse server.</td>
</tr>
<tr>
<td>config_file</td>
<td>The installation folder of the Fuse server.</td>
</tr>
<tr>
<td>install_folder</td>
<td>The version of the Fuse server.</td>
</tr>
<tr>
<td>version</td>
<td>The name configured for the Fuse server during installation.</td>
</tr>
</tbody>
</table>

**Data collected by Service Mapping during top-down discovery**

Service Mapping discovers the connection between the JBoss Fuse server and the IBM Informix Dynamic server.

**SAP System ID discovery**

An SAP System Identification code (SID) is a unique identification code for an SAP R/3 installation. An SID is a three-character code like D10, PRD, or E56. An R/3 installation consists of a database server plus several application servers. The SAP System ID pattern is a ServiceNow Store app. For details on system requirements, view the application listing on the ServiceNow Store website.

**Get the app on the ServiceNow Store**

Visit the ServiceNow Store website to get the app.

**Prerequisites**

Google Cloud Platform patterns work with Cloud Management. The Cloud Management application is available as a separate subscription and requires the Cloud Management plugin (com.snc.cloud.mgmt). Use your current Cloud Management instance or request a subscription from your sales representative.

Other prerequisites are the same as for discovery of the SAP application.
Components

Each SAP pattern app (CI, DI, JC, ASCS, SCS, and ERS) creates relations to the SAP SID CI `cmdb_ci_sap_sid` based on its version and SID name. If such a CI doesn't exist in the CMDB, the app also creates the SAP SID CI.

Horizontal discovery creates a new CI for each app. The SID name and version show which SAP app is related to which R/3 installation. The relationship to `cmdb_ci_sap_sid` is shown for each SAP application CI.

CI relationships

Connections discovered by Service Mapping during the top-down discovery

The CI of Storage Server should be discovered: `cmdb_ci_sap_sid`. Populated attributes: Name - SAP SID name Version – SAP SID version
Example

![Diagram of SAP systems](image)

Veritas Cluster Server

Discovery uses the Unix Cluster – VERITAS Cluster pattern to find Veritas Cluster Server components. You can use this pattern on the Now Platform using Kingston Patch 8, London, or Madrid.

Prerequisites

**SSH credentials**

On the Now Platform®, configure the SSH credentials for a user with elevated rights for running the `cat` command. For more information about commands, see Service Mapping commands requiring a privileged user under Service Mapping documentation.

**Permissions to read the Veritas Cluster Server configuration file**

Give the Unix OS user permissions to read the following configuration file: `/etc/VRTSvcs/conf/config/main.cf`.

**Permissions to run Veritas Cluster commands**

Give the Unix OS user permissions to run the following commands against the Veritas Cluster Server:

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Mandatory/Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;privilege user&quot; + <code>cat /etc/VRTSvcs/conf/config/main.cf</code></td>
<td>-</td>
<td>Mandatory</td>
<td>Read the Veritas Cluster Server configuration file.</td>
</tr>
<tr>
<td>Command</td>
<td>Parameter</td>
<td>Mandatory/Optional</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-----------</td>
<td>-------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>&quot;privilege user&quot; + /opt/VRTSvcs/bin/haclus -value ClusterUUID 2&gt;/dev/null</td>
<td>-</td>
<td>Mandatory</td>
<td>Get the Veritas Cluster Server cluster UUID.</td>
</tr>
<tr>
<td>&quot;privilege user&quot; + /opt/VRTSvcs/bin/haclus -value ClusterName 2&gt;/dev/null</td>
<td>-</td>
<td>Mandatory</td>
<td>Get the Veritas Cluster Server cluster name.</td>
</tr>
<tr>
<td>&quot;privilege user&quot; + /opt/VRTSvcs/bin/haclus -value EngineVersion</td>
<td>-</td>
<td>Mandatory</td>
<td>Get the Veritas Cluster Server cluster version.</td>
</tr>
<tr>
<td>&quot;privilege user&quot; + /opt/VRTSvcs/bin/haclus -value ClusterAddress</td>
<td>-</td>
<td>Mandatory</td>
<td>Get the Veritas Cluster Server cluster address.</td>
</tr>
<tr>
<td>&quot;privilege user&quot; + /opt/VRTSvcs/bin/haclus -value ClusState</td>
<td>-</td>
<td>Mandatory</td>
<td>Get the Veritas Cluster Server cluster status.</td>
</tr>
<tr>
<td>&quot;privilege user&quot; + /opt/VRTSvcs/bin/hares -state</td>
<td>-</td>
<td>Mandatory</td>
<td>Get the cluster resources of the Veritas Cluster Server.</td>
</tr>
<tr>
<td>&quot;privilege user&quot; + /opt/VRTSvcs/bin/hares -display</td>
<td>-</td>
<td>Mandatory</td>
<td>Get the cluster resource type of the Veritas Cluster Server.</td>
</tr>
<tr>
<td>&quot;privilege user&quot; + /opt/VRTSvcs/bin/hares -display</td>
<td>-</td>
<td>Mandatory</td>
<td>Get the cluster resource group of the Veritas Cluster Server.</td>
</tr>
<tr>
<td>&quot;privilege user&quot; + /opt/VRTSvcs/bin/hagrp -state</td>
<td>-</td>
<td>Mandatory</td>
<td>Get the resource group name and status of the Veritas Cluster Server.</td>
</tr>
</tbody>
</table>

**Classification probe for triggering the UNIX Cluster – VERITAS Cluster pattern**

Verify that the classification probe is set to trigger the UNIX Cluster – VERITAS Cluster pattern:

1. Navigate to **Discovery Definition > CI Classification > CI Classification > UNIX**.
2. In the **UNIX Classification** list, click **Solaris** or **Linux**.
3. On the **Triggers probes** tab, check that the **HorizontalDiscoveryProbe-HorizontalPatt** probe is assigned to the **UNIX Cluster – VERITAS Cluster** pattern.
Note: The discovery log shows the error for OS discovery step even if the discovery finished successfully.

System property for the new host class

Add a system property (sys_property) `sa.host_classes` and set the value to `cmdb_ci_unix_cluster`. Creating a new host class for Veritas Cluster servers helps to identify this type of hosts correctly.
Limitations

You cannot customize the Unix Cluster – VERITAS Cluster pattern in the Debug mode in the Pattern Designer.

Data collected by Discovery during horizontal discovery

<table>
<thead>

CI relationships

The Unix Cluster – VERITAS Cluster pattern creates the following CI relationships:

<table>
<thead>
<tr>
<th>CI</th>
<th>Relationship</th>
<th>CI</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unix Cluster <em>(cmdb_ci_unix_cluster)</em></td>
<td>Hosts: Hosted on</td>
<td>Linux Server <em>(cmdb_ci_linux_server)</em></td>
</tr>
<tr>
<td>Unix Cluster Node <em>(cmdb_ci_unix_cluster_node)</em></td>
<td>Hosts: Hosted on</td>
<td>Linux Server <em>(cmdb_ci_linux_server)</em></td>
</tr>
<tr>
<td>Cluster Virtual IPs <em>(cmdb_ci_cluster_vip)</em></td>
<td>Virtualized by: Virtualized</td>
<td>Unix Cluster <em>(cmdb_ci_unix_cluster)</em></td>
</tr>
<tr>
<td>Cluster Virtual IPs <em>(cmdb_ci_cluster_vip)</em></td>
<td>Uses: Used by</td>
<td>Unix Cluster Node <em>(cmdb_ci_unix_cluster_node)</em></td>
</tr>
</tbody>
</table>
Create CI types for Service Mapping and Discovery

Create CI types (or CI classes) for applications and devices, which Service Mapping and Discovery do not support by default.

Verify that there is no existing CI type for this application or device.

Role required: sm_admin, personalize_dictionary, or admin

All applications and hosts in your organization must have a corresponding configuration item (CI) type, which is necessary for discovering and processing applications and hosts correctly.

A wide range of preconfigured CI types that cover most commonly used applications are available to you. If your organization uses a less known or proprietary application that does not have a corresponding CI type, you must create it.

A CI type is a generic notion that is used by several ServiceNow applications, but there are some attributes that are specific to Service Mapping and Discovery.

Note: Service Mapping user interface refers to CI classes as CI types.

A CI type (or class) contains several important definitions that apply to all CIs belonging to it, such as:

- CI attributes are added as fields to the CMDB tables.
- Identifiers help Service Mapping and Discovery to differentiate between new and existing CIs. For example, if there is an Apache Web Server CI type defined in the CMDB, and Service Mapping and Discovery both discover an Apache Web Server CI, it processes it using identifiers. It then recognizes it as an updated version of the Apache Web Server CI that already exists in the system, not a new Apache Web Server CI.
- Related items, both CIs and non-CIs, serve as a reference and provide additional information about the CI. For example, you can define a serial number, a port and an network ARP table as related items for a hardware server. The system does not use these items for identification. After you configure related items for the CI type, you can use horizontal discovery for CIs of this type together with their related items. For information, see Discover related items together with the main CI.

Note: Non-CIs are items that do not extend the Configuration Item (cmdb_ci) table. Examples of non-CIs are ports, serial numbers, or Network ARP tables.
• There are reconciliation rules that help the ServiceNow platform to consolidate CI attributes received from different applications correctly. These rules are necessary for organizations where more than one application participates in the discovery process. Reconciliation rules define how attributes of the same CI discovered by different discovery sources are merged. For example, Service Mapping discovers the version and home directory attributes of an Apache Web Server CI, while Discovery discovers the version and patch level attributes for the same Apache Web Server CI. The Now Platform applies the reconciliation rule and as a result Service Mapping does not overwrite the attributes found by Discovery.

• CMDB stores CI class in the form of a hierarchy where some CI classes are parents to other CI classes, who automatically derive their parent's attributes in addition to attributes you configure specifically for child CI classes. CI class hierarchy is used widely for configuring CI behavior, relationships, and display. In this example, the Apache Web Server CI is a child of the Web Server CI and derives many attributes from its parent, such as name, version, model ID. By default, child CI classes inherit identifiers from their parent CI classes.

In addition to these CI type definitions, the horizontal discovery process uses a CI classification to define to which CI type a CI belongs. Create a device CI classification if you create a CI type for devices using SNMP and a process CI classification for an application CI type.

1. Navigate to Configuration > CI Class Manager.
2. To use an existing CI type as a parent for the new CI type, click Hierarchy to display the CI Classes list. Click the context menu for the required CI type and select Add Child Class.
3. Create a table to store the CI type attributes:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Label</td>
<td>CI type name. For example, Apache Web Server.</td>
</tr>
<tr>
<td>Name</td>
<td>The table name. For example, cmdb_ci_apache_web_server. Use a name similar to</td>
</tr>
<tr>
<td></td>
<td>the other CMDB classes (for example, u_cmdb_ci_laptop).</td>
</tr>
</tbody>
</table>
### Field

**Extends table**

The table name of the parent CI type. All CI types are extensions of the Configuration Item (cmdb_ci) table or its child tables. For example, if the new class is Laptops, which is a subclass of Computers, select the cmdb_ci_computer table. If the new class is a top-level class, select the cmdb_ci table.

The most commonly used parent CI types are:
- cmdb_ci - basic
- cmdb_ci_database - for databases
- cmdb_ci_app_server - for application servers
- cmdb_ci_infra_service - for infrastructure services
- cmdb_ci_endpoint_inclusion - for entry points of the inclusion type
- cmdb_ci_appl - for applications
- cmdb_ci_web_server - for web servers
- cmdb_ci_lb - for load balancers
- cmdb_ci_endpoint - for entry points

---

4. Configure how the instance determines if a discovered CI is an upgraded CI existing in the instance or a brand new CI. See [Create or edit a CI identification rule](#) for detailed procedure.

**Warning:** If there is no CI identification rule for a CI type, Service Mapping discovers CIs belonging to this type, but cannot interpret the results of the discovery process. In this case, the Now Platform rejects the discovery results for these CIs and their information is not updated.

a) On the **Identifiers** page, configure the parameters as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Use a meaningful name.</td>
</tr>
<tr>
<td>Applies to</td>
<td>Enter the CI type.</td>
</tr>
<tr>
<td>Active</td>
<td>Select the check box.</td>
</tr>
<tr>
<td>Independent</td>
<td>Clear the check box.</td>
</tr>
</tbody>
</table>

b) Configure the identifier entry parameters as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Criterion attributes</td>
<td>Select the attribute that you want to use for identifying the CI. For example, <strong>Class</strong>, <strong>Installation directory</strong>, or <strong>Serial number</strong>.</td>
</tr>
<tr>
<td>Allow null attribute</td>
<td>Select the check box.</td>
</tr>
</tbody>
</table>
5. Optional: Configure references to other CIs or non-CIs as related items for the CI type.

**Related Entry form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identifier</td>
<td>The CI identifier for which this related entry belongs to. By default it is set to the identifier you previously selected.</td>
</tr>
<tr>
<td>Related table</td>
<td>A related table that references the CI that is being matched.</td>
</tr>
<tr>
<td>Referenced field</td>
<td>A referenced field in Related table that should store the referenced CI. This field always references the cmdb_ci table, or a descendent of the cmdb_ci table.</td>
</tr>
<tr>
<td>Criterion attributes</td>
<td>The set of attributes to uniquely identify the related item. Attributes can belong to the current class, or to a parent class. Click the lock icon to view, add, or remove attributes from the identification rule.</td>
</tr>
<tr>
<td>Optional condition</td>
<td>Use the Add Filter Condition and the Add “OR” Clause buttons to construct a filter to narrow the set of records that will be searched for a matching related item.</td>
</tr>
<tr>
<td>Active</td>
<td>Check box that specifies that the related entry is active.</td>
</tr>
<tr>
<td>Allow null attribute</td>
<td>If at least one criterion attribute in the related table is not null, allow to attempt matching with an identifier entry even if there are criterion attributes which are null.</td>
</tr>
<tr>
<td>Priority</td>
<td>Priority of the related entry for the specified Related table. Rules with lower priority numbers are given higher priority while matching a related item for specific related table. Related entries for the specified related table with identical priorities are applied randomly. You can keep gaps between the priority numbers, so you can assign the unused priority numbers to new entries without modifying the existing priority order.</td>
</tr>
</tbody>
</table>

6. Optional: Configure the instance to consolidate CI attributes received from different data sources correctly. See [Create or edit a CI reconciliation rule](#).

Configure the following Service Mapping-related parameters correctly:
Create entry point types for Service Mapping

An entry point is how clients access an application service. If necessary, you can create a new entry point type in addition to preconfigured entry point types in Service Mapping.

If your ServiceNow instance uses domain separation and you have access to the global domain, select the domain to which the application service belongs from the domain picker. The selected domain must be a domain without any child domains.

Role required: sm_admin or admin

Service Mapping starts the discovery and mapping process for every application service from the entry point you define for it. In addition to this, Service Mapping patterns use entry points to discover CI outbound connections.

Service Mapping includes a wide range of preconfigured entry point types that cover most commonly used applications. If your organization uses a less known or proprietary application that does not have a corresponding entry point type in Service Mapping, you must create it.

Entry points are modeled in the ServiceNow CMDB as CIs of endpoint type. Entry points are stored as records in the Endpoint (cmtb_ci_endpoint) tables.

Like any other CI type, an entry point contains several important definitions that apply to all CIs belonging to it:

- CI attributes are added as fields to the CMDB tables.

---

Note: If you do not create a CI reconciliation rule, data discovered by patterns is used to update CI attributes.

7. Configure the CI classification for your CI type:
   - For CI types representing applications, perform configuration as described in Create a Discovery process classification.
   - For CI types representing SNMP devices, perform configuration as described in Create a Discovery CI classification.

Note: There is no need to create CI classifications for hosts because these classifications are included in the base system.

8. For CI types that represent inclusions, define the hierarchy for the new CI type. Clear the Reverse Relationship Direction check box while performing this configuration. See Create dependent relationships.

9. If necessary, customize icons that represent CIs in maps. See Create or modify map icons.

---

**ServiceNow Definition form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source</td>
<td>Select ServiceWatch.</td>
</tr>
<tr>
<td>Applies to</td>
<td>Select the relevant CI type.</td>
</tr>
<tr>
<td>Optional condition</td>
<td>Set a condition if necessary.</td>
</tr>
</tbody>
</table>

© 2020 ServiceNow, Inc. All rights reserved.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
Identifiers help Service Mapping and Discovery to differentiate between new and existing CIs. For example, if there is an Active Directory Forest endpoint CI type defined in the CMDB, and Service Mapping discovers an Active Directory Forest CI, it processes it using identifiers and recognizes it as an updated version of the Active Directory Forest CI that exists in the system, not a new Active Directory Forest CI. Unlike with regular CI types, identifiers for new endpoint CI types are created automatically.

CI type hierarchy. CMDB stores CI class in the form of a hierarchy where some CI classes are parents to other CI classes, who automatically derive their parent's attributes in addition to attributes you configure specifically for child CI classes. CI class hierarchy is used widely for configuring CI behavior, relationships, and display. Create standard entry points as child CIs for the endpoint CI type, which creates an extension for the cmdb_ci_endpoint table. For entry points of inclusion type create child CIs for the inclusion endpoint CI type extending the cmdb_ci_endpoint_inclusion table. In an inclusion, a server hosts applications that are treated as independent objects.

1. Navigate to Configuration > CI Class Manager.
2. To create a standard entry point, right-click Endpoint from the Class Hierarchy pane and select Add Child Class.
3. To create an entry point of the inclusion type, right-click Inclusion Endpoint from the Class Hierarchy pane and select Extend.
4. Create an entry point type using the following parameters.
   See Create a table.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Label</td>
<td>Entry point type name. For example, HTTP entry point.</td>
</tr>
<tr>
<td>Name</td>
<td>The table name. For example, cmdb_ci_endpoint_http.</td>
</tr>
<tr>
<td>Extends table</td>
<td>The table name of the parent CI type is automatically filled by the system:</td>
</tr>
<tr>
<td></td>
<td>• cmdb_ci_endpoint - for entry points</td>
</tr>
<tr>
<td></td>
<td>• cmdb_ci_endpoint_inclusion - for entry points of the inclusion type</td>
</tr>
</tbody>
</table>

5. Add entry point attributes on the Columns tab at the bottom of the page.
   By default the new entry point derives attributes from its parent CI, but you can modify the attributes as necessary.
6. Click Submit.

Create or modify patterns

Create or modify a discovery pattern and define its basic attributes.

Make sure that the application for which you want to create a pattern, has a corresponding configuration item (CI) type and a CI classification. If the CI type you require is not in the list, create it as described in Create CI types for Service Mapping and Discovery.
If your ServiceNow instance uses domain separation and you have access to the global domain, select the domain to which the application service belongs from the domain picker. The selected domain must be a domain without any child domains.

Role required: pd_admin

Basic knowledge of programming is desirable.

Patterns can be of infrastructure or application type. Infrastructure patterns are used only by Discovery for creating lists of devices. Application patterns serve both Service Mapping and Discovery that use the same application patterns for their purposes.

1. Navigate to Pattern Designer > Discovery Patterns.
2. Click New or select the relevant pattern from the list.
3. Define the basic pattern attributes on the Basic tab.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Pattern type</strong></td>
<td>Select <strong>Application</strong> for an application pattern. It can be used both for top-down discovery performed by Service Mapping and horizontal discovery performed by Discovery. Select <strong>Infrastructure</strong> for an infrastructure pattern used for the horizontal host discovery performed by Discovery.</td>
</tr>
<tr>
<td><strong>Name</strong></td>
<td>Enter the pattern name. This name must be unique to this pattern. Use self-explanatory names such as Apache on Unix pattern.</td>
</tr>
<tr>
<td><strong>CI type</strong></td>
<td>Select the <strong>CI type</strong> which you want this pattern to discover.</td>
</tr>
<tr>
<td><strong>Operating system</strong> (Application patterns only)</td>
<td>Select the operating system that the selected CI runs: Click <strong>All</strong> if the CI runs on more than one operating system. Or Select the relevant operating systems from the list.</td>
</tr>
</tbody>
</table>

### Field Description

**Run Order (Application patterns only)**

For an application pattern used by Service Mapping, select the order in which this pattern always runs:
- **Before**
- **After**

Then select the other applicable pattern. This field is only relevant if a particular pattern can be confused with another pattern.

For example, both IIS and MS Exchange applications have an HTTP entry point. However, MS Exchange uses some of the components of IIS. Therefore, if the IIS pattern ran first, discovery might incorrectly identify MS Exchange as IIS. To prevent this error, in the **Run Order** field in the MS Exchange pattern definition, select **Before** and **IIS**.

**Description**

Provide a description for this pattern.

---

4. (For application patterns only) To make the MID Server run this pattern only if the process identified on a CI matches the classification criteria for this pattern, select **Enforce Process Classification**.

All simplified patterns created from generic applications have this attribute enabled. For more information about creating process classification, see [Discovery classifiers](#).

5. Define a set of identification steps for every incoming connection of a configuration item (CI).
   
a) In the **Identification Section**, click **New** and then configure the following parameters:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Unique name for the identification section.</td>
</tr>
<tr>
<td>Entry Point Types (Application patterns only)</td>
<td>Select all relevant entry point types. Every CI has incoming connections that are referred to in Pattern Designer as entry points. You base your CI identification process on the CI entry points creating steps and defining step operations and variables for every entry point separately. For application patterns used by Discovery, enter either <strong>TCP</strong> or <strong>All</strong>.</td>
</tr>
</tbody>
</table>
## Field

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Find Process Strategy (Application patterns only)</td>
<td>Select the appropriate strategy for finding the process that populates the Process variable in the Temporary Variables table.</td>
</tr>
<tr>
<td></td>
<td>· <strong>Listening Port</strong>: The entry point is the listening port.</td>
</tr>
<tr>
<td></td>
<td>· <strong>Target Port and IP</strong>: The entry point port communicates with another server.</td>
</tr>
<tr>
<td></td>
<td>· <strong>None</strong>: The process variable is not populated.</td>
</tr>
<tr>
<td></td>
<td>Typically, the port type of the entry point determines the strategy.</td>
</tr>
<tr>
<td>Order</td>
<td>Select a number that determines the order in which Service Mapping or Discovery use identification sections. The section with the lowest order number is used first.</td>
</tr>
</tbody>
</table>

b) Click **Save**.

c) Click the identification section name.

d) Define discovery steps as described in [Define discovery steps](#).

e) Click **Save**.

6. If necessary, create more identification sections.

7. Save the pattern.

- For application type patterns, continue with [Define the connection section](#).

### Define discovery steps

For each Identification Section and Connection Section entry that you added to the discovery pattern, define discovery steps. These steps are the basis for discovery.

Role required: pd_admin

You can choose to define these steps immediately after adding an Identification or Connection section, or you can choose to do it after adding all Identification and Connection sections.

Define an operation for every step. The type of operation dictates which parameters and variables need to be configured.

1. On the pattern form, click the relevant entry in the Identification Sections or Connectivity Sections. **Connectivity Sections** is for Service Mapping only.

   The Pattern Designer opens showing the Steps tree on the left.

   If no discovery steps have been identified for this pattern, the Untitled Step appears in the Steps tree in the left pane of the window.
2. To add a new step:
   - Click 
     to add a step above the current step.
   - Click 
     to add a step below the current step.

3. Select an operation from the list and then fill in the fields that appear for the operation.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Objective</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change User</td>
<td>Use operating system credentials instead of the default administrative credentials.</td>
</tr>
<tr>
<td>Create Connection</td>
<td>Provide information about outgoing connections. This is for the connectivity section of a pattern that applies to Service Mapping only.</td>
</tr>
<tr>
<td>Filter Table</td>
<td>Filter a table according to specified criteria.</td>
</tr>
<tr>
<td>Find Matching URL</td>
<td>Find the best match for a URL in a list of URLs.</td>
</tr>
<tr>
<td>Get Registry Key</td>
<td>Query for registry keys.</td>
</tr>
<tr>
<td>Get Process</td>
<td>Search for a process according to specified criteria.</td>
</tr>
<tr>
<td>LDAP Query</td>
<td>Query an LDAP directory.</td>
</tr>
<tr>
<td>Library Reference</td>
<td>Combine a number of steps to be executed as a group.</td>
</tr>
<tr>
<td>Match</td>
<td>Match a condition and stop running the pattern if a condition is not met.</td>
</tr>
<tr>
<td>Merge Table</td>
<td>Merge two tables.</td>
</tr>
<tr>
<td>Parse Command Output</td>
<td>Extract information from the output of the command.</td>
</tr>
<tr>
<td>Parse File</td>
<td>Extract information from a file.</td>
</tr>
<tr>
<td>Parse a URL</td>
<td>Break down a URL into its components.</td>
</tr>
<tr>
<td>Operation</td>
<td>Objective</td>
</tr>
<tr>
<td>------------------------</td>
<td>---------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Parse Variable</td>
<td>Extract information from a variable.</td>
</tr>
<tr>
<td>HTTP Get Call</td>
<td>Extract information from devices using HTTP protocol.</td>
</tr>
<tr>
<td>Cloud Rest Call</td>
<td>Extract information from cloud computing devices like Microsoft Azure or Amazon Web Services</td>
</tr>
<tr>
<td>Create Relation/Reference</td>
<td>Create relationships and references between CIs that were discovered within the pattern.</td>
</tr>
<tr>
<td>Put File</td>
<td>Transfer a file to a remote system.</td>
</tr>
<tr>
<td>Run an SSH script file</td>
<td>Run composite commands or sequences of commands on Unix-based hosts.</td>
</tr>
<tr>
<td>Set a parameter value</td>
<td>Set the value of a parameter.</td>
</tr>
<tr>
<td>SNMP Query</td>
<td>Execute an SNMP query.</td>
</tr>
<tr>
<td>Transform Table</td>
<td>Add computed columns to an existing table.</td>
</tr>
<tr>
<td>Unchange User</td>
<td>Switch back to the default administrative credentials.</td>
</tr>
<tr>
<td>Union Tables</td>
<td>Append two tables that share the same format.</td>
</tr>
<tr>
<td>WMI Method Invocation</td>
<td>Execute a method using WMI (Windows Management Instrumentation).</td>
</tr>
<tr>
<td>WMI Query</td>
<td>Execute a WMI query.</td>
</tr>
</tbody>
</table>

If there are custom operations, which do not come with the base system, you can select a custom operation. For more information, see [Customize pattern operations](#).

4. Specify the following discovery step settings.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Precondition</td>
<td>Select this check box to add a specific criteria to the step. If the step is always performed as defined, leave this setting unchecked. For more than one condition, consider defining a step for each condition rather than multiple conditions. For more information, see <a href="#">Make a step conditional</a>.</td>
</tr>
<tr>
<td>CI Attributes</td>
<td>Table that is automatically populated with CI attribute variables that are generated when you add a CI type. This table does not support Container or Tabular variables. You can use shortcuts to enter values as described in <a href="#">Enter values and variables in patterns</a>. All variables are notated with a $ prefix and constants are formatted within double quotes. For more information, see <a href="#">Pattern variables</a>.</td>
</tr>
</tbody>
</table>
5. To add comments to any step, click the comment icon ( ), add the text in the comment text and click Post.

The comment icon changes to indicate that there is a comment associated with this pattern:

6. If in Debug mode, test the step by clicking Test and checking that the operation brings the result you expected.

7. To delete a step from the section, select the step and click the trash can icon.

8. After you define all steps, click Save.

9. On the pattern record, click Activate to make that pattern available for use.

Click Debug to access the additional actions and to browse to and open source files rather than looking them up separately.

**Enter values and variables in patterns**

There are several ways to enter values in Pattern Designer. You can use the following types of values in patterns: strings, variables, concatenated variables, and eval() functions. Do not use GlideRecords in patterns.

**Useful shortcuts in Pattern Designer**

<table>
<thead>
<tr>
<th>To enter this value</th>
<th>Follow these steps</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enter constant values, a string</td>
<td>Enclose the value in quote marks (&quot;),</td>
<td>Enter the path with quote marks (&quot; at the beginning and at the end of the string.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>To enter this value</th>
<th>Follow these steps</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enter a value that can change, a variable</td>
<td>Start the variable name with the dollar sign ($).</td>
<td>Enter the variable name beginning with the dollar sign ($).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Name: $process.pid</td>
</tr>
<tr>
<td>Enter a value that can change from a variable that contains several variables</td>
<td>Enter the variable name in the following format: $&lt;container_variable&gt;.&lt;variable&gt;</td>
<td>Enter the dollar sign ($), followed by process for the container variable name, period (.), and then pid for the name of the string variable.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Value: $process.pid</td>
</tr>
<tr>
<td>Enter a value from the specific field in a table</td>
<td>Enter the variable in the following format: $tabular_variable[row number].column_name</td>
<td>To use the value from the second row in the instanceID column from the IfTable variable, enter $IfTable[2].InstanceID.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>To enter this value</td>
<td>Follow these steps</td>
<td>Example</td>
</tr>
<tr>
<td>-----------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Enter values from a specific column in a table sequentially, starting from the current row</td>
<td>Enter the variable in this format: $tabular_variable().column_name</td>
<td>To use the value from the current row in the <strong>instanceID</strong> column from the <em>IfTable</em> variable, enter $IfTable[].InstanceID.</td>
</tr>
<tr>
<td>Enter values from a specific column in a table sequentially, starting from the first row</td>
<td>Enter the variable in this format: $tabular_variable(*).column_name</td>
<td>To use the value from the first row in the <strong>instanceID</strong> column from the <em>IfTable</em> variable, enter $IfTable[*].InstanceID.</td>
</tr>
</tbody>
</table>

*Note:* When used in **Match a condition** with the **Is Not Empty** operator, the system extracts values from fields, even if some fields are empty.
<table>
<thead>
<tr>
<th>To enter this value</th>
<th>Follow these steps</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Copy a value or a variable into a field</td>
<td>Select the variable or the value you want to copy from the CI Attribute pane and drag it into the target field.</td>
<td>Drag the <strong>company</strong> variable from the CI Attributes pane into the Values field.</td>
</tr>
<tr>
<td>To enter this value</td>
<td>Follow these steps</td>
<td>Example</td>
</tr>
<tr>
<td>--------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Enter a variable using auto-complete</td>
<td>1. Type the dollar character ($) and the first letters of the variable name.</td>
<td>Variables have a $ prefix. Typing $P in a field displays a list of possible values beginning with &quot;P&quot;.</td>
</tr>
<tr>
<td></td>
<td>2. Select the relevant value from the list showing all currently available values that match the characters you entered.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>If only one choice fits, that value is automatically entered into the field.</td>
<td></td>
</tr>
<tr>
<td>Specify complex (concatenated) values in fields</td>
<td>Enter a value, then add a plus sign (+), and then enter another value.</td>
<td>To specify the path, use the install_directory variable and extract of the actual path connected by a plus sign (+).</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> You can drag values and variables to create complex values.</td>
<td></td>
</tr>
<tr>
<td>To enter this value</td>
<td>Follow these steps</td>
<td>Example</td>
</tr>
<tr>
<td>-----------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Use the eval() function to evaluate a string in the field</td>
<td>1. Type <code>EVAL(</code> and click the edit button next to the field.</td>
<td>To use the eval() function for JavaScript serving as a parameter value, enter the script in the EVAL Script Editor window.</td>
</tr>
<tr>
<td></td>
<td>2. In the EVAL Script Editor window, ensure that the JavaScript mode is on or click Other for other types of scripts like Groovy.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>3. Type the script in the editor pane.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>4. If necessary, use the Search, Replace, and Format buttons to modify the script.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>5. Click <strong>Apply</strong>.</td>
<td></td>
</tr>
</tbody>
</table>

**Activate pattern Debug mode**

Working in Debug mode, Pattern Designer performs all operations as you configure them. It allows you to see results immediately.

Before starting this procedure, verify that the Debug mode is not activated. If the Debug mode is activated, the debug button appears with a green dot:

**Role required:** pd_admin

**Basic knowledge of programming is desirable.**

Many operations require that you enter a specific value from a specific source, for example, a particular value, or a particular location and delimiter, in a particular file. If you are not in Debug mode, you must type details such as path and file name, or an actual relevant value or related information. However, if you work in Debug mode, you can browse to and open information sources such as files, and then select specific values from those files.
Service Mapping and Discovery share a set of preconfigured patterns that cover most of the commonly used devices and applications. Patterns can be of infrastructure or application type. Infrastructure patterns are used only by Discovery for creating lists of devices. Application patterns serve both Service Mapping and Discovery that use the same application patterns for their purposes.

Service Mapping and Discovery share patterns, but execute them differently. Discovery runs infrastructure, application, and cloud resource patterns for horizontal discovery, while Service Mapping runs application patterns for the top-down discovery. When you activate Debug mode, you choose how pattern steps are run: as if by Discovery or as if by Service Mapping.

When you activate the Debug mode, Pattern Designer performs an operation in a pattern step and displays discovered values in the Temporary Variables pane.

When you activate the Debug mode, the following additional actions become available:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Temporary Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parse URL</td>
<td>install_folder</td>
</tr>
</tbody>
</table>
| Source: $entry_point.url | C:\Windows\sys...
| Target: $url_table     | name: IIS 7.5
|                 | version: 7.5         |
## Debug Mode Actions

<table>
<thead>
<tr>
<th>Action</th>
<th>Allows you to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Search assistant</td>
<td>Search within files or the registry.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>Perform additional configuration to enable this feature as described in</td>
</tr>
<tr>
<td></td>
<td>Configure Search Assistant for Windows.</td>
</tr>
</tbody>
</table>

| Command Prompt  | Check details of file structure, setup, or parameters and values inside specific files on a host before using this information in step operations. |

| Test            | Test the current step and populates variables with discovered values.         |

Activate the Debug mode for each browser window or tab separately. For example, if you have the same pattern section open in two or more tabs, you must activate the Debug mode in each tab.
Discovery and Service Mapping use algorithms to select a MID Server for discovery. While working in Debug mode, you can either rely on the MID Server chosen by the algorithm or select a different MID Server from the list. This list contains only MID Servers that are valid, running, and having the matching IP address range for the pattern step. Discovery and Service Mapping use the same MID Server for the entire Debug session, whether the algorithm selected this MID Server or you chose it.

1. In the Pattern Designer, click **Debug Mode**.
   The Debug Identification Section window is displayed.

2. Fill in the required details for the MID Server entry point:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select MID Server</td>
<td>(Optional) Select the MID Server for this Debug session.</td>
</tr>
<tr>
<td>Debug Type</td>
<td>Select <strong>Top down</strong> for performing top-down discovery with Service Mapping or <strong>Horizontal</strong> for performing horizontal discovery using Discovery.</td>
</tr>
<tr>
<td>Select Entry Point Type</td>
<td>Select the entry point type for the discovered CI. Entry point parameters depend on the type you select.</td>
</tr>
<tr>
<td>URL</td>
<td>Enter the URL of the CI you are discovering.</td>
</tr>
<tr>
<td>Host Name</td>
<td>Enter the host name of the server hosting the discovered application.</td>
</tr>
<tr>
<td>Comments</td>
<td>Any considerations or notes.</td>
</tr>
<tr>
<td>Use original IP</td>
<td>Select the check box and enter the IP for this entry point.</td>
</tr>
</tbody>
</table>

3. The Debug Identification Section window, click **Connect**.
   The Debug mode is activated. The **Debug** button shows the green dot. For connection sections the Debug Mode button also shows the Debug type you chose:

   ![Debug Mode - Top down](image)

   When you select a different section in the same pattern, the Debug mode stays activated if it can use the entry point you defined for the previous step.

4. Optional: If you click another section, to which Pattern Designer cannot connect using the entry point for the previous step, define the entry point again as described in step 2.

5. Optional: To activate the Debug mode for the same pattern section to which you navigated from the pattern form in a separate browser window or tab, define the entry point again as described in step 2.

6. To deactivate the Debug mode, click the **Debug Mode** button.

**Make a step conditional**
If necessary, create a condition that defines how Discovery and Service Mapping execute a pattern step.

Basic knowledge of programming is desirable.

Create a pattern or select a pattern that you want to modify.
Navigate to the relevant pattern step:

1. On the pattern form, select the relevant identification section for Discovery.
   Alternatively, select the relevant identification or connection section for Service Mapping.

2. Select the relevant pattern step or click to add a step.

Role required: pd_admin

You can define a single or multiple prerequisite conditions. For example, you can define that a step is run only during the horizontal or top-down discovery using the pattern_runtime_mode variable.

1. Click the Precondition check box next to the Operation list.
   Not all operations allow you to use preconditions.
2. In the first condition field, enter the required value.
   For example, enter the actual string or a variable name.

3. Select an operator from the list.
   If you select Is Empty, the second field is rendered irrelevant and disappears.
4. To add more conditions, click the plus icon and define the criteria.
5. If you create multiple conditions, define if this pattern must meet all or any of them: From the Meet list, select All or Any.
6. Define if the criteria must be satisfied or not for the step operations to run: From the If Condition is list, select True or False.

You create a pattern step to filter data in the cluster string table to receive a table containing only cluster names. You can set a precondition to filter the table only if the cluster string variable is not empty.
Customize pattern operations
As part of creating or modifying a discovery pattern, modify existing custom operations that come as part of the base system or add new ones.

Practical knowledge of Java scripting is required.

Role required: pd_admin

For standard pattern operations, you can define only input parameters. However, there are custom operations for which you can define the business logic and the mechanism of the operation itself in addition to input parameters. For example, you can make a parameter mandatory or define which input parameters to use.

The following custom operations are available:

Cloud REST Call
Extracts information from configuration items of the PaaS (Platform-as-a-Service) type, such as Microsoft Azure or Amazon Web Services. This Java-based custom operation is part of the base system.

HTTP Get Call
Extracts information from configuration items (CIs), which use the HTTP protocol. This custom operation is part of the base system.

Cloud REST Query
Extracts information from configuration items of the PaaS (Platform-as-a-Service) type, such as Microsoft Azure or Amazon Web Services. This Java-script based custom operation is available only after downloading patterns version 1.0.24 or later from ServiceNow Store. Use this operation instead of the Cloud REST Call operation.

In addition to these custom operations, you can create your own operations to serve the needs of your discovery process. Custom operations created by you appear in the list of operations along with operations, which are part of the base system.

1. Navigate to Pattern Designer > Custom Operations.
2. To add a custom operation, click **New**.

Or

3. To modify an existing custom operation, click its name in the table.

4. For the new custom operation, enter a name describing the new operation in the **Name** field. For example, if the purpose of this operation is to extract information using a certain protocol, you can name it NetApp protocol query.

5. Enter or modify the operation purpose or description in the **Description** field.

6. Write the Java script in the **Script** pane to define the business logic of the operation. The script must comply to the following guidelines:

   - Create variables for operation parameters using the dollar sign in front of the variable name, for example, `$fileName`.
   - `CTX` is an object containing all the information which resulted from a pattern execution.
   - Use `rtn` to indicate the string, which is the result of your custom operation.

   For example:

   ```java
   ms.info('message from Custom operation MIDLogWrite ' + $logMessage);
   ```

   Where `ms.info` is the MID Server log. The `$logMessage` variable refers to the message that is created inside this MID Server log.

7. In the **Custom Operation Parameters** related list, define the input parameters you used in the Java script.

   For example, if you used a variable for the log message file in the Java script, you must also define the parameter for this variable:
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Label</td>
<td>Enter a short and descriptive label for the parameter. The label shows in the table. For example, netapp_query.</td>
</tr>
<tr>
<td>Name</td>
<td>Enter a short and clear name for the parameter without spaces, for example, NetAppquery. This name appears in the list of operations on the pattern step page.</td>
</tr>
<tr>
<td>Default value</td>
<td>If relevant, enter the default value. For example, POST.</td>
</tr>
<tr>
<td>Mandatory</td>
<td>Set to true if this parameter is mandatory for this operation. Otherwise, set to false.</td>
</tr>
<tr>
<td>Order</td>
<td>Define the order in which parameters appear on the operation page. Use natural numbers, where 1 means this parameter appears at the top of the operation page.</td>
</tr>
</tbody>
</table>
## Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Domain</td>
<td>For domain-separated environments, specify the name of the domain for which this parameter is relevant.</td>
</tr>
<tr>
<td>Validation Regex</td>
<td>Specify a Java regular expression to validate the parameter with. During discovery process, the MID Server validates the operation result. The Pattern Designer module also runs validation when you click <strong>Test</strong> on the pattern step page.</td>
</tr>
</tbody>
</table>

**Explore remote host**

Check details of file structure, setup, or parameters and values inside specific files on a host before using this information in step operations.

Basic knowledge of programming is desirable.

1. Navigate to **Pattern Designer > Discovery Patterns**.
2. Select a pattern from the Discovery Patterns list.
3. Select an identification or connection section.

4. Switch to the debug mode as described in **Activate pattern Debug mode**.

Role required: pd_admin
Part of creating or modifying patterns is defining step operations that use information about the host on which they run. You can verify that the information you are going to use in operations is correct, by exploring hosts.

You can explore both remote hosts and MID Servers.

1. Click **Command Prompt** next to the Debug Mode button.
   The Command Prompt window opens.

2. Enter the command.
   To make the platform apply applicative credentials while executing this command, use placeholders for credentials using the following syntax:
   - $$username$$ - for the user name
   - $$password$$ - for the password

   For example, a parsing command for a Microsoft SQL Server uses credential placeholders:
   ```
   "su - " + $userid + " -c " + $ExecutableDir + "mysql --user=" + "$username$$" + " --password=" + "$password$$"
   ```

3. Optional: Click **Advanced Details**.

4. Optional: Specify the command and parameters:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Execute Mode</strong></td>
<td>Select the relevant option of running this command:</td>
</tr>
<tr>
<td></td>
<td>• Default (Remote) - on a remote device</td>
</tr>
<tr>
<td></td>
<td>• Local Script - on the MID Server</td>
</tr>
<tr>
<td></td>
<td>• Windows Service - on a remote Windows server</td>
</tr>
<tr>
<td><strong>CI Type</strong></td>
<td>If necessary, select the CI type whose credentials the platform applies while running the command.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Enter the management IP address of the host on which to run the command. You can also leave this value empty.</td>
</tr>
</tbody>
</table>

5. Click **Run Command**.
   The result is displayed in the Output pane.

6. Click **Close** when finished checking the result.

**Pattern variables**

You use variables in discovery patterns to refer to parameters or attributes of the CI that the pattern discovers.

There are several kinds of variables used in discovery: global variables, CI attribute variables, and temporary variables.
### Characteristics

<table>
<thead>
<tr>
<th>Characteristics</th>
<th>Global variable for which you create a pattern. <strong>entry point</strong></th>
<th>CI attributes</th>
<th>Temporary variables</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Contains information about the connection which serves as an entry point for the CI for which you create a pattern. <strong>process</strong></td>
<td>A variable can be: • Scalar: A single string • Tabular: A table, where each cell is a scalar variable. • Vector: A single, unnamed column with as many rows as needed</td>
<td>Scalar, tabular, or vector • Scalar: A single string • Tabular: A table, where each cell is a scalar variable. • Vector: A single, unnamed column with as many rows as needed</td>
</tr>
</tbody>
</table>

#### Type/structure

| Type/structure | Container variable: a variable can hold any combination of single strings and tabular variables. | A variable can be: • Scalar: A single string • Tabular: A table, where each cell is a scalar variable. • Vector: A single, unnamed column with as many rows as needed | Scalar, tabular, or vector • Scalar: A single string • Tabular: A table, where each cell is a scalar variable. • Vector: A single, unnamed column with as many rows as needed |

#### Origin

| Origin | Preconfigured in Service Mapping. | Service Mapping derives them from a CI type definition. | You create these variables while defining operations for pattern steps. |

| Modifiable in Pattern Designer | No | No | Yes |

Some process variables retrieve values from the CMDB. Run the horizontal discovery prior to performing the top-down discovery to use these variables.

**Note:** The **Pre CMDB process** variable is present for lightweight identification sections or for identification sections of patterns for discovery of load balancers.

Pattern Designer displays different kinds of variables in different areas of its interface.
Always prefix variables with the dollar symbol ($) which indicates variables, but is not actually a part of the variable name. For example, if you specify $Abc as the variable name, the actual name of the variable is Abc.

Change credentials to non-default
As part of creating or modifying a discovery pattern, you can define a **Change user** operation to make Service Mapping or Discovery use SSH or Windows credentials instead of the default administrative level credentials. This operation is relevant only for configuration items (CIs) hosted on Windows or Unix operating systems.

- Ensure that the OS credentials you want to use instead of the default credentials are correctly configured. Configure the credential alias to the OS CI type whose credentials you want to use. For operational information on how to create credentials, see [SSH credentials](#) and [Windows credentials](#).
- Navigate to the relevant pattern step:
  1. On the pattern form, select the relevant identification section for Discovery. Alternatively, select the relevant identification or connection section for Service Mapping.
2.

Select the relevant pattern step or click to add a step.

Basic knowledge of programming is desirable.
Role required: pd_admin
You can change the default credentials to any appropriate credentials belonging to a different CI type on the same or a different host.

1. Select Change user from the Operation list in one of the following locations.
2. Select the Use Different CI Type check box.
3. From the list, select the CI type whose credentials you want to use.
4. If in Debug mode, test the step by clicking Test and checking that the operation brings the result you expected.

<table>
<thead>
<tr>
<th>This operation is used in</th>
<th>This item</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hierarchy</td>
<td>Applications &gt; Business Integration Software</td>
</tr>
<tr>
<td>CI Type</td>
<td>IBM WebSphere MQ Queue</td>
</tr>
<tr>
<td>Pattern</td>
<td>WMQ Queue Unix Pattern</td>
</tr>
<tr>
<td>Section</td>
<td>Local queue connectivity</td>
</tr>
<tr>
<td>Step number and Name</td>
<td>3. Change user credentials</td>
</tr>
</tbody>
</table>

As part of discovery of an IBM WebSphere MQ Queue, you change credentials to IBM WebSphere MQ. It allows you to manipulate local IPs to discover connections on the local queue.

- Continue editing the pattern by adding a new step and defining its operation or
- Finalize the pattern.

Provide connection information
As part of creating or modifying a discovery pattern, use the Create connection operation to provide information about an outgoing connection. This operation is only available for connection sections.

Navigate to the relevant step:

1. On the pattern form, select the relevant connection section.
2. Select the relevant step or create a pattern step by clicking .

Basic knowledge of programming is desirable.

Role required: pd_admin

Always start with this step when creating a connection section entry for a new pattern.

1. Select **Create Connection** from the **Operation** list.

2. Fill in the fields, as appropriate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| Select Connection Type       | - **Application Flow**: Used between two applications (can be of the same type).
                                  - **Cluster**: Used for connections to CIs of the cluster type. Specify a cluster name.
                                  - **Inclusion**: Used for connections to an object that is included in the current object. For example, a connection from J2EE to EAR, and a connection from IIS to a website.
                                  - **Storage Flow**: Used for connections between configuration items (CIs) of host type and devices of storage type. |
| Select Entry Point           | Select the entry point type from the list. For more information, see: **Entry point attributes**. |
| Enter Connection Attributes  | Define attributes by either entering actual values or variables.             |
| Select Target CI Type        | Select the target CI type from the list.                                     |
| Is hidden                    | Select the check box if the connection should be hidden (that is, not shown in the user interface), but is used for continuing the discovery flow. |
| Is traffic based             | Select the check box to use the traffic-based discovery method for this connection. |

3. If in Debug mode, test the step by clicking **Test** and checking that the operation brings the result you expected.

<table>
<thead>
<tr>
<th>This operation is used in</th>
<th>This item</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hierarchy</td>
<td>Applications &gt; Business Integration Software</td>
</tr>
<tr>
<td>CI Type</td>
<td>IBM WebSphere MQ Queue</td>
</tr>
<tr>
<td>Pattern</td>
<td>WMQ Queue Unix Pattern</td>
</tr>
<tr>
<td>Section</td>
<td>Alias queues connectivity</td>
</tr>
<tr>
<td>Step number and Name</td>
<td>6. Create outgoing connection to alias queues</td>
</tr>
</tbody>
</table>

To create a connection from Microsoft Exchange CAS to Exchange Mailboxes, define the **Create Connection** operation as follows:
• Continue editing the pattern by adding a new step and defining its operation or
• Finalize the pattern.

**Merge tables**
As part of creating or modifying a discovery pattern, you can use the **Merge Table** operation to merge content from two source tables into a target table.

Navigate to the relevant pattern step:
1. On the pattern form, select the relevant identification section for Discovery.
   Alternatively, select the relevant identification or connection section for Service Mapping.
2. Select the relevant pattern step or click ![add step icon](image) to add a step.

Basic knowledge of programming is desirable.

Role required: pd_admin

Use this operation to unify information from different sources.
For example, during discovery of connections of IBM WebSphere Portal to IBM WebSphere MQ, you can merge the table containing queue names with the table containing JNDI reference names.

1. Select **Merge Table** from the **Operation** list.
2. Fill in the fields, as appropriate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>First table</td>
<td>Specify the name of the first source table.</td>
</tr>
<tr>
<td>Second table</td>
<td>Specify the name of the second source table.</td>
</tr>
<tr>
<td>Target table</td>
<td>To create a table to contain merged data, define the name of the new table.</td>
</tr>
<tr>
<td>Unmatched values</td>
<td>For tables that meet the merge criteria, select an action from the list for unmatched rows:</td>
</tr>
<tr>
<td></td>
<td>- <strong>Keep</strong>: If merge criteria is met for any row, it merges all rows from both source tables into the target table.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Remove</strong>: Merges only matching rows from both source tables into the target table, and excludes non-matching rows.</td>
</tr>
</tbody>
</table>

3. To merge tables based on one matching field value:
   a) Click **Field matching**.
   b) In the **First Table Field**, enter the value from the first source table.
   c) In the **Second Table Field**, enter the value from the second source table.

4. To merge tables based on multiple matching field values:
   a) Click **Condition**.
   b) In the first condition field, enter the required value.
      For example, enter the actual string or a variable name.
      You can use variables including values from tabular variables as described in *Enter values and variables in patterns*. 
c) Select an operator from the list.

d) To add more conditions, click the plus icon and define the criteria.

e) If you create multiple conditions, define if this pattern must meet all or any of them: From the *Meet* list, select *All* or *Any*.

5. If in Debug mode, test the step by clicking *Test* and checking that the operation brings the result you expected.

<table>
<thead>
<tr>
<th>This operation is used in</th>
<th>This item</th>

<tr>
<td>Pattern</td>
<td>Websphere Portal On Linux</td>
</tr>
<tr>
<td>Section</td>
<td>EAR TO MQ Connectivity</td>
</tr>
<tr>
<td>Step number and Name</td>
<td>8. Merge the q factories with the jndi ref names</td>
</tr>
</tbody>
</table>

To merge tables containing queue names with JNDI reference names, use the *Merge Table* operation as follows:
• Continue editing the pattern by adding a new step and defining its operation or finalize the pattern.

Find a matching URL
As part of creating or modifying a discovery pattern, you can use the Find Matching URL operation to find the best match for the main URL and create a variable to hold it.

• Make sure that you know the main URL of the application.
• Navigate to the relevant pattern step:
  1. On the pattern form, select the relevant identification section for Discovery. Alternatively, select the relevant identification or connection section for Service Mapping.
  2. Select the relevant pattern step or click to add a step.

Basic knowledge of programming is desirable.
Role required: pd_admin
Some application CIs have configuration files containing lists of possible URLs. You can search such lists to find the match for the URL that allows connecting to a configuration item (CI).

1. Select Find matching URL from the Operation list.
2. Fill in the fields, as appropriate.
### Field Description

<table>
<thead>
<tr>
<th>Values</th>
<th>Specify the table and records containing potential URLs. You can use values from variables, including temporary tabular variables: from a specific field or a specific column in a table sequentially, starting from the first row. For more information, see Enter values and variables in patterns.</th>
</tr>
</thead>
<tbody>
<tr>
<td>URL</td>
<td>Specify the URL for which you are seeking the best match.</td>
</tr>
<tr>
<td>Target Variable</td>
<td>Specify the variable name to contain the best match.</td>
</tr>
</tbody>
</table>

| 3. If in Debug mode, test the step by clicking **Test** and checking that the operation brings the result you expected. |

### This operation is used in This item

<table>
<thead>
<tr>
<th>Hierarchy</th>
<th>Applications &gt; Application Server</th>
</tr>
</thead>
<tbody>
<tr>
<td>CI Type</td>
<td>Jboss (cmdb_ci_app_server_jboss)</td>
</tr>
<tr>
<td>Pattern</td>
<td>Jboss pattern</td>
</tr>
<tr>
<td>Section</td>
<td>http identification section</td>
</tr>
<tr>
<td>Step number and Name</td>
<td>43. best match</td>
</tr>
</tbody>
</table>

To filter the table on Jboss and to create a variable to hold the best match for the Jboss entry point URL, define the **Find Matching URL** operation as follows:

- Continue editing the pattern by **adding a new step and defining its operation** or
- **Finalize the pattern**.

**Filter a table**

As part of creating or modifying a discovery pattern, you can use the **Filter table** operation to search a source table for a specified value. If found, values are logged in a specified target table.
Navigate to the relevant pattern step:

1. On the pattern form, select the relevant identification section for Discovery. Alternatively, select the relevant identification or connection section for Service Mapping.

2. Select the relevant pattern step or click to add a step.

Basic knowledge of programming is desirable.

Role required: pd_admin

1. Select **Filter Table** from the **Operation** list.
2. Fill in the fields, as appropriate:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source table</td>
<td>Name of source table to be searched. Use drag-and-drop or auto-complete to copy table names, fields, and values from the Temporary Variables and CI Attributes tables.</td>
</tr>
<tr>
<td>Target table</td>
<td>Name of target table to contain the values that were found.</td>
</tr>
</tbody>
</table>

3. Define the condition for this operation:
   a) In the first condition field, enter the required value. For example, the table name and the column from which to retrieve the values.

You can also use variables including values from tabular variables as described in [Enter values and variables in patterns](#).
b) Select an operator from the list.

c) Enter the string that Pattern Designer uses to filter values.

d) To add more conditions, click the plus icon and define the criteria.

e) If you create multiple conditions, define if this pattern must meet all or any of them: From the Meet list, select All or Any.

4. If in Debug mode, test the step by clicking Test and checking that the operation brings the result you expected.

<table>
<thead>
<tr>
<th>This operation is used in</th>
<th>This item</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hierarchy</td>
<td>Applications &gt; Application Servers</td>
</tr>
<tr>
<td>CI Type</td>
<td>WebSphere Portal (cmdb_ci_appl_webspere_portal)</td>
</tr>
<tr>
<td>Pattern</td>
<td>Websphere Portal On Linux</td>
</tr>
<tr>
<td>Section</td>
<td>DB2 JDBC connectivity</td>
</tr>
<tr>
<td>Step number and Name</td>
<td>8. Prepare different lists of connections per db type</td>
</tr>
</tbody>
</table>

To identify IBM WebSphere connections to Oracle applications, use the Filter Table operation as follows:

- Continue editing the pattern by adding a new step and defining its operation or
- Finalize the pattern.
Get a process
As part of creating or modifying a discovery pattern, use the **Get process** operation to search for a specific process to store in a tabular variable.

- Navigate to the relevant pattern step:
  1. On the pattern form, select the relevant identification section for Discovery.
     Alternatively, select the relevant identification or connection section for Service Mapping.
  2. Select the relevant pattern step or click \( \text{Add Step} \) to add a step.

Basic knowledge of programming is desirable.

Role required: pd_admin

You can manually specify the filtering criteria, or you can select a process from the list of all processes on the system. The values of the selected process are used to populate the filtering fields. Modify these criteria as needed (for example, to delete irrelevant criteria).

Processes that satisfy the specified filtering criteria are placed in a tabular variable whose name you specify. This tabular variable appears in the **Temporary Variables** table.

1. Select **Get process** from the **Operation** list.
2. If in the debug mode, perform the following steps:
   a) Click **Browse Process** to open a form containing a list of processes.
   b) Select a process and click **OK**. Filtering criteria are populated with values from the selected process.
3. If not working in the debug mode, define the field values as needed:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Process ID</td>
<td>Enter the process ID. Not recommended since this parameter can be modified.</td>
</tr>
<tr>
<td>Command Line</td>
<td>Enter the command line or a string which is part of it. For example, you can use &quot;bw&quot; to find &quot;bwengine.&quot;</td>
</tr>
<tr>
<td>Working Directory</td>
<td>Enter the working directory for the process. Not recommended, since this parameter can vary on different hosts.</td>
</tr>
<tr>
<td>Parent Process</td>
<td>Enter the process which is the parent of the process that you want to extract. Not recommended since this parameter can be modified or can extract many irrelevant sub processes.</td>
</tr>
<tr>
<td>Port</td>
<td>Enter the port on which the process runs. Not all processes are based on ports.</td>
</tr>
</tbody>
</table>

4. In the **Specify Target Variables** field, specify the name for the tabular variable to hold the list of processes that satisfy the filtering criteria.

You can also enter a value from the specific field in a tabular variable as described in **Enter values and variables in patterns**.

5. If in Debug mode, test the step by clicking **Test** and checking that the operation brings the result you expected.

This operation is used in | This item
---|---
Hierarchy | Application> Infrastructure Service > Web Server
CI Type | Microsoft Iis Web Server (cmdb_ci_microsoft_iis_web_server)
Pattern | IIS
Section | Identification for HTTP(S) entry point type(s) for IIS6 second logic
Step number and Name | 40. Get IIS process

Use the Get Process operation to get all Internet Information Services worker processes (w3wp.exe) running on the Windows Server and keep the results in the table variable iis_process.

- Continue editing the pattern by adding a new step and defining its operation or
- Finalize the pattern.

Get a registry key
As part of creating or modifying a discovery pattern, you can use the Get registry key operation to retrieve and select registry key attributes to store in a table.

Navigate to the relevant pattern step:
1. On the pattern form, select the relevant identification section for Discovery.
Alternatively, select the relevant identification or connection section for Service Mapping.

2. Select the relevant pattern step or click \[+\] to add a step.

Basic knowledge of programming is desirable.
Role required: pd_admin
This operation is relevant only for Windows.

1. Select \textbf{Get registry key} from the \textbf{Operation} list.
2. If working in the Debut Mode, perform the following steps:
   a) Click \textbf{Browse} and select the registry key.
      The selected key path is placed in the \textbf{Registry key path} field. A form opens and displays a list of keys next to the tree.
      You can use variables. You can also enter a value from the specific field in a tabular variable as described in \textit{Enter values and variables in patterns}.
   b) Select the key to show the attributes and click \textbf{OK}.

3. If not working in the Debug Mode, specify the registry key path in the \textbf{Registry key path} field.
4. Select the relevant option from the \textbf{Build Variables-Keys Table} list:
   \begin{itemize}
   \item Select \textbf{By Using All Keys From The Registry Directory}, and enter the name of the table to contain the keys and variables.
   \item Select \textbf{By Building The Table From The Browser or Manually}, and specify the keys on which you want to build the table. If there is more than one key, it creates a table to hold variables.
   \end{itemize}
5. Define the name of the table to which you want to save the operation result.
6. Select \textbf{Terminate} to stop discovery if no results are found.
7. If in Debug mode, test the step by clicking \textbf{Test} and checking that the operation brings the result you expected.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>

<tr>
<td>Step number and Name</td>
<td>2. get version from registry</td>
</tr>
</tbody>
</table>

Get registry keys and values of "HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft \inet\St" and save the value in the 'version' variable.
Continue editing the pattern by adding a new step and defining its operation or finalize the pattern.

Define an LDAP query
As part of creating or modifying a discovery pattern, you can use the LDAP query operation to query an LDAP directory.

Navigate to the relevant pattern step:

1. On the pattern form, select the relevant identification section for Discovery.
   Alternatively, select the relevant identification or connection section for Service Mapping.

2. Select the relevant pattern step or click to add a step.

Basic knowledge of programming is desirable.

Role required: pd_admin

1. Select LDAP query from the Operation list.
2. Fill in the fields, as appropriate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Base DN</td>
<td>Specify the point from where the LDAP server searches for users.</td>
</tr>
</tbody>
</table>
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Specify the name of the server that hosts the LDAP server.</td>
</tr>
<tr>
<td>Port</td>
<td>Specify the port name.</td>
</tr>
<tr>
<td>Query</td>
<td>Specify the query parameters.</td>
</tr>
</tbody>
</table>
| Scope | Specify the query scope from the list:  
  - **Sub Tree**: the object and all descendants.  
  - **Object**: the object only.  
  - **One Level**: the object and one level below. |

3. In the **Variable Table**, click **Add** and define the table name and column name to hold the query result.  
   For multiple results, click **Add** for each additional column that is needed.  
4. If in Debug mode, test the step by clicking **Test** and checking that the operation brings the result you expected.

<table>
<thead>
<tr>
<th>This operation is used in</th>
<th>This item</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hierarchy</td>
<td>Application &gt; Exchange Server Component</td>
</tr>
<tr>
<td>CI Type</td>
<td>ExchangeBackEndServer</td>
</tr>
<tr>
<td>Pattern</td>
<td>ExchangeBackEndServer On Windows Pattern</td>
</tr>
<tr>
<td>Section</td>
<td>Storage connectivity</td>
</tr>
<tr>
<td>Step number and Name</td>
<td>2. Query ldap - msExchStorageGroup.msExchESEParamSystemPath</td>
</tr>
</tbody>
</table>

To find storage devices connected to the Exchange BackEnd Server, you can use the following LDAP query: 
```
“(objectclass=msExchStorageGroup)“
```

The operation result is stored in a variable table with the following fields:  
msExchESEParamSystemPath and msExchStorageGroupFiles1v. You can use variables to specify Base DN that indicates where to begin the search, as well as the host name and port.
As part of creating or modifying a discovery pattern, you can use the **Match** operation to specify conditions that the discovery process must meet to continue. If these conditions are not met, the discovery process stops.

Navigate to the relevant pattern step:

1. On the pattern form, select the relevant identification section for Discovery.
   Alternatively, select the relevant identification or connection section for Service Mapping.

2. Select the relevant pattern step or click ![Add Step](image) to add a step.

Basic knowledge of programming is desirable.

Role required: pd_admin

While the discovery process always stops if the specified conditions are not met, you can control if the system regards this result as discovery error or not. In some cases you may run a pattern containing the match operation and expect the result not to match conditions. For example, in cloud environments different data centers may have different sets of devices and applications. You run a pattern for a certain application knowing that you do not find it on all data centers.
If you define that the lack of match is not a discovery error, the discovery log shows the message instead of the discovery error. Customize the message to provide useful information about why this result is expected.

1. Select **Match** from the **Operation** list.
2. In the first condition field, enter the required value.
   You can use an actual string or a variable. You can also use values from temporary tabular variables: from a specific field or a specific column in a table sequentially, starting from the first row. For more information, see **Enter values and variables in patterns**.

3. Select an operator from the list.
4. If necessary, enter the required value in the second condition field.
5. To add more conditions, click the plus icon and define the criteria.
6. If you create multiple conditions, define if this pattern must meet all or any of them: From the **Meet** list, select **All** or **Any**.
7. To consider the lack of match as not a discovery error:
   a) Select **Expected** from the **Termination type** field.
   b) Enter the text for the discovery message to provide useful information about the expected result.
      You can use variables in the discovery message. For example, you can enter the following text:
      
      The discovery was stopped due to the following error: $error.

8. If in Debug mode, test the step by clicking **Test** and checking that the operation brings the result you expected.

<table>
<thead>
<tr>
<th>This operation is used in</th>
<th>This item</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hierarchy</td>
<td>Applications &gt; Business Integration Software</td>
</tr>
<tr>
<td>CI Type</td>
<td>IBM WMB HTTP Listener</td>
</tr>
<tr>
<td>Pattern</td>
<td>WMB HTTP Listener On Unix Pattern</td>
</tr>
<tr>
<td>Section</td>
<td>Identification for HTTP</td>
</tr>
<tr>
<td>Step number and Name</td>
<td>1. Check process name to match http lstnr</td>
</tr>
</tbody>
</table>
During discovery of an IBM WMB HTTP Listener, use the Match operation to check the process name.

![Match operation screenshot]

- Continue editing the pattern by adding a new step and defining its operation or
- Finalize the pattern.

Parse command output
As part of creating or modifying a discovery pattern, you can use the Parse command output operation to extract information from the command output and to save the operation result in a variable. You can also save the whole of command output as a variable.

Navigate to the relevant pattern step:
1. On the pattern form, select the relevant identification section for Discovery.
   Alternatively, select the relevant identification or connection section for Service Mapping.
2. Select the relevant pattern step or click ![Add step icon] to add a step.

Basic knowledge of programming is desirable.
Role required: pd_admin
1. Select Parse command output from the Operation list.
2. Specify the command in Set Command Details.
   You can use variables. You can also enter a value from the specific field in a tabular variable as described in Enter values and variables in patterns.
   You can concatenate multiple commands.

Important: Avoid entering a specific path to a location or file because it can be different on different operating systems. You should use variables for paths.

To make the Now Platform apply applicative credentials while executing this command, use placeholders for credentials using the following syntax:
- $$username$$ - for the user name
- $$password$$ - for the password

For example, a parsing command for a Microsoft SQL Server uses credential placeholders:
"su - " + $userid + " -c '" + $ExecutableDir + "mysql --user=" + "$username$$" + " --password=" + "$password$$"

3. To change the execution mode or credentials, click Advanced and fill in the fields, as appropriate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execute Mode</td>
<td>Select the relevant option for running this command:</td>
</tr>
<tr>
<td></td>
<td>· Default (Remote) - on the remote device.</td>
</tr>
<tr>
<td></td>
<td>· Local Script - on the MID Server</td>
</tr>
<tr>
<td></td>
<td>· Windows Service - on the service running on the remote Windows server</td>
</tr>
<tr>
<td>CI Type</td>
<td>If necessary, select the CI type whose credentials the platform applies while running the command.</td>
</tr>
</tbody>
</table>

4. To save the whole of the command output as a variable, select NONE from the Define Parsing list and define the variable as described in 7.

5. Select the parsing strategy from the Define Parsing list.

<table>
<thead>
<tr>
<th>Parsing strategy</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle</td>
<td>Horizontal file parsing strategy (not vertical). You can use this parsing strategy only for text files. For more information, see Parse text from a horizontal file.</td>
</tr>
<tr>
<td>LDAP file</td>
<td>Retrieve text from a structured text file where each set of data spans multiple lines. For more information, see Parse text from a vertical file.</td>
</tr>
<tr>
<td>XML file</td>
<td></td>
</tr>
<tr>
<td>INI file</td>
<td></td>
</tr>
<tr>
<td>Properties file</td>
<td></td>
</tr>
<tr>
<td>JSON file (custom)</td>
<td></td>
</tr>
<tr>
<td>Vertical File</td>
<td>Retrieve text specified by its position from the end of the line. For more information, see Parse text using keyword, command, and positional type.</td>
</tr>
<tr>
<td>After Keyword</td>
<td>Retrieve text directly following a specific keyword. For more information, see Parse text using keyword, command, and positional type.</td>
</tr>
<tr>
<td>Command Line Java Style</td>
<td>Retrieve the value of a command-line parameter using Java-style parameters. For more information, see Parse text using keyword, command, and positional type.</td>
</tr>
<tr>
<td>Command Line Unix Style</td>
<td>Retrieve the value of a command-line parameter using standard Unix parameters. For more information, see Parse text using keyword, command, and positional type.</td>
</tr>
<tr>
<td>Position From End</td>
<td>Retrieve text specified by its position from the end of the line. For more information, see Parse text using keyword, command, and positional type.</td>
</tr>
</tbody>
</table>
### Parsing strategy

<table>
<thead>
<tr>
<th>Parsing strategy</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Position From Start</td>
<td>Retrieve text specified by its position from the beginning of the line. For more information, see Parse text using keyword, command, and positional type.</td>
</tr>
<tr>
<td>Regular Expression</td>
<td>Retrieve text specified by a regular expression. This option requires familiarity with Regex Java syntax. For more information, see Parse text using a regular expression.</td>
</tr>
<tr>
<td>Delimited Text</td>
<td>Retrieve text specified by delimiters and position within the line (the most common way to retrieve text from generic text files). See Parse text using delimited text.</td>
</tr>
</tbody>
</table>

6. If working in Debug mode, perform the following steps:
   a) Click **Run Command** to see the result in the **Output** pane.
   b) In the **Output** pane, mark text or symbols that you want a variable to contain.
   c) In the variable name box, enter the name for the new variable, for example ‘process_name’.
   d) Press **Enter**.

   The new variable is added in the **Variables** pane.

7. If you are not working in Debug Mode, define the parsing criteria as follows:
   a) In the Variables pane, click **Add Variable** and enter the name for the new variable.
   b) Click the **Advanced** icon.
c) Click **Add Column Label**.

d) Enter the parsing query.

e) Enter a value for the delimiter.

f) Enter a value for the position.

8. Select **Use Cache** to save the operation results in cache on the MID Server. Use cache to optimize discovery and avoid creating unnecessary load on central shared components, such as load balancers. The base system keeps operation results in cache for an hour.

9. Select **Terminate** to stop discovery if no results are found.

10. If in Debug mode, test the step by clicking **Test** and checking that the operation brings the result you expected.

In this example, the Tibco parser script contained in the `$TibcoParser` variable runs on the target host. The parsing method is delimited text with the `=` delimiter. The result of the parsing is the path to the directory containing all configuration files for Tibco Business Works and Tibco Business Works Process. This step creates a temporary variable to hold the result of the parsing.
Continue editing the pattern by adding a new step and defining its operation or Finalize the pattern.

Parse a file
As part of creating or modifying a discovery pattern, you can use the Parse file operation to extract information from a file and create variables to contain the extracted information.

Navigate to the relevant pattern step:
1. On the pattern form, select the relevant identification section for Discovery. Alternatively, select the relevant identification or connection section for Service Mapping.
2. Select the relevant pattern step or click to add a step.

Basic knowledge of programming is desirable.
Role required: pd_admin
Alternatively, you can use traffic-based connections to create a parse file step in the relevant CI pattern as described in *Fine-tune patterns using traffic-based discovery*.

1. Select **Parse file** from the **Operation** list.
2. Specify the file path in **Select file**.
   
   You can use variables. You can also use values from a temporary tabular variable: from a specific field or a specific column in a table sequentially, starting from the first row. For more information, see *Enter values and variables in patterns*.

   To specify the actual file, click **Browse**, navigate to the file, and click **Select**.

   **Important:** Avoid entering a specific path to a location or file because it can be different on different operating systems. You should use variables for paths.

3. Select the relevant parsing strategy from the **Define Parsing** list and define parsing criteria.

<table>
<thead>
<tr>
<th>Parsing strategy</th>
<th>Description</th>
</tr>

</tr>
<tr>
<td>Regular Expression</td>
<td>Retrieve text specified by a regular expression. This option requires familiarity with Regex Java syntax. For more information, see Parse text using a regular expression.</td>
</tr>
</tbody>
</table>
Delimited Text

Retrieve text specified by delimiters and position within the line (the most common way to retrieve text from generic text files). See Parse text using delimited text.

4. Select Terminate to stop discovery if no results are found.
5. If in Debug mode, test the step by clicking Test and checking that the operation brings the result you expected.

You can use the Parse File operation to extract data on prices and authors from an xml file using the XML File parsing strategy.

- Continue editing the pattern by adding a new step and defining its operation or Finalize the pattern.

Parse a URL
As part of creating or modifying a discovery pattern, you can use the Parse URL operation to break down a URL to the component level.
Navigate to the relevant pattern step:

1. On the pattern form, select the relevant identification section for Discovery.
   Alternatively, select the relevant identification or connection section for Service Mapping.

2. Select the relevant pattern step or click to add a step.

Basic knowledge of programming is desirable.
Role required: pd_admin

The URL parsing breaks a URL into the following components: protocol, hostname or IP, port, path and file.

1. On the Identification or Connectivity Sections form, select Parse URL from the Operation list.
2. Fill in the fields, as appropriate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source</td>
<td>Specify the URL:</td>
</tr>
<tr>
<td></td>
<td>• Enter a value that can change, a variable. Type the dollar character ($) and the first letters of the variable name. For example, $ldap_url.</td>
</tr>
<tr>
<td></td>
<td>• Specify complex (concatenated) values in fields. Enter a value, then add a plus sign (+), and then enter another value. For example, $install_directory+&quot;conf/httpd.conf&quot;.</td>
</tr>
<tr>
<td></td>
<td>• Enter constant values, a string. For example, &quot;/opt/ibm/mqsi/7.0/bin/&quot;.</td>
</tr>
<tr>
<td></td>
<td>• Enter a value from a tabular variable: from a specific field or a specific column in a table sequentially, starting from the first row. For more information, see Enter values and variables in patterns.</td>
</tr>
</tbody>
</table>

Important: Avoid entering a specific path to a location or file because it can be different on different operating systems. You should use variables for paths.

| Target     | Specify the table to hold the results. Use variables, complex values or strings as described above. |

3. Select Terminate to stop discovery if no results are found.
4. If in Debug mode, test the step by clicking Test and checking that the operation brings the result you expected.

<table>
<thead>
<tr>

To break an LDAP directory URL to components and save the results in a new table, use the Parse URL operation as follows:

- Continue editing the pattern by adding a new step and defining its operation or Finalize the pattern.

### Parse a variable

As part of creating or modifying a discovery pattern, you can use the Parse variable operation to extract information from a variable and to store it in a variable table.

Navigate to the relevant pattern step:

1. On the pattern form, select the relevant identification section for Discovery.
   Alternatively, select the relevant identification or connection section for Service Mapping.

2. Select the relevant pattern step or click to add a step.

Basic knowledge of programming is desirable.

Role required: pd_admin

1. Select Parse variable from the Operation list.
2. Define the variable that you wish to parse in the Enter Variable field.
   You can use regular variables. You can also use values from a temporary tabular variable: from a specific field or a specific column in a table sequentially, starting from the first row. For more information, see Enter values and variables in patterns.
3. Select the relevant parsing strategy from the Define Parsing list and define the parsing criteria.
<table>

</tbody>
</table>

4. Select Terminate to stop discovery if no results are found.
5. If in Debug mode, test the step by clicking Test and checking that the operation brings the result you expected.

You can use the Command Line Java Style parsing strategy to extract the path of the installation directory of the WebSphere Server.
• Continue editing the pattern by adding a new step and defining its operation or Finalize the pattern.

Define an HTTP Get Call query
As part of creating or modifying a discovery pattern, you can use the **Http Get Call** operation to extract information from configuration items (CIs), which use the HTTP protocol.

Navigate to the relevant pattern step:

1. On the pattern form, select the relevant identification section for Discovery.
   Alternatively, select the relevant identification or connection section for Service Mapping.
2. Select the relevant pattern step or click to add a step.

Basic knowledge of programming is desirable.
Role required: pd_admin

1. Select **Http Get Call** from the **Operation** list.
2. Define query parameters as necessary:

   ![Warning] If you customized this operation as described in [Customize pattern operations](#), the query parameters may be different.

<table>

<td>Retrieve text specified by delimiters and position within the line (the most common way to retrieve text from generic text files). See <a href="#">Parse text using delimited text</a>.</td>
</tr>
</tbody>
</table>

5. If working in the Debug Mode, define the parsing criteria as follows:
   a) Click **Run Operation** to see the result in the **Output** pane.
   b) In the **Output** pane, mark text or symbols that you want a variable to contain.
   c) In the variable name box, enter the name for the new variable, for example ‘process\_name’.
6. If you are not working in Debug Mode, define the parsing criteria as follows:
   a) In the Variables pane, click **Add Variable** and enter the name for the new variable.
   b) Click the **Advanced** icon.
   c) Click **Add Column Label**.

   d) Press **Enter**.

   The new variable is added in the **Variables** pane.
d) Enter the parsing query.

e) Enter a value for the delimiter.

f) Enter a value for the position.

7. Select **Terminate** to stop discovery if no results are found.

8. If in Debug mode, test the step by clicking **Test** and checking that the operation brings the result you expected.

You can use the HTTP Get Call operation to extract data on CI types using the XML File parsing strategy:

- Continue editing the pattern by adding a new step and defining its operation or
- Finalize the pattern.

Define an API Query for cloud computing devices

As part of creating or modifying a discovery pattern, you can use the **Cloud REST Call** operation to extract information from configuration items of the PaaS (Platform as a Service) type, such as Microsoft Azure or Amazon Web Services.

- Verify that the operating system of the configuration item (CI) for which you want to use the Cloud REST Call operation extends the Logical Data Center OS type (**cmdb_ci_logical_datacenter**):
1. Navigate to the Basic tab of the CI pattern.
2. Note the operating system for this CI.
3. Navigate to System Definition > Tables.
4. Set the search field to Label and enter the name of the operating system as stated on the Basic tab of the pattern.
5. Find the operating system in the list and verify that Logical Datacenter appears in the Extends table column.

- Navigate to the relevant pattern step:
  1. On the pattern form, select the relevant identification section for Discovery.
     Alternatively, select the relevant identification or connection section for Service Mapping.
  2. Select the relevant pattern step or click to add a step.

Basic knowledge of programming is desirable.

Role required: pd_admin

Deploy the Cloud REST Call operation in patterns used for discovery of PaaS CIs.

Refer to the official API-related documentation provided by manufacturers to obtain the query syntax for the device you want to query using the Cloud REST Call operation. For example:

- [https://docs.microsoft.com/en-us/rest/api/apimanagement/](https://docs.microsoft.com/en-us/rest/api/apimanagement/)

1. Select Cloud REST Call from the Operation list.
2. Define query parameters as necessary:

   **Warning:** If you customized this operation as described in Customize pattern operations, the query parameters may be different.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>URL</td>
<td>Specify the URL as described in the official Microsoft Azure or Amazon Web Services documentation. You can use variables. You can use variables. You can also enter a value from the specific field in a tabular variable as described in Enter values and variables in patterns.</td>
</tr>
</tbody>
</table>
### Field | Description
--- | ---
Method | Enter the method value as a string using all capital letters, for example “GET”. The supported methods are:
- GET
- POST
- PUT
Refer to the relevant API guide for information. If the API documentation does specifically mention the HTTP query method, use the GET method.

Body | (Optional) Enter a request body as a string. If the string contains quotation marks, use the backslash mark in front the quotation marks to indicate that the string does not end at the quotation marks.

Headers | (Optional) If the relevant API documentation states that HTTP headers must be sent, enter these headers in the following format:
```
Header_name1:header_value1,header_name2:header_value2
```
For example, `Content-Type:xml`.

3. To save the command output in its entirety as a variable, select **NONE** from the **Define Parsing** list and define the variable as described in 6.

4. Select the parsing strategy from the **Define Parsing** list.

| Parsing strategy | Description |
--- | ---
Oracle | Horizontal file parsing strategy (not vertical). You can use this parsing strategy only for text files. For more information, see [Parse text from a horizontal file](#).
LDAP file | 
XML file | 
INI file | 
Properties file | 
JSON file (custom) | 
Vertical File | Retrieve text from a structured text file where each set of data spans multiple lines. For more information, see [Parse text from a vertical file](#).
After Keyword | Retrieve text directly following a specific keyword. For more information, see [Parse text using keyword, command, and positional type](#).
Command Line Java Style | Retrieve the value of a command-line parameter using Java-style parameters. For more information, see [Parse text using keyword, command, and positional type](#).
<table>
<thead>
<tr>
<th>Parsing strategy</th>

</tbody>
</table>

5. If working in the Debug Mode, define the parsing criteria as follows:
   a) Click **Run Operation** to see the result in the **Output** pane.
   b) In the **Output** pane, mark text or symbols that you want a variable to contain.
   c) In the variable name box, enter the name for the new variable, for example ‘process_name’.
   d) Press **Enter**.
      The new variable is added in the **Variables** pane.

6. If you are not working in Debug Mode, define the parsing criteria as follows:
   a) In the Variables pane, click **Add Variable** and enter the name for the new variable.
b) Click the **Advanced** icon.

c) Click **Add Column Label**.

d) Enter the parsing query.

e) Enter a value for the delimiter.

f) Enter a value for the position.

7. Select **Terminate** to stop discovery if no results are found.

8. If in Debug mode, test the step by clicking **Test** and checking that the operation brings the result you expected.

<table>

</tbody>
</table>

Use the Cloud REST Call operation to extract information on Database instances running on the region us-west-2 in the Amazon cloud.
Continue editing the pattern by adding a new step and defining its operation or Finalize the pattern.

Create a relationship and a reference
As part of creating or modifying a discovery pattern, you can use the Relation and/or Reference condition to create relationships and references between CIs a pattern discovers. This operation is relevant for both infrastructure and application patterns that Discovery uses for horizontal discovery.

Decide on the nature of relationship or reference that you are going to create.

The CI relationship you define in the pattern must comply with the model you have created:

1. Check if the CI is dependent: The system uses the identification rules to identify the CI independently of other CIs. Refer to Create or edit a CI identification rule.

2. If the CI is dependent, check its dependent relationship rules which define dependency structure of the CI types and the relationship types in these service definitions. For example, you can discover a load balancer pool with pool members belonging to it. To correctly reflect
the type of relationship between these two CIs, create a containment rule, which defines the load balancer pool as the owner of pool members: **Runs on::Runs**. For more information, refer to **CMDB dependent relationship rules**.

Example of a dependent rule for Load Balancer Pool Member

For independent CI types without dependent relationship rules define for them, you can define any relationship.

3. (Optional for application patterns used for horizontal discovery) Make sure that the data discovered using this pattern is saved as a table using standard parsing operations.
4. (Optional for creating a reference) Navigate to the relevant table definitions for the parent and the child CIs and choose the field to use as a reference field.

5. Navigate to the relevant pattern step:
   a. On the pattern form, select the relevant identification section.
   b. Select the relevant step or create a pattern step by clicking .

Basic knowledge of programming is desirable.
Role required: pd_admin

Discovery uses some patterns to discover a CI with all its related CIs and non-CIs: items that do not extend the Configuration Item (cmdb_ci) table.

CIs can have different relationships. Dependent relationship rules describe relationships between CIs. The identification engine uses these Dependent relationship rules to uniquely identify CIs and determine if a specific CI exists in the CMDB or must be added to the CMDB.

When you create a relationship, the system uses the parent CI and the child CI tables and creates a third table with data on the relationship between the parent and child CIs.

In addition to a relationship between CIs, you can create a reference connection between them. If a reference exists, then information about referenced child CIs appears at the bottom of the parent CI form. For example, all load balancer pool members appear on the form of the load balancer pool, which owns these members.
1. Discover related items together with the main CI to be able to view and use attributes of related CI types.
2. Select Create Relation/Reference from the Operation list.
3. Add the related CI type to this pattern as described in Discover related items together with the main CI.
4. Complete the form using the fields in the table.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parent Table</td>
<td>Enter the name of the table for the CI that you want to use as a parent CI in the relation. For example, cmdb_ci_lb_pool for the load balancer pool CI.</td>
</tr>
<tr>
<td>Child Table</td>
<td>Enter the name of the table for the CI that you want to use as a child CI in the relation. For example, cmdb_ci_lb_pool_member for the load balancer pool member, which the load balancer pool owns.</td>
</tr>
<tr>
<td>Result Table</td>
<td>Enter the name for the new table to store information about relations and references between CIs, resulting from this operation.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| Relation Type         | Select the type of relationship between CIs from the specified target tables. The part in the type name before the separator (::) refers to the parent CI and the second part, after the separator (::), to the child CI. For example, in the Owns::Owned by option:  
  - ‘Owns’ indicates that a load balancer pool (cmdb_ci_lb_pool) owns a load balancer pool member (cmdb_ci_lb_pool_member).  
  - ‘Owned by’ indicates that a load balancer pool member (cmdb_ci_lb_pool_member) is owned by a load balancer pool (cmdb_ci_lb_pool). |
| Reference              | (Optional) Select this check box to create a reference between the parent and the child CIs. |
| Direction              | (Only if Reference is selected) Select the direction of the reference:  
  - **Parent to Child** to display the parent CI on the child CI form. For example, the load balancer pool member form displays load balancer pool, which owns this pool member.  
  - **Child to Parent** to display child CIs on the parent CI form. For example, the load balancer pool form displays load balancer pool members this pool owns. |
<p>| Column Name            | (Only if Reference is selected) Enter the name of the field in the child CI table that the system uses to create the reference. For example, load_balancer. |</p>
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Creation Criteria</td>
<td>Select the criteria used to create the relation and/or reference:</td>
</tr>
<tr>
<td></td>
<td><strong>All</strong></td>
</tr>
<tr>
<td></td>
<td>The system creates a relationship or reference without any additional criteria.</td>
</tr>
<tr>
<td></td>
<td><strong>Field matching</strong></td>
</tr>
<tr>
<td></td>
<td>The system creates the relationship or reference only if the value in the specified field in a parent CI matches the value of the specified field in a child CI.</td>
</tr>
<tr>
<td></td>
<td><strong>Condition</strong></td>
</tr>
<tr>
<td></td>
<td>The system creates the relationship or reference only if the specified criteria is matched.</td>
</tr>
</tbody>
</table>

Parent table field

(Only if Field matching is selected) Enter the field from the parent table to compare.

You can use variables including values from tabular variables as described in Enter values and variables in patterns.

Child table field

(Only if Field matching is selected) Enter the field from the child table to compare.

Unmatched values

Operation for values in the two tables that do not match. You can keep or remove unmatched values.

5. If you selected **Condition** from **Creation Criteria**, define this condition:
   a) In the first condition field, enter the required value.
   b) In the first condition field, enter the required value.
      For example, enter the actual string or a variable name.

   ![Set values](image.png)

   ![Add another condition](image.png)

   ![Select an operator](image.png)

   c) Select an operator from the list.
If you select Is Empty, the second field is rendered irrelevant and disappears.

d) To add more conditions, click the plus icon and define the criteria.

e) If you create multiple conditions, define if this pattern must meet all or any of them: From the Meet list, select All or Any.

Use the **Create Relation/Reference** operation to create the Owns::Owned by relation between a load balancer pool and a load balancer pool member. You also create a reference from a load balancer pool member to the load balancer pool.
Another example is using the **Create Relation/Reference** operation to create the **Provides::Provided by** relation between a storage device and a file system. This operation also creates a reference from the storage device to the load system.
Another example is using the **Create Relation/Reference** operation to create the reference between a disk partition and a iSCSI disk.
The example below shows how to add a non-CI item (a switch port (dscy_switchport)) to a CI (switch (cmdb_ci_ip_switch)).

```
```
```
- Continue editing the pattern by adding a new step and defining its operation or
- Finalize the pattern.
Reuse a shared step library
As part of creating or modifying a discovery pattern, you can reuse a sequence of discovery steps that you created for one pattern in other patterns. Saved shared step sequences become pattern modules referred to as shared libraries.

Basic knowledge of programming is desirable.

Role required: pd_admin

Reusing existing step sequences saves you from recreating the same steps manually.

First, you save the steps you want to reuse into a repository as a shared library. Then you can insert them wherever relevant and as many times as needed.

You can deactivate shared libraries, so that patterns using them, skip steps in deactivated shared libraries. For more information, see *Discovery Configuration Console*.

1. If the steps you want to reuse already exist, create a reusable step sequence as follows:
   a) Navigate to the pattern containing the steps that you want to reuse.
   b) Navigate to the steps that you want to combine.
   c) Select the steps, right-click, and choose *Create shared library*.
   d) Fill in the fields as appropriate:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shared Library Name</td>
<td>Specify a unique name for the library. For example, UNIX-OS for a step sequence used to discover the Unix operating system.</td>
</tr>
<tr>
<td>Library Description</td>
<td>Specify a meaningful description for the library.</td>
</tr>
</tbody>
</table>

   e) Click *Create*.
   The selected steps are saved as a shared library in the Discovery Patterns (sa_pattern) table.

2. Reuse the step sequence you created:
   a) Navigate to the pattern in which you want to insert your step sequence.
   b) Select the relevant identification section or connectivity section.
   c) Select *Library Reference* from the *Operation* list in one of the following locations:
      - the *Identification Sections* or *Connectivity Sections* for Service Mapping
      - the Step window for Discovery
   d) Select the required shared library from the *Library* list.
   The library is inserted as substeps inside an untitled step.
e) Rename **Untitled Step** to reflect the purpose of the step.

3. If in Debug mode, test the step by clicking **Test** and checking that the operation brings the result you expected.

- Continue editing the pattern by **adding a new step and defining its operation** or
- **Finalize the pattern**.

**Run an SSH script file**

As part of creating or modifying a discovery pattern, you can use the **Run SSH Script File** operation to run composite commands or sequences of commands on Unix-based hosts.

Navigate to the relevant pattern step:

1. On the pattern form, select the relevant identification section for Discovery.
   
   Alternatively, select the relevant identification or connection section for Service Mapping.

2. 

   Select the relevant pattern step or click ![icon](image) to add a step.

**Basic knowledge of programming is desirable.**

**Role required:** pd_admin

1. Select **Run SSH Script File** from the **Operation** list.

2. Enter file name of the SSH script file located on the MID Server in the **File Name**.

3. To save the command output in its entirety as a variable, select **NONE** from the **Define Parsing** list and define the variable as described in step 6.

4. If necessary, select the parsing strategy from the **Define Parsing** list.

**Note:** Alternatively, use EVAL scripts to manipulate collected data as described in **KB0647736: Examples of EVAL scripts used in discovery patterns**.
<table>
<thead>

<td>Retrieve text specified by delimiters and position within the line (the most common way to retrieve text from generic text files). See Parse text using delimited text.</td>
</tr>
</tbody>
</table>

5. If working in the Debug Mode, define the parsing criteria as follows:
   a) Click Run Operation to see the result in the Output pane.
   b) In the Output pane, mark text or symbols that you want a variable to contain.
   c) In the variable name box, enter the name for the new variable, for example ‘process_name’.
d) Press **Enter**.  
The new variable is added in the **Variables** pane.

6. If you are not working in Debug Mode, define the parsing criteria as follows:  
a) In the Variables pane, click **Add Variable** and enter the name for the new variable.  
b) Click the **Advanced** icon.

c) Click **Add Column Label**.
d) Enter the parsing query.
e) Enter a value for the delimiter.
f) Enter a value for the position.

7. Select **Terminate** to stop discovery if no results are found.
8. If in Debug mode, test the step by clicking **Test** and checking that the operation brings the result you expected.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

This pattern step uses the Run SSH Script File operation to collect all information about storage entities associated with the discovered Linux server.
- Continue editing the pattern by adding a new step and defining its operation or Finalize the pattern.

Set a parameter value
As part of creating or modifying a discovery pattern, you can use the Set Parameter Value operation to apply a value to a parameter.

Navigate to the relevant pattern step:
1. On the pattern form, select the relevant identification section for Discovery.
   Alternatively, select the relevant identification or connection section for Service Mapping.
2. Select the relevant pattern step or click to add a step.

Basic knowledge of programming is desirable.
Role required: pd_admin

1. On the Identification or Connectivity Sections form, select **Set Parameter Value** from the **Operation** list.
2. Fill in the fields, as appropriate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Value</strong></td>
<td>Specify the value that you want to assign to the parameter. You can use strings or variables. You can also use values from temporary tabular variables: from a specific field or a specific column in a table sequentially, starting from the first row. For more information, see <a href="#">Enter values and variables in patterns</a>.</td>
</tr>
<tr>
<td><strong>Name</strong></td>
<td>Specify the name of the variable to which to assign this value.</td>
</tr>
</tbody>
</table>

3. If in Debug mode, test the step by clicking **Test** and checking that the operation brings the result you expected.

<table>
<thead>
<tr>

<td>3. Set the display label</td>
</tr>
</tbody>
</table>

To set the CI name to “IIS” and the version number, define the **Set Parameter Value** operation as follows:
Transfer a file
As part of creating or modifying a discovery pattern, you can transfer a file from the MID Server to a computer in your organization.

Basic knowledge of programming is desirable.

Role required: pd_admin

1. Upload the file to the MID Server:
   a) Navigate to Pattern Designer > Uploaded Files.
   b) Click New.
   c) Enter a meaningful name in the Name field.
   d) Click the Operating Systems tab.
   e) Click OS Types and select the relevant type from the list.
f) Click **OS Architectures** and select the relevant option from the list.

   **Note:** You can select both 32-bit and 64-bit option for the same file if necessary.

   g) Click the **Manage Attachments** icon.

   h) Attach a file.

   See **Add and manage attachments**.

2. Navigate to the relevant pattern step:
1. On the pattern form, select the relevant identification section for Discovery. Alternatively, select the relevant identification or connection section for Service Mapping.

2. Select the relevant pattern step or click to add a step.

3. Select **Put file** from the **Operation** list.

4. Click **Refresh**.
   
The name of the uploaded file appears in the **File name** field.

5. Specify the variable that refers to the MID Server path on the remote computer in the **Full Path Target** field.

6. If in Debug mode, test the step by clicking **Test** and checking that the operation brings the result you expected.

<table>
<thead>
<tr>
<th>This operation is used in</th>
<th>This item</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hierarchy</td>
<td>Application</td>
</tr>
<tr>
<td>CI Type</td>
<td>ActiveMatrix Business Works (cmdb_ci_appl_tibco_matrix)</td>

<td>Tibco BW Identification</td>
</tr>
<tr>
<td>Step number and Name</td>
<td>20. put tibco script</td>
</tr>
</tbody>
</table>

Use the Put File operation to copy the TibcoParser file onto the target host and keep the full path to copied file in target host in the variable `$TibcoParser`. 
Continue editing the pattern by adding a new step and defining its operation or finalize the pattern.

Define an SNMP query
As part of creating or modifying a discovery pattern, you can use the SNMP query operation to execute SNMP queries on CIs that support the SNMP protocol, typically, load balancers.

Navigate to the relevant pattern step:
1. On the pattern form, select the relevant identification section for Discovery. Alternatively, select the relevant identification or connection section for Service Mapping.
2. Select the relevant pattern step or click to add a step.

Basic knowledge of programming is desirable.

Role required: pd_admin
1. Select SNMP query from the Operation list.
2. To browse to the SNMP OID that you want to query using the debug mode:
   a) Activate pattern Debug mode.
b) Click **Browse** and select the management information base (MIB) in the list or perform a search based on MIB values.

c) Select either a single scalar value or multiple columns in the MIB tree. Multiple columns must be in the same table.

d) Optional: Click **Get Data** to display the data in the SNMP Browser form.

e) Click **OK**.

3. To manually specify the SNMP OIDs for the query:

- If the result of the SNMP query is a single string, choose **Scalar** and fill in the fields:

  **Scalar fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Descriptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>SNMP OID</td>
<td>The SNMP OID to query.</td>
</tr>
<tr>
<td>Variable</td>
<td>Name of the scalar variable to hold the query result.</td>
</tr>
</tbody>
</table>

- If the result of the SNMP query is a table, choose **Table**, click the plus icon, and fill in the fields:

  **Table fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Descriptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table name</td>
<td>Replace <em>Table_Name</em> with the name of the Variables table.</td>
</tr>
<tr>
<td>Table OID</td>
<td>Replace <em>Table_OID</em> with the SNMP OID to query.</td>
</tr>
<tr>
<td>New column name</td>
<td>Replace <em>new-column-name</em> with the column name.</td>
</tr>
<tr>
<td>New OID</td>
<td>Replace <em>new_OID</em> with the SNMP OID to query.</td>
</tr>
</tbody>
</table>

4. Select **Use Cache** to save the operation results in cache on the MID Server.

Use cache to optimize discovery and avoid creating unnecessary load on central shared components, such as load balancers. The base system keeps operation results in cache for an hour.

5. Select **Terminate** to stop discovery if no results are found.

6. If in Debug mode, test the step by clicking **Test** and checking that the operation brings the result you expected.

The following configuration is an example of the **SNMP query** operation.

<table>
<thead>
<tr>
<th>This operation is used in</th>
<th>This item</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hierarchy</td>

<tr>
<th>This operation is used in</th>
<th>This item</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step number and Name</td>
<td>1. Get Name (BIG IP LB)</td>
</tr>
</tbody>
</table>

- Continue editing the pattern by **adding a new step and defining its operation** or **Finalize the pattern**.

**Add a column to a table**
As part of creating or modifying a discovery pattern, you can use the **Transform table** operation to add one or more computed columns to an existing table and place the results in a target table. The target table can be the source table.

Navigate to the relevant pattern step:
1. On the pattern form, select the relevant identification section for Discovery.
   Alternatively, select the relevant identification or connection section for Service Mapping.
2. Select the relevant pattern step or click to add a step.

Basic knowledge of programming is desirable.
Role required: pd_admin
1. Select **Transform table** from the **Operation**.
2. Fill in the fields, as appropriate.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source table</td>
<td>Specify the name of the source table.</td>
</tr>
<tr>

</tr>
<tr>
<td></td>
<td>the source table.</td>
</tr>
</tbody>
</table>

3. Click the plus icon to add each target field and fill in the fields, as appropriate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target Field Name</td>
<td>Specify a name for the column. It can be an existing column or a new one.</td>
</tr>
<tr>
<td>Value</td>
<td>Specify the operation expression that determines the values added to the</td>
</tr>
<tr>
<td></td>
<td>column. You can use variables including values from tabular variables as</td>
</tr>
<tr>
<td></td>
<td>described in Enter values and variables in patterns.</td>
</tr>
</tbody>
</table>

4. If in Debug mode, test the step by clicking Test and checking that the operation brings the result you expected.

Identity Integration Feature Pack

<table>
<thead>
<tr>
<th>This operation is used in</th>
<th>This item</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hierarchy</td>
<td>Applications &gt; Web Servers</td>
</tr>
<tr>
<td>CI Type</td>
<td>Load Balancer Service (cmdb_ci_lb_service)</td>

<td>Pattern</td>
<td>F5 BigIP LTM</td>
</tr>
<tr>
<td>Section</td>
<td>Identification for all entry point types</td>
</tr>
<tr>
<td>Step number and Name</td>
<td>9. Fix ip</td>
</tr>
</tbody>
</table>

For F5 load balancer, you want to translate IP addresses in the default hexadecimal format into decimal format. You use the Javascript that performs this translation in the value field. You add the "clean_ip" column containing IP addresses in decimal format to the existing (source) table.
Continue editing the pattern by adding a new step and defining its operation or finalize the pattern.

Change credentials to default
As part of creating or modifying a discovery pattern, you can use the Unchange user operation to switch back to default administrative credentials if you previously changed them to non-default using the Change user operation.

Navigate to the relevant pattern step:
1. On the pattern form, select the relevant identification section for Discovery.
   Alternatively, select the relevant identification or connection section for Service Mapping.
2. Select the relevant pattern step or click to add a step.

Basic knowledge of programming is desirable.
Role required: pd_admin
1. Select Unchange User from the Operation list.
2. If in Debug mode, test the step by clicking Test and checking that the operation brings the result you expected.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hierarchy</td>
<td>Applications &gt; Business Integration Software</td>
</tr>
<tr>
<td>CI Type</td>
<td>IBM WebSphere MQ Queue</td>

<td>WMQ Queue Unix Pattern</td>
</tr>
<tr>
<td>Section</td>
<td>Local queue connectivity</td>
</tr>
<tr>
<td>Step number and Name</td>
<td>11. exit change user credentials</td>
</tr>
</tbody>
</table>

As part of discovery of an IBM WebSphere MQ Queue, you change credentials to IBM WebSphere MQ. It allows you to manipulate local IPs to discover connections on the local queue. Once this segment of discovery is complete, you change credentials back to the default: IBM WebSphere MQ Queue credentials.
• Continue editing the pattern by **adding a new step and defining its operation** or **Finalize the pattern**.

**Append two tables**
As part of creating or modifying a discovery pattern, you can use the **Union table** operation to append two tables of the same format.

Navigate to the relevant pattern step:
1. On the pattern form, select the relevant identification section for Discovery.
   Alternatively, select the relevant identification or connection section for Service Mapping.
2. Select the relevant pattern step or click ![Add Step](image) to add a step.

Basic knowledge of programming is desirable.

Role required: pd_admin

Appending two tables adds the second table at the end of the first table and places the results in the additional, target table. If necessary, you can specify one of the source tables as the target table.

1. Select **Union Tables** from the **Operation** list.
2. Fill in the fields, as appropriate.
## Field | Description
--- | ---
First table | Specify the name of the first source table.
Second table | Specify the name of the second source table.
Target table | Specify the name of the table into which the results are placed.

3. If in Debug mode, test the step by clicking **Test** and checking that the operation brings the result you expected.

<table>
<thead>
<tr>
<th>This operation is used in</th>
<th>This item</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hierarchy</td>
<td>Applications &gt; Application Servers</td>
</tr>
<tr>
<td>CI Type</td>
<td>WebSphere EAR</td>
</tr>
<tr>
<td>Pattern</td>
<td>J2EE EAR on Linux</td>
</tr>
<tr>
<td>Section</td>
<td>Oracle JDBC connectivity</td>
</tr>
<tr>
<td>Step number and Name</td>
<td>5. Union JDBCProviders with JDBCProviders2</td>
</tr>
</tbody>
</table>

A WebSphere EAR on Linux has two tables containing data on JDBC Providers. To add data from the second table at the bottom of the first table, use the **Union Tables** operation as follows:

- Continue editing the pattern by **adding a new step and defining its operation** or **Finalize the pattern**.

**Define WMI method invocation**

As part of creating or modifying a discovery pattern, you can use the **WMI method invocation** operation to execute a method selected from a table returned by a WMI query.

Navigate to the relevant pattern step:

1. On the pattern form, select the relevant identification section for Discovery.
   Alternatively, select the relevant identification or connection section for Service Mapping.
2. Select the relevant pattern step or click to add a step.

Make sure that the step containing the WMI method invocation operation follows the step with the WMI query operation. The WMI query results in table which you must use as the source table for WMI method invocation operation.

Basic knowledge of programming is desirable.

Role required: pd_admin

This operation is relevant only for Windows.

1. Select WMI method invocation from the Operation list.
2. Fill in the fields, as appropriate:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enter Source Table</td>
<td>Specify the source table name. The source table must be the result of the WMI Query operation you perform before this step. You can enter a value from the specific field in a table as described in Enter values and variables in patterns.</td>
</tr>
</tbody>
</table>
| Enter WMI Method     | Select the desired method:
|                      |  - In the debug mode, click Get methods and select the method from the list. |
|                      |  - Not in the debug mode, enter the name of the method as a string, for example, “RunDetails”. |
| Enter Target Table   | Specify the target table name.                                              |
| Enter Target Column  | Specify the name of the column to contain the results of the method invocation. |

3. If in Debug mode, test the step by clicking Test and checking that the operation brings the result you expected.

<table>
<thead>
<tr>
<th>This operation is used in</th>
<th>This Item</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hierarchy</td>
<td>Applications &gt; Directory Services</td>
</tr>
<tr>
<td>CI Type</td>
<td>IIFP</td>
</tr>
<tr>
<td>Pattern</td>
<td>IIFP On Windows Pattern</td>
</tr>
<tr>
<td>Section</td>
<td>AD Home Forest connectivity stage-wmi</td>
</tr>
<tr>
<td>Step number and Name</td>
<td>2. invoke_wmi_method Run Details</td>
</tr>
</tbody>
</table>

During discovery of Identity Integration Feature Pack (IIFP), use the RunDetails WMI method to extract information on details from the ManagementAgents table. You discover this table earlier using the WMI query operation. In this case, the result is saved in the same table in the column named “details”.
- Continue editing the pattern by **adding a new step and defining its operation** or
- **Finalize the pattern**.

**Define a WMI query**

As part of creating or modifying a discovery pattern, you can use the **WMI query** operation to execute a query on a remote Windows system either explicitly or automatically. Successful values are logged in a specified target table.

Navigate to the relevant pattern step:

1. On the pattern form, select the relevant identification section for Discovery.
   Alternatively, select the relevant identification or connection section for Service Mapping.

2. Select the relevant pattern step or click to add a step.

Basic knowledge of programming is desirable.

Role required: pd_admin

This operation is relevant only for Windows.

1. Select **WMI Query** from the **Operation** list.
2. Define the namespace path in the **Namespace** field.
3. If in the debug mode:
   a) Click **Statement Accelerator** to populate the table and field values automatically.
   b) Select a table from the **Table name** pane.
      The field values are displayed in the **Fields** pane.
   c) Define parameters and operators for the condition in the **Add Condition Clause**.
      The actual query text is displayed in the **Get Full Statement**.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
4. If not in the debug mode, enter the WMI query string in the Get Full Statement.
5. Enter the variable for the table in which the retrieved data is saved in the Add Target Table field.
   You can enter a value from the specific field in a table as described in Enter values and variables in patterns.
6. Select Use Cache to save the operation results in cache on the MID Server.
   Use cache to optimize discovery and avoid creating unnecessary load on central shared components, such as load balancers. The base system keeps operation results in cache for an hour.
7. Select Terminate to stop discovery if no results are found.
8. If in Debug mode, test the step by clicking Test and checking that the operation brings the result you expected.

<table>
<thead>
<tr>
<th>This operation is used in</th>
<th>This item</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hierarchy</td>
<td>Applications &gt; Directory Services</td>
</tr>
<tr>
<td>CI Type</td>
<td>IIFP (cmdb_ci_directory_iifp)</td>
</tr>
<tr>
<td>Pattern</td>
<td>IIFP On Windows Pattern</td>
</tr>
<tr>
<td>Section</td>
<td>AD Home Forest connectivity stage-wmi</td>
</tr>
<tr>
<td>Step number and Name</td>
<td>1. Get all agents details via WMI step</td>
</tr>
</tbody>
</table>

This step uses the WMI Query operation to extract data on agents from the MicrosoftIdentityIntegrationAgent namespace and save this data in the variable table named $ManagementAgents.

- Continue editing the pattern by adding a new step and defining its operation or
- Finalize the pattern.
Parsing strategies
In discovery patterns, you can use parsing strategies to analyze syntax of the source file. You extract values from parsed files, which allows you later to convert these values into variables.

There are several parsing strategies coming with the base system:

<table>
<thead>
<tr>
<th>Parsing strategy</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle</td>
<td>Horizontal file parsing strategy (not vertical). You can use this parsing strategy only for text files. For more information, see Parse text from a horizontal file.</td>
</tr>
<tr>
<td>LDAP file</td>
<td>Retrieve text from a structured text file where each set of data spans multiple lines. For more information, see Parse text from a vertical file.</td>
</tr>
<tr>
<td>XML file</td>
<td>Retrieve text using keyword, command, and positional type.</td>
</tr>
<tr>
<td>INI file</td>
<td>Retrieve the value of a command-line parameter using standard Unix parameters. For more information, see Parse text using keyword, command, and positional type.</td>
</tr>
<tr>
<td>Properties file</td>
<td>Retrieve text specified by its position from the end of the line. For more information, see Parse text using keyword, command, and positional type.</td>
</tr>
<tr>
<td>JSON file (custom)</td>
<td>Retrieve text specified by delimiters and position within the line (the most common way to retrieve text from generic text files). See Parse text using delimited text.</td>
</tr>
</tbody>
</table>

In addition to these parsing strategies, you can create custom parsing strategies to answer the needs of your organization.

Parse text from a horizontal file
You can use the file type parsing strategy to parse text in files of the following formats: .ora file (used by various Oracle products), .properties file (common for Java), .xml file, and .ini file. For vertical files, use the vertical file parsing strategy instead.
Role required: pd_admin

Basic knowledge of programming is desirable.

You can use this parsing strategy only for text files.

⚠️ Warning: Do not use this parsing strategy for non-text files such as binary files.

You can define multiple extracts and variables. When identifying text for extraction into variables, what you are really doing is identifying the text location within a context.

You can use one of the following methods:

- In Debug mode, you can select the relevant string from the file contents in the text box. For each string you select, its position and delimiters relative to its context are stored. It enables the same definitions to apply to other files with the same structure even though the text varies. However, it selects the entire text within a context.

  For example, if you try to select only 456 in the text box of an XML file with the following line, the entire string between the keywords is selected.

  ```xml
  <ciTypeID>123-456-7890000000</ciTypeID>
  ```

- On the Advanced Parsing Options form (outside of Debug mode), you can specify a delimiter and position to identify the text string. You can also use this form to make a more refined selection than from within the text box.

  For example, you could specify a delimiter (→) and the number of positions to extract after the delimiter (3) to extract the string (456).

1. Select one of the parsing operations from the Operation list.
2. Select one of these options from the Parsing strategy list:
   - Oracle
   - JSON file
   - Properties file
   - XML file
   - LDAP file
   -INI file

3. If working in the Debug mode, perform the following steps:
   a) Click Retrieve or Retrieve File Content to display the content of what you are parsing in the Output pane.
   b) Select the string in the text box. All matching strings in the same context are automatically selected.
   c) Assign the string to a variable on the Define Variable Name form. Provide a unique and meaningful name and click OK.
   d) To identify additional strings and variables, click the plus icon.

4. Define the string to be parsed from within Debug mode, or on the Advanced Parsing Options form (outside of Debug mode).
2. Define Parsing

- XML File

Output

<table>
<thead>
<tr>
<th>Variables</th>
<th>Table</th>
<th>List</th>
<th>Add Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>There must be at least one entry</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Advanced Parsing Options

- Root Path

<table>
<thead>
<tr>
<th>Name</th>
<th>XPath query</th>
<th>Delimiter</th>
<th>Position</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Advanced Parsing Options form

1. Click Advanced and specify the root path. The root path is the section (hierarchical branch in the file structure) where parsing takes place.
2. Click the plus icon for each string and variable to be added and fill in the fields, as appropriate.
   - **Name**: Specify the column name.
   - **XPath query**: Specify the XPath query for the string. For example, appcmd/APP/@APP.NAME.
   - **Delimiter**: Specify the delimiter for the string.
   - **Position**: Specify the position of the string.

5. To end the discovery process if no results are found, select the **If not found** check box.
6. Click **Close Advanced**.

Parse text from a vertical file

In discovery patterns, you can use the **Vertical file** parsing strategy to parse text into variables for vertical files.

Basic knowledge of programming is desirable.

Role required: pd_admin

1. Select one of parsing operations from the **Operation** list in one of the following locations:
- the **Identification Sections** or **Connectivity Sections** for Service Mapping
- the Step window for Discovery

2. Select the **Vertical file** from the **Parsing strategy** list.
3. In the **Target Table** field, enter the name of the table to hold variables extracted during this operation.
4. In the **Section** field, enter the title of the section.
   This parameter is used to identify the beginning of sections in the file.
5. In the **Line** field, enter the line number. The lines are counted from top to bottom.
6. In the **Column** field, enter the column number. The columns are counted from left to right.
7. To end the discovery process if no results are found, select the **If not found** check box.

You can use the **Vertical File** parsing strategy for the Parse Command Output operation to extract information about a database. The section separator is `entry:`.
Parse text using keyword, command, and positional type

In discovery patterns, you can parse text into a variable for keyword, command, and positional type parsing strategies.

Basic knowledge of programming is desirable.

Role required: pd_admin

The following strategies are generally used to extract a value from a variable. You can use them to define only a single value for extraction. To extract multiple strings, define multiple steps.

- After keyword
- Command-line Java style
- Command-line Unix style
- Position from start
• Position from end

1. Select one of the parsing operations from the Operation list in one of the following locations:
   • the Identification Sections or Connectivity Sections for Service Mapping
   • the Step window for Discovery

2. Select one of the keyword, command, or positional types from the Define Parsing list.

3. Click Retrieve.
   The content of the file is displayed in the Output pane.

4. Define the string to extract as a variable from within Debug mode:
   a) Select the string in the Output box.
      All settings are automatically entered in the variable fields.
   b) Provide a unique and meaningful name for the variable and click OK. The variable is added to the Variables table.

5. Define the string to extract as a variable outside of Debug mode:
   a) Specify the value and delimiter for the Keyword, Position from Start, or Position from End.
   b) To add more strings and variables, click the plus icon.

6. To end the discovery process if no results are found, select the If not found check box.

You can use the Command Line Java Style parsing strategy to extract the path of the installation directory of the WebSphere Server.
Parse text using a regular expression

In discovery patterns, you can parse text into variables using **Regular expressions** as the parsing strategy.

- Familiarize yourself with the Regex Java syntax:
  
  [https://docs.oracle.com/javase/8/docs/api/java/util/regex/Pattern.html](https://docs.oracle.com/javase/8/docs/api/java/util/regex/Pattern.html)

- Navigate to the relevant pattern step:
  
  1. On the pattern form, select the relevant identification section for Discovery.
     
     Alternatively, select the relevant identification or connection section for Service Mapping.
2. Select the relevant pattern step or click to add a step.

Basic knowledge of programming is desirable.
Role required: pd_admin

1. Select one of the parsing operations from the Operation list.
2. Click Retrieve or Retrieve File Content to display the actual file in the Output pane.

3. Select the Regular expression from the Define Parsing list.
4. Fill in the fields, as appropriate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Regular expression</td>
<td>Specify the regular expression. You cannot select text in the text box using this parsing strategy. You can only specify a single expression. To extract multiple values, define several expressions enclosing each expression into parentheses. Matching of variables to parentheses occurs according to the order of the parentheses sets. (The first variable is matched to the first set of parentheses, and so on).</td>
</tr>
</tbody>
</table>
5. To end the discovery process if no results are found, select the **If not found** check box.

---

### Parse text using delimited text

In discovery patterns, you can parse text using the **Delimited text** parsing strategy.

Basic knowledge of programming is desirable.

Role required: `pd_admin`

You can use this parsing strategy for extracting data from any text file. Define which segment of this text file to extract by entering the symbol or word which serves as a boundary and defining the position.

1. Select **Delimited text** from the **Define Parsing** list in one of the following locations:
   - the **Identification Sections** or **Connectivity Sections** for Service Mapping
   - the Step window for Discovery

2. Fill in the fields, as appropriate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Include lines with</td>
<td>Specify the constraints used to determine which lines are included in the text selection.</td>
</tr>
<tr>
<td>Exclude lines with</td>
<td>Specify the constraints used to determine which lines are excluded in the text selection.</td>
</tr>
<tr>
<td>Line separator</td>
<td>Specify the non-default character used as a line separator in the text. Default separators are either NEWLINE or CARRIAGE RETURN, depending on the operating system.</td>
</tr>
</tbody>
</table>
3. To define parse the file and extract the string as a variable from within Debug mode:
   a) Select the string to be parsed in the text box. The name box appears.
   b) Provide a unique and meaningful name for the variable and press Enter. The variable is added to the Variables table. The Line Separator, Delimiters, and Positions attributes for the variable are filled in automatically.

4. To define parse the file and extract the string as a variable outside Debug mode:
   a) In the Variables pane, click Add Variable. The new variable with the default name _Name_ shows in the list of variables.
   b) Click the new variable and enter a unique and meaningful name.
   c) If necessary, enter a string in the Line Separator field. This string is used to identify where lines in the file end. For example, common line separators are "/n" or "/r".
   d) Click the Edit icon next to Delimiters, enter the symbol or word to use as a delimiter and click the Plus icon.
e) Specify the position. For multiple positions, use commas as separators.

5. To end the discovery process if no results are found, select the If not found check box.

You can use the Delimited Text parsing strategy for the Parse Variable operation to extract the Queue Manager name of an IBM WebSphere Message Broker.
Customize parsing strategies

You can modify parsing strategies that come as part of the base system or add new ones. Parsing strategies are part of discovery patterns, which Service Mapping and Discovery use to discover and map configuration items (CIs).

Practical knowledge of Java scripting is required.

Role required: pd_admin

Parsing serves to analyze syntax of the source file. You extract values from parsed files, which allows you to convert these values into variables. There are standard parsing strategies, which are part of the base system. If you cannot extract data using the standard parsing strategies, you can create your own parsing strategy. Custom parsing strategies are JavaScript files.

The JavaScript for parsing strategy must comply to the following guidelines:

- You may use the `content` variable to refer to the raw data resulting from executing the operation.
- Use `rtn` to indicate the string, which is the result of your custom parsing.
- The script output must be in well-formed XML syntax.

For example, the output must contain correct tags and markup:

```
<root>
  <OS>Windows</OS>
  <version>10</version>
```
• If necessary, you may use third-party JavaScripts to convert the content into XML.

For example, to convert the content from JSON into XML, use the X2JS JavaScript provided by open-source software.

```javascript
var xtojs = new X2JS();
var result = xtojs.js2xml(jsonObj);
var finalResult = "<root>" + result + "</root>";
```

1. Navigate to Pattern Designer > Custom Parsing Strategies.
2. To modify the JSON custom parsing strategy, select JSON file.
   Alternatively, click New to create a new JSON file.
3. For the new custom parsing strategy, enter a name describing the new strategy in the Name field.
   For example, if the purpose of this strategy is to extract information using a certain protocol, use this protocol as the name.
4. Enter or modify the parsing strategy purpose in the Description field.
5. Write the JavaScript in the Script pane to define the business logic of parsing.
6. Click Update or Submit.

Use this custom parsing strategy for defining operations inside pattern steps.

Define the connection section

Define a set of discovery steps to discover outbound connections of a configuration item (CI). This operation is relevant only for patterns of the application type used by Service Mapping.

Create a pattern or select a pattern that you want to modify as described in Create or modify patterns.

Basic knowledge of programming is desirable.

Role required: pd_admin

A connection section identifies a type of outgoing connection. CIs can have multiple outgoing connections. Configure a separate connection section for each type of outgoing connection. For example, a .NET application CI can have outgoing connections of several types: ADO.NET, XML Web Services, or .NET. So, you must add connection sections for these three types to the .NET Application pattern.

1. Navigate to Pattern Designer > Discovery Patterns and open the required pattern from the pattern list.
   The pattern must be of the Application type.
2. In the Connectivity Section, click New.
   Note: The Connectivity Section is grayed out if the pattern cannot be edited for Service Mapping.
3. Enter the name, and click Save.
4. On the pattern form, click Save to save the pattern.
5. Click the created connection section.
   The pattern designer opens showing the connection step.
6. Select Create Connection from the Operation list.
7. Fill in the fields, as appropriate.
### Field | Description
--- | ---
Select Connection Type | - **Application Flow**: Used between two applications (can be of the same type).
- **Cluster**: Used for connections to CIs of the cluster type. Specify a cluster name.
- **Inclusion**: Used for connections to an object that is included in the current object. For example, a connection from J2EE to EAR, and a connection from IIS to a website.
- **Storage Flow**: Used for connections between configuration items (CIs) of host type and devices of storage type.

Select Entry Point | Select the entry point type from the list. For more information, see [Entry point attributes](#).

Enter Connection Attributes | Define attributes by either entering actual values or variables.

Select Target CI Type | Select the target CI type from the list.

Is hidden | Select the check box if the connection should be hidden (that is, not shown in the user interface), but is used for continuing the discovery flow.

Is traffic based | Select the check box to use the traffic-based discovery method for this connection.

---

8. If necessary, create more connectivity sections on the pattern form.

<table>
<thead>
<tr>
<th>This operation is used in</th>
<th>This item</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hierarchy</td>
<td>Applications &gt; Business Integration Software</td>
</tr>
<tr>
<td>CI Type</td>
<td>IBM WebSphere MQ Queue</td>
</tr>
<tr>
<td>Pattern</td>
<td>WMQ Queue Unix Pattern</td>
</tr>
<tr>
<td>Section</td>
<td>Alias queues connectivity</td>
</tr>
<tr>
<td>Step number and Name</td>
<td>6. Create outgoing connection to alias queues</td>
</tr>
</tbody>
</table>

To create a connection from Microsoft Exchange CAS to Exchange Mailboxes, define the **Create Connection** operation as follows:
Example of creating an application pattern

Follow this example to see a step-by-step process of creating and defining the identification section for a new application pattern.

Basic knowledge of programming is desirable.

Role required: pd_admin

This example shows how to create a mapping pattern using the debug mode.

The pattern is for Apache Web Server on Unix.

1. Navigate to Pattern Designer > Discovery Patterns.
2. Click New.
3. Define the basic pattern attributes as follows:
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pattern type</td>
<td>Select Application.</td>
</tr>
<tr>
<td>Name</td>
<td>Enter Apache Web Server on Unix Pattern.</td>
</tr>
<tr>
<td>CI Type</td>
<td>Select Apache Web Server from the list.</td>
</tr>
<tr>
<td>Operating system (Application patterns only)</td>
<td>Clear the All check box and select the following check boxes from the list:</td>
</tr>
<tr>
<td></td>
<td>• AIX Server</td>
</tr>
<tr>
<td></td>
<td>• HPUX Server</td>
</tr>
<tr>
<td></td>
<td>• Linux Server</td>
</tr>
<tr>
<td></td>
<td>• Solaris Server</td>
</tr>
<tr>
<td></td>
<td>• UNIX Server</td>
</tr>
<tr>
<td>Run Order (Application patterns only)</td>
<td>Leave the default None setting.</td>
</tr>
<tr>
<td>Description</td>
<td>This pattern discovers Apache Web Servers on Unix versions up to 2.4.</td>
</tr>
</tbody>
</table>

4. Click Save.
5. Create the identification section and define its basic properties:
   a) Under Identification Section, click New.
   b) Configure the following parameters:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter Identification for HTTP(S) entry point type(s).</td>
</tr>
<tr>
<td>Entry Point Types (Application patterns only)</td>
<td>Select the following check boxes from the list:</td>
</tr>
</tbody>
</table>
**Find Process Strategy** (Application patterns only) | Select Listening Port.
---|---
**Order** | Enter 1.

6. Click the newly created identification section: **Identification for HTTP(S) entry point type(s)**. The new identification section opens on the separate tab.

7. Activate the debug mode:
   a) In the Pattern Designer, click **Debug Mode**.
      The Debug Identification Section window is displayed.
   b) Fill in the required details for the entry point type:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug Type</td>
<td>Select <strong>Top down</strong> for performing top-down discovery with Service Mapping or</td>
</tr>
<tr>
<td>Type</td>
<td>Select HTTP(S) for the entry point type from the list.</td>
</tr>
<tr>
<td>URL</td>
<td>Enter <a href="http://10.196.39.244:6080/ITO">http://10.196.39.244:6080/ITO</a>.</td>
</tr>
</tbody>
</table>

   c) Click **Connect**.
   The debug mode is activated and the green dot appears on the debug button:

   ![Debug Mode - Top down](image)

   Notice that the following variables are populated with values once the debug mode is active:
   - computer_system # the Apache host information
   - entry_point # identified by the URL in this case
   - process # the Apache process information

8. Check that the process name on the CI is Apache Web Server:
   a) Rename the first step of the identification section to **Check process name to match Apache**.
   b) Select **Match** from the **Operation** list.
   c) Enter `$process.executable` in the first condition field.
d) Select Contains from the conditional operator list.

e) Enter "httpd" in the second condition field.

f) Click the plus icon to add another condition.

g) Enter $process.executable in the first condition field.

h) Select Contains from the conditional operator list.

i) Enter "apache" in the second field.

j) Define that this match operation must match one of these conditions: Select Any from the Meet list.

k) Click Test and verify that you get the following message: No changes were made during this test.

9. Populate the label attribute for your CI:

   a) In the Steps tree, click to add a step blow the first step.
   b) Rename the new step to sets the display label.
   c) Select Set Parameter Value from the Operation list.
   d) Enter "Apache" in the Value field.
   e) Enter $name in the Name field.
   f) Click Test and verify that the following message appears:
g) Click **Close**.

10. Populate the home directory attribute:
   a) In the **Steps** tree, add a step and rename it to **Get home dir**.
   b) Select **Parse variable** from the **Operation** list.
   This operation extracts the value after the `-d` in the content box.
   c) Expand the **process** variable in the **Temporary Variables** pane.
   d) Drag the `commandLine` variable from the Temporary Variables pane into the variable field under operation.
Note: For more information on using the drag-and-drop feature, see Enter values and variables in patterns.

e) Select Command line Unix style from the Define Parsing list.

f) In the Variables pane, add the new install_directory variable.

g) Click Test.

11. Obtain the home directory attribute from the HTTP daemon.
If the previous step populated the home directory attribute, skip this step. In this example, it is necessary to perform it.

a) In the Steps tree, add a new step and rename it to Condition – check that home dir was set if not extract it from httpd -V.

b) Select Parse command output from the Operation list.
This operation extracts the value after the -d in the content box.

c) Click Precondition.

d) Enter $install_directory in the condition value field.

e) Select Is Empty from the conditional operator list.

f) Select True from the If condition Is list.

g) Enter $process.executablePath + " -V " in the Set Command Details field.

h) Click Run Command.

i) Select Delimited text from the Define Parsing list.

j) Enter HTTPD_ROOT in the Include lines field.
k) Click the **Edit** button next to **Delimiters**.

![Edit Delimiters window](image)

l) Add the two delimiters: equals (=) and quotes (").

m) Click **OK**.

n) Enter 2 in the **Positions** field.

o) Click **Test**.

   The Debug Results window shows the home directory attribute populated with a value.

p) Click **OK**.

12. Populate the CI configuration file attribute:
   a) In the **Steps** tree, add a new step and rename it to **Get config file**
   b) Select **Parse variable** from the **Operation** list.
   c) Expand the **process** variable in the **Temporary Variables** pane.
   d) Drag the commandLine variable from the **Temporary Variables** pane into the **Enter Variable** field.

   The value is populated: `/usr/sbin/httpd2-prefork -f /etc/apache2/httpd.conf`.

   e) Select **Command Line Unix Style** from **Define Parsing** list.
f) Click Retrieve.
g) Enter -d in the Keyword field.
h) Select the value in the Output pane and create a new variable named install_directory.
i) Click Test.

13. Extract the CI configuration file attribute from the HTTP daemon:
If the previous step populated the configuration file attribute, skip this step. In this example, it is necessary to perform it.
a) In the Steps tree, add a new step and rename it to Condition – check that conf_file was set if not extract it from httpd -V.
b) Select Parse command output from the Operation list.
c) Click Precondition.
d) Enter $config_file in the condition value field.
e) Select Is Empty from the conditional operator list.
f) Enter $process.executablePath" -V " in the Set Command Details field.

g) Click Run Command.

h) Select Delimited text from the Define Parsing list.

i) Enter SERVER_CONFIG_FILE in the Include lines field.

j) Click the Edit button next to Delimiters.

k) Add the two delimiters: equals (=) and quotes (").

l) Click OK.

m) Enter 2 in the Positions field.

n) If the new conf_file variable is not added automatically, create it in the Variables pane.

o) Click Test.
The Debug Results window shows the configuration file attribute populated with a value.

p) Click OK.

14. If the configuration file attribute is still not populated, perform this step:
   a) In the Steps tree, add a new step and rename it to default location of conf file.
   b) Select Set Parameter Value from the Operation list.
   c) Click Precondition.
   d) Enter $conf_file in the condition value field.
   e) Select Is Empty from the conditional operator list.
   f) Select True from the If condition is list.
   g) Enter $home_dir+"/conf/httpd.conf" in the Value field.
   h) Enter $conf_file in the Name field.
   i) Click Test and verify that the configuration file attribute is populated.

15. Concatenate the home directory and configuration file values:
   a) In the Steps tree, add a new step and rename it to check if the SERVER_CONFIG_FILE is relative or not.
   b) Select Set Parameter Value from the Operation list.
   c) Click Precondition.
   d) Enter $conf_file in the condition value field.
   e) Select Starts With from the conditional operator list.
   f) Enter "/" in the string value.
   g) Select False from the If condition is list.
   h) Enter $home_dir+"/$conf_file in the Value field.
   i) Enter $conf_file in the Name field.
   j) Click Test and verify that the configuration file attribute is populated.

16. Populate the version attribute:
   a) In the Steps tree, add a new step and rename it to get version from version.signature (IBM HTTPSERVER).
   b) Select Parse file from the Operation list.
   c) Enter the concatenated $install_directory variable and "/version.signature" string ("$home_dir+/version.signature") in the Select File field.
   d) Click Retrieve File Content.
   e) Create the Version variable in the Variables pane.
   f) Click Test and verify that the version attribute is populated.
   In this example, the version is not extracted at this stage.

17. Extract the version attribute from the HTTP daemon:
   a) In the Steps tree, add a step and rename it to Condition - check that version was set if not extract it from httpd -v.
   b) Select Parse command output from the Operation list.
   c) Click Precondition.
d) Enter $version in the condition value field.
e) Select Is Empty from the conditional operator list.
f) Click the plus icon (+) to add another condition.
g) Enter $version in the condition value field.
h) Select Contains from the conditional operator list.
i) Enter "directory" in the string value.
j) Select Any from the Meet list.
k) Select true from the If precondition is list.

l) Enter $process.executablePath+" -V | grep 'Server version' | cut -d '/' - f 2 | cut -d ' ' -f 1" in the Set Command Details field.
m) Click Run Command and verify that the version attribute appears in the Output pane.

n) Select Position From End from the Define Parsing list.
o) Enter 1 in the Positions field in the Variables pane.
p) Click **Test** and verify that the configuration file attribute is populated.

Note:
The version number appears only in the **Temporary Variables** pane, not in the **CI Attributes** pane.
Notice that at this stage you have successfully identified the Apache Web Server and populated its various attributes except the version attribute that is left blank on purpose.

18. If the version is still not populated, extract it from the IHS.product file:
   a) In the Steps tree, add a step and rename it to set version if still empty.
   b) Select Parse File from the Operation list.
   c) Click Precondition.
   d) Enter $version in the condition value field.
   e) Select Is Empty from the conditional operator list.
   f) Click the plus icon (+) to add another condition.
   g) Enter $version in the condition value field.
   h) Select Contains from the conditional operator list.
   i) Enter "directory" in the string value.
   j) Select Any from the Meet list.
   k) Select true from the If precondition is list.
   l) Enter $install_directory + "/properties/version/IHS.product" in the Select File field.
   m) Click Retrieve File Content.
      The content of the file is displayed in the Output pane.
   n) Select XML File from the Define Parsing list.
   o) Mark the version value in the Output pane, and then enter version in the variable pop-up.
19. Find additional attributes by reusing a shared step library.
   a) In the Steps tree, add a step, and rename the new step to reference to enrich library.
   b) 
   c) Select Library reference from the Operation list.
   d) Select Apache Enrich Attributes from the Library list.
      This operation inserts a sequence of preconfigured substeps into the step tree. For information on how to create shared step libraries, see Reuse a shared step library.
20. Populate process-related attributes:
   a) In the **Steps** tree, add a step and rename it to **get processes**.
   b) Select **Get process** from the **Operation** list.
   c) Enter "httpd" in the **Command Line** field.
   d) Enter in the $procs in the **Specify Target Variable** field.
   e) Click **Test** and verify that the attributes are displayed:
21. Discover the process IDs:
   a) In the **Steps** tree, add a step and rename it to **set process_ids**.
   b) Select **Parse variable** from the **Operation** list.
   c) Enter `$procs[*].pid` in the **Enter Variable** field.
   d) Select **Delimited text** from the **Define Parsing** list.
   e) Click **Retrieve**.
      The content is displayed in the **Output** pane.
   f) Create the **process_ids** variable in the **Variables** pane.
   g) Enter 1 in the **Positions** field.

f) Click **Close** when done.
h) Click **Test**.

i) Verify that all the necessary attributes are populated:
22. Click **Save**.

23. Verify that Discovery and Service Mapping can use the identification section you defined:
   a) Run the horizontal discovery of an Apache Web Server using this pattern.
   b) Navigate to the table of Apache Web Servers and check that there is an entry for this CI.
   c) Run the top-down discovery of the same CI.
   d) Check the same Apache Web Servers table.
   e) Verify that the record is not duplicated.
It means that the results of both horizontal and top-down discovery are written in the CMDB under the same record. The identification section of the pattern is correct.

Discover related items together with the main CI

Add related items to the patterns to perform horizontal discovery of configuration items with all their related items: CIs or non-CIs, like ports or serial numbers.

1. (Optional) Check if the CI is dependent: The system uses the identification rules to identify the CI independently of other CIs. Refer to Create or edit a CI identification rule.

2. (Optional) To understand the model better, check dependent relationship rules which define the dependency structure of the CI types and the relationship types in these service definitions. For example, you can discover a Tomcat server with Tomcat WARs belonging to it. For more information, refer to CMDB dependent relationship rules.
Example of the Containment rule for the Tomcat WAR CI type

3. To add a non-CI to the pattern, add it as a related item for the CI type to which the main CI belongs. For more information on adding related items for the CI type, see Configure references to other CIs or non-CIs as related items for the CI type.

Role required: pd_admin

Related items, both CIs and non-CIs, serve as a reference and provide additional information about the CI. For example, you can define a serial number, a port and an network APR table as
related items for a hardware server. The system does not use these items for identification. After you configure related items for the CI type, you can use horizontal discovery for CIs of this type together with their related items.

**Note:** Non-CIs are items that do not extend the Configuration Item (cmdb_ci) table. Examples of non-CIs are ports, serial numbers, or Network ARP tables.

Pattern Designer displays attributes of related CI types, which you added to the pattern in the CI attributes pane. You can view and use these attributes while creating or modifying the main CI pattern.

1. Navigate to Pattern Designer > Discovery Patterns.
2. Select the relevant pattern.
3. On the pattern form, select the relevant identification section.
4. Make sure that you are not in Debug mode.
5. On the CI Attributes pane, click the Manage related CIs icon.

![](image)

6. Select the relevant related CI type.
   You can use the search box to locate a specific CI type.
7. Click the Plus icon.
   The new related CI type is added to the list.
8. Optional: Add other related CI types.
9. Click OK.
   New tabs for related CI types you added appear under the tab for the main CI:
Continue editing the pattern by adding a new step and defining its operation. To view or use attributes of a related CI type, click the relevant tab in the CI Attributes pane.

Enhance patterns without changing their identification sections

Enable patterns to search for additional attributes and modify pattern discovery logic defined in identification sections by using extension sections.

If your ServiceNow instance uses domain separation and you have access to the global domain, select the domain to which the application service belongs from the domain picker. The selected domain must be a domain without any child domains.

Basic knowledge of programming is desirable.

Role required: pd_admin

Patterns can be of infrastructure or application type. Infrastructure patterns are used only by Discovery for creating lists of devices. Application patterns serve both Service Mapping and Discovery that use the same application patterns for their purposes. Each pattern including its identification and connection sections is an individual file. There are also reusable sequences of discovery steps referred to as shared libraries. Each shared library is an individual file, but it is always part of the infrastructure or application pattern and is not used as a standalone pattern. Records for both patterns and shared libraries reside in the Discovery Patterns (sa_pattern) table.
To modify the discovery logic in identification sections without changing the identification sections themselves, you can add extension sections to the pattern. Every extension section consists of a shared library, either new or existing.

When you create or modify a shared library in the extension section, you save changes only to the shared library, not to the pattern containing this extension section.

⚠️ **Warning:** The changes to the shared library affect all patterns using this shared library.

The MID Server runs extension sections after identification sections and only if at least one identification section completes successfully.

If there are more than one extension sections associated with this pattern, define the order in which the MID Server runs these extension sections.

You can deactivate shared libraries, so that patterns using them, skip steps in deactivated shared libraries. For more information, see *Discovery Configuration Console*.

1. Navigate to **Pattern Designer > Discovery Patterns** and open the required pattern from the pattern list.
   The pattern can be of the Infrastructure or Application type.
2. To define discovery steps for the new extension section.
   a) Click **New** under **Extension section**.
   b) Enter the name of this extension section.
   c) Click **Done**.
      The pattern form displays the new section under **Extension section**.
   d) Click the name of the new extension section.
      The Pattern Designer opens showing the Steps tree on the left.
      If no discovery steps have been identified for this pattern, the **Untitled Step** appears in the Steps tree in the left pane of the window.
   e) **Define discovery steps**.
   f) Click **Save** to save the extension section and make Service Mapping and Discovery use it.
You do not publish extension sections

3. To use an existing shared library for the new extension section:
   a) Click **Add** under **Extension section**.
   b) Select the shared library from the name list.

4. If there are more than one extension sections, define the order in which the MID Server runs the extension section.
   a) Select the check box next to the extension section.
   b) Click **Edit** under **Extension section**.
   c) Enter a number that determines the order in the **Order** field.
   If there is only one extension section, its order is 1 by default.
   The section with the lowest order number is used first.
   d) Click **Done**.

**Click Debug** to run the newly created extension section. Pattern Designer runs extension sections after running identification sections.

**Fine-tune patterns using traffic-based discovery**

As an alternative to customizing the pattern from the Pattern Designer side, improve existing patterns so that Service Mapping can use them to find configuration item (CI) connections previously found using traffic-based discovery.

Basic knowledge of programming is desirable.

Role required: pd_admin

Not only can Service Mapping discover CIs using patterns, it can also discover them by following traffic connections between CIs. This method is referred to as traffic-based discovery.

Using traffic-based discovery, Service Mapping may discover an important CI connection. In this case, you can make sure that this connection is always found for all CIs belonging to the same CI type. You do that by modifying the pattern used to discover CIs of that CI type. A pattern is a sequence of steps whose purpose is to detect attributes of a CI and its outbound connections.

You can search CI configuration files to locate data discovered using traffic-based discovery, for example IP address and port. If there are configuration files containing this data, you create a pattern step to parse this file. Next time Service Mapping discovers this CI using the modified pattern, it extracts the information about this connection directly from the configuration file.

1. Alternatively, if Service Mapping is deployed, navigate to **Service Mapping > Services > Application Services**.
2. Click **View Map** next to the relevant application service.
3. Right-click the relevant CI.
4. Select **Show traffic based connections**.
   The Traffic Based Connections List opens displaying the following information:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP</td>
<td>The IP address of the application connected to the selected CI.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Port</td>
<td>The port on the selected CI that is used to communicate to the other application.</td>
</tr>
<tr>
<td>Process</td>
<td>The ID of the process in the selected CI.</td>
</tr>
<tr>
<td>Already on map</td>
<td>• Yes — if this connection shows on the map.</td>
</tr>
<tr>
<td></td>
<td>• No — if this connection is not part of the application service and not on the map.</td>
</tr>
<tr>
<td>System decision</td>
<td>The setting defines if Service Mapping keeps the discovered traffic-based connection or removes it. The value comes from the algorithm that Service Mapping uses.</td>
</tr>
<tr>
<td>User decision</td>
<td>(Optional) The setting overrides the System decision setting, which defines if Service Mapping keeps the discovered traffic-based connection or removes it. For example, if the System decision setting for a connection is Keep, and you want to remove this connection, select Remove.</td>
</tr>
</tbody>
</table>

**Note:** There may be a case when you can see traffic-based connections on the map, but the Traffic Based Connections list does not display them. It happens for the connections that have been removed from the TCP Connection (cmdb_tcp) table less than three days.

5. Double-click the connection you want to use to create a pattern step.

6. If there are multiple patterns used to discover this CI, select the pattern for which you want to create the step, and click **OK**.

Pattern Designer creates a temporary connection section for this pattern with a new step.
The Debug Connection Section window is displayed with some fields automatically populated.

7. Click **Connect**.

The Debug mode is activated.

The Search Assistant window opens.

8. Search CI configuration files for data received using traffic-based discovery:
   a) Under **Free Text**, review data automatically filled in from the Traffic Based Connections List.
The File Patterns field displays file types in which Pattern Designer performs the search.

b) Click the **Search Files** tab and review files. If necessary, you can remove irrelevant files from the search by clicking the Minus icon.

c) Click **Search**.

After search completes, the **Search Result** tab opens with the list of files in which any of the search criteria was found.

9. Create a pattern step for parsing the configuration file containing information about the connection:

a) On the Search Result tab, click one of the files and review connection data found in this file.

b) Wait for the file content to load and select the relevant entry under the file name:
c) To use this data to create the pattern step, click **Create parse file step**.

Pattern Designer shows the new step with the Parse File operation. It automatically assigns this step the name in the following format: Parsing <file name>.

Pattern Designer automatically sets the file name, file path, and parsing strategy for the step. It also creates variables that contain data you searched for. If there is a variable, which contains the file path, Pattern Designer enters this variable for the path.
d) Optional: If necessary, you can modify parsing strategy.
e) Rename the section to provide a meaningful name, for example Discover HA Proxy client connection.

Or

Copy and paste the step into the relevant connection section.

10. Complete modifying the pattern as described in **Finalize a pattern**.

**Finalize a pattern**

After you finish defining your pattern, make it ready for use by Service Mapping and Discovery.

Role required: pd_admin

There are several ways to finalize a pattern after creating or modifying it:
• Saving — Save all the information you defined for the pattern creating a draft. You can continue working on the pattern draft at any time. Service Mapping and Discovery do not use the pattern draft for discovery and mapping.

• Discarding changes — If you realized that the changes you made to a pattern are incorrect, you can discard them.

• Checking — Actually run the pattern on the relevant configuration item (CI) to check that the operations that you defined for it are correct. Check your pattern before activating it. This option is available only for application patterns used by Service Mapping.

• Publishing — Make Service Mapping and Discovery use this pattern for discovery and mapping. A new version of this pattern is created. The state of the pattern version used previously changes to History.

1. On the pattern definition form, complete your pattern definition by performing one or more of the following actions:

<table>
<thead>
<tr>
<th>To accomplish this</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td>Save the pattern</td>
<td>Click <img src="Save.png" alt="Save" />.</td>
</tr>
<tr>
<td>Discard unwanted changes</td>
<td>Click <img src="Discard.png" alt="Discard" />.</td>
</tr>
</tbody>
</table>
| Check the pattern (only for application patterns used by Service Mapping) | 1. Click ![Check Pattern](Check Pattern.png).  
2. Enter parameters for connecting to this CI.  
3. Click ![Connect](Connect.png).  
4. Wait for Pattern Designer to run the pattern and check that there are no errors.  
5. Troubleshoot any errors. If there are no errors, you can publish or save your pattern. |

| Publish the pattern | Click ![Publish](Publish.png). |

2. Close the Pattern Designer tab.

**Copy patterns from one instance to another**

To copy patterns from one instance to another, create an update set containing new or modified patterns with their related items in your development instance. Then, import the update set into your production instance.

Role required: pd_admin
Typically, you maintain two ServiceNow instances in your organization: for production and for development. Create or modify patterns, test them, and verify results in the development instance. When you are satisfied with the discovery results, export relevant patterns from the development instance to create an update set.

Update sets is a ServiceNow feature for transferring customizations from one instance to another. Each update set is stored in the Update Set (sys_update_set) table. Specific customizations associated with the update set are the entries in the Customer Update (sys_update_xml) table, and they appear as a related list on the update set record. The method of creating update sets for patterns is different from creating update sets for other types of customizations.

**Warning:** Always follow this procedure to create update sets for patterns. Do not use the standard platform procedure for creating update sets.

Depending on the extent of the changes, you can use the following pattern export methods:

### Export patterns

This option creates an update set containing the modified patterns and the related items necessary for the patterns to work. The related items include:

- Extension sections
- Tracked files
- Related CI types
- Classification records
- Associated scripts

**Note:** Update sets do not include changes in script includes used in patterns.

### Export patterns with CMDB items

This option creates an update set that contains modified patterns with the related items from the previous option and the CMDB items associated with the modified patterns. The CMDB items include:

- Main CI type
- Entry point types
- Lookup tables
- Identifiers
- Hosting and reconciliation rules

The update set is an XML file with the following name convention:

```
sys_remote_update_set<random alphanumeric string>.xml.
```

1. In the development instance, perform these steps to export patterns:
   a) Navigate to Pattern Designer > Discovery Patterns.
   b) Select application or infrastructure patterns that you want to export.

**Note:** You cannot export shared libraries.

   c) At the bottom of the window, click the Actions on selected rows button.

**Note:** You cannot use more than 20 patterns at a time for the Export patterns with CMDB items method.
d) Click **Export patterns** or **Export patterns with CMDB items**.

e) When the system finishes exporting patterns, it creates the update set.

f) To view the list of items included in the update set, click **View Logs** in the success message.

g) Click **Close**.

The update set file in XML format is automatically downloaded on the computer.

h) Save the update set file locally for future use.

2. In the production instance, perform these steps to import the customized patterns:

   a) Elevate privileges to the security_admin role.

   b) Navigate to **System Update Sets > Retrieved Update Sets**.

   c) Click the link **Import Update Set from XML**.

   d) Click **Choose File** and select an XML file.

   e) Click **Upload**.

   The customization is now available as a retrieved update set with state Loaded.

3. **Preview a remote update set**.

   The system scans and validates the update set and displays its contents on the **Customer Updates** tab.

4. **Commit the update set**.

5. Click **Close** in the success message.

   The production instance contains all new or modified patterns with related items from the update set.

6. Upload the updated set of patterns and related items onto the MID Server:

   a) Navigate to **Discovery > MID Servers**.

   b) Alternatively, navigate to **Service Mapping > MID Servers**.

   c) Click **Pattern Sync to Mid**.

7. If the discovery fails or the result is not as expected, restart the MID Server to make sure that the MID Server runs the latest set of patterns.

**Choose the pattern version**

Every time you modify and save a pattern, you create a version of this pattern. Choose which pattern version Service Mapping and Discovery use for discovery.

Role required: pd_admin

By default, the latest version is used for discovery, but you can choose any other version to use.

If necessary, you can **compare pattern versions**.

1. Navigate to **Pattern Designer > Discovery Patterns**.

2. Click the required pattern.

   The form for this pattern opens.

3. Click the **Pattern** tab.

4. Scroll down to the **Versions** section.

   The state of the active pattern version that Service Mapping and Discovery use is **Current**.

5. Click the version you want to use.
6. Click **Revert to this version** under **Related Links**.

This pattern version becomes the active version that Service Mapping and Discovery use. Its state changes to Current.

**Compare pattern versions**

If you have multiple versions of the same pattern, you can compare them to decide which pattern version to use for discovery.

Role required: pd_admin
Service Mapping and Discovery use patterns in their discovery process. Every time you modify and save a pattern, you create a version of this pattern.

1. Navigate to **Pattern Designer > Discovery Patterns**.
2. Click the required pattern.
   The form for this pattern opens.
3. Click the **Pattern** tab.
4. Scroll down to the **Versions** section.
   The state of the active pattern version that Service Mapping and Discovery use is **Current**.
5. Click the previous pattern version, which you want to compare to the current version.
6. Click **Compare to Current** under **Related Links**.
7. In the Compare to Current window, click the **Pattern text** pane either under **Selected Version** or **Current Version**.

![Compare to Current Window](image)

The text comparison view opens showing the text of the selected pattern version and the current pattern version side by side. The step containing a difference appears highlighted. Highlight colors indicate the type of change:

- Updated step — purple
- New line or characters — green
- Deleted line or characters — red

8. Review the differences in the pattern versions.
9. If necessary, click **Revert chunk** to replace the step in the current version with the step from the previous version.
10. Click OK when done.

11. If you copied any steps from the previous version and want to save the change, click Save Merge.

**ITOM Health**

ServiceNow® ITOM Health product includes the ServiceNow® Event Management feature and the ServiceNow® Operational Intelligence feature, which together help you to track and maintain the health of services in your organization.

**Features of ITOM Health**

**Event Management**

Event Management gathers alerts from infrastructure events captured by third-party monitoring tools. Event Management uses IT-related information gathered by Discovery to map alerts to configuration items. Based on the collected information, Event Management then provides dashboards showing a consolidated view of all service-impact events.

**Operational Intelligence**

Use Operational Intelligence to proactively analyze your IT infrastructure to spot issues and prevent service outages. Using advanced machine learning to analyze information about your IT infrastructure, the application automatically determines dynamic thresholds and identifies anomalies that may indicate potential service outages.

Using guided setup to implement IT Operations Management applications

IT Operations Management Guided Setup provides a sequence of tasks that help you configure IT Operations Management applications on your ServiceNow instance. To open IT Operations Management guided setup, navigate to Guided Setup > ITOM Guided Setup. For more information about using the guided setup interface, see .

Event Management

The ServiceNow® Event Management helps you to identify health issues across the datacenter on a single management console. It provides alert aggregation and root cause analysis (RCA) for discovered services, application services, and automated alert groups. Event Management is available as a separate subscription from the rest of the ServiceNow platform.

Understanding Event Management

Monitor the health of business services and infrastructure using a single management console and respond appropriately to any issues that come up. Event Management provides intelligent event and alert analysis to ensure continuity of your business service performance. Event Management receives and processes events via the MID Server.

What Event Management can manage

Event Management can manage:

Discovered business services

A Business service is a definition of interrelated CIs from the CMDB. The discovered service, from Service Mapping, includes a business service map with: mapping relationships, an impact tree showing outage severity, active alerts, related alerts, and CI properties. Business
service information is discovered by Service Mapping. The mapping information appears on dashboards, the Alerts list, and the Events list.

**Application service**

An application service is a business service created by selecting CIs to include in the service. Application service information appears on dashboards with drill-down capability to a map view.

**Technical services**

A Technical service is a dynamic grouping of CIs, based on some common criteria. For example, you can create a technical service based on location for all web servers or all databases in Ireland.

**Alert groups**

Alert groups show sets of alerts for ease of maintenance. Alert groups are not the same as automated alert groups.

**Architecture**

As events occur on various systems, the MID Server connector instance sends the events to the instance. Event Management generates alerts, applies alert management rules, and prioritizes alerts for remediation and root cause analysis. View this information on dashboards, the alert list in Alert Intelligence, or from a service map.
Workflow

Event Management receives external events and generates alerts based on event and alert management rules. Events are sent directly to your instance using an email server, script, SNMP trap, or a web service API. The corresponding alerts appear on dashboards for tracking and remediation purposes.

As the computer, software, or service generates events, the MID Server polls the external event tracking tool. The MID Server, which maintains a connection to Event Management, sends the information to your instance for storage, processing, and remediation.

The instance stores events in the Event (em_event) table and attempts to generate alerts based on pre-defined rules and event mappings. Regardless of whether an alert generates, the original event is available for review and remediation. Alerts generate according to the following process flow:

1. Find the best matching event rule for an event. If the source of the event matches the source specified in an existing rule, then a rule is matched. Also, if the event matches the optional rule Filter and the event additional_info value matches the rule Additional Information filter. A rule without any filter is ignored, for example the source filter is missing or the Additional Information filter is missing. If multiple rules are defined for the same type of event, use the rule Order to determine the order of rule application.
• If the rule **Ignore** check box is selected, no alert generates. However, the event is still available for review and remediation.
• If transforms have been defined, apply them. If compose parameters are set, apply the additional content to display to the user in the alert.
• If **Active** in the threshold section is selected, accumulate all events until the threshold is met. Generate a single alert for the events.

2. Search for an event field mapping even if there was no event rule. If an event field mapping is found, apply the mapping information. If the event has no severity after the event transformations, retain the event for reference purposes and do not generate an alert.

3. Search the Alert (em_alert) table for a matching message key. If a matching message key exists, update the alert according to the event information. If a matching message key does not exist, create an alert. If another event has the same matching key, associate the events under a single alert. For root cause analysis purposes, bind the alert to a specific CI.
Event Management and Service Mapping

Event Management uses discovered services from Service Mapping and automated alert groups with root cause analysis (RCA) to expedite alert resolution.

When an event from an external source arrives from the MID Server, script, or web service API (not pictured), Event Management locates CI information for alert generation and CI remediation. CI information is stored in the CMDB from sources such as Service Mapping, Discovery, third-party sources, and manual population. You can use correlated alert group and root cause analysis information to resolve the issue.
Event Management interoperability

Request Event Management

Event Management plugin (com.glideapp.itom.snac) requires a separate subscription and must be activated by ServiceNow personnel. This plugin includes demo data and activates related plugins if they are not already active.
Role required: admin

To purchase a subscription, contact your ServiceNow account manager. The account manager can arrange to have the plugin activated on your organization's production and sub-production instances, generally within a few days.

If you do not have an account manager, decide to delay activation after purchase, or want to evaluate the product on a sub-production instance without charge, follow these steps.

1. From your instance, navigate to System Definition > Plugins.
2. On the All Applications page, click Request Plugin to open the request form on HI.
3. On HI, select to be redirected to the HI Service Portal Service Catalog.
4. On the Activate Plugin request form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target Instance</td>
<td>Instance on which to activate the plugin.</td>
</tr>
<tr>
<td>Plugin Name</td>
<td>Name of the plugin to activate.</td>
</tr>
<tr>
<td>Specify the date and time you would like this plugin to be enabled</td>
<td>Date and time must be at least two business days from the current time.</td>
</tr>
<tr>
<td>Reason/Comments</td>
<td>Information that would be helpful for the ServiceNow personnel who are activating the plugin. For example, if you need the plugin activated at a specific time instead of during one of the default activation windows, specify it in the comments.</td>
</tr>
</tbody>
</table>

5. Click Submit.

Enhance Event Management performance

The Event Management Accelerator plugin ensures that Event Management maintains performance at a high level. This plugin is optional.

Role required: admin

The `em_alert_history` and `em_impact_status` tables can grow to be very large, negatively impacting Event Management performance. Installing the Event Management Performance Accelerator plugin ensures that Event Management performs at a high level.

When upgrading from an earlier version with more than 5 million records in either the `em_alert_history` or `em_impact_status` tables, you must activate this plugin manually. When there are less than 5 million records, it runs automatically. You can customize this number by modifying the `evt_mgmt.plugin_activation.table_max_size` property.

To purchase a subscription, contact your ServiceNow account manager. The account manager can arrange to have the plugin activated on your organization's production and sub-production instances, generally within a few days.

If you do not have an account manager, decide to delay activation after purchase, or want to evaluate the product on a sub-production instance without charge, follow these steps.

1. From your instance, navigate to System Definition > Plugins.
2. On the All Applications page, click Request Plugin to open the request form on HI.
3. On HI, select to be redirected to the HI Service Portal Service Catalog.
4. On the Activate Plugin request form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target Instance</td>
<td>Instance on which to activate the plugin.</td>
</tr>
<tr>
<td>Plugin Name</td>
<td>Name of the plugin to activate.</td>
</tr>
<tr>
<td>Specify the date and time you would like this plugin to be enabled</td>
<td>Date and time must be at least two business days from the current time.</td>
</tr>
<tr>
<td>Reason/Comments</td>
<td>Information that would be helpful for the ServiceNow personnel who are activating the plugin. For example, if you need the plugin activated at a specific time instead of during one of the default activation windows, specify it in the comments.</td>
</tr>
</tbody>
</table>

5. Click Submit.

Out-of-the-box Event Management Performance Analytics Solutions

Performance Analytics Solutions contain preconfigured dashboards. These dashboards contain actionable data visualizations that help you improve your business processes and practices.

Performance Analytics Solutions

Use the Performance Analytics widgets on the dashboard to visualize data over time, analyze your business processes, and identify areas of improvement. With solutions, you can get value from Performance Analytics for your application with minimal setup.

**Important:** Set up and test Out-of-the-box Performance Analytics Solutions on a sub-production instance before enabling them in production. You can set up and test Performance Analytics on a sub-production instance without a subscription.

**Note:**
- Solutions include some dashboards that are inactive by default. You can activate these dashboards to make them visible to end users according to your business needs.
Out-of-the-box solutions and in-form analytics provide all the configuration records required to analyze default applications. Customize these records for use in your production environment.

To enable the solution for Event Management, an admin can navigate to Performance Analytics > Guided Setup. Click Get Started then scroll to the section for Event Management. The guided setup takes you through the entire setup and configuration process.

Implement Event Management in your instance

You can set up Event Management, including a MID Server, either with or without using guided setup in your instance.

Using guided setup to implement Event Management

Event Management guided setup provides a sequence of tasks that help you configure Event Management on your ServiceNow instance. To open Event Management guided setup, navigate to Guided Setup > ITOM Guided Setup. For more information about using the guided setup interface, see Using guided setup.

Setup to implement Event Management without using guided setup

Follow the specified tasks to setup Event Management. For more information, see Event Management setup.

Event Management setup

After activating Event Management, set it up to receive and process events, and generate and analyze alerts.

Event Management setup without using guided setup

Set up Event Management by completing these tasks in the following order:

1. Navigate to Event Management > Guided Setup and follow the configuration steps.
2. Configure a MID Server to receive and process events via the MID Server.
3. Configure connector definitions and connector instances to receive external events.
4. Configure event field mappings and alert binding to manage alert generation.
5. Alert management rules for resolving alerts, perform alert remediation, and CI remediation for alert management.
6. Get a top-down discovery to receive CI relationships for software and hardware.
7. Configure impact calculation for services, to establish priority for alert resolution.
8. Configure alert groups to consolidate related alerts.
9. Enable root cause analysis (RCA) for business services and for application services:
   a. Configure a dedicated RCA MID Server as described in Legacy: Configure a MID Server for RCA for business services.
   b. Set the sa_analytics.rca_enabled property to true.
c. To enable RCA for discovered business services, ensure that Service Mapping is enabled as described in Request Service Mapping. This step is not required for RCA for application services.

d. Request Service Mapping

e. Legacy: Configure a MID Server for RCA for business services

10. Configure any other general tasks that appear in this section as appropriate.

Note: Event Management does not support creating incidents on remote instances.

Note: Event Management does not support mobile devices.

Event Management setup using guided setup

Event Management guided setup provides a sequence of tasks that help you configure Event Management on your ServiceNow instance. To open Event Management guided setup, navigate to Guided Setup > ITOM Guided Setup. For more information about using the guided setup interface, see Using guided setup.

Event Management during a platform upgrade

During a platform upgrade Event Management jobs whose Upgrade safe flag is marked as true remain running.

During an upgrade of the platform, the Event Management connectors are working and continue to retrieve events. The events are being processed, transformed to an alert using event rules and if there is a suitable alert management rule, a task is created. However, the impact calculation is not supported during the platform upgrade.

Note: Event Management jobs that started running before the platform upgrade commenced continue to run during the upgrade.

The following Event Management jobs remain running as their Upgrade safe flag is marked as true:

- Event Management - Connector execution
- Event Management - Update stuck connect
- Event Management - Alert Priority Queue
- Event Management - close flapping alerts
- Event Management - close threshold alert
- Event Management - Evaluate Alert Management
- Event Management - Maintenance Calculator
- Event Management - process events

During the platform upgrade, all other Event Management jobs wait for the platform upgrade to finish.

Note: During an Event Management plugin upgrade, ALL Event Management jobs do NOT work.
**Domain separation and Event Management**

This is an overview of domain separation and Event Management. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can then control several aspects of this separation, including which users can see and access data.

### Overview

**Support: Level 1**

Domain separation is supported in this application. Not all ServiceNow applications support domain separation; some include limitations on the data and administrative settings that can be domain separated. To learn more, see Application support for domain separation.

### How domain separation works in Event Management

When domains are separated in Event Management, users can only see and manage alerts and events in their own (tenant) domain.

A domain column is present for Event Management tables that are provided in the base system. The column displays the name of the domain to which the event or alert belongs.

**Note:**

If the domain column does not display in the list, click (Update Personalized List) and add the required column. In addition, you can add a column that displays the domain path.

For information about domain separation limitations in Event Management, see Configure Event Management domain separation.

**Quick start tests for Event Management**

Validate that Event Management still works after you make any configuration change such as apply an upgrade or develop an application. Copy and customize these quick start tests to pass when using your instance-specific data.

Event Management quick start tests require activating the Event Management plugin (com.glideapp.itom.snac).

<table>
<thead>
<tr>
<th>Test</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EMSelfMonitoring</td>
<td>Track problems with the Event Management plugin after upgrade. To understand the details of issues found, open the Alert Console and search for alerts that failed, whose source is EMSelfMonitoring, and that were opened or reopened since the upgrade. The exact time for filtering can be found in the error message.</td>
</tr>
</tbody>
</table>

**Components installed with Event Management**

Activating the Event Management (com.glideapp.itom.snac) plugin adds several roles, scheduled jobs, and tables.
Roles installed with Event Management

Roles used by the Event Management application.

Event Management adds these roles.

<table>
<thead>
<tr>
<th>Role title (name)</th>
<th>Description</th>
<th>Contains roles</th>
</tr>
</thead>
<tbody>
<tr>
<td>Event Management Administrator</td>
<td>Has read and write access to all Event Management features to configure Event Management.</td>
<td></td>
</tr>
<tr>
<td>(evt_mgmt_admin)</td>
<td></td>
<td>• evt_mgmt_user</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• template_editor_global</td>
</tr>
<tr>
<td>Event Management Operator</td>
<td>In addition to the evt_mgmt_user permissions, can also activate operations on alerts such as acknowledge, close, open incident, and run remediations.</td>
<td>• evt_mgmt_user</td>
</tr>
<tr>
<td>(evt_mgmt_operator)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Event Management User</td>
<td>Has read access to all Event Management features. Has write access to alerts to manage the alert life. Has the itil role to be able to manage incidents that are created from alerts.</td>
<td>• itil</td>
</tr>
<tr>
<td>(evt_mgmt_user)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Event Management Integrator</td>
<td>Has create access to the Event (em_event) and Registered Nodes (em_registered_nodes) tables to integrate with external event sources.</td>
<td></td>
</tr>
<tr>
<td>(evt_mgmt_integration)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Scheduled jobs installed with Event Management

List of scheduled jobs that are provided with Event Management.

To review the list of scheduled jobs, navigate to **System Scheduler > Scheduled Jobs**. Event Management adds the following scheduled jobs.

<table>
<thead>
<tr>
<th>Scheduled job</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Event Management — Connector execution job</td>
<td>Compares current time with time when active connector instances were last run and sets relevant connectors to execute. Runs every 10 seconds.</td>
</tr>
<tr>
<td>Event Management — Handle Impact Stuck Service</td>
<td>Releases stuck services and marks them as requiring rebuilding in the Impact Changes table to rebuild the impact tree. Runs every 2 minutes, 31 seconds.</td>
</tr>
<tr>
<td>Event Management — Impact Calculator Trigger</td>
<td>Trigger the impact calculation. The Event Management dashboard and impact tree are refreshed using the calculated figures. Runs every 6 seconds.</td>
</tr>
<tr>
<td>Scheduled job</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Event Management — Impact Topology Consumer</td>
<td>Consumes topology changes and marks the related services as ‘require rebuilding’ in the Impact Changes table to rebuild their impact trees.</td>
</tr>
<tr>
<td></td>
<td>Runs every 19 seconds.</td>
</tr>
<tr>
<td>Event Management — Update stuck connectors</td>
<td>Release connector instances that are stuck.</td>
</tr>
<tr>
<td></td>
<td>Runs every 2 minutes.</td>
</tr>
<tr>
<td>Event Management — Alert Priority Queue</td>
<td>Calculate <em>alert priority</em>. Two Alert Priority Queue jobs are active and available and can be run multi-thread.</td>
</tr>
<tr>
<td></td>
<td>Runs every minute.</td>
</tr>
<tr>
<td>Event Management — auto close alerts</td>
<td>Alerts that are idle longer than 7 days (default time period) are closed. Modify the default using the <code>evt_mgmt.alert_auto_close_interval</code> property.</td>
</tr>
<tr>
<td></td>
<td>Runs every 10 minutes.</td>
</tr>
<tr>
<td>Event Management — Calculate Alert Priority Grouping</td>
<td>Runs and calculates the priority groups: urgent, high, moderate and low for the alerts according to the highest and lowest priority score in the system.</td>
</tr>
<tr>
<td></td>
<td>Runs every 30 minutes.</td>
</tr>
<tr>
<td>Event Management — Close Flapping Alerts</td>
<td>Close flapping alerts.</td>
</tr>
<tr>
<td></td>
<td>Runs every 5 minutes.</td>
</tr>
<tr>
<td>Event Management — Close Threshold Alerts</td>
<td>Close threshold alerts.</td>
</tr>
<tr>
<td></td>
<td>Runs every 2 minutes.</td>
</tr>
<tr>
<td></td>
<td>Runs every 11 seconds.</td>
</tr>
<tr>
<td>Event Management — Create/resolved Incidents by Alerts</td>
<td>Job to:</td>
</tr>
<tr>
<td></td>
<td>- Create incidents for alerts according to alert action rules.</td>
</tr>
<tr>
<td></td>
<td>- Update incidents according to alert state.</td>
</tr>
<tr>
<td></td>
<td>Runs every 11 seconds.</td>
</tr>
<tr>
<td>Event Management — Impact Tree Builder</td>
<td>Handles all services with changes from the <code>em_impact_changes</code> table and rebuilds their impact trees.</td>

<tr>
<td></td>
<td>Runs every 11 seconds.</td>
</tr>
<tr>
<td>Event Management — Insert Health Monitor</td>
<td>Job to produce the <strong>ServiceNow Event Management</strong> application service.</td>
</tr>
<tr>
<td></td>
<td>Runs once every hour.</td>
</tr>
<tr>
<td>Event Management — Maintenance Calculator</td>
<td>Calculate the maintenance for CIs.</td>
</tr>
<tr>
<td></td>
<td>Runs every minute.</td>
</tr>
<tr>
<td>Scheduled job</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Event Management — Node Count</td>
<td>Calculate <em>license usage</em>.</td>
</tr>
<tr>
<td></td>
<td>Runs once every hour.</td>
</tr>
<tr>
<td>Event Management — Process Events</td>
<td>Job that runs and processes each Ready event (apply event rule, mapping rule, and create or update alert)</td>
</tr>
<tr>
<td></td>
<td>Runs every 5 seconds.</td>
</tr>
<tr>
<td></td>
<td>Runs every 5 seconds.</td>
</tr>
<tr>
<td>Event Management — Queue Connector Processor</td>
<td>Bi-directional functionality. Processes all pending alerts in the Update Queue and sends them to the MID Server. By default, this dequeue process is performed in batches of 1,000 alerts.</td>
</tr>
<tr>
<td></td>
<td>Runs every 30 seconds.</td>
</tr>
<tr>
<td>Event Management — Recalculate Impact for Groups</td>

</tr>
</tbody>
</table>
| Health monitor scripts (em_monitor_scripts) | These scripts determine how to monitor or check, for example, when using the Connectors Monitor script. You can create customized script to monitor a device or an entity. The scripts provided with the base instance are:  
- Check delay in event processing  
- Connectors Monitor  
- Get Event Processing state  
- MID Server Threshold Alerts |
| Monitoring configuration (em_monitor_conf) | Use this table to configure what to monitor according to the scripts that are listed. Configure how often to run each script. If a script has a threshold, it determines what alert severity to display. Threshold values are in units of minutes and specify the delay time. Navigate to Event Management > Settings > Self-Health configuration to see the list of Monitoring Configurations or to create a new one. Use this script to test Data Center Monitoring.  
The scripts provided with the base instance are:  
- Connector’s idle state monitoring-monitor to verify whether any of the connectors was in idle state that surpassed the threshold (in minutes) that was configured.  
- Connectors Status- monitor to track the active status of the connectors.  
- Delay in event processing-monitor to track the duration (in minutes) of events that remained in ‘ready’ state and were not processed.  
- Event Processing job-monitors the state of the event processing jobs.  
- MID Server Threshold Alert-monitors MID Server health. |
| Monitoring state (em_monitor_state) | Use this table to set the threshold for each connector. When there is a value above the threshold, an alert is generated. A business service displays the status, for example, in the Event Management dashboard or Alert Console. |
| EM XMLStats Data (em_xmlstats_data) | Self-health statistics and diagnostic details for Operational Intelligence and Event Management, which are used to produce the XMLStats page. |

Event Management adds the following tables to support alert aggregation and RCA.
<table>
<thead>
<tr>
<th>Table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SA RCA Status (sa_rca_status)</td>
<td>Information (such as IDs) for the latest messages that were sent to the ECC Queue for a service during RCA.</td>
</tr>
<tr>
<td>SA RCA Output (sa_rca_output)</td>
<td>RCA learner output data.</td>
</tr>
<tr>
<td>SA RCA Group (sa_rca_group)</td>
<td>Automated alert groups for the RCA query.</td>
</tr>
<tr>
<td>SA Analytics Alert Staging (sa_analytics_alert)</td>
<td>Staging table for alerts used for analytics.</td>
</tr>
<tr>
<td>SA RCA Input (sa_rca_input)</td>
<td>Input data for the RCA learner.</td>
</tr>
<tr>
<td>SA Analytics Status (sa_analytics_status)</td>
<td>Last run information to be used for alert aggregation and RCA.</td>
</tr>
<tr>
<td>SA RCA Group Alert (sa_rca_group_alert)</td>
<td>Alerts associated with automated alert groups.</td>
</tr>
<tr>
<td>SA RCA Service Configuration Item Association (sa_rca_svc_ci_assoc)</td>
<td>Associations between CIs and services.</td>
</tr>
<tr>
<td>SA RCA SMC Config Base (sa_rca_smc_config_base)</td>
<td>State Model Configuration base. User defined RCA configurations. Each configuration is associated with one or more rules in the SA RCA SMC Rule Base (sa_rca_smc_rule_base) table, if applies.</td>
</tr>
<tr>
<td>SA RCA SMC Rule Base (sa_rca_smc_rule_base)</td>
<td>Service Analytics (SA) Root Cause Analysis (RCA) State Model. Individual rules that are associated with RCA configuration in the SA RCA SMC Config Base (sa_rca_smc_config_base) table.</td>
</tr>
<tr>
<td>SA RCA SMC Config (sa_rca_smc_config)</td>
<td>RCA Configuration revisions table. Snapshots of RCA configurations generated during configuration comparisons.</td>
</tr>
<tr>
<td>SA RCA SMC Deployment (sa_rca_smc_deployment)</td>
<td>Information about the current revision of the RCA configuration that is in effect, and the RCA configuration that is set to be deployed at the next daily run cycle of the Learner.</td>
</tr>
<tr>
<td>SA RCA SMC Run (sa_rca_smc_run)</td>
<td>RCA SMC (State Model Configuration) Run table. All comparisons between two RCA configurations that the user ran.</td>
</tr>
</tbody>
</table>
### Table

<table>
<thead>
<tr>
<th>Table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SA Alert Aggregation Learned Pattern (sa_agg_pattern)</td>
<td>Learned patterns from alert aggregation.</td>
</tr>
<tr>
<td>SA Alert Aggregation Learned Pattern Elements (sa_agg_pattern_element)</td>
<td>CI/Metric Name pairs associated with learned patterns.</td>
</tr>
<tr>
<td>SA Alert Aggregation Query Group Patterns (sa_agg_group_pattern)</td>
<td>Relationships between groups discovered in alert aggregation queries and patterns found in learning.</td>
</tr>
<tr>
<td>SA Alert Aggregation Query -- Staged (Recent) Alerts (sa_agg_group_alert_staging)</td>
<td>A staging table for alerts that have not yet been associated with any aggregated alert group.</td>
</tr>
<tr>
<td>SA Agg Pattern Attribute (sa_agg_pattern_attribute table)</td>
<td>CI/alert attributes to be used for finding patterns for alert aggregation.</td>
</tr>
<tr>
<td>SA Alert Attribute Populator Status (sa_alert_attribute_populator_status_table)</td>
<td>State and statistics for attribute populator job.</td>
</tr>
<tr>
<td>SA Alert Aggregation Learned Pattern Elements Pair wise Mutual Information and Joint Probability (sa_agg_pattern_element_pair)</td>
<td>Pairwise probabilities for pattern elements.</td>
</tr>
<tr>
<td>EM Agg Group Prediction (em_agg_group_prediction)</td>
<td>Alert predictions for alert groups.</td>
</tr>
</tbody>
</table>

### SLAs for business services and CIs

Event Management supports the creation of SLAs for business services and for CIs.

You can monitor and manage the quality of the business services offered by your organization. For example, you might want to set up an SLA that is triggered when the max alert severity of a business service or CI is **Critical**, and measure the time it takes to bring the business service or CI back to the **Info** state, when the conditions that caused the alert have been resolved.

### SLAs and the Task table

You can create SLA definitions only for tables that extend the Task table. The Event Management application provides a table named Event Management SLA (em_ci_severity_task), which extends the Task table. Use this table in your SLA definitions to specify the severity level that should trigger and stop the SLA. During alert impact calculation, changes in the severity level of business services and CIs are automatically updated in the Event Management SLA table. **Scheduled jobs** keep the information in this table up to date.

### How the Event Management SLA table is populated

The Event Management SLA table is populated differently for business services and CIs:
For business services, the system automatically populates the Event Management SLA table when a business service is created or when its max severity is changed.

For CIs, you must first identify which CIs can be made available for SLAs by creating an SLA configuration record. The system then automatically populates the Event Management SLA table with the CI max severity is changed.

**Note:** Duplicate CIs are not added to the Event Management SLA table even if the same CI matches more than one SLA configuration filter.

Create an SLA configuration for CIs

Create an SLA configuration from the Event Management application to determine which CIs are available for SLAs.

Role required: evt_mgmt_admin

The SLA configuration record is a filter on a table in the system. Select a table that has the CIs for which you want to create an SLA. If you are creating an SLA definition on a business service, you do not need to create an SLA configuration.

1. Navigate to **Event Management > Settings > SLA Configuration**.
2. Click **New**.
3. Fill in the form fields (see table).

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Provide a descriptive name.</td>
</tr>
<tr>
<td>Table</td>
<td>Select a table with the CIs for which you want to create the SLA. You can also use the Configuration Item to Host View (query_based_service_basic_view) table, which is used by <strong>technical services</strong>.</td>
</tr>
<tr>
<td>Filter</td>
<td>Configure the filter for the records.</td>
</tr>
</tbody>
</table>

4. Right-click the header and select **Save**.

The following is an example.

If you want to run an SLA on all Linux servers for major and critical alerts, first create an SLA configuration on the Linux Server (cmdb_ci_linux_server) table. Then create the SLA definition with this filter:

- **CI.class** $Linux Server
- **Severity** $Major Or $Critical

**Create an SLA definition** on the CIs that match this SLA configuration.

Limit the records for the SLA configuration filter

If too many records are returned by the SLA configuration filter, you can add a property to set the maximum number of records.

Role required: evt_mgmt_admin

By default, the size of technical service records is limited to 10,000 elements. The result view is truncated beyond this limit. If the filter configuration for a specified technical service returns too
many records, you can limit the number of records that are returned by setting the value of the `sa.qbs.max_num_of_cis` property. For more information, see Create a technical service.

1. Enter `sys_properties.list` in the application navigator.
2. Add the following property:
   
   `sa.qbs.max_num_of_cis`
3. Set the value to an integer that represents the maximum number of records to return.

Create an SLA definition for a CI or business service
You can create SLA definitions for CIs and business services just as you can for other task records in the instance.

Role required: `evt_mgmt_admin`

1. Navigate to Service Level Management > SLA > SLA Definitions.
2. Click New.
3. Fill out the fields on the SLA Definition form. For a description of each field, see .
4. For the Table field, select Event Management SLA (`em_ci_severity_task`).
5. Configure the Start condition filter by adding conditions, such as:

<table>
<thead>
<tr>
<th>SLA filter conditions</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>For all CIs where the Severity is Critical</strong></td>
</tr>
<tr>
<td><strong>Type</strong> is <code>Critical</code></td>
</tr>
<tr>
<td><strong>Severity is Critical</strong></td>
</tr>
<tr>
<td><strong>Business Service is Email</strong></td>
</tr>
<tr>
<td><strong>Severity is Critical</strong></td>
</tr>
</tbody>
</table>

6. Also configure pause, stop and reset conditions.
7. Click Submit.

Event Management configuration preferences
Preferred settings of properties and general configuration.

Use the Knowledge Base on HI and the Community to further help you find information issues.

General preferences

Self-health

By default, the self-health monitoring feature is not enabled. To enable it, navigate to Event Management > Settings > Properties and select Yes for the Enable Event Management self-health monitoring (`evt_mgmt.self_health_active`) property. Use this feature to monitor and track many Event Management features.
Use the following settings to help with preventing performance degradation.

<table>
<thead>
<tr>
<th>Topic</th>
<th>Details</th>
</tr>
</thead>
</table>
| **Business rules** |  - Avoid writing business rules for event (em_event) tables, as they do not run in the current default REST URL that is used for event injection.  
  - Business rules that are written for alert (em_alert) tables must be highly efficient or they may result in performance degradation. Instead of writing a business rule, consider whether it is more appropriate to write a job. An inefficient business rule can cause incident creation for an alert to fail and the alert impact calculation to fail.  
  - Do not write async business rules for alert tables.  
  - Business rules must not change the **Category** field on event (em_event) tables. |
| **Scaling up** | Check the average event processing time before scaling up event throughput when first starting with Event Management. Do this check after an initial flow of events and all rules are in place. If processing time takes over a few milliseconds per event, determine the cause for the processing slowdown before continuing to scale. Performance duration can be checked in the Performance Statistics (sa_performance_statistics) table. |
| **Configure for large-scale environments** |  - Set the `Enable multi node event processing` (**event_processor_enable_multi_node**) property to **Yes**.  
  Enable multi-node in production environments and set values based on the size of the deployment and expected event rate.  
  - Set the Number of events to process in bulk during each event processing job (**evt_mgmt.max_objs_in_alert_query**) property to 500.  
  - Set the Number of scheduled jobs processing events (**event_processor_job_count**) property to 4.  
  - Set the Maximum events to be processed by every scheduled job (**event_mgmt.max_events_processing_per_job**) property to 5000.  
  - If you are sending events from a custom source, verify that events have **Message Key** or **Source**, **Node**, **Type**, and **Resource** data. |
| **Latency issues for receiving events** | Check the following settings:  
  - Verify that the **Bucket** field in the event (em_event) table is set to a value that is greater than zero (**0**).  
  - Navigate to **System Scheduler > Scheduled Jobs** and search for - **process events**.  
  Check that all - **process events** jobs exist according to the Number of scheduled jobs processing events (**event_processor_job_count**) property configuration. Verify that the State is **Running** or **Ready**. If the state is **Queued** or **Error**, set the job state to **Ready**. |
| **Archive events** |  - Avoid changing the default retention time for events.  
  - To log events for a longer time, create an archive table and a job that copies new events to it. Do this by scheduling a job to regularly back up events (em_event) to a custom table.  
  - Do not extend table rotation by adding more days. |
Event integration

SNMP traps

- Use a monitoring tool to send SNMP traps, rather than sending them directly from devices.
- To avoid having to rewrite event rules, upload MIBs prior to defining the event rules.

Web service API

- Using a web service API for integration can reduce the number of event rules needed. This action avoids having to transform events (prepared data is sent in an event to the instance).
- Use dedicated credentials for integration. Optionally, designate credentials specific to each event source.

CloudWatch

Use dedicated credentials for integrating CloudWatch with ServiceNow.

Email

Use email only if the source has a low volume and other options are not available, such as, running a script or forwarding an SNMP trap.

Event rules

Configuration settings when creating event rules:

- Write Event Rules to apply to the broadest number of events possible. More specific rules can then be created as necessary and should use a lower-order value.
- If a more general rule can achieve the same outcome, avoid writing Event Rules that apply only to a certain subset of events.
- When Event Rules are applied to events, no changes are made to the original event. All processing occurs in memory, so use the Processing Notes field and/or use the Check Process of Event UI action link to troubleshoot.
- If you change a rule/transform that has existing mapping rules, you should review and retest with events that are either actual or simulated.
- Ensure that the From field value exactly matches a string in the JSON in the additional_info field of an event. This matching happens when a rule has been configured based on information in a MIB file. If the MIB file is not uploaded, the JSON for the SNMP trap shows varbinds (variable binding) with dotted names, instead of the translated name in the MIB. The event field mapping rule then fails to be applied.
- Establish a consistent naming convention. A common convention is: <customer acronym>.<Event Source>.<Description>. For example, ACME.OEM.Normalize
- If two Event Rules have similar conditions set, use the Order field to control which Event Rule runs.
- Use Event Rules to associate an alert with a CI.

Additional settings for constructing event rules:

<table>
<thead>
<tr>
<th>Desired result</th>
<th>Required activity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Effective de-duplication and enabling efficient parallel event processing</td>
<td>Populate the Source, Node, Type, Resource, Metric Name fields.</td>
</tr>
<tr>
<td>Desired result</td>
<td>Required activity</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-----------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CI binding</td>
<td>• Bind to host - by populating the Node field and optionally CI identifiers.</td>
</tr>
<tr>
<td></td>
<td>• Binding to application and / or device – by populating the CI identifiers field and the Additional information field.</td>
</tr>
<tr>
<td>Alert Correlation, using alert aggregation and RCA</td>
<td>Populate the Resource and Metric Name fields.</td>
</tr>
<tr>
<td></td>
<td>Note: If CI is also bound, Alert Correlation is improved.</td>
</tr>
</tbody>
</table>

**Custom event fields**

Include additional fields in the Additional information field of the event only.

Do not add additional fields to an event by adding a custom field to the event (em_event) table.

Do not add columns to the event (em_event) table.

For information about how to include additional fields in events, see [Custom alert fields](#).

**De-Duplication**

Configuration settings for de-duplication.

- The message_key field is used for De-Duplication. If reliable message key values are not provided with the source event, it is important to have a well-defined plan for constructing these identifiers.
- If the message key is not defined, then the default message key is `<Source + Node + Type + Resource + Metric Name>`.
- The guideline is to have the event source populate the `<Source + Node + Type + Resource + Metric Name>` fields out-of-the-box and populate the message key. This action enables a better distribution of event processing among instance workers and nodes.
- If the source event does not have values for these fields, make sure to populate them using transform rules. This action does not affect event processing, but is used for de-duplication. Populate as many of these fields as possible before they are sent to the instance. This action provides better distribution of events over the processor workers, and therefore better throughput and scale.

**CI binding**

- Where possible, always attempt to bind an alert to a CI.

  **Note:** Although Event Rules are defined on events, CIs are bound to alerts that result from those events, and are not bound to the event.

- To bind a host, machine or any device with an IP, populate the event Node field with a unique host name, FQDN, IP, or MAC address. If other identifiers are necessary to identify a host, then populate the ci_identifiers field with a JSON format. The JSON format must contain the CMDB field name and value to perform the match.

  **Note:** The event Node field must be populated from an event rule or populated with a unique host name from the source before the event is inserted.
The primary binding strategy is to use the **Node** field. If the **Node** field is not pre-populated in the event, it can be populated using event rules.

**Alert settings**

**Alert lifecycle**

General alert functionality:

- An alert is opened whenever an event is not ignored or its threshold is exceeded by an event rule, and de-duplication does not identify the event as belonging to an existing alert.
- An alert is closed when a closing event is sent on the same message key, or the alert is closed manually.
- An alert is reopened if an opening alert that has the same message key is sent within the timeframe defined in properties (default is one hour).
- If an alert is opened and closed at a high rate, as defined in properties, it becomes flapping. When this opening and closing rate stops, the alert goes out of flapping state.
- If an incident is opened from an alert, that alert remains open as long as the incident remains open. By default, when either the incident or the alert is closed the other is closed as well. This behavior can be configured using properties.
- Do not close an alert when creating a corresponding incident.
- Do not delete an open alert. Close an alert first and then delete it.
- Use **Acknowledge** to denote that the alert is known, and can temporarily be ignored.
- Do not use **Acknowledge** to mark an alert as needing attention.
- Do not create alerts in any of these states:
  - Closed
  - Info
  - Open

The **evt_mgmt.alert_auto_close_interval** property automatically closes alerts after the specified period. Do not specify 0, as this value disables the feature and may lead to performance degradation.

Do not create alerts in **Info** state. In some monitoring systems **Info** denotes that an issue has been resolved, while in other monitoring systems **Info** is used to denote events that are not of operational significance. For the former case, use **Clear** instead of **Info** using a Mapping Rule. For the latter case, have an Ignore rule, unless the events are of specific value.

**Alert action rules**

- A scheduled job applies Alert action rules to new Alerts every 1 1 seconds. If an Alert Rule does not immediately start, allow 10–15 seconds before you start troubleshooting.
- Use the **Order** field to control which Alert Rule runs if two Alert Rules have similar conditions set.
- Use Alert action rules with Task Templates to populate static values in an incident. Use the populator script to assign dynamic values in the incident. The populator script can return a value of false to abort incident creation.
- Create a user called Event Management (or a similar name). Then the **Created by** field in a task template (for example, **Incident**) can be set to indicate that user was the source of the task.
- To perform any dynamic value assignment or to override OOB dynamic value assignment, use the **EvtMgmtCustomIncidentPopulator** script include.
Remediation

- Always set orchestration workflow properties to the Remediation Task (em_remediation_task) table.
- Use ECC Queue and Workflow > Live Workflow > All Contexts to find more detailed information on remediation activities.

Business rules

- Business rules created on alert tables should not take more than a few milliseconds. In place of using a business rule, consider if the same functionality can be achieved using a job.
- Do not use business rules to associate an alert with a CI. Use event rules to do binding instead of using business rules.

Planning

- Organize event source configuration of filters, modules, and so on, into multiple parallel efforts, rather than in serial.
- Validate processed event formats to ensure that data that is parsed is aligned with desired results.
- Test production events in a non-production environment. Integrate with non-production element managers and ServiceNow instances. If non-production element managers are not available, send events from element managers to both production and non-production environments.

Services and dashboard

- Use Service Groups to group business services into logical groups to reduce the number of services displayed on the Service Health dashboard.
- Import manually built service maps.

Operational Intelligence collector logs and files

Operational Intelligence collector logs and files are located under the path $ (MID_SERVER_DIR)/agent. Use these logs and files for troubleshooting and monitoring purposes.

<table>
<thead>
<tr>
<th>Log or file</th>
<th>Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>PowerShell metric collector log file</td>
<td>Logs/retrieve_metrics(connector instance ID).log</td>
</tr>
<tr>
<td>PowerShell output file</td>
<td>work/metrics/metrics_output_{connector instance ID}.txt</td>
</tr>
<tr>
<td>PowerShell input file</td>
<td>work/metrics/parameters_{connector instance ID}.txt</td>
</tr>
</tbody>
</table>
Operational Intelligence performance can be checked in the MID Server log file when the `mid.log.level` MID Server parameter is in debug mode.

Operational Intelligence performance numbers are available in the Performance Statistics (sa_performance_statistics) table. To view the performance numbers, filter the Performance Statistics list for Metric Collector.

**Additional Event Management setup tasks**

After setting up and configuring Event Management to receive and process events and generate alerts, you can perform additional setup activities.

*Create a technical service*

A technical service is a dynamic grouping of configuration items (CIs), based on some common criteria. For example, you can create a technical service based on the location of all web servers in Detroit or all Oracle databases in Boston.

Role required: evt_mgmt_admin

Use the technical services form to create user defined collections of CIs.

**Note:** A technical service contains CIs. However, a technical service cannot contain other services.

This video explains Event Management basics, including showing how to create a technical service.

1. Navigate to Event Management > Services > Technical Services.

![Technical Services form](image)

2. Click New.

3. On the form, fill in the fields.

**Technical Service form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The business service name.</td>
</tr>
</tbody>
</table>
| Business criticality | The importance of this service to the business. This field can determine disaster recovery strategies for this service.  
|                   | • 1 - most critical  
|                   | • 2 - somewhat critical  
|                   | • 3 - less critical  
<p>|                   | • 4 - not critical |
| Owned by         | The party that is responsible for the business service.                    |
| Email            | Enter the email address of the owner who is responsible for this business service in the organization. |
| Business phone   | Enter the business phone number of the owner who is responsible for this business service in the organization. |</p>
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operational status</td>
<td>The status of the business service.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Operational</strong>: The business service is running. Impact calculation runs only on services in the Operational status.</td>
</tr>
<tr>
<td></td>
<td>Select this option to use this business service. If you customized preconfigured options for this category, select the option whose value is set to 1. Event Management calculates impact only on business services in use.</td>
</tr>
<tr>
<td></td>
<td>To use this business service at a later time, select one of these options:</td>
</tr>
<tr>
<td></td>
<td>- <strong>Non-Operational</strong>: The business service is unavailable, disabled, or down.</td>
</tr>
<tr>
<td></td>
<td>- <strong>DR Standby</strong>: The business service is available as a disaster recovery (DR) standby.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Repair in Progress</strong>: The business service is receiving maintenance.</td>
</tr>
<tr>
<td>Comments</td>
<td>Any additional notes and information.</td>
</tr>
</tbody>
</table>

4. Select a source table and specify the criteria for the technical service query.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>Name of source table to be searched.</td>
</tr>
<tr>
<td></td>
<td>You can use autocomplete to locate table names, or select the appropriate table from the list.</td>
</tr>
<tr>
<td>Filter</td>
<td>Specify the criteria for determining the values from the specified source table to be displayed:</td>
</tr>
<tr>
<td></td>
<td>1. Specify the filter condition.</td>
</tr>
<tr>
<td></td>
<td>2. Choose the relevant operator.</td>
</tr>
<tr>
<td></td>
<td>3. Choose the input field.</td>
</tr>
<tr>
<td></td>
<td>4. Choose the operator.</td>
</tr>
<tr>
<td></td>
<td>5. Choose the input value.</td>
</tr>
<tr>
<td></td>
<td>If the filter configuration returns too many records, you can limit the number of records that are returned by setting the value of the sa.qbs.max_num_of_cis property. By default, the technical service size is limited to 10,000 elements and the result view is truncated.</td>
</tr>
</tbody>
</table>

5. Click Submit.

*Convert manual services to application services*

You can convert existing manual services to application services. Event Management can use application services to monitor service performance and identify health issues.

Role required: evt_mgmt_admin
Manual services can no longer be created and this service type, as well as discovered services, have been replaced by application services. Existing manual services continue to work and can be updated. However, new services that are created should be application services. Existing manual services should be converted to application services.

During the conversion process:

- The manual service record is moved from the Manual Services (cmdb_ci_service_manual) table to the Application Services (cmdb_ci_service_discovered) table by changing the record class.
- All the original manual service attributes, such as, name, owner, and operational status, are retained in the application service.
- The configuration items (CIs) of the manual service are retained in the application service after the conversion.
- The system queries the CMDB for the latest CI changes and applies CI impact rules.

Application service does not support these CI types:

- cmdb_ci_endpoint
- cmdb_ci_translation_rule
- cmdb_ci_config_file
- cmdb_ci_qualifier
- cmdb_ci_application_cluster

If the preceding CI types are used in the manual service that you want to convert, the conversion fails. CIs of this type should be removed before conversion. They can be replaced by adding new CIs to the application service after conversion.

If your ServiceNow instance uses domain separation, the conversion fails if CIs from multiple domains are in the same service. Replace or remove relevant CIs before conversion. The converted application service contains only CIs assigned to the same domain as the application service.

2. Select the manual service that you want to convert to an application service.
3. Click **Migrate to Application Service**.
4. Click **OK**.

- The CIs from the manual service are added to the converted application service.
- After the conversion process is complete, the application service form opens.
Convert manual services to application services using API

You can use a JavaScript API to convert existing manual services to application services. Event Management can use application services to monitor service performance and identify health issues.

Manual services can no longer be created and this service type, as well as discovered services, have been replaced by application services. Existing manual services continue to work and can be updated. However, new services that are created should be application services. Existing manual services should be converted to application services.

During the conversion process:

- The manual service record is moved from the Manual Services (cmdb_ci_service_manual) table to the Application Service (cmdb_ci_service_discovered) table by changing the record class.
- All the original manual service attributes, such as, name, owner, and operational status, are retained in the application service.
- The configuration items (CIs) of the manual service are retained in the application service after the conversion.
- The system queries the CMDB for the latest CI changes and applies CI impact rules.

Application service does not support these CI types:

- cmdb_ci_endpoint
- cmdb_ci_translation_rule
- cmdb_ci_config_file
- cmdb_ci_qualifier
- cmdb_ci_application_cluster

If the preceding CI types are used in the manual service that you want to convert, the conversion fails. CIs of this type should be removed before conversion. They can be replaced by adding new CIs to the application service after conversion.

If your ServiceNow instance uses domain separation, the conversion fails if CIs from multiple domains are in the same service. Replace or remove relevant CIs before conversion. The converted application service contains only CIs assigned to the same domain as the application service.

The JavaScript API is:

```javascript
BusinessServiceManager.migrateManualToApplicationService(String service_id)
```

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
</tr>
<tr>
<td>service_id</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
</tr>
<tr>
<td>Boolean</td>
</tr>
</tbody>
</table>
Where the `sys_id` of an existing manual service is 451047c6c0a8016400de0ae6df9b9d76, run the following API to convert it to an application service:

```javascript
var bsManager = new SNC.BusinessServiceManager();
var res = bsManager.migrateManualToApplicationService("451047c6c0a8016400de0ae6df9b9d76");
```

### Manually create an Event Management application service

You can manually create an application service. Event Management can use application services to monitor service performance and identify health issues.

**Role required:** evt_mgmt_admin

An application service is a set of interconnected applications and hosts which are configured to offer a service to the organization. Application services can be internal, like an organization email system or customer-facing, like an organization website. Use application services to organize, maintain, and monitor services in your organization.

Application Services do not support these CI types:
- cmdb_ci_endpoint
- cmdb_ci_translation_rule
- cmdb_ci_config_file
- cmdb_ci_qualifier
- cmdb_ci_application_cluster

1. Navigate to **Event Management > Services > Application Services**.
2. Click **New**.
3. On the form, fill in the fields.

#### Create a Service form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a unique application service name.</td>
</tr>
<tr>
<td>Owned by</td>
<td>Specify an owner who is responsible for this application service in the organization</td>
</tr>
</tbody>
</table>

**Add entry points:**

- **CI Type**
  - Select the CI type (CI class) for the CI you are adding. Every CI belongs to a CI type which contains a set of attributes configured for this kind of CI, for example, cmdb_ci_appl for applications.

- **CI Name**
  - Select the CI from the list of CIs of the selected CI type.

The CI type list includes only allowed CI types. For example, you cannot add an application cluster.

4. Click **Submit**.
Control user access to application services
Assign user roles to service groups to grant users access to application services in your organization. Your organization may restrict access to some services for security or secrecy reasons.

Make sure that you have performed the user provisioning tasks for the users you want to grant access:

1. Add users to user groups.
2. Create new roles.
3. Assign roles to users or user groups.

Also, make sure that you have created service groups as described in Group application services.

Role required: app_service_admin or sm_admin

In the base system, the following roles provide access to application services:

app_service_admin
Creates and modifies application services, creates service groups, views, and edits application service maps.

app_service_user
Views application service maps. The itil role that serves as the basic helpdesk technician role contains the app_service_user role.

Service Mapping provides these preconfigured roles:

sm_admin
Sets up the Service Mapping application. Maps, fixes, and maintains application services. Also performs advanced configuration and customization of the product. Assign this role to application administrators.

sm_user
Views maps for operational application services to plan change or migration, as well as analyze the continuity and availability of services. Assign this role to application users.

sm_app_owner
Provides information necessary for successful mapping of an application service. Once a service is mapped, this user reviews the results and either approves it or suggests changes. Assign the sm_app_owner role to users who own application services and are familiar with the infrastructure and applications that make up the services.

Event Management provides these preconfigured roles:

evt_mgmt_admin
Has read and write access to all Event Management features to configure Event Management.

evt_mgmt_operator
In addition to the evt_mgmt_user permissions, can also activate operations on alerts such as acknowledge, close, open incident, and run remediations.

evt_mgmt_user
Has read access to all Event Management features. Has write access to alerts to manage the alert life. Has the itil role to be able to manage incidents that are created from alerts.

**evt_mgmt_integration**

Has create access to the Event (em_event) and Registered Nodes (em_registered_nodes) tables to integrate with external event sources.

Typically, enterprises have hundreds of services which makes it impractical to manage them individually. Service groups can make service lists much shorter and easier to manage, especially in large organizations or service providers. In a hierarchy of service groups, access to a parent service group automatically grants access to all the child service groups.

Users inherit permissions from roles that are assigned to them. You can assign some roles directly to service groups to allow all users with this role to access all application services belonging to this group. However, most enterprises choose to organize their roles as a hierarchy. It helps to manage roles across multiple ServiceNow applications. For example, the Service Mapping administrator (sm_admin) can be part of a broader administrator role like administrator (admin). You can add users to user groups and then assign roles to the user groups to give permissions of this role simultaneously to all the group users.

**Assigning a role to an application service group**

By default, all services are assigned to the **All** service group that lets all users view and manage application services. When you assign a role to a service group, the users with this role can access only application services in this service group. To enable users with this role to access other services, assign this role to the respective service group.
1. Navigate to either of the following:
   - Configuration > Application Services > Service Group Responsibilities.
   - If Service Mapping is activated: Service Mapping > Services > Service Group Responsibilities.
   - If Event Management is activated: Event Management > Services > Service Group Responsibilities.

2. Click New and fill out the Business Service Group Responsibilities form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Business Service Group</td>
<td>Service group to which you want to assign a role.</td>
</tr>
<tr>
<td>Role</td>
<td>Role you want to assign to the selected service group.</td>
</tr>
<tr>
<td></td>
<td>For example, financial_services_admin.</td>
</tr>
</tbody>
</table>

3. Click Submit.

To manage access to services that contain sensitive financial information in your organization:
1. Organize the services into the Financial Services group.
2. Create a new user role, financial services administrator (financial_services_admin) role, that contains the (app_service_it) role.
3. Assign the Financial Services administrator role to the Financial Services group.

As a result, only users with the Financial Services administrator role can access application services belonging to the Financial Services group.

Group application services
Organize application services by groups to perform actions simultaneously on multiple services, and to control user access to services. You can use Event Management to track service health by service groups.

Role required: sm_admin or app_service_admin

Typically, enterprises have hundreds of services which makes it impractical to manage them individually. Service groups can make service lists much shorter and easier to manage, especially in large organizations or service providers.

How you group application services depends on the user and on service provisioning policies in your enterprise. The relation between application services in groups is purely logical and the same application service can belong to multiple groups. For example, the Mobile service can be part of the following service groups: sales, Beijing, and telephony.
You can embed a service group within another service group to create a hierarchy of service groups. If users have access to a parent service group, they automatically have access to all its child groups. By default, all services are assigned to the All service group that lets all users view and manage application services. When you assign a role to a service group, the users with this role can access only application services in this service group. To enable users with this role to access other services, assign this role to the respective service group.

If Service Mapping is activated, service groups can contain a mixture of manually created application services and application services discovered by Service Mapping.

1. Navigate to Configuration > Application Services > Service Groups. Or, if Service Mapping is activated, navigate to Service Mapping > Services > Service Groups.
2. Click New.
3. Enter the name of the new application service group in the Name field.
4. To embed this group in another group, enter the name of the other group in the Parent Group field.
5. Right-click the form header and click Save.
6. Add an application service to the newly created service group.
   a) In the Service Group Members section, click New.
   b) In the Name field, enter the name of the application service. If you are using Event Management, you can also enter an alert group name.
   c) Click Submit.
7. Alternatively, add an application service to a group from the application service form.
   a) Navigate to Configuration > Application Services > Application Services.
   b) Select the application service you want to add to a service group.
   c) In the Service Group Members section, double-click Insert a new row.
d) Enter the name of the service group to which you want to add the selected application service.

e) Click the OK icon.

f) Click Update.

Create an alert group

An alert group is a set of alerts that meet special criteria for a particular business service.

Navigate to Event Management > Services > Properties and ensure that the Enable alert group support (evt_mgmt.impact_calculation.alert_group_support) property is set to Yes.

Role required: evt_mgmt_admin or evt_mgmt_operator

The main motivation to use alert groups is a modeling solution based on data contained in the alert itself, as an alternative to using either discovered, application, or technical services.

Create alert groups to combine similar alerts that meet the specified criteria. Alert groups appear on the Event Management dashboard.

Note: Alert groups that are created in this procedure do not display in the Alerts console.

You can learn about Event Management basics, including alert groups, from this video:

1. Navigate to Event Management > Services > Alert Groups.
2. Click New
3. Fill in the fields, as appropriate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The alert group name.</td>
</tr>
<tr>
<td>Business criticality</td>
<td>The importance of this service to the business. This field can determine disaster recovery strategies for this service.</td>
</tr>
<tr>
<td>Used for</td>
<td>Specify the purpose of the alert group. Select from:</td>
</tr>
<tr>
<td>Owned by</td>
<td>The party that is responsible for the business service.</td>
</tr>
<tr>
<td>Email</td>
<td>The email alias for the alert group.</td>
</tr>
<tr>
<td>Business phone</td>
<td>The phone number for the business.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>Operational status</td>
<td>The status of the business service.</td>
</tr>
<tr>
<td></td>
<td>· <strong>Operational</strong>: The business service is running. Impact calculation runs only on services in the Operational status.</td>
</tr>
<tr>
<td></td>
<td>Select this option to use this business service. If you customized preconfigured options for this category, select the option whose value is set to 1. Event Management calculates impact only on business services in use.</td>
</tr>
<tr>
<td></td>
<td>If you do not want to use this business service now, select one of these options:</td>
</tr>
<tr>
<td></td>
<td>· <strong>Non-Operational</strong>: The business service is unavailable, disabled, or down.</td>
</tr>
<tr>
<td></td>
<td>· <strong>Repair in progress</strong>: The business service is receiving maintenance.</td>
</tr>
<tr>
<td></td>
<td>· <strong>DR Standby</strong>: The business service is available as a disaster recovery (DR) standby.</td>
</tr>
<tr>
<td></td>
<td>· <strong>Ready</strong>: Prepared for use.</td>
</tr>
<tr>
<td></td>
<td>· <strong>Retired</strong>: Withdrawn from active use.</td>
</tr>
<tr>
<td>Comments</td>
<td>Any additional notes and information.</td>
</tr>
<tr>
<td>Service Group Members</td>
<td>The business services group which contains this service.</td>
</tr>
<tr>
<td>Filter</td>
<td>The conditions for sending a notification to the alert group. The conditions must meet the alert values.</td>
</tr>
</tbody>
</table>

**Note:** In the **Filter** field:
- The filter that defines Alert Groups should not be on fields that do not appear in the `em_alert_history` table because impact calculation is not calculated properly. This situation occurs because fields like Event Count, Priority, and Priority Group are not copied to the `em_alert_history` table for impact calculation.
- Do not specify a dynamic time condition. For example, in the filter, do not specify "Created" condition of "Last 45 minutes" because impact calculation is triggered by a change of Alert or Alert group. However, for the dynamic time condition, none of these conditions have changed.

4. Click **Update**.

**Create a service group**
Create service groups to combine similar services. Organize services by groups to perform actions simultaneously on multiple services and to control user access to services.

Role required: evt_mgmt_admin
Service groups appear on the Event Management dashboard.

1. Navigate to Event Management > Services > Service Groups.
2. Click New.
3. In the Name field, enter the name of the new service group.
4. Optional: In the Parent Group field, enter the name of another group in which to embed the new group.
   Users with access to a parent service group automatically have access to all its child groups.
5. Click Submit.

Assign a role to a service group

Assign an Event Management role to the business service group to ensure that group members can manage and act on alerts.

Configure a service group to enable users to manage business services, application service, or alert groups.

Role required: evt_mgmt_admin

1. Navigate to Event Management > Services > Service Group Responsibilities.
2. Click New.
3. In the Business Service Group field, select the name of the service group.
4. In the Role field, select an Event Management role:
   - evt_mgmt_admin
   - evt_mgmt_integration
   - evt_mgmt_operator
   - evt_mgmt_user
5. Click Submit.
6. To find users who are assigned to the role, navigate to User Administration > Users > Roles and search for the role.

Configure Event Management domain separation

You can configure Event Management for domain separation to create logically defined domains that limit unauthorized access to data. When domains are separated in Event Management, users can only see and manage alerts and events in their own (tenant) domain.

Role required: evt_mgmt_admin and evt_mgmt_integration

The following Event Management features have limited domain separation support.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Business service groups</td>
<td>Supported. Limitation: The user can define a business service that is visible in other domains with services that are not visible in other domains. In this case, other domains can see impact results but cannot see how this result was calculated.</td>
</tr>
<tr>
<td>Feature</td>
<td>Support</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------</td>

</tr>
<tr>
<td></td>
<td>relevant workflows.</td>
</tr>
<tr>
<td></td>
<td>For information on invoking domain separation through subflows, see</td>
</tr>
<tr>
<td></td>
<td><a href="#">Invoke domain separation through subflows</a>.</td>
</tr>
<tr>
<td></td>
<td>For more information on domain separation in the Flow Designer, see</td>
</tr>
<tr>
<td></td>
<td><a href="#">Domain separation and Flow Designer</a>.</td>
</tr>
<tr>
<td></td>
<td>1. If it is not already active, activate the Domain Support – Domain</td>
</tr>
<tr>
<td></td>
<td>Extension Installer plugin.</td>
</tr>
<tr>
<td></td>
<td>2. Configure a connector instance to use a MID Server from the same</td>
</tr>
<tr>
<td></td>
<td>domain as Event Management.</td>
</tr>
</tbody>
</table>

Get top-down discovery service mapping
A top-down discovery provides a list of CIs and their interrelationships. This information is useful for managing software services and hardware issues that are associated with alerts.

Role required: evt_mgmt_admin
You can use Service Mapping to get top-down discovery information. Service Mapping, which is closely related to Event Management, provides tools to discover the relationships between network, hardware, software, storage, and other devices.

In Event Management, Service Mapping relationships appear on alerts. You can view the related CI and other information in the Event Management dashboard. The mapping relationships
appear in a business service map with the generated alert, any CIs that are bound to the alert, and all related CIs.

*Rotate event tables and alert table cleanup*

The growth of data tables impedes performance. Preserve instance performance by event table rotation and alert table cleanup for status and alert history retention.

**Containing the growth of event tables**

By default, the Event Management event (em_event) table uses table rotation. The table rotation schedule ensures that new data is written to one of the tables in the rotation group. According to the value of **Clean base rotation** setting, the base table is deleted and then a new round of writing the tables in a daily rotation commences. By default, this table deletion occurs after seven rotations.

To back up events to a custom table, see *Event Management configuration preferences*.

**Containing the growth of alert tables**

By default, a scheduled job cleans out the alert (em_alert) table. Alert table cleanup is recommended for status and alert history retention.

**Event table rotation**

Table rotation is used by Event Management, by default, to contain the growth of event (em_event) tables within the rotation table group.

**Role required:** evt_mgmt_admin

Table rotation ensures that event tables grow to a reasonable size.

Each table rotation has a schedule, according to which new data is written to one of the tables in the rotation group. A table rotation group includes the original table plus several additional tables. After the rotation procedure has written the last table in a rotation, the rotation overwrites the first table in the rotation. By default, the table rotation for Event Management is to rotate the em_table to an offload table and the base table cleanup takes place after seven table rotations.

**Purge status and alert history**

You can configure automatic table cleanup to improve performance. Automatic table cleanup is recommended for status and alert history retention.

**Role required:** evt_mgmt_admin

If records are older than 90 days, by default they are purged. If records are retained for a longer period, larger volumes of data are stored, and performance may be impacted.

**Note:** Event (em_event) table growth is contained, by default, by the use of table rotation. For information about backing up events to a custom table, see *Event Management configuration preferences*.

1. **Navigate to Automated Test Framework > Administration > Table Cleanup.**
2. **If required, shorten the retention period (in seconds) for records of the following tables:**
   - Alerts (em_alert) (Default: 7,776,000)
   - Alert History (em_alert_history) (Default: 7,776,000)
   - Impact Status (em_impact_status) (Default: 7,776,000)

**Alert table clean-out**
The Schedule Jobs feature executes a script that closes alerts, in the alerts (em_alert) table, that meets specified conditions.

Role required: evt_mgmt_admin

When the Event Management plugin is activated, by default a job is scheduled to run the Event Management - auto close alerts script to automatically close alerts in the alerts table that meet the specified conditions.

The Event Management - auto close alerts script runs automatically and repeatedly at the scheduled time and closes alerts that meet the specified conditions.

Configure email notification on business service severity change
Configure an email notification to notify users when there is a business service severity change.

Role required: evt_mgmt_admin

Configure an email notification to notify users when there is a business service severity change. The notification involves specifying when to send it, who receives it, and what it contains.

1. Navigate to System Properties > Email Properties.
2. In the Outbound Email Configuration section, in the Email sending enabled option, select Yes to enable sending severity information by email.
3. Click Save.
4. Navigate to System Notification > Email > Notifications.
5. Click New.
   a) In the Email Notification Actions form, specify these values.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Type a descriptive name, for example, Business Service severity change.</td>
</tr>
<tr>
<td>Table</td>
<td>Select the required service type and its corresponding table: Alert Group, Discovered Service, Technical Service, or Application service.</td>
</tr>
<tr>
<td>Active</td>
<td>Select the check box to enable email notification.</td>
</tr>
</tbody>
</table>

b) Click the Who will receive tab. In the Users area, search for and select the required user (the user does not require System Administrator credentials). Repeat this step for as many users that are required to receive this notification.

c) Click the When to send tab. In the choose field box, search for and select Severity.

d) Click the What will it contain tab. In the Subject field, type meaningful text that makes it clear to the receiver of the email notification what the content of the email is.

e) In the Message HTML message area, using the Select variables functions, compose the conditions under which the email notification is to be sent. For example, configure these variables to change severity:

- severity changed
- Severity: ${severity}
- on business service
- Name: ${name}
6. Click Submit.

View Event Management license usage
Event Management is licensed based on the number of nodes that can send events to the instance directly or through a third-party monitoring tool during the last year.

Role required: evt_mgmt_admin or evt_mgmt_operator

The Event Management - Node Count job calculates the number of unique nodes that send event information, either directly or through third-parties, to Event Management and are eligible for licensing in the last year. The information from this job is stored in the License Usage (em_unique_nodes) table for visibility by all users. All nodes that send event information are counted, whether the alert generated from the event was bound to a CI or not.

Navigate to Event Management > Settings > License Usage. The License Usage list appears.

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMDB CI</td>
<td>The CI that is bound to the alert that is generated from the event. If there is a value for this field, the Node field is empty.</td>
</tr>
<tr>
<td>Node</td>
<td>The string value of the Node field of the event. If there is a value for this field, the CMDB CI field is empty.</td>
</tr>
<tr>
<td>Type</td>
<td>One of these values:</td>
</tr>
<tr>
<td></td>
<td>• Unknown - A CI has not bound to the generated alert.</td>
</tr>
<tr>
<td></td>
<td>• Server - The source of the event was a server.</td>
</tr>
<tr>
<td></td>
<td>• PaaS - The source of the event was Platform as a Service.</td>
</tr>
<tr>
<td>Is licensable</td>
<td>One of these values:</td>
</tr>
<tr>
<td></td>
<td>• True - The event listed is counted towards the license usage.</td>
</tr>
<tr>
<td></td>
<td>• False - The event listed is not counted towards the license usage.</td>
</tr>
</tbody>
</table>

Configure contextual colors and icons
Use the Contextual colors and icons form to configure color, text, and icons to have different default or custom contexts, identified by a context ID.

Role required: evt_mgmt_admin

You can customize the colors or icons of elements in the Contextual colors and icons form to affect the displayed colors or icons of severities in related Event Management screens, either when accessibility mode is off or on. For more information about accessibility, see Accessibility features.

In each color selection field, you have the option of entering the value of the color as any of the following Cascading Style Sheet (CSS) formats that determine how HTML elements should be displayed:

- Name: predefined color names, for example, red, green, olive, blue, darkblue, or lightblue
- RGB decimal: RGB(102, 153, 204)
- RGB hex: #223344

See the following websites for information about CSS color declarations (including hex or RGB notation):
- HTML Colors (W3CSchools) for more information on hex and RGB notation.
- HTML Color Names (W3CSchools) for valid color names.

The context IDs that are provided with the base instance are:
- information_severity
- warning_severity
- minor_severity
- major_severity
- critical_severity
- topology_connection

1. Navigate to Event Management > Settings > Contextual colors and icons.
2. Click New or modify an existing configuration.
3. Configure the following fields.

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Context details</td>
<td></td>
</tr>
<tr>
<td>Context ID</td>
<td>Enter a unique ID for the context, for example,</td>
</tr>
<tr>
<td></td>
<td>clear_severity.</td>
</tr>
<tr>
<td>Context Name</td>
<td>Readable name for the context. This text is</td>
</tr>
<tr>
<td></td>
<td>available to be read out by screen readers.</td>
</tr>
<tr>
<td>Batch</td>
<td>The batch that this context is a member of.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of uses for the context.</td>
</tr>
<tr>
<td>Colors</td>
<td></td>
</tr>
<tr>
<td>CSS Color</td>
<td>The corresponding CSS color code for the context</td>
</tr>
<tr>
<td></td>
<td>color name.</td>
</tr>
<tr>
<td>CSS Color on Interaction</td>
<td>CSS color code that appears on hover or focus.</td>
</tr>
<tr>

<td>Icon that is displayed when the context includes</td>
</tr>
<tr>
<td></td>
<td>an icon.</td>
</tr>
<tr>
<td>Accessible Icon</td>
<td>Icon that is displayed when the context includes</td>
</tr>
<tr>
<td></td>
<td>an icon and when accessibility mode is enabled.</td>
</tr>
<tr>
<td></td>
<td>To add your own icon, or to see a list of</td>
</tr>
<tr>
<td></td>
<td>available icons, see Upload one or more images.</td>
</tr>
</tbody>
</table>

4. Click Submit.
Administer events

An event is a notification from one or more monitoring tools that indicate something of interest has occurred, such as a log message, warning, or error.

The manner in which events process and alerts generate are based on the following factors:

- Event collection configuration via MID Server, script, SNMP trap collector, email.
- Event rule, alert binding, and event field mapping configuration for processing events from various sources.

You can view event information in the following places:

- The event list view displays the entire list of events.
- Under Event rules, see Create or edit an event rule, you can view a list of individual events or a group of events that are not associated with any event rule.
- If an event rule or event field mapping used the event or group of events to generate an alert, the event information appears in the Activity section of the alert.

View events

Event Management tracks individual events to manage external systems. An event is a notification from one or more monitoring tools that indicate that something of interest has occurred, such as a log message, warning, or error. Event Management receives or pulls events from one or more external event sources and stores them in the Event (em_event) table. Event Management provides a list of raw incoming events.

Role required: evt_mgmt_admin, evt_mgmt_operator, evt_mgmt_user, or evt_mgmt_integration

Note: Business rules must not change the Category field on event (em_event) tables.

The event monitoring tool generates the values of the source and resource fields. Event Management implementers can define event types and register nodes to help uniquely identify incoming events and create alerts for the specific needs of the enterprise. Event Management uses this information to determine whether to create an alert or update an existing one.

An event source may generate duplicate events with the same identifying information. For events with the same identifying information, Event Management uses the time interval between events to determine if events represent an existing issue or new issue.

Additional fields should be included in the Additional information field of the event. Do not add additional fields to an event by adding a custom field to the event (em_event) table. For more information about how to include additional fields in events, see Custom alert fields.

Note: Avoid writing business rules for event (em_event) tables as they can result in performance degradation.

1. Navigate to Event Management > All Events.

The All Events list displays the following columns.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
<th>Populated by</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time of event</td>
<td>The time that the event occurred, in the network node time zone.</td>
<td>External event monitoring tool</td>
</tr>
<tr>
<td>Column</td>
<td>Description</td>
<td>Populated by</td>
</tr>
<tr>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------------------------</td>
</tr>
<tr>
<td>Source</td>
<td>Event monitoring software that generated the event, such as SolarWinds or SCOM. This field has a maximum length of 100 digits.</td>
<td>External event monitoring tool</td>
</tr>
<tr>
<td>Description</td>
<td>Reason for event generation. Shows extra details about an issue. For example, a server stack trace or details from a monitoring tool. This field has a maximum length of 4000 digits.</td>
<td>External event monitoring tool</td>
</tr>
<tr>
<td>Node</td>
<td>Node name, fully qualified domain name (FQDN), IP address, or MAC address that is associated with the event, such as IBM-ASSET. This field has a maximum length of 100 digits.</td>
<td>External event monitoring tool</td>
</tr>
<tr>
<td>Type</td>
<td>Pre-defined event type, such as high CPU, which is used to identify an event record. This field has a maximum length of 100 digits.</td>
<td>External event monitoring tool</td>
</tr>
<tr>
<td>Resource</td>
<td>Node resource that is relevant to the event. For example, Disk C, CPU-1, the name of a process, or service. This field has a maximum length of 100 digits.</td>
<td>External event monitoring tool</td>
</tr>
<tr>
<td>Message Key</td>
<td>Unique event identifier to identify multiple events that relate to the same alert. If this value is empty, it is generated from the <strong>Source</strong>, <strong>Node</strong>, <strong>Type</strong>, <strong>Resource</strong>, and <strong>Metric Name</strong> field values. This field has a maximum length of 1024 digits.</td>
<td>External event monitoring tool</td>
</tr>
<tr>

<td>Description</td>
<td>Populated by</td>
</tr>
<tr>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------------------------</td>
</tr>
<tr>
<td>State</td>
<td>The status of the event:</td>
<td>Event</td>
</tr>
<tr>
<td></td>
<td>• <strong>Ready</strong>: Event has been received and is waiting to be processed.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>Queued</strong>: Event is queued by the event processor job.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>Processed</strong>: Event was successfully processed.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>Error</strong>: Failure occurred while processing the event. For example, the</td>
<td></td>
</tr>
<tr>
<td></td>
<td>event collection method or event <strong>Severity</strong> is blank.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>Ignored</strong>: Value is not in use.</td>
<td></td>
</tr>
<tr>
<td>Severity</td>
<td>Mandatory. The options are typically interpreted as follows:</td>
<td>Event</td>
</tr>
<tr>
<td></td>
<td>• <strong>Critical</strong>: Immediate action is required. The resource is either not</td>
<td></td>
</tr>
<tr>
<td></td>
<td>functional or critical problems are imminent.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>Major</strong>: Major functionality is severely impaired or performance has</td>
<td></td>
</tr>
<tr>
<td></td>
<td>degraded.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>Minor</strong>: Partial, non-critical loss of functionality or performance</td>
<td></td>
</tr>
<tr>
<td></td>
<td>degradation occurred.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>Warning</strong>: Attention is required, even though the resource is still</td>
<td></td>
</tr>
<tr>
<td></td>
<td>functional.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>Info</strong>: An alert is created. The resource is still functional.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>Clear</strong>: No action is required. An alert is not created from this event.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Existing alerts are closed.</td>
<td></td>
</tr>
<tr>
<td>Alert</td>
<td>If an alert was created as a result of the event, this field contains the</td>
<td>A matching event rule or event field</td>
</tr>
</tbody>
</table>
For further ways to see which event rules were applied to the event, in the Events list, you can optionally select to display the Event rule and Processing Notes fields.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Matching Event rule</td>
<td>Contains the event rule that matches the current event rule definitions. This information is primarily used to create event rule recommendations for events that currently are not covered by rules. If event rules have been modified, this information can be retrieved from the Processing Notes field, described below.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This field does not show the history of event rules that were applied to the event.</td>
</tr>
<tr>
<td>Processing Notes</td>
<td>View information related to the binding to CI type and the event rules that were applied to the event.</td>
</tr>
</tbody>
</table>

4. To create an event rule if an event is not associated with an event rule:
   a) Click the required event. The event opens in the Event form.
   b) Click Create Event Rule.
      The fields of the new Event rule are populated with data from the event. You can use the event information, for example, when composing fields for alerts.

**Event identifiers**

Event fields uniquely identify each event. Event Management uses this information to determine whether to create a new alert or update an existing one.
By default, each event is uniquely identified by the **Message Key**. If the **Message Key** is not populated, a concatenation of the **Source**, **Type**, **Node**, **Resource**, and **Metric Name** fields are used and these fields populate the **Message Key**. If identifiers are not supplied in the event, you can add them with event rules.

**Automatic CI creation**

IT and Operational Intelligence events pushed from specified sources can automatically create CIs.

The source being configured must be registered in the system.

Role required: evt_mgmt_admin

You can configure from which source Event Management automatically creates CIs in cases where CIs could not be found in the CMDB. For the registration of CIs that result from raw Operational Intelligence data, see [Create or configure data source registration](#).

1. In the application navigation filter, enter `sa_metric_registration.list`. Existing registrations are displayed.

2. Configure an existing registration or click **New**.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source</td>
<td>Specify the name of the source exactly as it appears in the <strong>Source</strong> field of the event.</td>
</tr>
<tr>
<td>Registration Mode</td>
<td>Not relevant to the creation of CIs that do not result from raw Operational Intelligence data. Specify <strong>None</strong> (default). For CIs that do result from raw Operational Intelligence data, see <a href="#">Create or configure data source registration</a>.</td>
</tr>
<tr>
<td>Type default mode</td>
<td>Not relevant to the creation of CIs that do not result from raw Operational Intelligence data. Specify <strong>None</strong> (default). For CIs that do result from raw Operational Intelligence data, see <a href="#">Create or configure data source registration</a>.</td>
</tr>
<tr>
<td>Generate Missing CIs</td>
<td>Select to create CIs automatically.</td>
</tr>
</tbody>
</table>

3. Click **Submit**.

**Event field format for event collection**

Event Management requires all events to use a standard form, regardless of how they arrive at the instance.

In the application navigation filter, enter `em_event.list`.

**Event form**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>em_event.source</td>
<td>Event monitoring software that generated the event, such as SolarWinds or SCOM. This field has a maximum length of 100 digits.</td>
</tr>
<tr>
<td>(Source)</td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>em_event.node (Node)</td>
<td>Node name, fully qualified domain name (FQDN), IP address, or MAC address that is associated with the event, such as IBM-ASSET. This field has a maximum length of 100 digits.</td>
</tr>
<tr>
<td>em_event.type (Type)</td>
<td>Optional. Pre-defined event type, such as high CPU, which is used to identify an event record. This field has a maximum length of 100 digits.</td>
</tr>
<tr>
<td>em_event.resource (Resource)</td>
<td>Node resource that is relevant to the event. For example, Disk C, CPU-1, the name of a process, or service. This field has a maximum length of 100 digits.</td>
</tr>
<tr>
<td>metric_name (Metric Name)</td>
<td>Unique name to identify the metric.</td>
</tr>
<tr>
<td>em_event.event_class (Source instance)</td>
<td>If the em_event.node field is not specified, it is mandatory for alerts to be created automatically. Values for the em_event.event_class field originate from either the source generating the events or by event rule. Name of the machine or software that generated the event. For example, SolarWinds on 10.22.33.44. Corresponding field display name is Source Instance.</td>
</tr>
<tr>
<td>em_event.message_key (Message key)</td>
<td>Unique event identifier to identify multiple events that relate to the same alert. If this value is empty, it is generated from the Source, Node, Type, Resource, and Metric Name field values. This field has a maximum length of 1024 digits.</td>
</tr>
<tr>
<td>em_event.ci_type</td>
<td>JSON string that represents a configuration item. For example, {&quot;name&quot;:&quot;SAP ORA01&quot;,&quot;type&quot;:&quot;Oracle&quot;}. The CI identifier that generated the event appears in the Additional information field. This field has a maximum length of 1000 digits. Note: Reference pop-ups and click-throughs are hidden by default for read-only fields. For Configuration item and other read only fields, you can optionally change the read-only setting. For more information, see Configure pop-ups on read-only fields.</td>
</tr>
</tbody>
</table>
| em_event.severity (Severity) | Event severity options are:  
  - **Critical**: Immediate action is required. The resource is either not functional or critical problems are imminent.  
  - **Major**: Major functionality is severely impaired or performance has degraded.  
  - **Minor**: Partial, non-critical loss of functionality or performance degradation occurred.  
  - **Warning**: Attention is required, even though the resource is still functional.  
  - **Info**: An alert is created. The resource is still functional.  
  - **Clear**: No action is required. An alert is not created from this event. Existing alerts are closed. |
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>em_event.resolution_state</strong></td>
<td>Optional. If the field is empty, the resolution on corresponding alerts is still pending. Event state from the event source is either <strong>New</strong> or <strong>Closing</strong>.</td>
</tr>
<tr>
<td>(Resolution state)</td>
<td>- <strong>New</strong>: the resolution on corresponding alerts is open.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Closing</strong>: event state closes corresponding alerts.</td>
</tr>
<tr>
<td><strong>em_event.time_of_event</strong></td>
<td>Time that the event occurred in the source system. This field is a GlideDateTime field in UTC or GMT format. This field has a maximum length of 40 digits.</td>
</tr>
<tr>
<td>(Time of event)</td>
<td></td>
</tr>
<tr>
<td><strong>em_event.state</strong></td>
<td>Current processing state of the event:</td>
</tr>
<tr>
<td>(State)</td>
<td>- <strong>Ready</strong>: Event has been received and is waiting to be processed.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Processed</strong>: Event was successfully processed.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Ignored</strong>: Value is not in use.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Error</strong>: Failure occurred while processing the event. For example, the event collection method or event Severity is blank.</td>
</tr>
<tr>
<td><strong>em_event.alert</strong></td>
<td>If an alert was created as a result of the event, this field contains the unique ID that Event Management generates to identify the alert.</td>
</tr>
<tr>
<td>(Alert)</td>
<td></td>
</tr>
<tr>
<td><strong>em_event.description</strong></td>
<td>Reason for event generation. Shows extra details about an issue. For example, a server stack trace or details from a monitoring tool. This field has a maximum length of 4000 digits.</td>
</tr>
<tr>
<td>(Description)</td>
<td></td>
</tr>
<tr>
<td><strong>em_event.additional_info</strong></td>
<td>Optional. A JSON string that gives more information about the event. The JSON data is supported for String values only, other value types are not supported. You must convert numbers to String values by enclosing them in double quotes. For example, this value is not supported:</td>
</tr>
<tr>
<td>(Additional information)</td>
<td><code>{&quot;CPU&quot;:100}</code> while this value is supported: <code>{&quot;CPU&quot;:&quot;100&quot;}</code>, Another example of a valid JSON string is: <code>{evtComponent&quot;:&quot;Microsoft-Windows-WindowsUpdateClient&quot;,&quot;evtMessage&quot;:&quot;Installation Failure: Windows failed. Error 0x80070490\&quot;}</code>.</td>
</tr>
<tr>
<td></td>
<td>This information can be used for third-party integration or other post-alert processing. Values in the <strong>Additional information</strong> field of an Event that are not in JSON key/value format are normalized to JSON key/value format when the event is processed. For example, assume that the following plain text is in the Additional information field &quot;Connection instance is successful&quot;.</td>
</tr>
<tr>
<td></td>
<td>When the event is processed, all this plain text becomes one JSON string and might not be useful within an alert. In the resultant alert, this string is in the <strong>Additional information</strong> field in JSON key/value format, containing the data:</td>
</tr>
<tr>
<td></td>
<td><code>{&quot;additional_content&quot;: &quot;Connection instance is successful&quot;}</code>.</td>
</tr>
</tbody>
</table>
### Event field mapping configuration

Use Event field mappings rules to map values from specific fields to values in other fields.

Event Management stores event field mappings in the Event Field Mapping (em_mapping_rule) table. The mappings apply after event rule processing and prior to alert generation. The mapping values from the Event Mapping Pair (em_mapping_pair) table apply to the alert. The original event severity remains unchanged.

For example, if events come with the field `org_severity` with the values `Low, Medium, High` and you want the alert Severity to hold this value, create an event field mapping rule that maps the field `org_severity` to Severity, with these values:

**Example showing org_severity mapped to Severity**

<table>
<thead>
<tr>
<th>Original org_severity value</th>
<th>Map to alert Severity value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Low</td>
<td>Warning</td>
</tr>
<tr>
<td>Medium</td>
<td>Major</td>
</tr>
<tr>
<td>High</td>
<td>Critical</td>
</tr>
</tbody>
</table>

### Default event field mappings

Event Management provides default event field mappings for commonly used system monitoring tools. The Event Mapping Pairs from event field mappings format the incoming event data for Event Management.

You can view the default event field mappings and mapping pairs by navigating to Event Management > Rules > Event Field Mappings and double-clicking Name. The default event field mappings that are available for the following event sources:

- enterprises.20006.1.5
- enterprises.20006.1.7
- HPOMWIN
- Hyperic
- Microsoft Operations Manager (mom)
- netappDataFabricManager
- Oracle EM
- oraEM4Traps
- SNMPv2 Generic Trap
- SolarWinds
- Trap From Enterprise 9
- vCenter
- vmwVC
- whatsup-whatsupState
For HP Operations Manager, the following default event field mappings are active by default in the **HPOMWIN** Source category.

**Default HP Operations Manager event field mappings**

<table>
<thead>
<tr>
<th>Event field mapping name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HPOMWIN-hpomSeverity</td>
<td>Maps the source <code>hpomSeverity</code> field to the event severity.</td>
</tr>
</tbody>
</table>

**NetApp DataFabric Manager**

For NetApp DataFabric Manager, the following default event field mappings are active by default in the **netappDataFabricManager** Source category.

**Default NetApp DataFabric Manager event field mappings**

<table>
<thead>
<tr>
<th>Event field mapping name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>netappDataFabricManager-dfmEventSeverity</td>
<td>Maps the source <code>dfmEventSeverity</code> field to the event severity.</td>
</tr>
</tbody>
</table>

**NetDiscover**

For NetDiscover, the following default event field mappings are active by default in the **enterprises.20006.1.5** and **enterprises.20006.1.7** Source categories.

**Default Net Discover event field mappings**

<table>
<thead>
<tr>
<th>Event field mapping name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enterprises.20006.1.5-trap_severity</td>
<td>Maps the source <code>trap_severity</code> field to the event severity.</td>
</tr>
<tr>
<td>enterprises.20006.1.7-trap_severity</td>
<td>Maps the source <code>trap_severity</code> field to the event severity.</td>
</tr>
</tbody>
</table>

**Microsoft Operations Manager**

For Microsoft Operations Manager, the following default event field mappings are active by default in the **mom** Source category.

**Default Microsoft Operations Manager event field mappings**

<table>
<thead>
<tr>
<th>Event field mapping name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mom-momSeverity</td>
<td>Maps the source <code>momSeverity</code> field to the event severity.</td>
</tr>
</tbody>
</table>

**Oracle**

For Oracle, the following default event field mappings are active by default in the **oraEM4Traps** Source category.
Default Oracle event field mappings

<table>
<thead>
<tr>
<th>Event field mapping name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oraEM4Traps-oraEM4AlertSeverity</td>
<td>Maps the source oraEM4AlertSeverity field to the event severity.</td>
</tr>
</tbody>
</table>

SNMP traps

For SNMP Traps, the following default event field mappings are active by default in the SNMPv2 Generic Trap Source category.

Default SNMP Traps event field mappings

<table>
<thead>
<tr>
<th>Event field mapping name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ifOperStatus</td>
<td>Maps the source ifOperStatus field to the ifOperStatus.</td>
</tr>
<tr>
<td>ifAdminStatus</td>
<td>Maps the source ifAdminStatus field to the ifAdminStatus.</td>
</tr>
</tbody>
</table>

SolarWinds

For SolarWinds, the following default event field mappings are active by default in the SolarWinds Source category.

Default SolarWinds event field mappings

<table>
<thead>
<tr>
<th>Event field mapping name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>solarwinds-icon-severity</td>
<td>Maps the source icon field to the event severity.</td>
</tr>
<tr>
<td>solarwinds-Availability-severity</td>
<td>Maps the source Availability field to the event severity.</td>
</tr>
<tr>
<td>solarwinds-ComponentStatus-severity</td>
<td>Maps the source ComponentStatus field to the event severity.</td>
</tr>
<tr>
<td>solarwinds-Status-severity</td>
<td>Maps the source Status field to the event severity.</td>
</tr>
<tr>
<td>solarwinds-type</td>
<td>Maps the source eventType field to the event type.</td>
</tr>
</tbody>
</table>

Trap from Enterprise 9

For Trap from Enterprise 9, the following default event field mappings are active by default in various Source categories.

Default Trap from Enterprise 9 event field mappings

<table>
<thead>
<tr>
<th>Event field mapping name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mnState (mnState category)</td>
<td>Maps the source mnState field to the mnState.</td>
</tr>
<tr>
<td>tslineSesType (tslineSesType category)</td>
<td>Maps the source tslineSesType field to the tslineSesType.</td>
</tr>
<tr>
<td>cisco.snmpTrapOID (snmpTrapOID category)</td>
<td>Maps the source snmpTrapOID field to the snmpTrapOID.</td>
</tr>
</tbody>
</table>
### Event field mapping name | Description
--- | ---
ciscoFlashCopyStatus (ciscoFlashCopyStatus category) | Maps the source `ciscoFlashCopyStatus` field to the `ciscoFlashCopyStatus`.
tcpConnState (tcpConnState category) | Maps the source `tcpConnState` field to the `tcpConnState`.

### VMware vCenter

For VMware VCenter, the following default event field mappings are active by default in the `vmwVpxdNewStatus` Source category.

**Default VMware VCenter event field mappings**

| Event field mapping name | Description |
--- | ---
vmwVC-vmwVpxdNewStatus | Maps the source `vmwVpxdNewStatus` field to the event `severity`.

### Whatsup

For *whatsup*, the following default event field mappings are active by default in the *whatsup* Source category.

**Default whatsup event field mappings**

| Event field mapping name | Description |
--- | ---
whatsup-whatsupState | Maps the source `whatsupState` field to the event `severity`.

### Create event field mappings

Use event field mappings to provide more comprehensive information in an event alert by substituting values from the event field mapping rule into the event.

Role required: `evt_mgmt_admin`

Create the rule to match the event by its class and original values. Also specify the new values to replace the original values in the event.

1. Navigate to **Event Management > Rules > Event Field Mapping**.
2. Click **New** or open an existing rule to edit.
3. Fill in the fields, as appropriate.
### Event Field Mapping form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Event field mapping name.</td>
</tr>
<tr>
<td>Source</td>
<td>Event monitoring software that generated the event, such as SolarWinds or SCOM. This field has a maximum length of 100 digits.</td>
</tr>
<tr>
<td>Order</td>
<td>Number to define the order in which this action should be processed. Actions with lower numbers are processed first.</td>
</tr>
</tbody>
</table>
Mapping type

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mapping type</td>
<td>Mapping mechanism that is used to change an event field value.</td>
</tr>
<tr>
<td></td>
<td>· <strong>Single field</strong>: Mapping rule that transforms specific values from one event field to another event field. For example, whenever the <code>ciscoFlashCopyStatus</code> mapping rule finds the specific value 8 in the <code>ciscoFlashCopyStatus</code> name-value pair, the mapping rule updates the field value to <code>copyDeviceBusy</code>.</td>
</tr>
<tr>
<td></td>
<td>· <strong>Constant</strong>: Mapping rule that transforms any value in the specified field to the new value provided. For example, a mapping rule could transform any value in the <code>Node</code> field to a hard-coded value such as <code>Linux1</code>.</td>
</tr>
</tbody>
</table>

Active

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active</td>
<td>Check box that activates or deactivates the event field mapping. If possible, find and apply another event field mapping rule.</td>
</tr>
</tbody>
</table>

4. Right-click the form header and select **Save**.

5. If you selected **Single field**, fill in the fields, as appropriate.

**Single value fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>From field</td>
<td>Event field to replace.</td>
</tr>
<tr>
<td>To field</td>
<td>Event field where the mapping rule inserts or updates the value. When this field is identical to the <code>From field</code>, the mapping rule updates the value in memory of the event field.</td>
</tr>
</tbody>
</table>

6. If you selected **Constant**, fill in the fields, as appropriate.

**Constant fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Value</td>
<td>Value you want to use for the <code>To field</code>. This field appears when the Mapping type is <code>Constant</code>.</td>
</tr>
<tr>
<td>Value (Event Mapping Pairs section)</td>
<td>Value you want to insert or update into the <code>To field</code>. The mapping rule overwrites any existing value in the <code>To field</code>. This field appears when the Mapping type is <code>Single field</code>.</td>
</tr>
</tbody>
</table>

7. In the **Key** field, fill in the fields, as appropriate. Click + to add more **Key** fields, as required.
Key fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key (Event Mapping Pairs section)</td>
<td>Value that the mapping rule searches for. Whenever the event field has this value, the mapping rule adds the value listed in the Value field to the field listed in the To field. This field appears when the Mapping type is Single field.</td>
</tr>
</tbody>
</table>

8. Click **Submit**.

For example, see these values for a predefined rule that is applied to events in the Trap From Enterprise 9 class. If the events contain the `snmpTrapOID` element with a value of `iso.org.dod.internet.private.enterprises.cisco.0.0`, the mapping rule changes the value to `reload` in alerts. If the events contain the `snmpTrapOID` element, a value of `iso.org.dod.internet.private.enterprises.cisco.0.1`, the mapping rule changes the value to `tcpConnectionClose` in alerts.

<table>
<thead>
<tr>
<th>Field</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>cisco.snmpTrapOID</td>
</tr>
<tr>
<td>Source</td>
<td>Trap From Enterprise 9</td>
</tr>
<tr>
<td>Mapping type</td>
<td>Single field</td>
</tr>
<tr>
<td>From field</td>
<td>snmpTrapOID</td>
</tr>
<tr>
<td>To field</td>
<td>snmpTrapOID</td>
</tr>
<tr>
<td>Event Mapping Pairs</td>
<td></td>
</tr>
<tr>
<td></td>
<td>· Pair 1</td>

<tr>
<td></td>
<td>· Key: <code>iso.org.dod.internet.private.enterprises.cisco.0.0</code></td>
</tr>
<tr>
<td></td>
<td>· Value: <code>reload</code></td>
</tr>
<tr>
<td></td>
<td>· Pair 2</td>
</tr>
<tr>
<td></td>
<td>· Key: <code>iso.org.dod.internet.private.enterprises.cisco.0.1</code></td>
</tr>
<tr>
<td></td>
<td>· Value: <code>tcpConnectionClose</code></td>
</tr>
</tbody>
</table>

Test an event field mapping by sending an event that contains a field that is present in the event field mapping.

**Manually create and send events**

You can manually create and send events to confirm that Event Management properly manages events and generates alerts.

Role required: evt_mgmt_admin

For example, you can manually send events to:

- Confirm that the MID Server is using an event connector definition and instance to send events.
- Confirm that event rules, event field mapping, and other configurations do generate alerts.
• Track an operation or action that did not generate an event.

1. Navigate to Event Management > All Events.
2. Click New.
3. On the form, fill in the fields.

**Event form**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source</td>
<td>Event monitoring software that generated the event, such as SolarWinds or SCOM. This field has a maximum length of 100 digits.</td>
</tr>
<tr>
<td>Node</td>
<td>Node name, fully qualified domain name (FQDN), IP address, or MAC address that is associated with the event, such as IBM-ASSET. This field has a maximum length of 100 digits.</td>
</tr>
<tr>
<td>Type</td>
<td>Pre-defined event type, such as high CPU, which is used to identify an event record. This field has a maximum length of 100 digits.</td>
</tr>
<tr>
<td>Resource</td>
<td>Unique event identifier to identify multiple events that relate to the same alert. If this value is empty, it is generated from the Source, Node, Type, Resource, and Metric Name field values. This field has a maximum length of 1024 digits.</td>
</tr>
<tr>
<td>Metric Name</td>
<td>Unique name to identify the metric.</td>
</tr>
<tr>
<td>Source instance</td>
<td>Name of the machine or software that generated the event. For example, SolarWinds on 10.22.33.44. Corresponding field display name is Source Instance.</td>
</tr>
<tr>
<td>Message key</td>
<td>Unique event identifier to identify multiple events that relate to the same alert. If this value is empty, it is generated from the Source, Node, Type, Resource, and Metric Name field values. This field has a maximum length of 1024 digits.</td>
</tr>
<tr>
<td>Severity</td>
<td>The severity of the event. The options are typically interpreted as follows:</td>
</tr>
<tr>
<td></td>
<td>• Critical: Immediate action is required. The resource is either not functional or critical problems are imminent.</td>
</tr>
<tr>
<td></td>
<td>• Major: Major functionality is severely impaired or performance has degraded.</td>
</tr>
<tr>
<td></td>
<td>• Minor: Partial, non-critical loss of functionality or performance degradation occurred.</td>
</tr>
<tr>
<td></td>
<td>• Warning: Attention is required, even though the resource is still functional.</td>
</tr>
<tr>
<td></td>
<td>• Clear: No action is required. An alert is not created from this event. Existing alerts are closed.</td>
</tr>
<tr>
<td></td>
<td>• Info: An alert is created. The resource is still functional.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| Resolution state        | Optional. If the field is empty, the resolution on corresponding alerts is still pending. Event state from the event source is either **New** or **Closing**.  
  - **New**: the resolution on corresponding alerts is open.  
  - **Closing**: event state closes corresponding alerts. |
| Time of event           | Time that the event occurred in the source system. This field is a GlideDateTime field in UTC or GMT format. This field has a maximum length of 40 digits. |
| State                   | The current processing state of the event:  
  - **Ready**: Event has been received and is waiting to be processed.  
  - **Processed**: Event was successfully processed.  
  - **Ignored**: Value is not in use.  
  - **Error**: Failure occurred while processing the event. For example, the event collection method or event **Severity** is blank. |
| Alert                   | If an alert was created as a result of the event, this field contains the unique ID that Event Management generates to identify the alert. |
| Description             | Reason for event generation. Shows extra details about an issue. For example, a server stack trace or details from a monitoring tool. This field has a maximum length of 4000 digits. |
### Additional information

A JSON string that gives more information about the event. The JSON data is supported for String values only, other value types are not supported. You must convert numbers to String values by enclosing them in double quotes. For example, this value is not supported: `{"CPU":100 }` while this value is supported: `{"CPU":"100"}`. Another example of a valid JSON string is: `{"evtComponent":"Microsoft-Windows-WindowsUpdateClient","evtMessage":"Installation Failure: Windows failed. Error 0x80070490"}`. This information can be used for third-party integration or other post-alert processing. Values in the **Additional information** field of an Event that are not in JSON key/value format are normalized to JSON key/value format when the event is processed. For example, assume that the following plain text is in the **Additional information** field "Connection instance is successful". When the event is processed, all this plain text becomes one JSON string and might not be useful within an alert. In the resultant alert, this string is in the **Additional information** field in JSON key/value format, containing the data: {"additional_content": "Connection instance is successful"}.

4. Click **Submit**.

### Event rules

Use event rules to generate alerts for tracking and remediation. Event rules are stored in the Event Rule (em_match_rule) table. Configure and customize event rules to manage events and alert generation.

Event rules do not change the event records in the Event table. Changes to event data are stored in the ServiceNow instance memory.

Use the Event rule designer to create and configure event rules. See the following video:

You can use the default event rules or event rules that you have created to:

- Apply an event rule filter to determine whether the rule applies to an event.
- Apply a transform with **Event Match Fields** and optional **Event Compose Fields** to format the alert text.
- Apply a threshold to create custom alerts for rapidly recurring events.
- Automatically create or close alerts.
- Bind alerts to CI information from the CMDB.
Create or edit an event rule
You can create event rules to generate alerts for tracking and remediation.

Role required: evt_mgmt_admin

You can view the list of available event rules on the event rule page.

You can create rules that:

- Transform information in events to populate specified alert field values and compose alert fields from various values.
- Configure threshold rules that create or close alerts only when the incoming matching events exceed the specified threshold.
- Bind alerts to CIs using CI identifiers.

Options to create the rule are:

- Create an event rule and assign event fields for alert generation.
- Create a rule from an existing event or groups of events that do not have a rule. In this case, the event fields are copied to the Event Match Fields section of the rule.
- Edit an existing event rule.

Note: Event rules that are not configured to perform any action are skipped. Therefore, if the rule is not configured as ignore, threshold, or binding, it is important to specify either the match or the compose fields.

1. Navigate to Event Management > Rules > Event Rules and take one of the following actions:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an event rule from an existing event</td>
<td>1. Click the link for unassociated events or grouped events that are not mapped to rules.</td>
</tr>
<tr>
<td></td>
<td>2. Select the event that you want to use for creating the rule.</td>
</tr>
<tr>
<td></td>
<td>The event fields are copied to the Event Field Rules section of the rule.</td>
</tr>
</tbody>
</table>
## Edit an existing event rule

In the event rule list, click the required event rule to be modified. The event rule opens in the event rule designer where you can modify the values of the fields.

- Click **Save and Upgrade**

## Create an event rule

Click **New**.

### 2.

Ensure that **Active** is selected. When the rule is deactivated, Event Management finds and applies another event rule. An alert is still created for the event unless **Ignore** is selected in another applicable rule or when configuring the filter for this event rule.

### 3.

Enter a unique and meaningful name and fill in the form.

### Event Rule Info form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source</td>
<td>Category to which this matching rule applies. The mapping rule only applies to events with the same event class value. If this value is empty, apply the rule to all events.</td>
</tr>
<tr>
<td>Order</td>
<td>Order in which an event rule is evaluated when multiple rules are defined for the same type of event. Event rules are evaluated in ascending order.</td>
</tr>
<tr>
<td>Description</td>
<td>Type additional information that describes the event rule.</td>
</tr>
</tbody>
</table>

### 4.

Optional: Define the event rule using these Event Rule designer features:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Event Filter</strong></td>
<td>Define a filter to restrict to which events the event rule must apply. See <a href="#">Filter the events that an event rule applies to</a>.</td>
</tr>
<tr>
<td><strong>Transform and compose alert output</strong></td>
<td>Configure the customization of alert content. See <a href="#">Configure an event rule to customize alert content</a>.</td>
</tr>
<tr>
<td><strong>Threshold</strong></td>
<td>Create or close alerts according to the specified threshold. See <a href="#">Set a threshold to suppress alert generation</a>.</td>
</tr>
</tbody>
</table>
5. Click Save, Submit, or Update.

Use event input information
The Event Input pane that is included in the steps to create an event rule provides a reference to the information that you can use when configuring an event rule.

In the Transform and compose alert output pane, you can also drag the information into the required fields to customize alert content. The fields in the right-hand pane appear as a reference to which fields, expressions, and their values are available when working in the Event Rule designer. The fields that display in the Transform and compose alert output left-hand workarea become the fields in the generated alert form.

General components and navigation
The Event Input pane consists of these sections:

- Event Additional Info
- Expressions
- Event Raw Info

The Event Input pane displays in all Event Rule designer sections, except for the Event Rule Info section. The fields in the right-pane can be modified only in the Transform and compose alert output section. In all the other sections, the Event Input pane is read-only and available for reference purposes.

Note: If Accessibility enabled is selected in System Settings, standard edit mode is not available.

Edit modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standard edit mode</td>
<td>Text selected in the left-hand workarea cannot be edited. Undo is not available. In this mode, you can only mark the text or values and transform it by selecting a field name.</td>
</tr>
<tr>
<td>Mode</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Regex edit mode</td>
<td>Edit text in the left-hand workarea by selecting it, as required. After you have edited the text, you cannot go back to the standard mode. <strong>Undo</strong> is not available. However, <strong>Reset</strong> is available, returning the field to its original value. You can compose text using regular expression (regex) format conventions, for example, type (.*) to create a field name. You cannot use field values like: type &quot;$&quot; to include the value of a field and specify the name of the field in parentheses (). You can include special characters in a field by ‘escaping’ them, that is, by prefixing the character with a ‘\‘. For example, to include a ‘\‘ in your text, enter &quot;.</td>
</tr>
</tbody>
</table>

**Event additional info**

The Event additional info section displays default event form fields, plus fields that were created to display in alerts and that are added to the Additional information section of the alert.

When configuring text in the fields in the left-hand workarea, you can drag field names and/or their value from this section into the fields.

**Expressions**

The Expressions section is available only if an additional information field was created. You can create expressions from event raw data or from additional information data.

1. Click in a field in the Event Input pane to perform transformation actions.

2. Create an expression by transforming information and associating it with a field name. Either select a field name from the suggested list, or create a field name, as required.

<table>
<thead>
<tr>
<th>EXPRESSIONS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Metric Name</td>
</tr>
<tr>
<td>High condition</td>
</tr>
</tbody>
</table>

3. Click in a field in the Event Input pane. In the left-hand workarea, select the required information.

Create expressions by transforming information and associating it with a field name. Select a field name from the suggested list, or you can create a field name, as required.

**Event raw info**

The Event raw info section is always available. Its contents are the fields from the Event form.

To transform text, click a field in the right-panel to open it in the work area on the left-panel, in the Mark Expressions section. You can select text in the Mark Expressions section where the selected
text becomes the value of a newly created field. Name the new field. This new field is added to the Expressions section.

**Note:** When creating regex expression for input, ensure that you create input with the variables in sequential order. While variables can be skipped for inclusion, the selected order must be maintained.

Controlling how fields appear:

- Use the blacklist (em_event_rule_black_list) table to hide fields from the right-pane.
- Use the em_event_rule_order form to order the position of each field.
- Fields that are not in the blacklist and also not part of the em_event_rule_order table, still appear in the event rule designer, in the right-panel and in the **Transform and Compose Alert Output** tab.

**Filter the events that an event rule applies to**

Define a filter to restrict to which events the event rule must apply. Configure the filter by providing a set of conditions that each event must match to be either excluded or included from applying to the event rule.

Ensure that a name is specified for the event rule.

Role required: evt_mgmt_admin

To construct the required condition statement, you can use event fields as well as additional fields that are defined in the **Additional Information** field of the event. Use these fields to configure conditions that can exclude events. Alternatively, you can filter incoming events to ensure that only those events that meet the required conditions are included.

**Note:** Event rules matching is case-sensitive.

While working in the Event Filter tab:

- In the Event rule list, if you selected a recommended rule or an existing rule, the filter fields are populated with values from these events. You can use these filter fields to compose filter conditions.
- You can click another tab (for example, **Threshold**), work in that area and then return to work in the Event Filter area without losing information.
- Use the right-panel as a source of reference for which fields are available to be used when composing filter conditions.

**Note:** Event filters created on additional_info fields only perform a string comparison and not a numeric comparison, even if the information entered into the value field appears as if it is numeric, as depicted in the following graphic:

1. Navigate to **Event Management > Rules > Event Rules**.
2. Click **New** or open an event rule.
3. Click **Event Filter**.
4. To ignore events, select **Ignore events that match this filter**. All events that match this event rule are ignored. You can add more conditions to the filter by clicking either **OR** or **AND**.

**Note:** Even if an event is ignored by an event rule, the event is still recorded in the Event (em_event) table. Select this option to inhibit an alert from being created and be associated with the event.

5. To configure conditions to which the event rule must apply, click **New Criteria**. You can add further conditions by clicking either **OR** or **AND**.

6. You can add field names to the Event Rule Simple Field Black Lists (em_event_rule_black_list) table to either show or hide fields from the filter.

   - To remove fields from the filter and the right panel, add a new black list field with **Show in rule** not selected.
   - To remove fields only from the filter and still enable it to appear in the right panel, add a black list field with **Show in rule** selected.

7. Click either **Save** or **Submit**.

   Example showing filter conditions that are specified to run a rule when the metric name starts with the word "disk". For this example, any resource is
acceptable, as long as it is not "cpu" and the node name is "MyServer".

Example to filter events using time conditions. In the Select Field or add New field, select Time of event.

Specify the required time conditions, for example, anytime after yesterday.
Find events that are not matched to rules
Find events that are not matched to any rules, and determine if it is necessary to create event rules to manage them.

Role required: evt_mgmt_admin

This video describes event rules and how to find events that are not matched to rules.

2. Near the top of the form, click the link for events or grouped events that are not mapped to rules.
Create an event rule. For example, event rules are useful for managing events that occur regularly.

View event rules
You can view all event rules on the Event Rules list.

Role required: evt_mgmt_admin

You can learn about event rules from the following video tutorial.

Navigate to Event Management > Rules > Event Rules.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The event rule name.</td>
</tr>
<tr>
<td>Override default binding</td>
<td>Legacy binding criteria. If, in the Bind section criteria have not been specified or if the specified bind criteria are not matched, then the legacy binding criteria are considered.</td>
</tr>
<tr>
<td>Order</td>
<td>Order in which an event rule is evaluated when multiple rules are defined for the same type of event. Event rules are evaluated in ascending order.</td>
</tr>
<tr>
<td>Source</td>
<td>Event monitoring software that generated the event, such as SolarWinds or SCOM. This field has a maximum length of 100 digits.</td>
</tr>
<tr>
<td>Updated</td>
<td>Update date and time for the rule.</td>
</tr>
</tbody>
</table>

**Note:** You can filter the Event Rule list to display the required subset of the information. However, if you create a favorite link after filtering, when the link is clicked the Event Rule list does not display the correct filter.

Find rules that were applied to events or alerts
View the rules that were applied to events and alerts to confirm how events are processed.

Role required: evt_mgmt_admin, evt_mgmt_operator, or evt_mgmt_user

Do one of the following:
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| Find rules that apply to an event | 1. Navigate to Event Management > All Events, and then click an event Number.  
2. Under Related Links, click Check process of event.  
3. Review the information that appears above the Source field, and review all Processing Notes. |
| Find rules that apply to an alert | 1. Navigate to Event Management > All Alerts, and then click an alert number.  
2. In the processing notes, review information about the applied event rule. |

**Configure an event rule to customize alert content**
You can configure an event rule to customize alert content. You can customize the order of the fields and select which fields display. The fields in the left-hand workarea of the Transform and Compose Alert Output section of an event rule are the fields that appear in the generated alert.

Role required: evt_mgmt_admin

You can customize alert content by adding the required event fields and modifying the text in the fields.

**Note:** When creating regex expression for input, ensure that you create input with the variables in sequential order. While variables can be skipped for inclusion, the selected order must be maintained.

Format alert text by using one or both of these methods:

**Format alert text**

<table>
<thead>
<tr>
<th>Format method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transform</td>
<td>Create a field to display in an alert. The field and its value appear in the Additional Information section of an alert. In the Event Input pane, the new field is listed in the Expressions section.</td>
</tr>
<tr>
<td>Compose</td>
<td>Determine which text to display in the selected field.</td>
</tr>
</tbody>
</table>

**Note:**
- Configure which fields display in the Event Input pane by configuring the blacklist (em_event_rule_black_list).
  A field entered into the blacklist that already appears in an existing event rule is not removed from the rule; instead, it is moved to the Manual Attributes section in the rule.
- Control the order of event form fields by configuring em_event_rule_order.

2. Click New or open an event rule.
3. Click **Transform and compose alert output**. In this section, you can use the **Transform** mode and the **Compose** mode.

4. To transform information in fields—standard mode:

   ![Note: In this step, the selection of text is made in standard edit mode. In this mode, undo is available.](image)

1. Click the required field in the Event Input pane. The value and contents of the selected field appear in the workarea on the left.

2. Select standard edit mode.

3. Select the required text. You can double-click text in the field to select a word or select the required text and symbols.
4. Select a field name from the list or enter the required expression name. The field name appears in the Expressions pane and the selected text is highlighted. Both the text and the expression name are highlighted in the same color. Each additional expression that you create, plus its value, is highlighted in a different color.

Note: Transform field names cannot contain a ` (single quote) character.

5. Click Done. The expression name appears in the Expressions section of the Event Input pane.

6. If you click an expression or its value in the Event Input pane, the details display in the workarea on the left.

5. To transform information in fields—regex mode:

Note:
- In regex mode, undo is not available.
- When building a regex expression from variables that are highlighted in the event, place the selected variables in the same order that they appear in the event field.
- When composing the event rule regex, specify the terms using an exact match of the input from the event fields. For example, for the text vhxy2stlgwc_8888_hec03v012979, the regex
  
  ^([^_]+)_.

  looks as if it should catch the text “vhxy2stlgwc” that appears before the underscore. However, it does not work as this text is not an exact match. Use the full regex, as follows:

  ^([^_]+)_.*

- Java flavor is the only regex engine in use.
- The Java regex engine “matches” method is used. With this implementation, the regex engine attempts to match the entire input sequence against the specified pattern. Other matching methods, for example, the find method, are not supported.
- No regex flags are set by default, except the Pattern.DOTALL flag. With this implementation of Java regex, the DOT character `.` matches any character, including a line terminator.
- Aside from Pattern.DOTALL, other regex flags cannot be changed.
1. Click the required field in the Event Input pane. The value and contents of the selected field appears in the workarea on the left.

2. Select regex edit mode.

3. Select the required text and symbols. Replace the highlighted text with (.*) to create a regex expression.

4. In the Expressions pane, click the Select or Add Field field and select a field name from the list or enter the required expression name.

5. Click Done.

Note:
- When building a regex expression from variables that are highlighted in the event, place the selected variables in the same order that they appear in the event field.
- When composing the event rule regex, specify the terms using an exact match of the input from the event fields. For example, for the text
To compose text, in the Transform and compose alert output section, click in the required field.

**Transform and compose alert output**

Click Event Raw values to create new regex expressions.

<table>
<thead>
<tr>
<th>Description</th>
<th>${description}</th>
</tr>
</thead>
<tbody>
<tr>
<td>Node</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>${type}</td>
</tr>
</tbody>
</table>

Compose text in the alert fields by performing any of these actions:

- Drag a field from the Event Info pane into the required field.
- Use the Event Info pane as a reference of which fields are available. Write the field name details, using the format $\{<fieldname>\}$, where "$\$" means "use the value". Between the brackets, the name of the event field replaces the $\{fieldname\}$ variable.
- Freely enter text, spaces, or characters. For example, use spaces or underscore symbols (_) to make the text in the alert field readable.

7. Select Manual attributes to specify fields that must display in the generated alert. These fields, and their values, display in the Additional Information section of the generated alert.

8. Click Save or Update.

You can filter event rules. See [Filter the events that an event rule applies to](#).

**Set a threshold to suppress alert generation**

The event threshold is the rate upon which Event Management generates an alert. Receiving multiple events for a device over a short interval may warrant creating an alert, as the condition may be serious. However, receiving events over a longer interval may indicate a less serious situation which would not warrant creating an alert.

Role required: evt_mgmt_admin

You can configure the properties in an event rule to create alerts, suppress alert generation, or close existing alerts according to a specified threshold. The threshold is based on the value of event fields or number of occurrences over a specified period.

**Note:** Field Name can be the name of any numeric field in the Additional information field of the event. Therefore, if CPU is an additional information field for a specific event, then CPU can be used as a Field Name.

Assume that you want to generate an alert when CPU utilization reaches or exceeds 80% three times with no more than 20 seconds between any two consecutive events. Create an event rule with these settings (an explanation for each value is given in parentheses):
**Create Alert Operator**: >= (operator to determine whether utilization of **Field Name** reaches or exceeds the specified value)

- **Field Name**: CPU (events regarding high CPU usage)
- **Threshold Value**: 80 (percent)
- **Occurs**: 3 (three events occur where the CPU usage is at or above ”>=” 80%)
- **Over(seconds)**: 20 (20 seconds or less between events)

To demonstrate how the preceding settings are evaluated, assume that the following events are received:

<table>
<thead>
<tr>
<th>Scenario</th>
<th>Outcome</th>
</tr>
</thead>
</table>
| Reported elapsed time and the CPU usage for each event:  
  - First event elapse time 20, CPU=85  
  - Second event elapse time 40, CPU=80  
  - Third event elapse time 60, CPU=70 | In this scenario, no alert is generated since one event has a CPU utilization that is under 80%. |
| Reported elapsed time and the CPU usage for each event:  
  - First event elapse time 20, CPU=85  
  - Second event elapse time 40, CPU=90  
  - Third event elapse time 70, CPU=95 | In this scenario, an alert is not generated since the elapsed time in one event is over the specified 20 seconds. |
| Reported elapsed time and the CPU usage for each event:  
  - First event elapse time 20, CPU=85  
  - Second event elapse time 40, CPU=95  
  - Third event elapse time 60, CPU=90 | In this scenario, an alert is generated since in all events the elapsed time is within the specified time and the CPU usage is over 80%. |

**Note:**

- When configuring an event rule to create or close alerts according to a threshold, events that arrive at the same second, as determined by the `time_of_event` field, are skipped. This occurs because these events are considered to be duplicates.
- When threshold conditions are configured, alerts close when the **Close Alert Operator** condition is met, and not when an event is received with `Severity = Clear` or `Resolution state = Closing`.

1. Navigate to **Event Management > Rules > Event Rules**.
2. Create or open an event rule.
3. Click **Threshold**.
4. Select **Active**. If **Active** is not selected, the fields on this page do not appear.
5. In the **Create Alert Operator** field, select an operator.
   - If you select **Count**, specify the corresponding **Occurs** and **Over(seconds)** fields.
   - If you select any operator other than **Count**, the **Threshold Metric** and **Value** fields appear. Specify the required values in these fields.
Note: The value of the Threshold Value property can be the name of any field in the Additional information of the event. For example, if CPU is a field in Additional information for a specific event, then CPU can be used as the Threshold Value.

- In the Occurs field, specify the required value.
- In the Over(seconds) field, specify the required period.

6. To automatically close alerts, in the Close Alert Operator field, select an operator. Extra fields appear according to your selection.
   - If Count is specified as the operator for the Create Alert Operator field, then the selection in the Close Alert Operator field is either None or Idle. Specify the required value.
   - If you select Idle, configure the Over(seconds) field.
   - In the Close Alert Operator field, if you select an operator other than Idle, then configure the Value, Occurs, and Over(seconds) fields.

7. Click Save or Submit.

To create an alert when a specific event occurs 5 times in 10 minutes, in Threshold:

1. In the Threshold Metric field, specify the name of any field that exists in the Additional information field in the event. The value of the field is irrelevant.
2. In the Create Alert Operator field, select Count.
3. In the Occurs field, specify 5.
4. In the Over field, 600 (10 * 60 seconds).
5. Click Save or Submit.

To create an alert when a specific event occurs 5 times in 10 minutes with a metric value greater than 55. Assume that "metric_value" is a field in the Additional information of the event. Specify:

1. Select the Active check box.
2. In the Create Alert Operator field, select >=.
3. In the Threshold Metric field, specify metric_value.
4. In the Value field, specify 55.
5. In the Occurs field, specify 5.
6. In the Over field, specify 600 (10 * 60 seconds).
7. Click Save or Submit.

Alert binding to CIs with event rules
When alerts are associated with CIs, the task of remediation is simplified. During alert generation, Event Management uses event rules and other mechanisms to automatically bind alerts to CI information from the CMDB. For tracking purposes and remediation, the alert shows information about the CI that caused the event.

Alert binding process flow
Alerts bind to CIs based on the following process flow:
1. When an event arrives, Event Management checks the node or CI identifiers.

2. If no node exists, the generated alert can bind to the CI using the alert Type, Additional information, or Configuration item identifier fields.

3. If the event has a node value, search for a valid host.

4. If the event has a host and a CI type, try to bind to a device CI.

5. If the event has a host, try to bind to the application CI.
How alerts bind to CIs

1. Node or CI Identifiers Exist in Event?
   - Yes: Non-host CI (Service or Group) Binding
   - No: Node Empty but CI Identifiers Exist in Event?

2. CI Type Exists in Event?
   - No: Search for Any CI
   - Yes: CI Found?

3. Host CI Binding
   - Search for Host
     - Host Found?: Yes
     - No: Node or CI Identifiers Exist in Event?

4. Device CI Binding on Host
   - Event Has Device Type?
     - Yes: Search for Device
     - No: No Binding
     - Device Found?: Yes
     - No: Bind to Device On Host

5. Application CI Binding on Host
   - Event Has Process Info or App Type?
     - Yes: Search for Process
     - No: Process Found
     - Yes: Bind to Application CI

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
The event can contain the binding process flow in its *Processing Notes* field.

**Tracking and remediation**

Alerts can be bound to CIs from the CMDB for tracking purposes and remediation. Event Management uses event rules and various mechanisms to automatically bind CIs to alerts. When information from an event populates a field with a value, the value either originates from the event source or from event rules. This enhances remediation, functionality, and integration with other ITOM products.

**Binding to an application running on a specific host**

If the event is specific to an application type, use the following steps to bind alerts to a specific application:

- Use the procedures in the topic.
- Create an event rule with a filter that captures events on the application type you want.
- In the event rule, select **Binding**.

**Binding**

---

Select to bind alert to CI using CI identifiers.

Default binding: Value of Node field will be used to try and match CI names in Host CIs, such as Computer, OS, Switch Router (any CI type extending CI).

- **Override default binding**

**Binding type**

- **CI Identification**

- Click **Override default binding**.
- In the Binding Type field, select either **CI's Identification** or **CI field matching**.
• For **CI’s Identification**, specify the **Class**.

**Binding**

Select to bind alert to CI using CI identifiers.

**Default binding**: Value of Node field will be used to try and match CI for Host CIs, such as Computer, OS, Switch Router (any CI type except for the current CI type).

- **Override default binding**

**Binding type**: CI Identification

**Class**: Tomcat Connector

**Criterion attributes** - Fill at least one set of criterion attributes

- **Select an Identifier** ▼ is Add Value

**Container level 1**: Tomcat

**Criterion attributes** - Fill at least one set of criterion attributes

- **Select an Identifier** ▼ is Add Value

**Container level 2**: Select a Class

• In the **Criterion attributes field**, specify name and sys_class_name.
In the name Add Value field, specify the required name.

In the Container level 1 area, specify the required values.

If further container level fields appear, specify the required values.

For CI field matching, specify the required CI Type.

- In the binding process, after the host is found, the algorithm matches all additional_info attributes that have the same name as CI fields for that CI type. If the match is successful, the event is bound to the CI.
- If more than one matching application is found on the host, the alert is bound to the host and not to the application.

Where there is no CI Type, for example, if you want to bind alerts to a SQL server application when the CPU on sqlServer.exe is over 90%, instead use these procedures:

- Populate the Node field in the event with the Cl name, FQDN, IP, or MAC address value. The bind is successful even if host has more than one IP address or MAC address.
- If you want to use a unique identifier that is not one of the four mentioned above, populate the event rule CI Identifier (ci2metric_id) field with one or more unique identifiers of the CI. This field should be in JSON format. For example, to use a unique identifier that is not one of the four mentioned above, add a CI Identifier (ci2metric_id) filter field with one or more unique identifiers of the CI. If the host CI is VMWare VM, and it has a field called MOID, use the JSON format and specify: {"moid":"<CI moid>"}
- Create an event rule with an event match field which maps the process name to the mapping variable sa_process_name. In this case, do not use the CI type.

Binding procedures

Use the procedures in these topics to bind alerts.

Bind alerts to a host CI

You can create an event rule to bind alerts to host CIs.

Role required: evt_mgmt_admin

An incoming event from a host CI can bind to an alert based on the event Node field value. If the value resides in a different event field, you can use an event rule transform to copy the data to the Node field on the alert.

When binding alerts to a host, such as a computer, switch, or router CI:

- Populate the Node field in the event with the CI name, FQDN, IP, or MAC address value. The bind is successful even if host has more than one IP address or MAC address.
- If you want to use a unique identifier that is not one of the four mentioned above, populate the event rule CI Identifier (ci2metric_id) field with one or more unique identifiers of the CI. This field should be in JSON format. For example, to use a unique identifier that is not one of the four mentioned above, add a CI Identifier (ci2metric_id) filter field with one or more unique
identifiers of the CI. If the host CI is VMWare VM, and it has a field called MOID, use the JSON format and specify: "moid": "<CI moid>")

2. Click New, and in Event Rule Info, fill in the appropriate fields of the event rule.
3. In the Event Filter condition builder, select Node, select an operator, and then enter one of these values: CI name, FQDN, IP, or MAC address.
4. Click Transform and Compose Alert Output and specify any Additional information mappings that you require.
5. Click Submit.

Bind alerts to a specific host CI
You can create an event rule to bind alerts to the correct device CI. An incoming event from a device CI can bind to an alert based on event rule transform information. However, first identify the host CI that the device is running on.
Role required: evt_mgmt_admin

In the binding process, after the host is found, the algorithm matches all additional_info attributes that have the same name as CI fields for that event type. If the match is successful, the event is bound to the CI. If more than one matching device is found on the host, the alert is bound to the host and not the application. Use the following steps to bind alerts to a specific device:

- When binding alerts to a host, such as a computer, switch, or router CI:
  - Populate the Node field in the event with the CI name, FQDN, IP, or MAC address value. The bind is successful even if host has more than one IP address or MAC address.
  - If you want to use a unique identifier that is not one of the four mentioned in the preceding point, populate the event rule CI Identifier (ci2metric_id) field with one or more unique identifiers of the CI. This field should be in JSON format. For example, to use a unique identifier that is not one of the four mentioned above, add a CI Identifier (ci2metric_id) filter field with one or more unique identifiers of the CI. If the host CI is VMWare VM, and it has a field called MOID, use the JSON format and specify: "moid": "<CI moid>"

- Create an event rule with a filter that captures events on the device type you want. In the event rule, select the Transform check box and select the appropriate CI Type:

<table>
<thead>
<tr>
<th>Device to bind</th>
<th>CI Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>File System</td>
<td>cmdb_ci_file_system</td>
</tr>
<tr>
<td>Port</td>
<td>cmdb_ci_network_adapter</td>
</tr>
<tr>
<td>Storage Device</td>
<td>cmdb_ci_storage_device</td>
</tr>
<tr>
<td>Volume</td>
<td>cmdb_ci_storage_volume</td>
</tr>
</tbody>
</table>

2. Click New and fill in the appropriate fields of the event rule.
3. Click Transform.
4. Click Active.
5. From the CI type list, select the device that is used in the filter condition. For example, if you build a filter condition for a port, select Port.

<table>
<thead>
<tr>
<th>Device to bind</th>
<th>CI type</th>
</tr>
</thead>
<tbody>
<tr>
<td>File System</td>
<td>cmdb_ci_file_system</td>
</tr>
<tr>
<td>Port</td>
<td>cmdb_ci_network_adapter</td>
</tr>
</tbody>
</table>
In the Event Match Fields section, specify any **Additional information** mappings.

Click **Submit**.

To bind to custom device types, configure the alert binding to a process and add the custom device type to the Process to CI Type Mapping (em_binding_process_map) table.

Example showing binding to a specific device using CI field matching to bind to the following string values in the **Additional information** field of an event: "file_system":"ext2", "mount_point":"mp1".

1. Navigate to **Event Management > Rules > Event Rules**.
2. Click **New**, and in **Event Rule Info**, fill in the appropriate fields of the event rule.

   **Event Rule Info**

<table>
<thead>
<tr>
<th>Name</th>
<th>test binding</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source</td>
<td>source1</td>
</tr>
<tr>
<td>Order</td>
<td>100</td>
</tr>
</tbody>
</table>

   **Description**: Example using CI field matching to bind to the following string values in the **Additional information** field of an event: "file_system":"ext2", "mount_point":"mp1".

3. Click **Binding**.
   a. Click **Override default binding**.
   b. In the **Binding type** field, select **CI field matching**.
   c. In the **CI type** field, select **File System**.

© 2020 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
4. Click **Save**.

In the Binding Device Maps (em_binding_device_map) table, ensure that File System is mapped to cmdb_ci_file_system.
In the File Systems (cmdb_ci_file_system) table, ensure that the required values exist, for example, name1 and name2, as depicted in the following image.

![File Systems Table](image)

The result of the binding performed by the 'test binding' event rule is shown in the Processing Notes field of the event.

![Processing Notes](image)

Bind alerts for non-host CIs

An incoming event from a discovered business service, application service, or alert group can bind to an alert based on an event rule and the corresponding event field mapping. The event field mapping requires a URL or the port number and corresponding IP address for each service or alert group.

Role required: evt_mgmt_admin

If the event is specific to a non-host CI, for example a business service, application service, or alert group, use these steps to bind alerts to a non-host CI:

- Leave the **Node** field empty.
- Populate the **CI Type** with the CI type you want to bind.
- Make sure the **additional_info** field has enough information to uniquely identify the CI. The algorithm matches all **additional_info** attributes that have the same name as CI fields for that **Event Type**. If the match is successful, the event will be bound to the CI.

Optional method:
- Leave the **Node** field empty.
- Populate the **CI Identifier** (ci2metric_id) field with attributes, as described above, that uniquely identify the CI.

1. Navigate to **Event Management > Rules > Event Rules**.
2. Click **New** and fill in the appropriate fields of the event rule.
3. Click **Transform**.
4. From the **CI type** list, select **cmdb_ci_service_auto**.
5. In the Event Match Fields section, insert a new row with these parameter values:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Field</td>
<td>node</td>
</tr>
<tr>
<td>Regular Expression</td>
<td>(.*)</td>
</tr>
<tr>
<td>Mapping</td>
<td>temp node</td>
</tr>
</tbody>
</table>

6. In the Event Compose Fields section, insert a new row with these parameter value:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Field</td>
<td>node</td>
</tr>
<tr>
<td>Composition</td>
<td>(empty)</td>
</tr>
</tbody>
</table>

7. Click **Submit**.
8. Navigate to **Event Management > Rules > Event Field Mapping**.
9. Create the corresponding event field mapping with these parameter values:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source</td>
<td>Specify the event monitor software that generated the event.</td>
</tr>
<tr>
<td>Mapping type</td>
<td>Select <strong>Single field</strong>.</td>
</tr>
<tr>
<td>From field</td>
<td>Specify temp node.</td>
</tr>
<tr>
<td>To field</td>
<td>Specify name.</td>
</tr>
</tbody>
</table>

10. In the Event Mapping Pairs section, insert new rows for each event mapping pair.
   a) Set the **Key** with the URL or an IP address with corresponding port value.
   b) Set the **Value** with the discovered business service, application service, technical service, or alert group name.

For example, you can add an event mapping pair for each business service.
11. Click **Submit**.

Bind alerts for application CIs

An incoming event from an application CI can bind to an alert based on event rule transform information. Create an event rule to bind alerts to the host CI and also to the application CI.

**Role required:** evt_mgmt_admin

For example, you can bind alerts to a SQL server application when the CPU on sqlServer.exe is over 90%:

- Make sure that the event includes the host name.
- Create an event rule with an Event Match Field entry that maps the process name to the `sa_process_name` mapping variable. In this case, do not use the **CI type**.
- Use the Process to CI Type Mapping module to add custom patterns.

In the binding process, the following steps occur:

- Identify the host.
- If the host is found, find the application on the host. An application is considered to be running on the host if it has a 'Runs on: Runs' relationship from the application to the host CI in the cmdb_rel_ci table.
- If the event rule for the transform **CI type** is defined, find an application CI on that host in the CMDB.
- If all the alert **additional_info** about the CI matches CMDB CI fields, bind the alert to the application CI.

1. Navigate to **Event Management > Rules > Event Rules**.
2. Click **New** and fill in the appropriate fields of the event rule.
3. In the **Event Filter** tab, select **Node**, select an operator, and then enter the CI name, FQDN, IP, or MAC address values for the host binding. For example, you can specify that the node is FQDN.
4. Click **Submit**.

**Trigger alerting bind to a CI**

You can manually bind an alert to a CI by triggering a new alert.

**Role required: evt_mgmt_admin**

If an alert did not automatically bind to a CI, you can manually trigger a new alert and rebind:

- Delete the alert and resend the event.
- Close the alert, temporarily set the `evt_mgmt.active_interval` system property time to 0, and then resend the alert. After the bind completes, reset the property back to the previous value.

**Custom alert fields**

You can populate custom alert fields with data contained in **Additional information** field of the event.

Valuable data contained in **Additional information** fields of events can be useful, for example, for reporting. Alert fields are automatically populated from fields that have the same name in the event. This behavior holds true for **Additional information** event fields and for **Additional information** fields that Event Rule adds. Therefore, to populate a custom alert field with the value in **Additional information** fields, use the custom field name in the **Additional information** field. You can also use Event Rules for this purpose. Values in the **Additional information** field of an Event that are not in JSON key/value format are normalized to JSON format when the event is processed.

The short description field of an alert is automatically written using the type, node, and description of the alert. To prevent the short description field from being over-written, open the **sys_properties** table, locate the `evt_mgmt.override_alert_short_description` property, change the value to `false`, and then click **Update**.

Depending on permissions, you may only be able to create fields with the **user_** prefix. If so, use Event Rules to create an **Additional information** field with the same name. To prevent some fields to be copied to the alert field, use the `evt_mgmt.alert_black_list_fields` property and add the field names that must be excluded. By default, the fields that are not copied are:

- `message_key`
- `category`
- `additional_info`
- `sys_updated_on`
- `sys_updated_by`
- `sys_created_by`
- `sys_created_on`
- `sys_mod_count`
- `sys_id`
**View patterns for event group creation**

Event groups are sets of events that do not have a matching event rule. You can view the patterns in a group of events to learn the impact of creating a rule based on the event source and description patterns.

Role required: evt_mgmt_admin, evt_mgmt_operator, or evt_mgmt_user

Events are grouped according to their source and description.

2. Click the event or grouped event link.
3. In the list of events, click an event.
4. To change the pattern of an event, double-click the pattern, make your changes, and then click **Update**.

---

**Event collection configuration**

Event Management receives external events via an event collector or script. If you are using a script to collect events, no configuration is required. All other methods of collecting events require configuration.

After event collection configuration, Event Management can collect events that are sent directly to the instance, or via the MID Server, SNMP trap, or email.

**Standard event form**

A standard event form must be used by all events, regardless of how they arrive at the instance. For more information, see [Event field format for event collection](#).
**Event collection via MID Server**

The MID Server facilitates communication and movement of data between external applications, data sources, services, and the ServiceNow instance.

<table>
<thead>
<tr>
<th>Connector operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pull</td>
<td>You can configure connector instances to use connector definitions (script instructions) that enable the MID Server to connect to external servers to obtain event information using a pull operation. For more information, see <a href="#">Configure event collection that uses the pull operation</a>.</td>
</tr>
<tr>
<td>Push</td>
<td>You can configure listeners to push event information to the instance or MID Server. For example, configure the MID WebService Event Collector to push event messages to the MID Server. For more information, see <a href="#">Event collection to MID Server using web service API</a>.</td>
</tr>
</tbody>
</table>

**Event field format for event collection**

Event Management requires all events to use a standard form, regardless of how they arrive at the instance.

In the application navigation filter, enter `em_event.list`.

**Event fields**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>em_event.source</code></td>
<td>Event monitoring software that generated the event, such as SolarWinds or SCOM. This field has a maximum length of 100 digits.</td>
</tr>
<tr>
<td><code>em_event.node</code></td>
<td>Node name, fully qualified domain name (FQDN), IP address, or MAC address that is associated with the event, such as IBM-ASSET. This field has a maximum length of 100 digits.</td>
</tr>
<tr>
<td><code>em_event.type</code></td>
<td>Pre-defined event type, such as high CPU, which is used to identify an event record. This field has a maximum length of 100 digits.</td>
</tr>
<tr>
<td><code>em_event.ci_type</code></td>
<td>Pre-defined definition for a configuration item (CI) that resides in the CMDB that describes a category for hardware, software application, or web service.</td>
</tr>
<tr>
<td><code>em_event.ci_identifier</code></td>
<td>JSON string that represents a configuration item. For example, <code>{&quot;name&quot;:&quot;SAP ORA01&quot;,&quot;type&quot;:&quot;Oracle&quot;}</code>. The CI identifier that generated the event appears in the Additional information field. This field has a maximum length of 1000 digits. Note: Reference pop-ups and click-throughs are hidden by default for read-only fields. For Configuration item and other read only fields, you can optionally change the read-only setting. For more information, see <a href="#">Configure pop-ups on read-only fields</a>.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>em_event.resource</td>
<td>Node resource that is relevant to the event. For example, Disk C, CPU-1, the name of a process, or service. This field has a maximum length of 100 digits.</td>
</tr>
<tr>
<td>metric_name</td>
<td>Unique name to identify the metric data.</td>
</tr>
<tr>
<td>em_event.event_class</td>
<td>If the <code>em_event.node</code> field is not specified, it is mandatory for alerts to be created automatically. Values for the <code>em_event.event_class</code> field originate from either the source generating the events or by event rule. Name of the machine or software that generated the event. For example, SolarWinds on 10.22.33.44. Corresponding field display name is <strong>Source Instance</strong>.</td>
</tr>
<tr>
<td>em_event.message_key</td>
<td>Unique event identifier to identify multiple events that relate to the same alert. If this value is empty, it is generated from the <strong>Source, Node, Type, Resource, and Metric Name</strong> field values. This field has a maximum length of 1024 digits.</td>
</tr>
<tr>
<td>em_event.severity</td>
<td>Event severity options are:</td>
</tr>
<tr>
<td></td>
<td>- <strong>Critical</strong>: Immediate action is required. The resource is either not functional or critical problems are imminent.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Major</strong>: Major functionality is severely impaired or performance has degraded.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Minor</strong>: Partial, non-critical loss of functionality or performance degradation occurred.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Warning</strong>: Attention is required, even though the resource is still functional.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Info</strong>: An alert is created. The resource is still functional.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Clear</strong>: No action is required. An alert is not created from this event. Existing alerts are closed.</td>
</tr>
<tr>
<td>em_event.resolution_state</td>
<td>If the field is empty, the resolution on corresponding alerts is still pending. Event state from the event source is either <strong>New</strong> or <strong>Closing</strong>.</td>
</tr>
<tr>
<td></td>
<td>- <strong>New</strong>, the resolution on corresponding alerts is open.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Closing</strong> event state closes corresponding alerts.</td>
</tr>
<tr>
<td>em_event.time_of_event</td>
<td>Time that the event occurred in the source system. This field is a GlideDateTime field in UTC or GMT format. This field has a maximum length of 40 digits.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>em_event.state</td>
<td>Current processing state of the event:</td>
</tr>
<tr>
<td>(State)</td>
<td>- <strong>Ready</strong>: Event has been received and is waiting to be processed.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Processed</strong>: Event was successfully processed.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Ignored</strong>: Value is not in use.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Error</strong>: Failure occurred while processing the event.</td>
</tr>
<tr>
<td></td>
<td>For example, the event collection method or event Severity is blank.</td>
</tr>
<tr>
<td>em_event.alert</td>
<td>If an alert was created as a result of the event, this field contains the</td>
</tr>
<tr>
<td>(Alert)</td>
<td>unique ID that Event Management generates to identify the alert.</td>
</tr>
<tr>
<td>em_event.description</td>
<td>Reason for event generation. Shows extra details about an issue. For</td>
</tr>
<tr>
<td>(Description)</td>
<td>example, a server stack trace or details from a monitoring tool. This field</td>
</tr>
<tr>
<td></td>
<td>has a maximum length of 4000 digits.</td>
</tr>
<tr>
<td>em_event.additional_info</td>
<td>A JSON string that gives more information about the event. The JSON data is</td>
</tr>
<tr>
<td>(Additional information)</td>
<td>supported for String values only, other value types are not supported. You</td>
</tr>
<tr>
<td></td>
<td>must convert numbers to String values by enclosing them in double quotes.</td>
</tr>
<tr>
<td></td>
<td>For example, this value is not supported: <code>{&quot;CPU&quot;:100}</code> while this value is</td>
</tr>
<tr>
<td></td>
<td>supported: <code>{&quot;CPU&quot;:&quot;100&quot;}</code>. Another example of a valid JSON string is:</td>

</table>

**Connectors and listeners**
Event Management provides many connectors and listeners with your subscription to pull or push events from external devices. Connectors and listeners are also available from the ServiceNow store as well as from third parties. You can also create custom connectors and listeners.
## Provided connectors (pull)

This table lists the connectors that are provided with Event Management. For more information, see [Configure event collection that uses pull operation](#).

**Note:** You can also create [custom pull connectors](#).

**Note:** The AzureConnector connector displays in the base system only when the Operational Intelligence plugin (com.snc.sa.metric) is activated.

### Third party connectors and listeners
<table>
<thead>
<tr>
<th>Link</th>
</tr>
</thead>
<tbody>
<tr>
<td>Splunk Integration</td>
</tr>
</tbody>
</table>

Integrate the Splunk Add-on with ServiceNow to enable Splunk users to create incidents and events in Event Management. For more information about the configuration of this integration, see [Splunk Add-on for ServiceNow](#).

### Configure a connector instance
Configure a connector instance to schedule the frequency of event collection.

Before starting this procedure:

- Locate or define a connector definition.
- Create the credentials to connect to the event source.
- If the connector instance is to be used for the collection of Operational Intelligence metric data, the Operational Intelligence plugin must be activated.

**Role required: evt_mgmt_admin**

You can use a connector instance to control the location and manner in which events arrive from external sources. You can optionally select to collect Operational Intelligence information from the external sources that you are connecting to. The Operational Intelligence feature is for the analysis of trends, threshold definitions, and anomaly detection. You can run a test to confirm that connector instance parameters let the MID Server receive events from a supported external event source to the Event (em_event) table. The test also confirms:

- The MID Server is running.
- The host is running on the IP address that is in the **Host IP** field.
- Both the MID Server and the host are running in the same domain.
- The connector instance value fields are valid.
- A connection can be made to the event source, using API, to retrieve events.

1. Navigate to **Event Management** > **Event Connectors (Pull)** > **Connector Instances**.
2. Click **New**.
3. Fill in the fields, as appropriate.

### Connector Instance Form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name for the connector instance record, such as the name of event source host.</td>

<td>Description</td>
</tr>
<tr>
<td>----------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Bi-directional</td>
<td>Select to invoke the bi-directional option. This option is available only when the specified connector definition has been configured with bi-directional values. When selected, this option enables the bi-directional exchange of values to-and-from the external event source. The <strong>Last bi-directional status</strong> option appears only when this option is selected. This option appears only if the connector definition that is selected is SCOM.</td>
</tr>
</tbody>
</table>
| Last bi-directional status             | The value of this field is automatically populated. The status values are:  
  - **None** - A valid connection has not yet been established.  
  - **Success** - A successful connection was established.  
  - **Error** - A connection was established. However the external event source was not updated.  
  This option appears only if the connector definition that is selected is SCOM. |
| Metrics collection                     | Designates collection of Operational Intelligence metric data.  
  **Note:** The metrics connector supports working against the SCOM database (MSSQL) that is configured to work with SSL.  
  This option appears only if the connector definition supports metric collection, such as SCOM. |
| Metrics collection last run time       | The date and time of the most recent metric data collection. The value of this field is automatically populated.                                                                                                                                                        |
| Last metrics collection status         | Status of the metric data collection activity. The value of this field is automatically populated.  
  This option appears only if the connector definition that is selected supports metric collection (such as SCOM) and if the **Metrics collection** option is selected.                                                             |
| Metrics collection schedule (seconds)  | The time, in seconds, to repeat the metric data collection scheduled job.  
  This option appears only if the connector definition that is selected supports metric collection (such as SCOM) and when the **Metrics collection** option is selected.                                                                 |
| Metrics database host                  | Enter either the IP address or the host name of the metrics database host.  
  This option appears only if the connector definition that is selected supports metric collection (such as SCOM).                                                                                             |
| Connect using a named instance         | Select to specify the MSSQL named instance to connect to.  
  This option appears only if the connector definition that is selected is SCOM.                                                                                                                              |
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Metrics database named instance</td>
<td>The name of the metrics database instance. This option appears only if the connector definition that is selected supports metric collection (such as SCOM).</td>
</tr>
<tr>
<td>Metrics database port</td>
<td>The port used by the metric database. The connection is made using JDBC. The base system value is 1,433. This option appears only if the connector definition that is selected supports metric collection (such as SCOM).</td>
</tr>
<tr>
<td>Database login with Windows authentication</td>
<td>Perform database login with the credentials of the logon user that is defined on the MID Server service. This option appears only if the connector definition that is selected is SCOM.</td>
</tr>
<tr>
<td>Metrics collection running</td>
<td>When selected, indicates that the Operational Intelligence collection is running. This option appears only if the connector definition that is selected supports metric collection (such as SCOM).</td>
</tr>
<tr>
<td>Metrics database credential</td>
<td>Credentials for the metric database. This option appears only if the connector definition that is selected supports metric collection (such as SCOM).</td>
</tr>
<tr>
<td>Connector Instance Values</td>
<td>The related list containing connection parameters for the event source host. The list of parameters depends on the selected connector definition.</td>
</tr>
<tr>
<td>MID Servers for Connectors</td>
<td>The name of the MID Server to process events from the event server.</td>
</tr>
</tbody>
</table>

4. Right-click the form header and select **Save**.
5. Click **Test connector** to verify that the MID Server can communicate with the external server host.
6. If the test fails, follow the instructions on the page to correct the problem and then run another test. The description of the reason for failure is shown in the MID Server log, according to the type of error, such as Events, Metrics, or Bi-Directional.
7. After a successful test, select the **Active** check box and then click **Update**.
8. Confirm that Event Management processes events using this connector instance by manually creating an event.

Create a connector definition
Each connector definition is specific to an event source vendor. The connector definition specifies the MID Server script include that pulls events from the external event source. In addition, the connector definition specifies what connector instance value parameters are needed to connect to the external event source host.

Write custom JavaScript code that accomplishes these actions:
- Connect to an event monitoring tool.
- Retrieve events from an event monitoring tool.
- Send events to the Event (em_event) table using the web service API.

Role required: evt_mgmt_admin or evt_mgmt_operator
Create a connector definition to support a new external event source from which to receive events. This procedure automatically creates a JavaScript code file using the name that you enter in the **Name** field as the filename.

1. Navigate to **Event Management > Event Connectors (Pull) > Connector Definitions**.
2. Click **New**.
3. In the **Name** field, type a descriptive name for the connector definition.
4. In the **Script type** field, select **Javascript**.
5. Right-click the form header and select **Save**.
6. The **Javascript to run** field is automatically populated with the name of the JavaScript template file. You can optionally replace the default JavaScript with your JavaScript code, see *Create a custom pull connector*. To edit the default JavaScript file, click the exclamation symbol to the right of the JavaScript file name and follow these steps:
   a) Specify the information required for the **testConnection** function. This function tests the connector definition to verify if the connection to the target is valid.
   b) Specify the information required for the **execute** function. This function retrieves the information from the external source.
   c) Specify the information required for the **retrieveKpi** function. This function retrieves the metric data from the external source.
7. Fill in the fields, as appropriate.

<table>
<thead>
<tr>
<th>Connector Definition form</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Field</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>Default schedule</td>
<td>The number of seconds between attempts to receive events.</td>
</tr>
<tr>
<td>Bi-directional</td>
<td>Specify to enable the external monitoring system to be updated if the alert is changed. There is default implementation for SCOM.</td>
</tr>
<tr>
<td>Alert field identifier</td>
<td>Specify the alert field that, if changed manually, causes the external monitoring system to be updated.</td>
</tr>
<tr>
<td>Collect metrics</td>
<td>Select to enable the collection of metrics.</td>
</tr>
<tr>
<td>Metrics collection default schedule (seconds)</td>
<td>Specify the number of seconds of information that must be collected. The default is 10 seconds.</td>
</tr>
<tr>
<td>Connector Parameters</td>
<td>Specify the parameters to enable communication with an event server.</td>
</tr>
</tbody>
</table>
Field | Description
--- | ---
Connector Definition to MID Server Capabilities | The MID Server name to process events from the event server. If not specified, an available MID Server is used.

8. Click **Submit**.

Configure a default MID Server for connectors
You can set a default MID Server for connectors to ensure that there is always a MID Server available to receive external events.

Role required: evt_mgmt_operator

The default MID Server must have connectivity to all external event sources.

1. Enter `sys_properties.list` in the navigation filter to open the System Property (`sys_properties`) table.
2. Select the `mid.server.connector_default` system property.
3. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| mid.server.connector_default | Default MID Server for connectors  
Determine the MID Server connectors to use when no MID Server is specified. Must match a MID Server name.  
- **Type**: select **string** from the list  
- **Value**: enter the name of an existing MID Server, for example, SNC MID Server  
- **Location**: System Property (`sys_properties`) table |

**Note:** You can reset the default MID Server by clearing the `mid.server.connector_default` property or by updating the value of this property to a different MID Server. This property is not automatically reset in all scenarios.

4. Click **Update**.

Legacy: Configure a MID Server for RCA for business services
Configuring MID Servers for Event Management root cause analysis (RCA) for business services is not supported for new instances in the New York release. However, instances upgraded from a previous release that use MID Servers for RCA can continue to do so.

Role required: admin

If the Domain Support - Domain Extensions Installer plugin is activated, then you can configure a dedicated MID Server with the RCA for business services capability per domain. In this case, RCA for a business service is done on the MID Server that is in the same domain as the business service. Otherwise, a MID Server from the global domain is used.

Role required: admin

To enable the Event Management root cause analysis (RCA) for business services capability, configure at least one dedicated MID Server with the ServiceAnalytics as a supported application, and with the RCA capability. To ensure uninterrupted services, you can configure a fail-over MID Server cluster for RCA.

The RCA for business services MID Server supports the Event Management RCA for business services process by hosting the RCA Learner and the real-time RCA query handler. On the RCA for business services MID Server, the system builds models that support responses to root cause queries. The learner data on the RCA for business services MID Server persists by default for a maximum of 90 days.

By default, the MID Server is set up as a dedicated MID Server for Event Management RCA for business services, and an attempt to add additional supported applications to the same MID Server is prevented. You should implement Operational Intelligence with its own dedicated Operational Intelligence MID Server. This ensures a high level of performance. However, if needed, you can modify this default behavior and configure the RCA for business services MID Server or the Operational Intelligence MID Server with additional supported applications. For information
about modifying the behavior of the ALL option when selecting supported applications, see Select applications to include in the definition of All for a MID Server.

1. Ensure that the MID Server is validated. For more information, see Validate the MID Server.
2. Navigate to MID Server > Servers.
3. Double-click the MID Server that you want to configure as an RCA for business services MID Server.
4. Add the ServiceAnalytics application:
   a) At the center of the MID Server form, click Supported Applications.
   b) In the Supported Applications section click Edit.
   c) In the slushbucket select ServiceAnalytics and click the > add button.
   d) click Save.

If the MID Server needs to support ServiceAnalytics as well as one or more other applications, you can modify the definition of the ALL option to include these applications, and then select ALL in the slushbucket. ALL is the only option to which it is valid to add the ServiceAnalytics option. Performance might be compromised with these settings.

5. Add the RCA capability:
   a) At the center of the MID Server form, click Capabilities.
   b) In the Capabilities section click Edit.
   c) In the slushbucket select RCA and click the ‘>’ add button.
   d) click Save.

6. Click Update.

The RCA for business services MID Server is automatically configured with a Discovery IP range set to 0.0.0.0-0.0.0.0.

Create a failover cluster for RCA. In this cluster, add the MID Servers that were configured for RCA for business services. For more information, see Configure a MID Server cluster.

Configure event collection that uses pull operation
Event Management provides default connector instances to use connector definitions (script instructions).

Configure the default connectors to connect to external servers to obtain event information using a pull operation.

Event Management and Operational Intelligence share connector definitions and connector instances to pull events and metric data from the same data source. Therefore, if a connector instance for a specific data source already exists, you can configure that connector instance to also obtain event information.

Configure event collection from HP OMI
Configure the HP Operations Manager i (OMI) connector instance to receive alerts from the HP OMI server.

Supported versions: 10.01, 10.10, 10.11, 10.12, 10.60, and 10.61

The OMI connector is not supported on versions below version 10.

Create Basic Auth type of credential to connect to OMI.

Role required: evt_mgmt_admin

1. Navigate to Event Management > Event Connectors (Pull) > Connector Instances.
2. Click **New** and create a connector instance with the following details:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Descriptive name for the OMi connector.</td>
</tr>
<tr>
<td>Description</td>
<td>Description for the use of the OMi event collection instance.</td>
</tr>
<tr>
<td>Host IP</td>
<td>Specify the OMi IP address.</td>
</tr>
<tr>
<td>Credential</td>
<td>Click in the <strong>Credential</strong> field. Select a Basic Auth credential from the list or click the search icon. <td>Frequency in seconds that the system checks for new events from OMi. The default value is 120 seconds.</td>
</tr>
<tr>
<td>Last error message</td>
<td>Last error message. Automatically updated.</td>
</tr>
<tr>
<td>Connector Definition</td>
<td>Select <strong>OMi</strong>.</td>
</tr>
<tr>
<td>MID Servers (MID Server for Connectors section)</td>
<td>Optional. Name of a MID Server. If no MID Server is specified, an available MID Server that has a matching IP range is used. In the MID Servers for Connectors section, specify a MID Server that is up and valid. You can configure several MID Servers. If the first is down, the next MID Server is used. If that MID Server is not available, the next is selected, and so on. MID Servers are sorted according to the order that their details were entered into the MID Server for Connectors section.</td>
</tr>
</tbody>
</table>

3. Right-click the form header and select **Save**.
The connector instance values are added to the form and the parameters that are relevant to the connector appear.
4. In the Connector Instance Values section, specify the OMi values.
   a) **days_from.** Specify the number of days for which events must be collected on the first collection cycle. Default 7.
   b) **debug.** Default false. To enter debug mode, specify true.
   c) **port.** Default 80.
   d) **protocol.** Default http.
   e) **query_filter.** Default value is false. If you do want to use this extra filter to query events, specify the event attributes. For example, `assigned_user = "admin" AND title = "My Title"`.

The query filter criteria are:
- A filter property that specifies an event attribute, such as, `related_ci`
- A supported operator, for example, `OR` or `AND`
- A value for the filter property, for example, `admin` or `integrator`

Everything from the `query_filter` field undergoes URL encoding and is then passed as a parameter to the OMi API call. For detailed information on how to build the filter query, see “Filtering by Event Attributes: query” in the HP OMi Extensibility Guide. For example, to query the events for a list of events that are assigned to the admin user, specify:

```
event_list?query=assigned_user%20EQ%20"admin"
```

To nest `query_filter` event attributes, specify the hierarchy using square brackets `( )`. 
f) **whitelist.** Default value: `false`. Specify a comma-separated list to include this feature to add attributes that should be collected and added to the Event Management **Additional information** field.

**5.** Right-click the form header and select **Save**.
**6.** Click **Test Connector** to verify the connection between the MID Server and the connector.
**7.** If the test fails, follow the instructions that the error issues to correct the problem and then run another test.

Note: Use a network tool, such as ping, to verify credential correctness and network connectivity from the MID Server to the HP OMi server.

**8.** After a successful test, select the **Active** check box and then click **Update**.

Configure event collection from HPOM

Configure the HPOM connector instance to receive events from HP Operations Manager (HPOM).

Role required: `evt_mgmt_admin`

Supported version: **08.60.005**

**1.** Navigate to **Event Management > Event Connectors (Pull) > Connector Instances**.
**2.** Click **New** and create an HPOM connector instance with the following details:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Specify a unique name for the HPOM connector instance.</td>
</tr>
<tr>
<td>Host IP</td>
<td>Specify the HPOM IP address.</td>
</tr>
<tr>
<td>Credential</td>
<td>Click in the <strong>Credential</strong> field. Select a credential from the list or click the search icon. Either select the required credentials from the list or click <strong>New</strong> and create the required credentials. If you create the credentials, save them using a unique and recognizable name, for example, HPOMOPS.</td>
</tr>
<tr>
<td>Schedule (seconds)</td>
<td>The frequency in seconds that the system checks for new events from HPOM.</td>
</tr>
<tr>
<td>Description</td>
<td>Type a description for the use of the HPOM event collection instance.</td>
</tr>
<tr>
<td>Connector definition</td>
<td>The vendor and protocol used to gather events from the external event source. Select the <strong>HPOM</strong> connector definition.</td>
</tr>
<tr>
<td>Last error message</td>
<td>The last error message is automatically updated.</td>
</tr>
<tr>
<td>Last run time</td>
<td>The last run time value is automatically updated.</td>
</tr>
<tr>
<td>Last run status</td>
<td>The last run time status is automatically updated.</td>
</tr>
<tr>
<td>MID Servers (MID Server for Connectors section)</td>
<td>Optional. Name of a MID Server. If no MID Server is specified, an available MID Server that has a matching IP range is used. In the MID Servers for Connectors section, specify a MID Server that is up and valid. You can configure several MID Servers. If the first is down, the next MID Server is used. If that MID Server is not available, the next is selected, and so on. MID Servers are sorted according to the order that their details were entered into the MID Server for Connectors section.</td>
</tr>
</tbody>
</table>

**3.** Right-click the form header and click **Save**.

The connector instance values are added to the form and the parameters that are relevant to the connector appear.
4. In the Connector Parameters section, specify the values of the mandatory HPOM parameters.
   - **driver.** Specify the driver to be used to make the call. This driver is specific to the type of database you are calling into.
     - For an IBM DB2 Universal driver, specify: `com.ibm.db2.jcc.DB2Driver`
     - For an Oracle driver, specify: `oracle.jdbc.OracleDriver`
     - For a Microsoft SQL driver, specify: `com.microsoft.sqlserver.jdbc.SQLServerDriver`
     - For a MySQL driver, specify: `com.mysql.jdbc.Driver`
     - For a Sybase driver, specify: `com.sybase.jdbc3.jdbc.SybDriver`
   - **url.** Specify a URL. The JDBC protocol uses a connection string to establish the authentication and other parameters to establish a connection between the client and the database. Each database has its own connection string format. In the following URLs, replace the variables, for example, `<username>` and `<password>`, with your values.
     - For an IBM DB2 Universal URL, specify: `jdbc:db2://<IP address>:<port number>/<database name>:user=<username>;password=<password>`
       For example: `jdbc:db2://sysmvs1.stl.ibm.com:5021/regionsdb:user=example;password=w1rs2`
     - For an Oracle URL, specify: `jdbc:oracle:thin:@<IP address>:<port number>:<database name>`
       For example: `jdbc:oracle:thin:@172.31.255.255:4028:OracleMain`
     - For a Microsoft SQL URL, specify: `jdbc:sqlserver://<IP address>;user=<username>;password=<password>`
       For example: `jdbc:sqlserver://localhost;user=example;password=w3lrs2`
     - For a MySQL URL, specify: `jdbc:mysql://<IP address>/database?user=<username>;password=<password>`
       For example: `jdbc:mysql://localhost/database?user=example;password=65wlrs`
     - For a Sybase URL, specify: `jdbc:sybase:Tds:<IP address>:<port number>/<database name>?user=<username>;password=<password>`
       For example: `jdbc:sybase:Tds:172.31.255.255:4100/SYBMAIN?user=example;password=w1rs1m`

5. Use a network tool, such as ping, to verify that the HPOM server is running and the IP address matches the value in the **Host IP** field.

6. Click **Test connector** to verify the connection between the MID Server and the HPOM connector.

7. If the test fails, follow the instructions that the error issues to correct the problem and then run another test.

   **Note:** Use a network tool, such as ping, to verify credential correctness and network connectivity from the MID Server to the HPOM server.

8. After a successful test, select **Active** and then click **Update**.

Configure event collection from Hyperic
Configure the Hyperic connector instance to receive events from the VMware vRealize Hyperic server.

Role required: **evt_mgmt_admin**

Supported version: 5.8.4.0

1. Navigate to **Event Management > Event Connectors (Pull) > Connector Instances.**
2. Click **New** and create a Hyperic connector instance with the following details:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Specify a unique name for the Hyperic connector instance.</td>
</tr>
<tr>
<td>Host IP</td>
<td>Specify the Hyperic IP address.</td>
</tr>
<tr>
<td>Credential</td>
<td>In the Credentials form, click <strong>New</strong> and create the required credentials. Save the credentials using a unique and recognizable name, for example, HypericOPS.</td>
</tr>
<tr>
<td>Schedule (seconds)</td>
<td>The frequency in seconds that the system checks for new events from Hyperic.</td>
</tr>
<tr>
<td>Description</td>
<td>Type a description for the use of the Hyperic event collection instance.</td>
</tr>
<tr>
<td>Connector definition</td>
<td>The vendor and protocol used to gather events from the external event source. Select the <strong>Hyperic</strong> connector definition.</td>
</tr>
<tr>
<td>Last error message</td>
<td>The last error message is automatically updated.</td>
</tr>
<tr>
<td>Last run time</td>
<td>The last run time value is automatically updated.</td>
</tr>
<tr>
<td>Last run status</td>
<td>The last run time status is automatically updated.</td>
</tr>
<tr>
<td>MID Servers (MID Server for Connectors section)</td>
<td>Optional. Name of a MID Server. If no MID Server is specified, an available MID Server that has a matching IP range is used. In the MID Servers for Connectors section, specify a MID Server that is up and valid. You can configure several MID Servers. If the first is down, the next MID Server is used. If that MID Server is not available, the next is selected, and so on. MID Servers are sorted according to the order that their details were entered into the MID Server for Connectors section.</td>
</tr>
</tbody>
</table>

3. Right-click the form header and select **Save**. The connector instance values are added to the form and the parameters that are relevant to the connector appear.

4. In the Connector Parameters section, specify the values of the mandatory Hyperic parameters.
   a) **port** Default value 7080.
   b) **protocol** Default value http.

5. Click **Test connector** to verify the connection between the MID Server and the Hyperic connector.

6. If the test fails, follow the instructions that are issued by the error to correct the problem and then run another test.

   **Note:** Use a network tool, such as ping, to verify credential correctness and network connectivity from the MID Server to the Hyperic server.

7. After a successful test, select the **Active** check box and then click **Update**.

Configure event collection from IBM Netcool

Configure the IBM Netcool connector to receive events from IBM Netcool/OMNIbus Object Servers and Impact Servers.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
Role required: evt_mgmt_admin

Connector validation performed on IBM NetCool/OMNIbus version 7.3.1

To use the Netcool connector, configure a connector instance for the MID Server and add the jconn3-1.0.jar file that contains the necessary Netcool Sybase jar file.

1. Navigate to MID Server > JAR Files.
2. Click New.
3. Fill in the Name and Description fields.
4. Attach the file that was uploaded in the Before you begin section:
   a) Click the attachments icon ( ).
   b) Click Choose Files and navigate to the temporary download directory.
   c) Select the jconn3.jar file and click Open.
   d) Close the pop-up window to return to the form.

5. Click Submit.
7. Click New and create a connector instance with the following details:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Specify a unique name for the Netcool connector instance.</td>
</tr>
<tr>
<td>Description</td>
<td>Type a description for the use of the Netcool event collection instance.</td>
</tr>
<tr>
<td>Host IP</td>
<td>Specify the Netcool IP address.</td>
</tr>
<tr>
<td>Credential</td>
<td>In the Credentials form, click New and create the required credentials. Save the credentials using a unique and recognizable name, for example, NetcoolOPS.</td>
</tr>
<tr>
<td>Event collection last run time</td>
<td>The last run time value is automatically updated.</td>
</tr>
<tr>
<td>Last event collection status</td>
<td>The last run time status is automatically updated.</td>
</tr>
<tr>
<td>Event collection schedule (seconds)</td>
<td>The frequency in seconds that the system checks for new events from Netcool. The default value is 120 seconds.</td>
</tr>
<tr>
<td>Last error message</td>
<td>The last error message is automatically updated.</td>
</tr>
<tr>
<td>Connector definition</td>
<td>The vendor and protocol used to gather events from the external event source. Select the IBM Netcool connector definition.</td>
</tr>
<tr>
<td>Field</td>
<td>Value</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MID Servers (MID Server for Connectors section)</td>
<td>Optional. Name of a MID Server. If no MID Server is specified, an available MID Server that has a matching IP range is used. In the MID Servers for Connectors section, specify a MID Server that is up and valid. You can configure several MID Servers. If the first is down, the next MID Server is used. If that MID Server is not available, the next is selected, and so on. MID Servers are sorted according to the order that their details were entered into the MID Server for Connectors section.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Specify a unique name for the Netcool connector instance.</td>
</tr>
<tr>
<td>Description</td>
<td>Type a description for the use of the Netcool event collection instance.</td>
</tr>
<tr>
<td>Host IP</td>
<td>Specify the Netcool IP address.</td>
</tr>
<tr>
<td>Credential</td>
<td>In the Credentials form, click <strong>New</strong> and create the required credentials. Save the credentials using a unique and recognizable name, for example, NetcoolOPS.</td>
</tr>
<tr>
<td>Event collection last run time</td>
<td>The last run time value is automatically updated.</td>
</tr>
<tr>
<td>Last event collection status</td>
<td>The last run time status is automatically updated.</td>
</tr>
<tr>
<td>Event collection schedule (seconds)</td>
<td>The frequency in seconds that the system checks for new events from Netcool. The default value is 120 seconds.</td>
</tr>
<tr>
<td>Last error message</td>
<td>The last error message is automatically updated.</td>
</tr>
<tr>
<td>Connector definition</td>
<td>The vendor and protocol used to gather events from the external event source. Select the <strong>IBM Netcool</strong> connector definition.</td>
</tr>
<tr>
<td>MID Servers (MID Server for Connectors section)</td>
<td>Specify a MID Server that is up and is valid. You can configure several MID Servers. If the first is down, the next MID Server is used. If that MID Server is not available, the next is selected, and so on. MID Servers are sorted according to the order that their details were entered into the MID Server for Connectors section. If no MID Server is specified, an available MID Server that has a matching IP range is used.</td>
</tr>
</tbody>
</table>

8. Right-click the form header and click **Save**. The connector instance values are added to the form and the parameters that are relevant to the connector appear.

9. In the Connector Parameters section, specify the value of the mandatory Netcool parameter, **url**. Build a URL using the provided format.

   For example: `jdbc:sybase:Tds:10.11.15.118:4100/NCOMS`

**Note:** After updating the **Host IP** field, you must update the URL parameter, as it does not update automatically.
10. Use a network tool, such as ping, to verify that the Netcool server is running and the IP address matches the value in the **Host IP** field.

11. Right-click the form header and click **Save**.

12. Click **Test connector** to verify the connection between the MID Server and the Netcool connector.

13. If the test fails, follow the instructions that are issued by the error to correct the problem and then run another test.

**Note:** Use a network tool, such as ping, to verify credential correctness and network connectivity from the MID Server to the Netcool device.

14. After a successful test, select the **Active** check box and then click **Update**.

Configure event collection from an Icinga2 connector

Configure the Icinga 2 (Icinga) connector instance to receive events while monitoring your network resources.

Supported version: 2.4.1

Role required: evt_mgmt_admin

1. Navigate to **Event Management > Event Connectors (Pull) > Connector Instances**.

2. Click **New**.

3. On the form, fill in the fields.

<table>
<thead>
<tr>
<th><strong>Connector Instance form</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td>Descriptive and unique name for the Icinga connector.</td>
</tr>
<tr>
<td><strong>Description</strong></td>
<td>Description for the use of the Icinga event collection instance.</td>
</tr>
<tr>
<td><strong>Connector definition</strong></td>
<td>Name of the required connector definition. Select <strong>Icinga2</strong>.</td>
</tr>
<tr>
<td><strong>Host IP</strong></td>
<td>IP address where Icinga is installed.</td>
</tr>
<tr>
<td><strong>Credential</strong></td>
<td>Permission to connect to Icinga. Click the search icon in the <strong>Credential</strong> field. Use Basic Authentication credentials. Either select the required credentials from the list or click <strong>New</strong> and create the required credentials on the Credentials form. If you create the credentials, save them using a unique and recognizable name, for example, <strong>ICINGA2CHCK</strong>.</td>
</tr>
<tr>
<td><strong>Event collection last run time</strong></td>
<td>Last run time value. Automatically updated.</td>
</tr>
<tr>
<td><strong>Last event collection status</strong></td>
<td>Last run status. Automatically updated.</td>
</tr>
<tr>
<td><strong>Event collection schedule (seconds)</strong></td>
<td>Frequency, in seconds, that the system checks for new events from Icinga. The default value is 120 seconds.</td>
</tr>
<tr>
<td><strong>Last error message</strong></td>
<td>Last error message. Automatically updated.</td>
</tr>
</tbody>
</table>

4. Right-click the form header and select **Save**.

The connector instance values are added to the form and the parameters that are relevant to the connector appear.
5. In the Connector Instance Values section, verify and where required, modify the default connector instance values.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>debug</td>
<td>Display debug messages. Default value: false. Specify true to see debug messages.</td>
</tr>
<tr>
<td>port</td>
<td>Number of the connector port. Default value: 5665.</td>
</tr>
<tr>
<td>protocol</td>
<td>Type of protocol. Default protocol type: https.</td>
</tr>
</tbody>
</table>

6. Optional: In the MID Servers for Connectors section, specify a MID Server that is up and is valid.

   If no MID Server is specified, an available MID Server that has a matching IP range is used.

   You can configure several MID Servers. If the first is down, the next MID Server is used. If that MID Server is not available, the next is selected, and so on. MID Servers are sorted according to the order that their details were entered into the MID Server for Connectors section.

7. Right-click the form header and select **Save**.

8. Test the connection between the MID Server and the Icinga connector.
   a) Click **Test Connector**.
      
      If the test fails, follow the instructions that the error issues to correct the problem and then run another test.

      **Note**: Use a network tool, such as ping, to verify credential correctness and network connectivity from the MID Server to the external monitoring tool.

   b) After a successful test, select the **Active** check box.

9. Click **Update**.

Configure event collection from NNMi

Configure the HP Network Node Manager i (NNMi) connector instance to receive events while monitoring your network resources.

Supported version: 10.30.653
Role required: evt_mgmt_admin

1. Navigate to Event Management > Event Connectors (Pull) > Connector Instances.
2. Click New.
3. On the form, fill in the fields.

**Connector Instance form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Descriptive and unique name for the NNMi connector.</td>
</tr>
<tr>
<td>Description</td>
<td>Description for the use of the NNMi event collection instance.</td>
</tr>
<tr>
<td>Connector definition</td>
<td>Name of the required connector definition. Select NNMi.</td>
</tr>
<tr>
<td>Host IP</td>
<td>IP address where NNMi is installed.</td>
</tr>
<tr>
<td>Credential</td>
<td>Permission to connect to NNMi. Click the search icon in the Credential field. Either select the required credentials from the list or click New and create the required credentials on the Credentials form. If you create the credentials, save them using a unique and recognizable name, for example, NNMICHCK.</td>
</tr>
<tr>
<td>Event collection last run time</td>
<td>Last run time value. Automatically updated.</td>
</tr>
<tr>
<td>Last event collection status</td>
<td>Last run status. Automatically updated.</td>
</tr>
<tr>
<td>Event collection schedule (seconds)</td>
<td>Frequency, in seconds, that the system checks for new events from NNMi. The default value is 120 seconds.</td>
</tr>
<tr>
<td>Last error message</td>
<td>Last error message. Automatically updated.</td>
</tr>
</tbody>
</table>

4. Right-click the form header and select Save.
   The connector instance values are added to the form and the parameters that are relevant to the connector appear.
5. In the Connector Instance Values section, verify and where required, modify the default connector instance values.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>days_from</td>
<td>Number of days for which events must be collected at the first collection cycle. Default value: 7 days.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> The maximum number of past events that can be collected is 3,000. The first time that the connector runs, it collects all events (up to the 3,000 limit) that were created from the days_from date until the current date.</td>
</tr>
<tr>
<td>debug</td>
<td>Display debug messages. Default value: \texttt{false}. Specify \texttt{true} to see debug messages.</td>
</tr>
<tr>
<td>port</td>
<td>Number of the connector port. Default value: 80.</td>
</tr>
<tr>
<td>protocol</td>
<td>Type of protocol. Default protocol type: \texttt{http}.</td>
</tr>
</tbody>
</table>

6. Optional: In the MID Servers for Connectors section, specify a MID Server that is up and is valid.

   If no MID Server is specified, an available MID Server that has a matching IP range is used.

   You can configure several MID Servers. If the first is down, the next MID Server is used. If that MID Server is not available, the next is selected, and so on. MID Servers are sorted according to the order that their details were entered into the MID Server for Connectors section.

7. Right-click the form header and select \textbf{Save}.

8. Test the connection between the MID Server and the NNMi connector.
   a) Click \textbf{Test Connector}.
      
      If the test fails, follow the instructions that the error issues to correct the problem and then run another test.
      
      **Note:** Use a network tool, such as ping, to verify credential correctness and network connectivity from the MID Server to the external monitoring tool.
   
   b) After a successful test, select the \textbf{Active} check box.

9. Click \textbf{Update}.

Configure event collection from NagiosXI

Configure the NagiosXI connector instance to receive events from the Nagios Core monitor.

Supported version: 5.5.2

The NagiosXI connector instance requires a credential that lets the instance access NagiosXI accounts. You can use an existing credential or \textbf{create a new one}.

Role required: \texttt{evt_mgmt_admin}

1. Navigate to \textbf{Event Management > Event Connectors (Pull) > Connector Instances}.
2. Click \textbf{New}.
3. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Descriptive name for the Nagios connector.</td>
</tr>
<tr>
<td>Description</td>
<td>Description for the use of the NagiosXI event collection instance.</td>
</tr>
</tbody>
</table>
Field          | Description                                                                                       |
-------------|--------------------------------------------------------------------------------------------------|
Host IP      | Specify the Nagios XI IP address.                                                                |
Credential   | Select the credential with basic authentication that you created for this connector. For more information, see Create Nagios XI server credentials. Ensure that the user password contains the NagiosXI user API key, for example 04lquEPqf4JimWCm8RWBshOykOpW8L8YBIFeV4p09O05H5Ye4QDrHFPndYbW. |
Event collection last run time | The last run time value is automatically updated.                                                |
Last event collection status | The last run time status is automatically updated.                                            |
Event collection schedule (seconds) | The frequency, in seconds, that the system checks for new events from Nagios. The default value is 120 seconds. |
Last error message | The last error message is automatically updated.                                                |
Connector Definition | Select NagiosXI.                                                                                     |
MID Servers (MID Server for Connectors section) | Optional. Name of a MID Server. If no MID Server is specified, an available MID Server that has a matching IP range is used. In the MID Servers for Connectors section, specify a MID Server that is up and valid. You can configure several MID Servers. If the first is down, the next MID Server is used. If that MID Server is not available, the next is selected, and so on. MID Servers are sorted according to the order that their details were entered into the MID Server for Connectors section. |

4. Right-click the form header and select Save. The connector instance values are added to the form and the parameters that are relevant to the connector appear.

5. In the Connector Instance Values section, specify the Nagios values.
   a) initial_sync_in_days. Specify the number of days for which events must be collected at the first collection cycle. Default value 7 days.
   b) port. Default value 80.
   c) protocol. The default protocol type is http.
   d) time_zone. The default time zone is GMT.

6. Right-click the form header and select Save.
7. Click Test Connector to verify the connection between the MID Server and the connector.
8. If the test fails, follow the instructions that the error issues to correct the problem and then run another test.

   If this message appears: Connection test failed: Failed to connect to Nagios on test connector. Invalid API Key, then enter the API Key for the specific user to be able to read the Nagios events.

   Note: Use a network tool, such as ping, to verify credential correctness and network connectivity from the MID Server to the Nagios Core monitor.

9. After a successful test, select the Active check box and then click Update.

Create Nagios XI server credentials
Create credentials to access Nagios XI server.
Role required: evt_mgmt_admin

1. Navigate to Connections & Credentials > Credentials.
2. Click New.
3. Select Basic Auth Credential.
4. On the form, fill in the fields.

### Basic Auth Credentials form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a unique and descriptive name for this credential. For example, you might call it Nagios authentication.</td>
</tr>
<tr>
<td>User name</td>
<td>Name to identify the user. Ensure that the user password contains the NagiosXI user API key, for example, 041quEPqf4JimWCm8RWbJokOpW8LYBUfEvJp90SHSRY.</td>
</tr>
<tr>
<td>Password</td>
<td>Password to use this credential.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to enable the use of this credential.</td>
</tr>
<tr>
<td>Order</td>
<td>The order (sequence) in which the platform tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), the instance tries the credentials in a random order. Default value: 100</td>
</tr>
</tbody>
</table>

5. Click Submit.

The credential for use with the Nagios XI server connector is created.

---

Configure OP5 connector

Configure the OP5 Monitor connector instance to receive alerts from an OP5 Monitor source.

Role required: evt_mgmt_admin

Supported version: 7.3.15

1. Navigate to Event Management > Event Connectors (Pull) > Connector Instances.
2. Click New and create a connector instance with the following details:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Descriptive name for the Op5 connector.</td>
</tr>
<tr>
<td>Description</td>
<td>Description for the use of the Op5 event collection instance.</td>
</tr>
<tr>
<td>Host IP</td>
<td>Specify the Op5 IP address.</td>
</tr>
<tr>
<td>Credential</td>
<td>Either select the required credentials from the list or click New and create the required credentials. If you create the credentials, save them using a unique and recognizable name, for example, Op5OPS.</td>

<tr>
<td>MID Servers (MID Server for Connectors section)</td>
<td>Optional. Name of a MID Server. If no MID Server is specified, an available MID Server that has a matching IP range is used. In the MID Servers for Connectors section, specify a MID Server that is up and valid. You can configure several MID Servers. If the first is down, the next MID Server is used. If that MID Server is not available, the next is selected, and so on. MID Servers are sorted according to the order that their details were entered into the MID Server for Connectors section.</td>
</tr>
</tbody>
</table>

3. Right-click the form header and select Save. The connector instance values are added to the form and the parameters that are relevant to the connector appear.

4. In the Connector Instance Values section, specify the Op5 values.
   a) days_from. Specify the number of days for which events must be collected at the first collection cycle. Default value 7 days.
   b) debug. Default value false.
   c) port. Default value 443.
   d) state_types. Specify filters for event collection based on the state_types attribute. You can filter events based on state type. Specify the type, for example, soft or hard.

5. Right-click the form header and select Save.

6. Click Test Connector to verify the connection between the MID Server and the connector.

7. If the test fails, follow the instructions that the error issues to correct the problem and then run another test.

   If this message appears: Connection test failed: Failed to connect to Op5 on test connector. Invalid API Key, then enter the API Key for the specific user to be able to read the Op5 events.

   **Note:** Use a network tool, such as ping, to verify credential correctness and network connectivity from the MID Server to the OP5 Monitor source.

8. After a successful test, select the Active check box and then click Update.

Configure Opsview connector

Configure the Opsview Monitor connector instance to receive alerts from an Opsview Monitor source.

Role required: evt_mgmt_admin

Supported version: 5.4.0

1. Navigate to Event Management > Event Connectors (Pull) > Connector Instances.

2. Click New and create a connector instance with the following details:
<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Descriptive name for the Opsview connector.</td>
</tr>
<tr>
<td>Description</td>
<td>Description for the use of the Opsview event collection instance.</td>
</tr>
<tr>
<td>Host IP</td>
<td>Specify the Opsview IP address.</td>
</tr>
<tr>
<td>Credential</td>
<td>Either select the required credentials from the list or click <strong>New</strong> and create the required credentials. If you create the credentials, save them using a unique and recognizable name, for example, OpsviewOPS.</td>
</tr>
<tr>
<td>Event collection last run time</td>
<td>The last run time value is automatically updated.</td>
</tr>
<tr>
<td>Last event collection status</td>
<td>The last run time status is automatically updated.</td>
</tr>
<tr>
<td>Event collection schedule (seconds)</td>
<td>The frequency in seconds that the system checks for new events from Opsview.</td>
</tr>
<tr>
<td>Last error message</td>
<td>The last error message is automatically updated.</td>
</tr>
<tr>
<td>Connector definition</td>
<td>Select <strong>Opsview</strong>.</td>
</tr>
<tr>
<td>Connector Instance Values section</td>
<td>The parameters that are specific to <strong>Opsview</strong> display here when the form is saved.</td>
</tr>
<tr>
<td>MID Servers (MID Server for Connectors section)</td>
<td>Optional. Name of a MID Server. If no MID Server is specified, an available MID Server that has a matching IP range is used. In the MID Servers for Connectors section, specify a MID Server that is up and valid. You can configure several MID Servers. If the first is down, the next MID Server is used. If that MID Server is not available, the next is selected, and so on. MID Servers are sorted according to the order that their details were entered into the MID Server for Connectors section.</td>
</tr>
</tbody>
</table>

3. Right-click the form header and select **Save**. The connector instance values are added to the form and the parameters that are relevant to the connector appear.

4. In the Connector Instance Values section, specify the Opsview values.
   a) **days_from**. Specify the number of days for which events must be collected at the first collection cycle. Default value 7 days.
   b) **debug**. Default value false.
   c) **eventtype_filter**. Specify filters for event collection based on the **eventtype** attribute. Specify one of these values 0,1,2,3
   d) **port**. Default value 80.
   e) **protocol**. The default protocol type is HTTPS.

5. Right-click the form header and select **Save**.
6. Click **Test Connector** to verify the connection between the MID Server and the connector.
7. If the test fails, follow the instructions that the error issues to correct the problem and then run another test.
   If this message appears: **Connection test failed: Failed to connect to Opsview on test connector. Invalid API Key**, then enter the API Key for the specific user to be able to read the Opsview events.
8. After a successful test, select the **Active** check box and then click **Update**.

Configure PRTG connector

Configure the PRTG connector instance to receive alerts from a Paessler PRTG Network Monitor source.

Role required: evt_mgmt_admin

Supported version: 18.2.4

1. Navigate to **Event Management > Event Connectors (Pull) > Connector Instances.**
2. Click **New** and create a connector instance with the following details:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Descriptive name for the PRTG connector.</td>
</tr>
<tr>
<td>Description</td>
<td>Description for the use of the PRTG event collection instance.</td>
</tr>
<tr>
<td>Host IP</td>
<td>Specify the PRTG IP address.</td>
</tr>
<tr>
<td>Credential</td>
<td>Either select the required credentials from the list or click <strong>New</strong> and create the required credentials. If you create the credentials, save them using a unique and recognizable name, for example, <strong>PRTGOPS</strong>.</td>
</tr>
<tr>
<td>Event collection last run time</td>
<td>The last run time value is automatically updated.</td>
</tr>
<tr>
<td>Last event collection status</td>
<td>The last run time status is automatically updated.</td>
</tr>
<tr>
<td>Event collection schedule (seconds)</td>
<td>The frequency in seconds that the system checks for new events from PRTG.</td>
</tr>
<tr>
<td>Last error message</td>
<td>The last error message is automatically updated.</td>
</tr>
<tr>
<td>Connector definition</td>
<td>Select <strong>PRTG</strong>.</td>
</tr>
<tr>
<td>Connector Instance Values section</td>
<td>The parameters that are specific to <strong>PRTG</strong> display here when the form is saved.</td>
</tr>
<tr>
<td>MID Servers (MID Server for Connectors section)</td>
<td>Optional. Name of a MID Server. If no MID Server is specified, an available MID Server that has a matching IP range is used. In the MID Servers for Connectors section, specify a MID Server that is up and valid. You can configure several MID Servers. If the first is down, the next MID Server is used. If that MID Server is not available, the next is selected, and so on. MID Servers are sorted according to the order that their details were entered into the MID Server for Connectors section.</td>
</tr>
</tbody>
</table>

3. Right-click the form header and select **Save**.

The connector instance values are added to the form and the parameters that are relevant to the connector appear.

4. In the Connector Instance Values section, specify the PRTG values.

   a) **add_columns**. Specify which columns to be returned by the connector. Separate the names with a comma and without a space between the names. The output is stored in the **Additional information** field of the event. Default value **false**. If **false** is specified, only the default list of columns is retrieved: parent, name, type, objid, tags, message, status, priority, datetime, actions, baselink, basetype, modifiedby.
**Note:** Only column names that are applicable to the **Message** content type can be specified.

b) **date_format.** The format date and time. Default format M/d/yyyy/ h:mm:ss a
   If you receive an event whose date is in a different format, modify this value to match the format of the incoming event. If you do not, the event will not be processed correctly.
   For example, if an event arrives on June 27, 2019 at 11:25 AM with a listed date of 2019/06/27/ 11:25:00 a, modify the **date_format** value to yyyy/M/d/ h:mm:ss a to match the format of the received event.
   In the **date_format**, a represents AM, and p represents PM.

c) **days_from.** Specify the number of days for which events must be collected at the first collection cycle. Default value 7 days.

d) **debug.** Default value false.

e) **port.** Default value 80.

f) **protocol.** The default protocol type is **http.**

g) **prtg_api_fetched_events_num.** Maximum number of events, per query, that can be fetched from the PRTG client into the MID Server. Default number: 50,000.

5. Right-click the form header and select **Save.**

6. Click **Test Connector** to verify the connection between the MID Server and the connector.

7. If the test fails, follow the instructions that the error issues to correct the problem and then run another test.
   If this message appears: **Connection test failed: Failed to connect to PRTG on test connector. Invalid API Key,** then enter the API Key for the specific user to be able to read the PRTG events.

**Note:** Use a network tool, such as ping, to verify credential correctness and network connectivity from the MID Server to PRTG.

8. After a successful test, select the **Active** check box and then click **Update.**

**Configure SAP Solution Manager connector**

Configure the SAP Solution Manager (Solman) connector instance to enable communication between the SAP Solution Manager and Event Management. This configuration enables you to receive events while monitoring your network resources.

Role required: admin

Supported versions: Tested on SAP Solution Manager 7.1 and 7.2. Might also work on other versions.

1. Navigate to **Event Management > Event Connectors (Pull) > Connector Instances.**
2. Click **New** and create a connector instance.
3. Fill in the fields on the form.

**Connector instance form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Descriptive name for the SAP Solman connector.</td>
</tr>
<tr>
<td>Description</td>
<td>Description for the use of the SAP Solman event collection instance.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Active</td>
<td>Option that activates the connector instance. Select this option only after running a successful test.</td>
</tr>
<tr>
<td>Connector definition</td>
<td>The vendor and protocol used to gather events from the external event source. Select SAP Solman.</td>
</tr>
<tr>
<td>Host IP</td>
<td>The IP address where SAP Solman is installed.</td>
</tr>
<tr>
<td>Credential</td>
<td>Required credentials entered either by selecting them from the results of a search through the search icon or by clicking New, or creating them. If you create credentials, save them using a unique and recognizable name, such as SAPSOLMANOPS.</td>
</tr>
<tr>
<td>Event collection last run time</td>
<td>The last run time value. Automatically updated.</td>
</tr>
<tr>
<td>Last event collection status</td>
<td>The last run time status. Automatically updated.</td>
</tr>
<tr>
<td>Event collection schedule (seconds)</td>
<td>The frequency in seconds that the system checks for new events from SAP Solman.</td>
</tr>
<tr>
<td>Bi-directional</td>
<td>Option to invoke the bi-directional option. This option enables the bi-directional exchange of values to-and-from the external event source. The Last bi-directional status option appears only when selecting this option.</td>
</tr>
<tr>
<td>Last bi-directional status</td>
<td>This field appears only when Bi-directional is selected. This field is automatically populated with the most recent bi-directional status.</td>
</tr>
<tr>
<td>Last error message</td>
<td>Last error message. Automatically updated.</td>
</tr>
<tr>
<td>Connector Instance Values section</td>
<td>The parameters that are specific to SAP Solman, automatically displayed when saving the form.</td>
</tr>
<tr>
<td>MID Servers (MID Server for Connectors section)</td>
<td>MID Server that is up and valid. You can configure several MID Servers so that if the first server is down, the next MID Server is used. If that MID Server is not available, the next is selected, and so on. MID Servers are sorted according to the order in which their details are entered into the MID Server for Connectors section. If no MID Server is specified, an available MID Server that has a matching IP range is used.</td>
</tr>
</tbody>
</table>

4. Right-click the form header and select Save.

   The connector instance values are added to the form and the parameters that are relevant to the connector appear.

5. In the Connector Instance Values section, specify the default connector instance values.
   - **Client**: Default value = 001
   - **Port**: Default value = 8000

6. Right-click the form header and select Save.

7. Click Test Connector to verify the connection between the MID Server and the connector.

   If the test fails, follow the instructions in the error message and then run another test.

   **Note:** Use a network tool such as ping to verify the credentials and the network connectivity from the MID Server to the SAP Solman monitor.
8. After a successful test, select the **Active** check box and click **Update**.

SAP configurations enabling the SAP Solution Manager connector

Configure your SAP environment to work with the ServiceNow Event Management platform so you can use the SAP Solution Manager connector.

When integrating your SAP environment with Event Management, the SAP Solution Manager sends events through a MID Server to Event Management, which generates an alert from the event.

After the MID Server processes events, you can perform the following actions in the SAP Solution Manager:

- Add comments
- Confirm alerts
- Set status to **Externally Managed**

The following diagram illustrates the flow of data between SAP and Event Management.
Data moves between SAP and Event Management using both Push and Pull interfaces.

- **Pull interface:**
  
The Connector Update Queues table (em_connector_update_queue) lists manual updates of alerts and sends them to the SAP Solution Manager.
  
The table’s business rule identifies each manual update of alerts in Event Management and updates the connector queue with these changes. By default, changes to all alert fields are tracked. For information on adjusting this setting, see the SAP Solution Manager documentation.
  
The Event Management - Queue connector processor scheduled job removes alert changes from the queue and sends them to the MID Server. By default, the system performs
this process in batches of 1,000 alerts. You can customize this batch size by setting the `evt_mgmt.max_update_source_records` property.

**Note:** You must define the Pull interface to enable bi-directional functionality in the SAP Solution Manager connector. For details, see the SAP Solution Manager documentation.

- **Push interface:** Because SAP can only push data to an external source, the integration uses the Push interface to store alerts sent from SAP to Event Management.

  SAP alerts create events in Event Management that use both event rules and CI identification rules to create Event Management alerts.

  After Event Management creates alerts, a business rule listens for a change to the alert. If it detects a change, Event Management updates the SAP Solution Manager alerts. For details, see [Create a custom pull bi-directional connector](#).

Use the SAP Solution Manager Pull connector

The SAP Solution Manager Pull connector sends information from Event Management to the SAP Solution Manager. The Pull connector sends responses received from a Push connector in a bi-directional environment.

Role required: `evt_mgmt_admin`

1. Navigate to **Event Management > Event Connectors (Pull) > Connector Instances**.
2. Click **New**.
   
   The **Connector Instance New Record** page appears.
3. Enter values in the required fields, which are indicated by a red asterisk.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Descriptive name for the connector.</td>
</tr>
<tr>
<td>Connector definition</td>
<td>Search for and select <strong>SAP Solution Manager</strong>.</td>
</tr>
<tr>
<td>Credential</td>
<td>Select <strong>Basic auth</strong> for basic authentication.</td>
</tr>
<tr>
<td>Host IP</td>
<td>The SAP Solution Manager IP address.</td>
</tr>
</tbody>
</table>

   The Connector Update Queues table ([em_connector_update_queue](#)) lists manual updates of alerts and sends an event to the SAP Solution Manager, using the Pull interface.

**Note:** When adding bi-directional functionality for a Push connector, the Connector instance name must match the Source Instance field of the event generated by that source. The **Connector Instance** field value is a combination of `SID + _ + Mandant`.

For example, the following image displays an event generated by the instance source **PSM_001**. To enable sending information back, you would have to name your connector instance **PSM_001**.

4. Set the following values for the connector instance:
   - **Client:** Represents the client value in SAP, usually 001.
   - **Port:** The SAP Solution Manager WebService port. Default value = 8000.
The following table lists the actions you can perform in Event Management, and the resulting updates occurring in SAP Solution Manager.

### Event Management actions and SAP Solution Manager updates

<table>
<thead>
<tr>
<th>Action in Event Management</th>
<th>Result in SAP Solman</th>
</tr>
</thead>
<tbody>
<tr>
<td>Close an alert.</td>
<td>Confirms an alert in the alert inbox. The alert is removed.</td>
</tr>
<tr>
<td>Select the <strong>Maintenance</strong> setting in an alert.</td>
<td>Adds a comment indicating that the alert is in Maintenance mode.</td>
</tr>
<tr>
<td>Clear the <strong>Maintenance</strong> setting in an alert.</td>
<td>Removes the Maintenance mode comment.</td>
</tr>
<tr>
<td>Select the <strong>Acknowledged</strong> setting in an alert.</td>
<td>Adds a comment indicating that the alert is in the Acknowledged mode.</td>
</tr>
<tr>
<td>Clear the <strong>Acknowledged</strong> setting in an alert.</td>
<td>Removes Acknowledged mode comment.</td>
</tr>
</tbody>
</table>

Note the following behaviors:

- The Update queue business rule in the Alert table identifies each manual update of the alert and updates the connector queue accordingly. By default, changes to all alert fields are tracked.
- The Event Management — Queue Connector Processor job removes alert changes from the queue and sends them to the MID Server. By default, Event Management performs this dequeue process in batches of 1,000 alerts. You can configure the batch size by setting the `evt_mgmt.max_update_source_records` property.

Use the SAP Solution Manager Push connector

The MID Server web service Event Collector enables you to collect alerts sent from the SAP Solution Manager through event stream notification capabilities. The interface runs both a Push and a Pull interface to interact directly with the SAP Solution Manager.

- Deploy and start the MID Server.
- Configure and start the MID Web Server.
- Configure and start the MID Server web service Event Collector.

Role required: `evt_mgmt_admin`

SAP Solution Manager sends JSON formatted event messages to the MID Server. The MID Server parses the collected alert messages and transforms them using the SAP Solman Transform (`TransformEvents_SAPSolman`) script.

JSON formatted messages are collected using basic authentication. For details on other supported authentication methods, see [Configure the MID Web Server extension](#).

1. Navigate to **Event Management** > **Event Listener (Push)** > **Listener Transform Scripts**.
2. Select the `TransformEvents_SAPSolman` script.
3. Use the following URL to push alert messages from SAP Solution Manager to the MID Server:

   ```
   http://<MID_Server_IP>:<MID_Web_Server_Port>/api/mid/em/inbound_event?
   Transform=TransformEvents_SAPSolman, where the following are true:
   - **MID_Server_IP** is the IP address of the MID Web Server extension
   - **MID_Web_Server_Port** is the listening port of the MID Web Server extension
   ```

Create an Remote Function Call (RFC) in the SAP Solution Manager and install a transport, as described in Configure RFC in SAP Solution Manager.

SAP Solution Manager setup configurations
As part of the SAP Solution Manager setup, you must perform several configurations to enable SAP Solution Manager to interact with Event Management.

Configure RFC in SAP Solution Manager
As part of enabling communication with Event Management, you must create an Remote Function Call (RFC) in the SAP Solution Manager and install a transport.

Download the following .psm files and import them into the SAP Solution Manager system:
- Transport File 1
- Transport File 2

Role required: evt_mgr_admin

1. On the SAP UI, enter the transaction code SM59 and create a new RFC with the following parameters on the Technical Settings tab:

<table>
<thead>
<tr>
<th>SAP Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target Host</td>
<td>Name of the MID Server.</td>
</tr>
<tr>
<td>Service No</td>
<td>Listener port on the MID Server</td>
</tr>
<tr>
<td>Path Prefix</td>
<td>The URL of the MID Server transform script: /api/mid/em/inbound_event? Transform=TransformEvents_SAPSolman</td>
</tr>
</tbody>
</table>
2. On the **Logon & Security** tab, select **Basic Authentication** and enter your Event Management logon credentials in the **User** and **Password** fields.
A custom SAP BADI (Business Add-in) named Z_ALRTREACTION_IMPL is created and stored as a workbench transport request. After installation, this BADI calls the RFC to connect to Event Management.
Configure SAP to forward alerts to your BADI

After setting up SAP Solution Manager monitoring, you must configure SAP to forward alerts to the BADI (Business Add-in) you create as the first step in the SAP integration setup.

Role required: evt_mgt_admin

Third-party alerts get forwarded globally. You can configure the alert reaction only for a specific monitoring template.

1. On the SAP UI, navigate to Application Operations > System Monitoring.
2. In the ribbon at the top of the System Monitoring configuration page, select Configure Infrastructure > 2.3 Default Settings.
   The Default Settings page appears.
3. Configure and activate a third-party component.
   a) Enter edit mode by clicking the **Edit** button.
   b) Select the **Third-Party Components** tab.
   c) Click **Add** and add the following value as the third-party connector: **Implementation:** BADI Definition for Alert Reactions ZSNOW with scope = All Alerts and Metrics.
   d) Click **Save** to activate third-party components globally.

4. Define the objects to which the monitoring template will be assigned.
   a) In the ribbon at the top of the page, select **5 Define Scope**. The Define Scope page appears.
b) Select the managed object to which you want to assign the monitoring template. The monitoring template is assigned to the selected objects.

5. Reactivate the monitoring of templates.
   a) Select 6 Setup Monitoring.
   b) Search for and locate entries with Setup Status = Reconfigure Required and assign the monitoring template to those entries.
   c) Select Apply and Activate. When the jobs finish, verify that the Assignment Status is green. All templates and active alerts assigned to the selected objects use the new forwarding method.

View alerts generated in SAP Solution Manager to see any pressing issues, as described in View alerts in the SAP Solution Manager inbox.

View alerts in the SAP Solution Manager inbox
You can view alerts generated in SAP Solution Manager to see any pressing issues. All alerts also forward to Event Management automatically.

Role required: evt_mgt_admin

1. On the SAP UI, open Solution Manager and select the System Alerts tab.
The system alerts are listed on the page.

2. Navigate to (Event Management > All Alerts) to view the alerts in Event Management.
The following table describes the field mapping between SAP Solution Manager and Event Management for alerts.

**Field mapping for SAP Solution Manager and Event Management**

<table>
<thead>

</tbody>
</table>
View and update your SAP Solution Manager certificate
View your SAP Solution Manager certificate, and update the certificate if necessary.

Role required: evt_mgmt_admin

1. Connect to SAP on client 00.
2. Enter the \texttt{strust} transaction.
3. In the Trust Manager UI, open the SSL client.
4. Import the SSL certificate and save it.
5. Use the \texttt{smicm} transaction to enable the system to work with both HTTP and HTTPS clients.

The ICM module restarts.

View the SAP interface log
View the SAP interface log to help you debug issues.
Role required: admin

Select a transaction in the SAP UI.
The ZSNOW interface debugging table appears.

SAP Solution Manager transaction codes
The transaction code abbreviations that you can use in the SAP interface when working with the SAP Solution Manager connector.

<table>
<thead>
<tr>
<th>Transaction Code</th>

</table>
Configure alert collection from SCOM
Alerts from the Microsoft System Center Operations Manager (SCOM) are collected using the SCOM connector instance.

The SCOM connector instance requires configuration before receiving alerts and Operational Intelligence raw data from the SCOM server. You can limit the collection of SCOM alerts to only those alerts that belong to the SCOM group that you specify.

Configure the SCOM connector instance
Configure the Microsoft System Center Operations Manager (SCOM) connector instance to receive alerts and Operational Intelligence raw data from the SCOM server.

Role required: evt_mgmt_admin

Supported versions:
- 2007 – version 6.1.7221.0
- 2012 - version 7.1.10226.0
- 2016 - version 7.2.117190 and 7.3.13261.0

Before starting the procedure to configure the connector, ensure:
- The MID Server is running with a user that has local admin permissions to enable the MID Server to run PowerShell and the user has read access to the SCOM API.
- The MID Server resides in the same domain as the SCOM server.
- The MID Server uses the same time zone as the SCOM server.
- The MID Server is running on Windows.
- The MID Server has .NET framework version 3.5.
- If you want to activate Metric Collection, ensure that the MID Server that retrieves metrics is configured with the Operational Intelligence extension and that the extension is in Started mode. See Manually configure the Operational Intelligence extension.

If Bi-directional is selected, ensure that:
- PowerShell version 3.0 is installed on Windows.
- That the MID Server is running with a user that has local admin permissions to enable the MID Server to run PowerShell.

If Metric Collection is selected and the Database login with Windows authentication option is also selected, ensure that:
- As Windows authentication is used by the connector to access the SCOM database (OperationsManagerDW), the MID Server service should be running with a user having read access to the SCOM database. Ensure that the correct credentials are used:
  1. In the local services, right-click the MID Server service and select Properties.
  2. In the Log On tab, ensure that This account is selected with the details of the user in the Windows domain having read access to the SCOM database.
Note: If the OperationsManagerDW database has been renamed, also change the database name in the SCOMConnector.groovy MID Server Script as well as in the MetricCollector script include.

- If you upgraded from a release earlier than Istanbul and a SCOM connector was defined:
  1. Define the Log On user on the MID Server service.
  2. Ensure that This account is selected with the details of the user in the Windows domain having read access to the SCOM database.

To receive SCOM alerts, you can obtain the redistributable SCOM files from your SCOM application. Add the files to the MID Server, and then configure a SCOM connector instance to collect the alerts and Operational Intelligence raw data.

The collection of Operational Intelligence is performed using JavaScript running JDBC in place of PowerShell.

1. On the SCOM server, download the following files to a local computer.

<table>
<thead>
<tr>
<th>Version and location</th>
<th>SCOM path and library names</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCOM 2012R2 or SCOM 2012</td>
<td>%ProgramFiles%\Microsoft System Center 2012 R2 or 2012\Operations Manager\Server\SDK Binaries</td>
</tr>
<tr>
<td></td>
<td>• Microsoft.EnterpriseManagement.Core.dll</td>
</tr>
<tr>
<td></td>
<td>• Microsoft.EnterpriseManagement.OperationsManager.dll</td>
</tr>
<tr>
<td></td>
<td>• Microsoft.EnterpriseManagement.Runtime.dll</td>
</tr>
<tr>
<td>SCOM 2007</td>
<td>%ProgramFiles%\System Center Operations Manager 2007\SDK Binaries</td>
</tr>
<tr>
<td></td>
<td>• Microsoft.EnterpriseManagement.OperationsManager.dll</td>
</tr>
<tr>
<td></td>
<td>• Microsoft.EnterpriseManagement.Runtime.dll</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Version and location</th>
<th>SCOM path and library names</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCOM 2016</td>
<td>%ProgramFiles%\Microsoft System Center 2016\Operations Manager \Server\SDK Binaries</td>
</tr>
<tr>
<td></td>
<td>• Microsoft.EnterpriseManagement.Core.dll</td>
</tr>
<tr>
<td></td>
<td>• Microsoft.EnterpriseManagement.OperationsManager.dll</td>
</tr>
<tr>
<td></td>
<td>• Microsoft.EnterpriseManagement.Runtime.dll</td>
</tr>
</tbody>
</table>

Note: The MID Server must be installed with .NET 4.6 or higher.

Note: A connection cannot be made to SCOM 2012 and SCOM 2007 from the same MID Server. To work with both SCOM 2012 and SCOM 2007 in your instance, before uploading the following files to your instance, append .2012 to the end of the filename Microsoft.EnterpriseManagement.OperationsManager.dll that is found in the 2012 path and append .2007 to the end of the filename.
2. Navigate to MID Server > JAR Files.
3. Click **New** and add a separate record for the SCOM version for each of the DLL files that you downloaded from the SCOM server.
   a) In the **Name** field, specify the SCOM version and an identifier to make the name unique, for example 2012-1. If you are using SCOM 2016, specify 2012 as the version.
   b) Click the paper clip icon in the form header and then attach one of the appropriate DLL files that you downloaded.
   c) Click **Submit**.
4. Repeat step 3, creating a separate record for each of the remaining DLL files. Ensure that you have a unique identifier after the SCOM version for each file that you attach, for example 2012-2.
6. Click **New** and create a connector instance with the following details:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Unique name for the SCOM connector instance.</td>
</tr>
<tr>
<td>Description</td>
<td>Description for the use of the SCOM event collection instance.</td>
</tr>
<tr>
<td>Active</td>
<td>Select this option only after running a successful test.</td>
</tr>
<tr>
<td>Connector definition</td>
<td>The vendor and protocol used to gather events from the external event source. Select the <strong>SCOM</strong> connector definition.</td>
</tr>
<tr>
<td>Host IP</td>
<td>Specify the SCOM IP address.</td>
</tr>
<tr>
<td>Credential</td>
<td>Select Windows credentials.</td>
</tr>
<tr>
<td>Event collection last run time</td>
<td>The last event collection run time value is automatically updated.</td>
</tr>
<tr>
<td>Last event collection status</td>
<td>The last event collection run time status is automatically updated.</td>
</tr>
<tr>
<td>Event collection schedule (seconds)</td>
<td>The frequency in seconds that the system checks for new events from SCOM Operations.</td>
</tr>
<tr>
<td>Bi-directional</td>
<td>Select to invoke the bi-directional option. This option enables the bi-directional exchange of values to-and-from the external event source. There is default implementation for SCOM. The <strong>Last bi-directional status</strong> option displays only when this option is selected.</td>
</tr>
<tr>
<td>Last bi-directional status</td>
<td>The value of this field is automatically populated.</td>
</tr>
<tr>
<td>Last error message</td>
<td>The last error message field is automatically updated. This message is the last error message received by the connector. If the test connector fails, an error message is displayed in this field.</td>
</tr>
<tr>
<td>Metrics collection</td>
<td>Select to enable the collection of Operational Intelligence.</td>
</tr>
<tr>
<td>Field</td>
<td>Value</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Metrics collection last run time</td>
<td>The last run time of the metrics collection scheduled job. This option displays only when the <strong>Metrics collection</strong> option is selected.</td>
</tr>
<tr>
<td>Last metrics collection status</td>
<td>Status of the Operational Intelligence collection activity. The value of this field is automatically populated. This option displays only when the <strong>Metrics collection</strong> option is selected.</td>
</tr>
<tr>
<td>Metrics collection schedule (seconds)</td>
<td>The time, in seconds, to repeat the Operational Intelligence collection scheduled job. This option displays only when the <strong>Metrics collection</strong> option is selected.</td>
</tr>
<tr>
<td>Metrics database host</td>
<td>The IP address or the host name of the metrics database host. This option displays only when the <strong>Metrics collection</strong> option is selected.</td>
</tr>
<tr>
<td>Connect using a named instance</td>
<td>When selected, the connection is made using the specified named instance. Otherwise, the connection is made using the specified port. This option displays only when the <strong>Metrics collection</strong> option is selected.</td>
</tr>
<tr>
<td>Metrics database port</td>
<td>The port used by the metrics database. The connection is made using JDBC. Default port number 1,433. This option displays only when the <strong>Metrics collection</strong> option is selected. However, if <strong>Connect using a named instance</strong> is selected, this option no longer displays.</td>
</tr>
<tr>
<td>Metrics database named instance</td>
<td>The metrics database instance name. This option displays only when the <strong>Metrics collection</strong> option is selected.</td>
</tr>
<tr>
<td>Database login with Windows authentication</td>
<td>Perform database login with the credentials of the log-on user that is defined on the MID Server service. This option displays only when the <strong>Metrics collection</strong> option is selected.</td>
</tr>
<tr>
<td>Metrics database credential</td>
<td>Credentials for the metric database. Use JDBC credentials for the local database user. This option displays only when the <strong>Metrics collection</strong> option is selected. However, if <strong>Database login with Windows authentication</strong> is selected, this option no longer displays.</td>
</tr>
</tbody>
</table>
### Field | Value
--- | ---
MID Servers (MID Server for Connectors section) | Optional. Name of a MID Server. If no MID Server is specified, an available MID Server that has a matching IP range is used. In the MID Servers for Connectors section, specify a MID Server that is up and valid. You can configure several MID Servers. If the first is down, the next MID Server is used. If that MID Server is not available, the next is selected, and so on. MID Servers are sorted according to the order that their details were entered into the MID Server for Connectors section. The port requirement from the MID Server to the SCOM server is 5724 and this is fixed. If the specified MID Server is in a cluster, it might not be selected and another available MID Server is then selected in its place.

7. Right-click the form header and select **Save**.
   The connector instance values are added to the form and the parameters that are relevant to the connector appear.

8. In the Connector Instance Values section, you can edit the values of the mandatory SCOM parameters.
   a) **login_with_windows_authentication** Default value: **false**.
      Set to **true** to enable SCOM event collection and the bi-directional exchange of event values to work with Windows authentication.
      When invoking this value, ensure that you do the following on the MID Server:
      1. Navigate to the list of local services, right-click the MID Server service and select **Properties**.
      2. In the **Log On** tab, ensure that **This account** is selected with the details of the user in the Windows domain having read access to the SCOM database.

   b) **metric_chunk_size** Default value 50000.

   c) **scom_date_format** Default format M/d/yyyy/ h:mm:ss a
      If you receive an event whose date is in a different format, modify this value to match the format of the incoming event. If you do not, the event will not be processed correctly.
      For example, if an event arrives on June 27, 2019 at 11:25 AM with a listed date of 2019/06/27/ 11:25:00 a, modify the **scom_date_format** value to yyyy/M/d/ h:mm:ss a to match the format of the received event.
      In **scom_date_format**, a represents AM, and p represents PM.

   d) **scom_initial_sync_in_days** Default value 7.

   e) **scom_version** It is mandatory to specify the SCOM version, select from 2016, 2012, or 2007.

9. Right-click the form header and select **Save**.
10. Restart the MID Server service to copy the files.
11. Click **Test connector** to verify the connection between the MID Server and the connector.
12. If the test fails, correct the problem by following the instructions issued by the error and then run another test.

   **Note:** Use a network tool, such as ping, to verify credential correctness and network connectivity from the MID Server to SCOM.

13. After a successful test, select the **Active** check box and then click **Update**.
Note:
The default binding rules that contain SCOM as the external source, that applies to IT alerts and Operational Intelligence raw data, are the following SCOM Management Packs:

- All OS Management Packs
- MS SQL Server
- IIS

If bi-directional is configured, the bi-directional exchange of values to-and-from the external event source is enabled.

These scenarios describe the default bi-directional functionality for SCOM connectors:

- When an alert is resolved in SCOM, it is auto-closed in ServiceNow. However, it is updated irrespective of the bi-directional feature because during each collection cycle, all alert changes are updated.
- When an alert is manually closed in ServiceNow, it is auto-closed in SCOM. If the alert state is changed to Reopen, SCOM is also updated.
- When an incident is created and associated to an alert in ServiceNow, SCOM receives the incident number as a ticket ID. However, the state of the incident is not available on SCOM. Therefore when the incident is resolved in ServiceNow, SCOM is not updated as the incident number remains the same. When the alert is associated with a new incident, the new incident number is updated in SCOM.

Limit collected SCOM alerts to specific SCOM groups
Limit the collection of SCOM alerts to only those alerts that belong to the specified SCOM group.

1. Use the SCOM Authoring workspace and Operations console to define a SCOM group. Ensure that the group contains the required computers or instances. For further information about SCOM groups, see the SCOM documentation.
2. Create a role that has a scope of the SCOM group.
3. Add the new role to the SCOM user.
4. Assign the role to the user defined in the credentials given to the SCOM connector instance.
5. Remove all other roles from the user.

Only alerts from the specified SCOM group arrive at the instance.

Configure event collection from SolarWinds monitor
Configure the SolarWinds monitor connector instance to receive events from the SolarWinds monitor.

Supported versions:

- SAM 6.2.1
- NPM 12.0

Note: The SolarWinds monitor connector instance can import events from:

- Network Performance Monitor (NPM)
- SolarWinds Service & Application Monitor (SAM)

The SolarWinds monitor connector instance requires a credential that lets the instance access SolarWinds monitor accounts. You can use an existing credential or create a new one.

Role required: evt_mgmt_admin and evt_mgmt_integration

1. Navigate to Event Management > Event Connectors (Pull) > Connector Instances.
2. Click New.
3. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Type a descriptive name for the SolarWinds monitor connector.</td>
</tr>
<tr>
<td>Description</td>
<td>Type a description for the use of the SolarWinds monitor event collection instance.</td>
</tr>
<tr>
<td>Connector Definition</td>
<td>Select Solarwinds.</td>
</tr>
<tr>
<td>Host IP</td>
<td>Specify the SolarWinds monitor IP address.</td>
</tr>
<tr>
<td>Credential</td>
<td>Select the credential with basic authentication that you created for this connector. For more information, see Create SolarWinds monitor credentials.</td>
</tr>
<tr>
<td>Event collection last run time</td>
<td>The last run time value of the scheduled job. This field is updated automatically.</td>
</tr>
<tr>
<td>Last event collection status</td>
<td>The last event collection status. This field is updated automatically.</td>
</tr>
<tr>
<td>Event collection schedule (seconds)</td>
<td>The frequency in seconds that the system checks for new events from the SolarWinds monitor server.</td>
</tr>
<tr>
<td>Last error message</td>
<td>The last error message received by the connector is automatically updated.</td>
</tr>
</tbody>
</table>

4. Right-click the form header and select Save.
The connector instance values are added to the form and the parameters that are relevant to the connector appear.

5. In the Connector Instance Values section, specify these fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>initial_sync_in_days</td>
<td>Specify how many days the initial pull must contain to retrieve events. The default value is 7 days.</td>
</tr>
<tr>
<td>nodes_custom_properties</td>
<td>Specify the SolarWinds monitor property names that are associated with the relevant node. This information is added to the Additional Information field of the event in JSON format. The SolarWinds monitor custom properties are user-defined fields, for example, country, building, or serial number, that you can associate with monitored network objects. Separate multiple entries with a comma.</td>
</tr>
</tbody>
</table>
Create SolarWinds monitor credentials

Create credentials to access SolarWinds monitor.

Role required: evt_mgmt_admin

1. Navigate to Connections & Credentials > Credentials.
2. Click New.
3. Select Basic Auth Credential.
4. On the form, fill in the fields.

### Basic Auth Credentials form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a unique and descriptive name for this credential. For example, you might call it SolarWinds authentication.</td>
</tr>
<tr>
<td>User name</td>
<td>Name to identify the user.</td>
</tr>
<tr>
<td>Password</td>
<td>Password to use this credential.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to enable the use of this credential.</td>
</tr>
<tr>
<td>Order</td>
<td>The order (sequence) in which the platform tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), the instance tries the credentials in a random order. Default value: 100</td>
</tr>
</tbody>
</table>

5. Click Submit.

The credential for use with the SolarWinds monitor connector is created.
Configure event collection from vCenter

Configure the VMware vCenter Server (vCenter) connector instance to receive events from your VMware vSphere environment.

Events collected by this connector are events that match the vCenter ESX Servers event rule.

Supported version: 6.5

Role required: evt_mgmt_admin

1. Navigate to Event Management > Event Connectors (Pull) > Connector Instances.
2. Click New.
3. On the form, fill in the fields.

**Connector Instance form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Descriptive and unique name for the vCenter connector.</td>
</tr>
<tr>
<td>Description</td>
<td>Description for the use of the vCenter event collection instance.</td>
</tr>
<tr>
<td>Connector definition</td>
<td>Name of the required connector definition. Select vCenter.</td>
</tr>
<tr>
<td>Host IP</td>
<td>IP address where vCenter is installed.</td>
</tr>
<tr>
<td>Credential</td>
<td>Permission to connect to vCenter. Click the search icon in the Credential field. Either select the required credentials from the list or click New and create the required credentials on the Credentials form. If you create the credentials, save them using a unique and recognizable name, for example, vCenterCHCK.</td>
</tr>
<tr>
<td>Event collection last run time</td>
<td>Last run time value. Automatically updated.</td>
</tr>
<tr>
<td>Last event collection status</td>
<td>Last run status. Automatically updated.</td>
</tr>
<tr>
<td>Event collection schedule (seconds)</td>
<td>Frequency, in seconds, that the system checks for new events from vCenter. The default value is 120 seconds.</td>
</tr>
<tr>
<td>Last error message</td>
<td>Last error message. Automatically updated.</td>
</tr>
</tbody>
</table>

4. Right-click the form header and select Save.
The connector instance values are added to the form and the parameters that are relevant to the connector appear.

5. In the Connector Instance Values section, specify the vCenter values.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>collect_stateless_events</td>
<td>Events that have a status (stateful) are collected when this field is set to <strong>false</strong> (default). These events are of type AlarmStatusChangedEvent and AlarmClearedEvent. If this field is set to <strong>true</strong>, events of other types are collected as well.</td>
</tr>
<tr>
<td>port</td>
<td>Specify the value of the port. Default value: <strong>443</strong>.</td>
</tr>
<tr>
<td>protocol</td>
<td>Specify the protocol. Default value: <strong>https</strong>.</td>
</tr>
</tbody>
</table>

6. Optional: In the MID Servers for Connectors section, specify a MID Server that is up and is valid.
   If no MID Server is specified, an available MID Server that has a matching IP range is used.
   You can configure several MID Servers. If the first is down, the next MID Server is used. If that MID Server is not available, the next is selected, and so on. MID Servers are sorted according to the order that their details were entered into the MID Server for Connectors section.

7. Right-click the form header and select **Save**.

8. Test the connection between the MID Server and the vCenter connector.
   a) Click **Test Connector**.
      
      If the test fails, follow the instructions that the error issues to correct the problem and then run another test.
      
      **Note:** Use a network tool, such as ping, to verify credential correctness and network connectivity from the MID Server to the external monitoring tool.

   b) After a successful test, select the **Active** check box.

9. Click **Update**.

Configure event collection from vRealize
Configure the VMware vRealize Operations (vRealize) connector instance to receive events from
the vRealize Operations Log and Event Management servers.

Supported version: 6.5.0

**Note:** Connect to vRealize using a local account with at least Read-only vRealize
Operations permission. You can use an existing credential or [create a new one](#).

Role required: evt_mgmt_admin

1. Navigate to Event Management > Event Connectors (Pull) > Connector Instances.
2. Click **New** and create a vRealize Operations connector instance with the following details:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Specify a unique name for the vRealize Operations connector instance.</td>
</tr>
<tr>
<td>Host IP</td>
<td>Specify the vRealize Operations IP address.</td>
</tr>
<tr>
<td>Credential</td>
<td>Select the credential with basic authentication that you created for this connector. For more information, see <a href="#">Create vRealize credentials</a>.</td>
</tr>
<tr>
<td>Schedule (seconds)</td>
<td>The frequency in seconds that the system checks for new events from vRealize Operations.</td>
</tr>
<tr>
<td>Description</td>
<td>Type a description for the use of the vRealize Operations connector.</td>
</tr>
<tr>
<td>Connector definition</td>
<td>The vendor and protocol used to gather events from the external event source. Select the vRealize connector definition.</td>
</tr>
<tr>
<td>Last error message</td>
<td>The last error message is automatically updated.</td>
</tr>
<tr>
<td>Last run time</td>
<td>The last run time value is automatically updated.</td>
</tr>
<tr>
<td>Last run status</td>
<td>The last run time status is automatically updated.</td>
</tr>
<tr>
<td>MID Servers (MID Server for Connectors section)</td>
<td>Optional. Name of a MID Server. If no MID Server is specified, an available MID Server that has a matching IP range is used. In the MID Servers for Connectors section, specify a MID Server that is up and valid. You can configure several MID Servers. If the first is down, the next MID Server is used. If that MID Server is not available, the next is selected, and so on. MID Servers are sorted according to the order that their details were entered into the MID Server for Connectors section.</td>
</tr>
</tbody>
</table>

3. Right-click the form header and select **Save**.
   The connector instance values are added to the form and the parameters that are relevant
   to the connector appear.

4. In the Connector Parameters section, specify the values of the mandatory vRealize Operations parameters.
   a) **port** Default value 443.
b) **protocol** Default value https.

5. Click Test connector to verify the connection between the MID Server and the vRealize Operations connector.

6. If the test fails, follow the instructions that are issued by the error to correct the problem and then run another test.

   **Note:** Use a network tool, such as ping, to verify credential correctness and network connectivity from the MID Server to vRealize.

7. After a successful test, select **Active** and then click **Update**.

Create vRealize credentials

Create credentials to access vRealize.

Role required: evt_mgmt_admin

Create Basic Auth type of credential to connect to vRealize.

1. Navigate to **Connections & Credentials > Credentials**.
2. Click **New**.
3. Select **Basic Auth Credential**.
4. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a unique and descriptive name for this credential. For example, NewvRealize.</td>
</tr>
<tr>
<td>User name</td>
<td>Name to identify the user.</td>
</tr>
<tr>
<td></td>
<td>• If the username is internal in vRealize, use it as is.</td>
</tr>
<tr>
<td></td>
<td>• If vRealize is integrated with Active Directory (AD), use the format</td>
</tr>
<tr>
<td></td>
<td>DOMAIN\username@sourceauth. For example, local\administrator@All vCenter Servers.</td>
</tr>
<tr>
<td>Password</td>
<td>Password to use this credential.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to enable the use of this credential.</td>
</tr>
<tr>
<td>Order</td>
<td>The order (sequence) in which the platform tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), the instance tries the credentials in a random order. Default value: 100</td>
</tr>
</tbody>
</table>

5. Click **Submit**.

The credential for use with the vRealize connector is created.
Configure event collection from Zabbix server
Configure the Zabbix server connector instance to receiving alerts from the Zabbix server.

Supported version: 3.0.3

The Zabbix server connector instance requires a credential that lets the instance access Zabbix server accounts. You can use an existing credential or create a new one.

Role required: evt_mgmt_admin

1. Navigate to Event Management > Event Connectors (Pull) > Connector Instances.
2. Click New.
3. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Descriptive name for the connector.</td>
</tr>
<tr>
<td>Host IP</td>
<td>IP address for the Zabbix server.</td>
</tr>
<tr>
<td>Credential</td>
<td>Select the credential with basic authentication that you created for this connector. For more information, see Create Zabbix server credentials.</td>
</tr>
<tr>
<td>Schedule (seconds)</td>
<td>Frequency, in seconds, that the system checks for new events from the Zabbix server.</td>
</tr>
<tr>
<td>Description</td>
<td>Description for the use of the Zabbix server event collection instance.</td>
</tr>
<tr>
<td>Connector Definition</td>
<td>Name of the connector definition. Select Zabbix.</td>
</tr>
<tr>
<td>Last error message</td>
<td>Last error message. Automatically updated.</td>
</tr>
<tr>
<td>Last run time</td>
<td>Last run time value. Automatically updated.</td>
</tr>
<tr>
<td>Last run status</td>
<td>Last run time status. Automatically updated.</td>
</tr>
<tr>
<td>MID Servers (MID Server for Connectors section)</td>
<td>Optional. Name of a MID Server. If no MID Server is specified, an available MID Server that has a matching IP range is used. In the MID Servers for Connectors section, specify a MID Server that is up and valid. You can configure several MID Servers. If the first is down, the next MID Server is used. If that MID Server is not available, the next is selected, and so on. MID Servers are sorted according to the order that their details were entered into the MID Server for Connectors section.</td>
</tr>
</tbody>
</table>

4. Right-click the form header and select Save.
The connector instance values are added to the form and the parameters that are relevant to the connector appear.

5. In the Connector Instance Values section, the default connector instance values appear. Verify and modify the values, as needed.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>days_from</td>
<td>Number of days for which events must be collected at the first collection cycle. Default value: 2</td>
</tr>
<tr>
<td></td>
<td>Note: The maximum number of past events that can be collected is 3,000. The first time that this connector runs, the number of past events is counted in the past from the current date.</td>
</tr>
<tr>
<td>port</td>
<td>Port number. Default: 80</td>
</tr>
<tr>
<td>protocol</td>
<td>Protocol type. Default: https</td>
</tr>
</tbody>
</table>

6. Right-click the form header and select **Save**.
7. Click **Test Connector** to verify the connection between the MID Server and the connector.
8. If the test fails, follow the instructions that are issued by the error to correct the problem and then run another test.

Note: Use a network tool, such as ping, to verify credential correctness and network connectivity from the MID Server to the Zabbix server.

9. After a successful test, select **Active** and then click **Update**.

Create Zabbix server credentials
Create credentials to access Zabbix server.

Role required: evt_mgmt_admin

1. Navigate to **Connections & Credentials > Credentials**.
2. Click **New**.
3. Select **Basic Auth Credential**.
4. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a unique and descriptive name for this credential. For example, you might call it Zabbix authentication.</td>
</tr>
<tr>
<td>User name</td>
<td>Name to identify the user.</td>
</tr>
<tr>
<td>Password</td>
<td>Password to use this credential.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to enable the use of this credential.</td>
</tr>
<tr>
<td>Order</td>
<td>The order (sequence) in which the platform tries this credential as it attempts to log on to devices. The smaller the number, the higher in the list this credential appears. Establish credential order when using large numbers of credentials or when security locks out users after three failed login attempts. If all the credentials have the same order number (or none), the instance tries the credentials in a random order. Default value: 100</td>
</tr>
</tbody>
</table>

5. Click Submit.

The Basic Auth credential for use with the Zabbix server connector is created.

Create a custom pull connector

You can create a customized pull connector that requires a script, connector definition, and connector instance, to retrieve events on behalf of an event source.

Role required: evt_mgmt_admin

A custom connector script can make remote API calls for a new event source to send events to the ServiceNow instance. You can create a script, and then add it as part of a new Event Management connector definition and connector instance. The custom code that accomplishes these actions must:

- Connect to an event monitoring tool.
- Retrieve events from an event monitoring tool.
- Send events to the Event (em_event) table using a web service API. See .

1. Create a custom MID Server script include. This example uses Groovy (deprecated). In place of a script include in Groovy, it is recommended to use JavaScript.
   a) Implement these methods:
      - @Override OperationStatus testConnection()
      - @Override OperationStatus execute()
   b) Design the class to extend the ThirdPartyConnector.

```java
public class HypericConnector extends ThirdPartyConnector
```

c) Import platform classes for event creation, sending, logging, and third-party connector base classes.

```java
package com.service_now.mid.probe.tpcon.test
import com.glide.util.Log
```
import com.service_now.mid.MIDServer
import com.service_now.mid.probe.event.IEventSender
import com.service_now.mid.probe.event.SNEventSender
import com.service_now.mid.probe.tpcon.OperationStatus
import com.service_now.mid.probe.tpcon.OperationStatusType
import com.service_now.mid.probe.tpcon.ThirdPartyConnector
import com.snc.commons.eventmgmt.Event

2. Navigate to **MID Server** > **MID Server Script Files** and create a script. Specify the **Parent** field as **Groovy**, complete the form as appropriate, and then click **Submit**.

3. Navigate to **Event Management** > **Event Connectors (Pull)** > **Connector Definitions** and create a connector definition.

4. In the **Groovy script to run** field, select the MID Server script file, complete the form as appropriate. In addition to **username** or **host**, you can add any other parameter, for example, **port**, and then click **Submit**.

5. Navigate to **Event Management** > **Event Connectors (Pull)** > **Connector Instances** and create a connector instance.

6. In the **Connector definition** field, select the connector definition, complete the form as appropriate, and then click **Submit**.

7. To confirm or debug the script, use debug printouts from Groovy to the MID Server log.

8. To monitor incoming events using the custom connector instance, navigate to **ECC > Queue** and filter on **ConnectorProbe**.

Custom connector code sample

The code sample used in this connector definition demonstrates how to manage events using web service API.
Note: The sample connector code is not updated automatically. Check the connector code on the instance from time-to-time as it might be updated.

You can use the Find Packages Calls script to generate proposed changes to remove Packages calls or replace them with GlideScriptable names. For more information, see Packages Call Removal tool.

You can use the following code sample to create a JavaScript connector for receiving events from a SolarWinds external source.

```javascript
var SolarWindsJS = Class.create();

var SUCCESS = Packages.com.service_now.mid.probe.tpcon.OperationStatusType.SUCCESS;
var FAILURE = Packages.com.service_now.mid.probe.tpcon.OperationStatusType.FAILURE;
var Event = Packages.com.snc.commons.eventmgmt.Event;
var SNEventSenderProvider = Packages.com.service_now.mid.probe.event.SNEventSenderProvider;

Create a custom pull bi-directional connector

Create a bi-directional connector definition to send changes made to an alert back to the external event source.

Role required: evt_mgmt_admin

Currently, the SCOM connector is the only connector with bi-directional functionality by default. However, you can customize any connector to have bi-directional functionality.

When a connector definition is created, the boilerplate code that it contains is for the exchange of values from the external event source to the ServiceNow instance. Implement bi-directional functionality as one of these options:

- Connector with full abilities, where there is an exchange of values to-and-from the external event source and the ServiceNow instance. Do this implementation by adding the `updateSource` method to the connector code.
- A pull connector with bi-directional functionality. In a case where events are pushed to the ServiceNow instance from the event source (such as using REST or SNMP), the connector must contain an implementation only for forwarding updates back to the event source. Do this implementation by replacing the connector boilerplate code with the code sample in this document.

**Note:** Users must have write permission to the external source to provide the bi-directional functionality.

The MID Server can update any connector when manual changes to alerts are received, as depicted in this diagram.
1. Navigate to **Event Management > Event Connectors (Pull) > Connector Definitions** and click **New**.

2. In the **Connector Definition** form, select the **Bi-directional** option. When the connector instance is configured as bi-directional, each manual update of an alert from this source instance is logged in the Update Queue table (em_connector_update_queue).

3. In the **Alert field identifier** field, specify the alert field that contains the identifier used to associate the ServiceNow alert with the corresponding event or alert in the external event source. This identifier must be an actual alert field, not a field in the **Additional information** of the alert. To include a field that is contained only in the **Additional information** field, see **Custom alert fields**.

   - The **Update queue** business rule on the Alert table identifies each manual update of the alert and updates the connector queue with these changes. By default, changes to all alert fields are tracked.
   - The **Event Management - Queue connector** processor schedule job dequeues alert changes and sends them to the MID Server. By default, this dequeue process is performed in batches of 1,000 alerts. You can configure this batch size using the `evt_mgmt.max_update_source_records` property.

4. In the connector JavaScript, specify the information required for the **updateSource** function. This function receives the manual changes from alerts and sends them to the external source, according to the source instance. Use this **updateSource** function to handle and parse all the alert fields that should be updated in the external source.

5. After adding the update source method, update the test connection method.
Note: When adding bi-directional functionality for a Push connector, the Connector Instance name must match the **Source Instance** field of the alerts generated by that event source.

For an example of a connector script with full connector abilities, see the SCOM connector script that is provided with the base instance.

To match alerts to the specific connector instance in the following example, the manual update of the alert is sent to the correct connector instance by matching the source instance name.

When using the `updateSource` method, specify which fields you are looking to find and send to the source. In this code, you can find an example of **Incident** and **State** fields. Whenever a new incident is associated to the alert or the state of the alert is being changed manually, an update is sent to the external source monitor. External server users must have write permission to the external source to provide the bi-directional functionality. The following script example is of a new custom connector with bi-directional ability only, without retrieving events. The `execute` method must still appear in the script, but it is an implementation that returns success without performing any action.

```javascript
var ConnectorJS = Class.create();

var SUCCESS = Packages.com.service_now.mid.probe.tpcon.OperationStatusType.SUCCESS;
var FAILURE = Packages.com.service_now.mid.probe.tpcon.OperationStatusType.FAILURE;

                argument = alert.value[j].newValue;
            } else if (alert.value[j].fieldName == 'state' && alert.value[j].oldValue == 'Open' || alert.value[j].oldValue == 'Reopen' && alert.value[j].newValue == 'Closed'){
                command = 'close';
            } else if (alert.value[j].fieldName == 'state' && alert.value[j].oldValue == 'Closed' && alert.value[j].newValue == 'Open' || alert.value[j].newValue == 'Reopen'){
                ;
            }
```
command = 'open';
}
if (command != ''){
    this.probe.setParameter("action_performed", "true");

    var alertToSend = {};
    alertToSend.id = alert.key;
    alertToSend.command = command;
    alertToSend.ticket_id = argument;

    alertsToSend[alertId] = alertToSend;

    command = ''; 
    argument = ''; 
    jsonRes = JSON.stringify(alertsToSend);
    ms.log("jsonRes: " + jsonRes);
    result = this.sendAlert(url, username, password, jsonRes);
    if (result == false){
        retVal['status'] = "" + FAILURE.toString();
        retVal['error_message'] = errorMessage;
        return retVal;
    }
    alertsToSend = [];
    alertId = 0;
}

retVal['status'] = "" + SUCCESS.toString();
return retVal;
}

sendAlert : function(url, user, pw, body) {
    try {
        var PostMethod = Packages.org.apache.commons.httpclient.methods.PostMethod;
        var GlideHTTPCient = Packages.com.glide.communications.HTTPClient;
        var httpClient = new GlideHTTPCient();

        var postMethod = new PostMethod(url); // put your endpoint URL here
        postMethod.addRequestHeader('X-Auth-Token', '...'); // add request
        headers, can use user and pw parameters for authentication
        postMethod.setRequestBody(body);

        var httpStatus = httpClient.executeMethod(postMethod);
        var response = postMethod.getResponseAsString();
        postMethod.releaseConnection();

        if(response.haveError()) {
            this.addError("ERROR: " + response.getErrorMessage() + " " + 
            response.getBody());
            return false;
        }
        return true;
    }
    catch(err) {
        this.addError("Error on sendAlert function. Failed to send data to the
        source. Error: " + err.message);
        return false;
    }
},

addError : function(message){
    if (errorMessage === "")
        errorMessage = message;
    else
        errorMessage += "\n" + message;
    ms.log(message);
},

Troubleshooting

If manual changes from alerts do not update the external source monitor, perform these checks:

- Check to see if the bi-directional status on the connector is in error.
- Check if changes are written to the queue (em_connector_update_queue) and check for their status.
- Check if changes are being processed on the queue:
  - Yes: Check the MID log for errors.
  - No: Check the ECC queue for processing issues.

Assume that a custom bi-directional connector must be created. The connector must receive event information from an OMi device. When a manual update is made to an alert, the connector must forward the changes back to the OMi external device. Required:

- Write the MID Server custom bi-directional connector script include to enable the exchange of values to-and-from the OMi device external event source and the ServiceNow instance.
  - In the connector JavaScript, specify the information required for the updateSource function. This function receives the manual changes from alerts and sends them to the external source, according to the source instance. Use this updateSource function to handle and parse all the alert fields that should be updated in the external source.
  - After adding the update source method, update the test Connection method to test the bi-directional API as well.
  - Modify an existing connector definition, or create a new connector definition, to which the bi-directional connector script is associated. Thereafter, a custom connector instance is created that uses this connector definition.

In this step, create the custom bi-directional connector definition.

2. Fill in the fields as appropriate, including selecting the Bi-directional option.
   When the connector instance is configured as bi-directional, each manual update of an alert from this source instance is logged in the Update Queue (em_connector_update_queue) table.

3. In the Alert field identifier field, specify the alert field that, if changed manually, causes the external monitoring system to be updated.
The **Update queue** business rule that runs on the Alert table identifies each manual update of the alert and updates the connector queue with these changes. To determine if an update to the alert was caused manually or automatically from an event, the **Last Update Time By Event** field is examined. If this field has not changed, the business rule accepts the alert update as a manual update.

4. Right-click the form header and select **Save**.
5. In the **Script type** field, select **JavaScript**.
6. In the **JavaScript to run** field, select the custom bi-directional connector script include.
7. Click **Update**.

In this step, create the custom bi-directional connector instance and associate the new custom connector definition with it.

1. Navigate to **Event Management > Event Connectors (Pull) > Connector Instances** and click **New**.
2. Fill in the fields as appropriate. In the **Connector definition** field, select the custom connector definition that you created in the preceding procedure.
3. Select the **Bi-directional** option
4. Right-click the form header and select **Save**.
5. Click **Test Connector**. If a failure result is returned, follow the instructions that are issued by the error to correct the problem and then run another test.
6. When **Test Connector** returns a successful result, click the **Active** option
7. Click **Update**.

Every 30 seconds the **Event Management - Queue connector processor** job runs and processes all pending alerts in the Update Queue. These updates are sent to the MID Server using the **ConnectorUtil** script include.

The Event Management - Queue connector processor schedule job dequeues alert changes and sends them to the MID Server. By default, this dequeue process is performed in batches of 1,000 alerts. You can configure this batch size using the **evt_mgmt.max_update_source_records** property.

---

**Collect raw metric information from a custom metric connector instance**

You can customize a pull metric connector to collect raw metric information from an external source.

The process of collecting raw metric information from a custom metric connector instance is:

- Create a custom metric connector script to collect raw metric information.
- Add the custom metric connector script to a new Event Management connector definition in the **JavaScript to run** field. The connector definition uses the script to enable the MID Server to connect to the external server to obtain metric raw data.
- Define a custom metric connector instance. The custom connector definition is specified in this connector instance.
- The **Event Management - Connector execution job** job executes all connectors in “running mode” and sends a message to the MID Server on the ECC queue.
- The MID Server executes the custom metric connector script.
The custom metric connector script collects raw metric information that it adds to be processed on the MID Server.

- The custom metric connector script returns results to the instance.
- The Event Management – Connector business rule on the ecc_queue table updates the custom metric connector instance with the results, such as, status, error, and signature.

The custom metric connector script must:

- Be written in JavaScript.
- In the connector definition, be specified in the JavaScript to run field.
- Include the retrieveKpi() method. The connector framework uses the retrieveKpi() method to collect metrics. In this method, include the logic for reading data from the external source system and transform to the RawMetric object (in ServiceNow format).
- Read the required connector instance parameters defined in the probe object.
- Collect raw metric data from the metric source.
- Prepare a RawMetric record. The RawMetric object can be created by passing these attributes in the constructor:

<table>
<thead>
<tr>
<th>RawMetric record description</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metricType</td>
<td>Name of the metric.</td>
</tr>
<tr>
<td>metricTypeId</td>
<td>SysId of the metric, if available. Otherwise pass the value null</td>
</tr>
<tr>
<td>resource</td>
<td>Information about the resource for which metric data is being collected.</td>
</tr>
<tr>
<td>node</td>
<td>IP, FQDN, name of the CI, or host. For example, the name of the Linux server where the disks are installed.</td>
</tr>
<tr>
<td>ci</td>
<td>SysId of the CI if available. Otherwise use the provided information as part of ciIdentifier for the binding.</td>
</tr>
<tr>
<td>value</td>
<td>Value of the metric.</td>
</tr>
<tr>
<td>timestamp</td>
<td>Epoch timestamp of the metric in milliseconds.</td>
</tr>
<tr>
<td>ciIdentifier</td>
<td>List of key-value pairs to identify the CI.</td>
</tr>
<tr>
<td>source</td>
<td>Data source that is monitoring the metric type.</td>
</tr>
<tr>
<td>sourceInstance</td>
<td>Source instance.</td>
</tr>
<tr>
<td>monitoredObjType</td>
<td>Monitored Object Type</td>
</tr>
</tbody>
</table>

- Use the handleMetric function to add the raw metric information from the RawMetric record to be processed in the MID Server. To get access to the MetricHandle object, make the following call to the MetricFactory:

```javascript
var metricHandler = MetricFactory.getMetricHandler()
```

Then for each RawMetric object execute:

```javascript
metricHandler.handleMetric(rawMetric)
```

- Write error logs to the MID Server log using ms.log. You can use the debugLog() function in the MetricCollector script as an example to write debug messages.

Note: You can use the MetricCollector MID Server script include that is provided in the base instance as an example for these items.
The custom script should return this data:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Status</td>
<td>Success or Failure</td>
</tr>
<tr>
<td>error_message</td>
<td>Error Message</td>
</tr>
<tr>
<td>last_kpi_signature</td>
<td>last metric time in milliseconds. This instruction is used for the next query to start from this time. Use any signature that you want to save to retrieve the next metric. This value is updated according to the metric collector Last signature field.</td>
</tr>
<tr>
<td>metric_source</td>
<td>Your source</td>
</tr>
<tr>
<td>metric_count</td>
<td>Count of retrieved metrics</td>
</tr>
<tr>
<td>metric_duration</td>
<td>Duration time of the retrieve metrics process in milliseconds</td>
</tr>
</tbody>
</table>

Test connector requirements - Implement the testConnection() function. The function returns either Success or Failure. If Failure, check the writeError() function for a failure message. You can also check the sa_performance_statistics table to see that metrics are being received. For an example of test connector script, see the SolarWindsJS Mid Server script include.

Metric types that the connector collects:

- Use set active: true/false to define the types you want to collect.
- In the metric collector script use HandleTypes.getActiveTypesForSql(“Your Source”): for a comma-separated list of supported types. If the type is not active, the type is not returned. If the metric source is in registration mode, not type is retrieved. In registration mode, all types are collected to be able to add any missing types.
- You can collect all metrics types. The metricHandler.handleMetric() function filters the types that are collected. However, using only active types in the query commands should improve performance.

Create a custom pull metric connector

A custom pull metric connector requires a script, connector definition, and connector instance to retrieve raw metric information from an external source.

Role required: evt_mgmt_admin

Ensure that the Operational Intelligence plugin is activated, see Request Operational Intelligence.

Prepare the prescribed requirements, see Collect raw metric information from a custom metric connector instance.

The custom metric connector makes remote API calls to an external source to get raw metric data. The connector then writes or sends that data to the instance using the handleMetric() function.

1. Create a custom MID Server script include. As an example, you can use the MetricCollector script that is provided with the base instance.

2. Navigate to MID Server > Script Includes and click New.
   a) In the Name field, specify the name.
   b) Select Active.
c) In the **Script** field, enter the custom metric collector script. Use JavaScript to compose this script.

3. Complete the form as appropriate, and then click **Submit**.
4. Configure a dedicated MID Server. For more information, see *Manually configure a MID Server for Operational Intelligence*.
5. Navigate to **Event Management > Event Connectors (Pull) > Connector Definitions** and click **New**.
   a) In the **Name** field, specify the name.
   b) Select the **Collect metrics** option.
   c) Right-click the form header and select **Save**.
   d) In the **JavaScript to run** field, select the newly created custom MID Server script file.
6. In the **Connector Parameters** area, specify the parameters for all additional information needed for the connector, for example, topics that you want to subscribe to.
7. In the **Connector Definition to MID Server Capabilities** area, specify the details of the MID Server. Use a MID Server with **Operational Intelligence** as a supported application, and with the Metrics capability. For more information, see *Configure a MID Server for Operational Intelligence*.
8. Complete the form as required, then click **Submit**.
9. Navigate to **Event Management > Event Connectors (Pull) > Connector Instances** and click **New**.
   
   **Note:** Remember to specify values for parameters that you defined.
   
   a) In the **Name** field, specify the name.
   b) In the **Connector definition** field, select the newly created custom metric connector definition.
   c) Select the **Metrics collection** option.
   d) In the **Metrics collection schedule** field, specify the number of seconds for the metrics collection schedule job to wait before it repeats.
   e) Right-click the form header and select **Save**.
   f) Complete the form as required, then click **Save**.
10. Click **Test Connector** to verify the connection between the MID Server and the custom metric connector.
11. Click **Active**.
12. Click **Update**.

- To confirm or debug the custom metric connector script, use debug printouts to the MID Server log.
- To monitor incoming events using the custom metric connector instance, navigate to **ECC > Queue** and filter on **ConnectorProbe**.

**Custom connector considerations**

Considerations for custom connector configuration settings when connecting to an external source.
<table>

</tr>
<tr>
<td></td>
<td><code>ms.log('Solarwinds testing connection')</code></td>
</tr>
<tr>
<td></td>
<td>To find the log, search in the MID Server for <code>agent\logs\agent0.log.0</code> file. If there is failure, search the log for more information. The log must reveal the cause of the failure, for example, missing DLLs files or incorrect credentials.</td>
</tr>
<tr>
<td>Execution</td>
<td>• Differentiate between the first pull of events with the subsequent events that are pulled. The first pull of events:</td>
</tr>
<tr>
<td></td>
<td>• Takes events that exist.</td>
</tr>
<tr>
<td></td>
<td>• Must be limited either in time or number of events that are pulled.</td>
</tr>
<tr>
<td></td>
<td>• Must only pull open alerts.</td>
</tr>
<tr>
<td></td>
<td>• Use the main API to get all events data since last signature and limit the number of events.</td>
</tr>
<tr>
<td></td>
<td>• Create ServiceNow events by parsing.</td>
</tr>
<tr>
<td></td>
<td>• Send all event using: <code>var sender = SNEventSenderProvider.getEventSender()</code></td>
</tr>
<tr>
<td></td>
<td>• Update the <code>lastSignature</code> timestamp.</td>
</tr>
<tr>
<td></td>
<td>• Fill the resultant record with the status.</td>
</tr>
</tbody>
</table>
Configure event collection that uses the pull operation
Configure connector instances to use connector definitions (script instructions) that enable the MID Server to connect to external servers to obtain event information.

Use one connector instance for each type of event server that sends events via a MID Server. You can configure connector instances to use the default connector definitions for supported event sources. Alternatively, you can create a custom definition that enables the MID Server to run a script for event collection.

Collect events from external servers using a pull operation

The schedule for the pull interval is set in the Schedule field of the connector instance. Users of the external servers must have read permission. However, if the connector instance is also configured to be bi-directional, the external server users must also have write permission. After configuring the connector instance, use the Test connector to verify the connection with the external source. Thereafter, set the connector instance to Active and events start to be received from the external server according to the pull interval schedule.

<table>
<thead>
<tr>
<th>Activity</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Last signature</td>
<td>Each time that events are pulled, all events are pulled with the time of that the event occurred, which is &gt;= last signature timestamp. In cases where the last event arrives at the last signature time, it is pulled repeatedly. To prevent this, ‘remember’ the last event ID. Thereafter, when events are next pulled, exclude this event ID if it is in the group of pulled events and its time of event remains unchanged.</td>
</tr>
</tbody>
</table>
| Parameters                       | Determine which parameters are available and how to use them.  
- For context parameters, such as, connector name, user name, password, host, and last event signature. For example: this.probe.getParameter("connector_name").  
- For connector instance values. For example: this.probe.getAdditionalParameter("port"). |
| Target monitor information collection | Collect information about the target monitor.  
- APIs in use, for example, DB or web service.  
- How to connect to the external source:  
  - Credentials.  
  - Parameters (for example, url, port, protocol).  
  - Required Jar or dll files needed to run commands on the MID server. |
| Test connection                  | Verify the connection with the monitor:  
- A valid connection returns a SUCCESS status.  
- Use the main API that returns alerts/events data without sending data.  
- Fill the result record with status information according to the result of the connection test: 
  
  ```java
  retVal['status'] = **SUCCESS.toString()** / FAILURE.toString(). Detailed failure information must be saved to a log.
  ``` |
| Time of event                    | The Time of event is the time that the event occurred. Convert the event time to GMT using the yyyy-MM-dd HH:mm:ss format. |
Connector instances

Configure connector instances to use script instructions that enable the MID Server to connect to external servers to obtain event information. Each connector instance is specific to an event source vendor.

Configure push operation event collection
You can configure listeners to push event information to the instance or MID Server.

Event Management receives external events through an event collector or script. If you are using a script to collect events, no configuration is required. All other methods of collecting events require configuration. For more information, see Event collection using script.

After event collection configuration, Event Management can collect events that are sent directly to the instance, or via the MID Server, SNMP trap, or email.

Standard event form
All events must use a standard event form, regardless of how they arrive at the instance. For more information, see Event field format for event collection.

Event collection via MID Server
The MID Server facilitates communication and movement of data between external applications, data sources, services, and the ServiceNow instance.

</tbody>
</table>

Configure a MID Server for event collection using a push operation (listener)
The MID Server supports the collection of event messages, using the MID Web Server to collect data from external sources and transforming (parsing) them to the format required for event fields in the event (em_event) table. The transformed events are then transmitted to the instance.

Role required: evt_mgmt_admin

The MID Web Server extension enables external clients to push metric data and events to the MID Server. See Configure the MID Web Server extension. Use the MID WebService Event Collector to enable a URL method to push event messages to the MID Server. See Configure the MID WebService Event Collector Context.

Configure a MID Server with either EventManagement or All in the Supported Applications List.

To ensure uninterrupted services, consider also configuring a failover MID Server cluster.

1. Navigate to MID Server > Servers.
2. Double-click the MID Server that you want to configure, or click New to create a new MID Server.
3. In the Supported Applications section, click Edit.
   a) Click Edit.
   b) In the slushbucket, either select Event Management or ALL and click the > add button.
   c) Click Save.
4. Ensure that the MID Server is validated. Under Related Links, click Validate.
   For more information, see Validate a MID Server.
5. Click Update.

Configure the MID WebService Event Collector to enable a URL method to push event messages to the MID Server. For more information, see Configure the MID WebService Event Collector Context.

Event collection to MID Server using web service API

Configure the MID WebService Event Collector to provide a URL method to push event messages to the MID Server.

The MID WebService Event Collector, by default, enables you to connect to an event generator and send event messages through the MID Server, using a URL in the format: http://{MID_Server_IP}:{MID_Web_Server_Port}/api/mid/em/jsonv2

The JSON v2 format is the same as the format that clients use to send event messages to the instance. This URL provides good performance.

For more information, see Configure the MID WebService Event Collector Context.

Note: Event Management accepts events in the timezone of the MID Server through which the listener has sent the event message. If you require a different timezone, you can configure the script as required, see Configure listener transform scripts.

URL to push custom payloads

The MID Server can also receive a custom payload in JSON, XML, or plain text format. In this case, the MID Server transforms the event messages using the script include that you provide, and then sends the events to the instance. The URL in this case is:

http://{MID_Server_IP}:{MID_Web_Server_Port}/api/mid/em/inbound_event?
Transform={Transform_script_name} For an example of a script include, see the default TransformEvents_xmlSample script include.
For an example of how the MID WebService Event Collector transforms JSON formatted event messages, see Event collection from BMC TrueSight.

To send events in generic JSON format, you can use the URL in this format:

http://{MID_Server_IP}:{MID_Web_Server_Port}/api/mid/em/inbound_event?Transform=TransformEvents_MidJsonGeneric

In this case, the TransformEvents_MidJsonGeneric MID script include that is provided in the base instance transforms the event messages into the event fields. All fields are added as Additional Information fields into the ServiceNow event that is generated.

Note: The URL in the format http://{MID_Server_IP}:{MID_Web_Server_Port}/api/mid/em/{transform_script_name} is also supported.

Script include to transform collected events

Use the required MID Server script include to transform (parse) collected event messages and populate them into the mapped event field. The MID Server script include name is composed of a prefix and suffix. The prefix is the mandatory text TransformEvents_ and the suffix is the transform name on the URL, for example, http://{MID_Server_IP}:{MID_Web_Server_Port}/api/mid/em/xmlSample. The composed script name is therefore TransformEvents_xmlSample.

You must supply a script include that receives the event messages in a text variable. The script must have a transform() function that performs the transformation and prepares the return array of Event objects. When the Event Management plugin is activated, you are provided with the TransformEvents_xmlSample sample include script that transforms events from XML format.

Note: Event fields that are not identical to fields in the event table are saved in the Additional information field.

Event message headers

Specify the relevant request header value for the Content-Type field according to the format of the event message.

Request header values for the Content-Type

<table>
<thead>
<tr>
<th>Message format</th>
<th>Content-Type value</th>
</tr>
</thead>
<tbody>
<tr>
<td>JSON</td>
<td>application/json</td>
</tr>
<tr>
<td>XML</td>
<td>application/xml</td>
</tr>
<tr>
<td>text</td>
<td>text/plain</td>
</tr>
</tbody>
</table>

Authentication and data security options

Options for authentication and data security:

- **Authentication type**, which can be set to either Basic or the more advanced Keybased option.
- **Secure Connection**, which lets you choose whether incoming and outgoing data is secured when transmitted. If you choose the advanced secured option, it requires that you obtain a
Users must supply a script that receives the JSON, XML, or text formatted event messages in a text variable. The script must have a `transform()` function that performs the transformation and prepares the return array of event objects. The `TransformEvents_xmlSample` include script that transforms events from XML format is provided as an example when the Event Management plugin is activated.

For more information about authentication and data security, see [Configure the MID Web Server extension](#).

**Event collection to the instance using web service API**

You can use a web service interface, supported by ServiceNow, that operates on the JSON object as the data input and output format.

**Role required:** `evt_mgmt_integration`

To insert records in the event (`em_event`) table with a single call, use this web service API:

```
https://<instancename>.service-now.com/api/global/em/jsonv2
```

**Note:** Business rules on the event table are not invoked when this URL is used.

Do not add additional fields to an event by adding a custom field to the event table (`em_event`). However, additional fields should be included in the `Additional information` (`additional_info`) field of the event. For more information about how to include additional fields in events, see [Custom alert fields](#).

The URL in the format: `http://<instancename>.service-now.com/em_event.do?JSONv2&sysparm_action=insertMultiple` is also supported. However, the performance of the first URL is superior.

To work with the URL that ends with `=insertMultiple`, add the following properties, with their respective values, to the MID Server:

- `"mid.probe.event.queue.compress"` - value: `false`
- `"mid.probe.event.bulk_size"` - value: `100`
- `"mid.probe.event.endpoint.url"` - value: `em_event.do?JSONv2%26sysparm_action=insertMultiple`

1. Send the request with these headers:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>String</td>
<td>The acceptable type for this message.</td>

<td>The default value is <code>application/json</code>.</td>
</tr>
<tr>
<td>Content-Type</td>
<td>String</td>
<td>The content type for this message.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The default value is <code>application/json</code>.</td>
</tr>
<tr>
<td>POST</td>
<td>String</td>
<td>The request type is POST, with one or more trailing records.</td>
</tr>
</tbody>
</table>

2. One or more events in JSON format can be sent as the payload of the web service call. Event fields that should be populated are:
<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source</td>
<td>The name of the event source type. For example, SCOM or SolarWinds.</td>
</tr>
<tr>
<td>Source Instance (event_class)</td>
<td>Specific instance of the source. For example, SCOM 2012 on 10.20.30.40.</td>
</tr>
<tr>
<td>node</td>
<td>The <code>node</code> field should contain an identifier for the Host (Server/switch/Router/etc.) that the event was triggered for. The value of the <code>node</code> field can be one of the following identifiers of the Host:</td>
</tr>
<tr>
<td></td>
<td>· Name</td>
</tr>
<tr>
<td></td>
<td>· FQDN</td>
</tr>
<tr>
<td></td>
<td>· IP</td>
</tr>
<tr>
<td></td>
<td>· Mac Address</td>
</tr>
<tr>
<td></td>
<td>If it exists in the CMDB, this value is also used to bind the event to the corresponding ServiceNow CI.</td>
</tr>
<tr>
<td>resource</td>
<td>If the event refers to a device, such as, Disk, CPU, or Network Adapter, or to an application or service running on a Host, the name of the device or application must be populated in this field. For example, Disk C:\ or Nic 001 or Trade web application.</td>
</tr>
<tr>
<td>metric_name</td>
<td>Name of the metric that triggered the alert. For example, Used Memory or Total CPU utilization.</td>
</tr>
<tr>
<td>type</td>
<td>The type of event. This type might be similar to the <code>metric_name</code> field, but is used for general grouping of event types.</td>
</tr>
<tr>
<td>message_key</td>
<td>This value is used for de-duplication of events. For example, there might be two events for the same CI, where one event has CPU of 50% and the next event has CPU of 99%. Where both events must be mapped to the same ServiceNow alert, they should have the same message key. The field can be left empty, in which case the field value defaults to <code>source+node+type+resource+metric_name</code>. The <code>message_key</code> should be populated only when there is a better identifier than the default.</td>
</tr>
<tr>
<td>severity</td>
<td>Severity of the event. ServiceNow values for severity range from 1 – Critical to 5 – Info, with the severity of 0 – Clear. Original severity values should be sent as part of the additional information.</td>
</tr>
<tr>
<td>Variable</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>additional_info</td>
<td>This field is in JSON key/value format, and is meant to contain any information that might be of use to the user. It does not map to a pre-defined ServiceNow event field. Examples include IDs of objects in the event source, event priority (if it is not the same as severity), assignment group information, and so on. Values in the Additional information field of an Event that are not in JSON key/value format are normalized to JSON format when the event is processed.</td>
</tr>
<tr>
<td>time_of_event</td>
<td>Time when the event occurred on the event origin. The format is: yyyy-MM-dd HH:mm:ss GMT</td>
</tr>
<tr>
<td>resolution_state</td>
<td>Optional – To indicate that an event has been resolved or no longer occurring, some event monitors use ‘clear’ severity, while other event monitors use a ‘close’ value for severity. This field is used for those monitors proffering the latter. Valid values are New and Closing.</td>
</tr>
</tbody>
</table>

3. To create multiple records with a single call, trigger the event web service using the following URL, where the <instance name> variable is replaced with the name of the required instance:

https://<instancename>.service-now.com/api/global/em/jsonv2

Example showing the payload for two events that are sent in a single web service call:

```json
{
  "records": [
    {
      "source":"SCOM",
      "event_class":"SCOM 2012 on scom.server.com",
      "resource":"D:",
      "node":"name.of.node.com",
      "metric_name":"Percentage Logical Disk Free Space",
      "type":"Disk space",
      "severity":"4",
      "description":"The disk D: on computer V-W2K8-abc.abc.com is running out of disk space. The value that exceeded the threshold is 38% free space.",
      "additional_info":{
        'scom-severity':'Medium',
        'metric-value':'38',
        'os_type':'Windows.Server.2008'
      }
    },
    {
      "source":"SCOM",
      "event_class":"SCOM 2012 on scom.server.com",
      "resource":"MSSQL-database-name",
      "node":"other.node.com",
      "metric_name":"DB Allocated Size (MB)",
      "type":"Database Storage",
      "severity":"3",
      "description":"High number of active connections for MSSQL-database-name running on name.of.node.com. Active connections exceed 5000.",
      "additional_info":{
        'scom-severity':'High',
      }
    }
  ]
}
```
4. To create one record with a single call, trigger the event web service using the following URL, where the `<instancename>` variable is replaced with the name of the required instance:

http://<instancename>.service-now.com/api/global/em/jsonv2

**Note:** Use of this URL is limited as far as the rate of events it can support.

Example showing the payload for one event that is sent in a single web service call:

```json
{
  "records": [
    {
      "source": "SCOM",
      "event_class": "SCOM 2007 on scom.server.com",
      "resource": "C:",
      "node": "name.of.node.com",
      "metric_name": "Percentage Logical Disk Free Space",
      "type": "Disk space",
      "severity": "4",
      "description": "The disk C: on computer V-W2K8-dfg.dfg.com is running out of disk space. The value that exceeded the threshold is 41% free space.",
      "additional_info": {
        "scom-severity": "Medium",
        "metric-value": "41",
        "os_type": "Windows.Server.2008"
      }
    }
  ]
}
```

Configure the MID Web Server extension

The MID Web Server is an extension that enables external clients to push metric data and events to the MID Server. This extension is used to listen for raw metric data and external events and it provides options for authentication and data security. The raw data is collected by the MID Server and then transmitted to the instance.

If you plan to use Operational Intelligence data, then see Get started with Operational Intelligence for the high level steps of setting up Operational Intelligence.

Role required: evt_mgmt_admin

- Deploy and start a MID Server.
- Enable the MID Web Server (com.snc.sa.mid.webserver) plugin.
- Select the Enable REST Listener option in the Operational Intelligence Metrics Context. For more information, see Manually configure the Operational Intelligence extension.
- If the Secure Connection option is going to be selected, first obtain a server certificate. For more information, see Setup certificate for secure connection.

The MID Web Server extension runs for as long as it is enabled. The extension starts a web server on the MID Server to serve web requests from external systems. The raw data is pushed to the extension from a client or using customized script.
The configuration of the MID Web Server extension includes these settings:

- **Authentication type**, which can be set to the more advanced option - **Keybased**.
- **Secure Connection**, which lets you choose whether incoming and outgoing data is secured when transmitted. If you choose the advanced secured option, it requires that you obtain a certificate from a well-known certificate authority, and then provide the **Keystore Certificate Alias** and the **Keystore Password**.

1. Navigate to **MID Server > Extensions > MID Web Server**.
2. In the MID Web Server Contexts list, click **New**.
3. Fill in the fields, as appropriate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name for this MID Web Server collector for easy identification.</td>
</tr>
<tr>
<td>Short description</td>
<td>Enter a brief, meaningful description of this collector.</td>
</tr>
<tr>
<td>Status</td>
<td>This field is auto-populated with the status of the extension. The field is blank until the extension is started. After issuing a command to the extension, one of the following values is displayed:</td>
</tr>
<tr>
<td></td>
<td>- <strong>Started</strong>: The extension is running.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Stopped</strong>: The extension is not running.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Offline</strong>: The MID Server is down.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Error</strong>: The extension failed with an error (the error message is displayed in <strong>Error Message</strong>).</td>
</tr>
<tr>
<td></td>
<td>- <strong>Warning</strong>: A run-time exception has occurred. The extension continues to work.</td>
</tr>
<tr>
<td>HTTP/HTTPS Port</td>
<td>Port number on which you want to listen to incoming requests.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Authentication Type</td>
<td>Select one:&lt;br&gt;&lt;br&gt;&lt;strong&gt;Keybased&lt;/strong&gt;&lt;br&gt;- Create an authentication token that is sent with each request.&lt;br&gt;- Send this authentication token in the request header &lt;strong&gt;Authorization&lt;/strong&gt;.&lt;br&gt;&lt;br&gt;To create an authentication token:&lt;br&gt;1. Construct a string using defined elements of the HTTP/HTTPS request.&lt;br&gt;2. Create a Hash Message Authentication Code (HMAC) of the string, that is, sign the string generated in previous step with the auto-generated secret key. The key is unique per context.&lt;br&gt;&lt;br&gt;See example, <a href="#">Manually configure MID Web Server for metric data</a>.&lt;br&gt;&lt;br&gt;&lt;strong&gt;Note&lt;/strong&gt;: A valid timestamp (using the HTTP Date header) is required for the authenticated request. In addition, the timestamp must be within 15 minutes of the time on the MID Server.</td>
</tr>
<tr>
<td>Basic</td>
<td>- The user must provide a username and password. The same username and password must be provided for every request.&lt;br&gt;- On the instance, the password is stored encrypted and it is sent also to the MID Server encrypted.&lt;br&gt;- In the MID Server, the password is saved in memory.&lt;br&gt;- When the request is received, the password is decrypted and matched with the password provided in the request.</td>
</tr>
<tr>
<td>Secret Key</td>
<td>The value that is generated when keybased authentication is selected for the Authentication Type field.</td>
</tr>
<tr>
<td>Error Message</td>
<td>Message describing any error that causes a command, such as Start or Stop, to fail. This field only appears when the value in the Status field is Error.</td>
</tr>
<tr>
<td>Execute on</td>
<td>Location for running this extension. The available options are Specific MID Server or Specific MID Server Cluster.</td>
</tr>
</tbody>
</table>
### Field Description

**MID Server**

Depending on your selection in **Execute on**, the name of the designated MID Server, or MID Server cluster respectively:

- If you selected **Specific MID Server**, the name of the designated MID Server.
- If you selected **Specific MID Server Cluster**, the name of the designated MID Server cluster.

The MID Web Server extension supports MID Server clusters that are configured for failover. If you selected the MID Server cluster option, an algorithm determines which MID Server in the cluster runs the extension. The extension can run on only one MID Server. If the MID Server in the cluster that runs the MID Web Server extension goes down, the extension automatically starts to run on the secondary MID Server. The secondary is the MID Server that is up when the primary goes down.

**Note:** Ensure that in the Supported Applications section of the MID Server **ALL applications** is selected.

**Executing on**

The name of the MID Server on which the extension is running. This field shows the name of the MID Server even if the MID Server is down. If the user stops the extension, this field is empty.

### Commands in the MID Web Server form

<table>
<thead>
<tr>
<th>Related Link</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start</td>
<td>If it is not running, starts the MID Web Server.</td>
</tr>
<tr>
<td>Stop</td>
<td>Stops the MID Web Server. If the collector is not running, no action is taken.</td>
</tr>
<tr>
<td>Restart</td>
<td>Stops, then starts the MID Web Server.</td>
</tr>
<tr>
<td>Test parameters</td>
<td>The test is not relevant to the MID Web Server. Parameters are not tested or validated when <strong>Test</strong> is run.</td>
</tr>
</tbody>
</table>
For an example that describes how to prepare an authentication token, see [Manually configure MID Web Server for metric data](#).

Configure the MID WebService Event Collector Context

Configure the MID WebService Event Collector Context to provide a URL method to push event messages from an external source to the MID Server.

Role required: evt_mgmt_admin

The default format of the URL to push event messages from an external source to the MID Server is http://{MID_Server_IP}:{MID_Server_IP}:{MID_Web_Server_Port}/api/mid/em/jsonv2. This URL provides good performance.

From an external source, to push event messages that are not in jsonv2 format, the format of the URL is: http://{MID_Server_IP}:{MID_Web_Server_Port}/api/mid/em/inbound_event?Transform={Name_of_Transform_Script}, where the {Name_of_Transform_Script} variable is the full name of the script and always begins with the text: TransformEvents_.

For example, assume the following values:

- {MID_Server_IP}: 10.118.69.27
- {MID_Web_Server_Port}: 8097
- Transform script name: EventsToProcess

The URL to be used is therefore: http://10.118.69.27:8097/api/mid/em/inbound_event/TransformEvents_EventsToProcess

**Note:** The URL in the format http://{MID_Server_IP}:{MID_Web_Server_Port}/api/mid/em/{transform_script_name} is also supported.

**Note:** The date format for events is yyyy-M-d h:mm:ss.

If you receive an event whose date is in a different format, you must use a {transform_script_name} that is appropriate for the incoming event's date format. If you do not, the event will not be processed correctly.

For example, if an event arrives on June 27, 2019 at 11:25 AM with a listed date of 2019/06/27/11:25:00 a.m., use a {transform_script_name} with a date format of yyyy/MM/dd/ HH:mm:ss a to match the format of the received event.

2. In the MID WebService Event Collector Contexts list, click New.
3. On the form, fill in the fields.

### MID WebService Event Collector Context form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name for this collector for easy identification.</td>
</tr>
</tbody>
</table>
### Field | Description
--- | ---
Short description | Enter a brief, meaningful description of this collector.

MID Web Server Extension | Specify and then start the MID Web Server extension. The supported authentication methods are listed in the **Authentication Type** field of the MID Web Server extension. For information about how to configure a MID Web Server extension, see [Configure the MID Web Server](#).

Status | This field is auto-populated with the status of the MID Web Server extension. This field is blank until the MID Web Server extension is started. After issuing a command to the MID Web Server extension, one of the following values is displayed:
- **Started**: The collector is running.
- **Stopped**: The collector is not running.
- **Offline**: The MID Server is down.
- **Error**: The collector failed with an error (the error message is displayed in **Error Message**).
- **Warning**: A run-time exception has occurred.

Execute on | **Specific MID Server** or **Specific MID Server Cluster**, as defined on the specified MID Web Server extension.

MID Server | The **Specific MID Server** or **Specific MID Server Cluster**, as defined on the specified MID Web Server extension.

Executing on | The name of the MID Server on which the MID Web Server extension is running.

---

4. Right-click the form heading and click **Save**.
5. Under **Related Links**, click **Start** to start the collector.

### Commands in the Event Management Context form

<table>
<thead>
<tr>
<th>Related Link</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start</td>
<td>If it is not running, start the collector. This action verifies that a web service API endpoint with the Event Management application is running on the MID Server.</td>
</tr>
<tr>
<td>Stop</td>
<td>Stops the running collector on the configured MID Server. If the collector is not running, no action is taken.</td>
</tr>
<tr>
<td>Restart</td>
<td>Stops, then starts the collector on the configured MID Server.</td>
</tr>
</tbody>
</table>
Showing the use of the URL to transform JSON v2 formatted event messages

Assume that JSON v2 formatted event messages are sent to the MID Server. When using the `jsonv2` URL, there is no need to use a script include.

**Data for the JSON v2 example**

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>MID_Server_IP</td>
<td>10.218.64.27</td>
</tr>
<tr>
<td>MID_Web_Server_Extension_Port</td>
<td>8097</td>
</tr>
<tr>
<td>Event message format</td>
<td>jsonv2</td>
</tr>
</tbody>
</table>

Replace the variables in the default format of the URL `http://<my-instance>.service-now.com/api/global/em/jsonv2` with values from the preceding table:`http://10.218.64.27:8097/api/global/em/jsonv2`

**Example showing the URL to push messages not in jsonv2 format**

The format of the URL to push event messages from an external source that are not in jsonv2 format is `http://{MID_Server_IP}:{MID_Web_Server_Port}/api/mid/em/inbound_event/Transform={Name_of_Transform_Script}` where the `{Name_of_Transform_Script}` variable is the full name of the script and always begins with the text: TransformEvents_. The script name must be specified as the Transform header parameter and must always start with the prefix TransformEvents_.

For this example, assume that the script name is EventsToProcess, the URL is therefore:`http://10.138.64.27:8097/api/mid/em/inbound_event/TransformEvents_EventsToProcess`

**Example showing JSON v2 formatted event messages**

**Note:** When copying and pasting the text following, hidden characters might also be copied and can cause unexpected results.

```
```
Event collection from BMC TrueSight

The MID WebService Event Collector enables you to collect JSON formatted event messages sent from BMC TrueSight Operations Management (TrueSight), previously known as BMC ProactiveNet Performance Management (BPPM), utilizing event stream notification capabilities.

Ensure that you:

- Deploy and start the MID Server. See Configuring MID Servers.
- Configure and start the MID Web Server. See Configure the MID Web Server extension.
- Configure and start the MID WebService Event Collector. See Configure the MID WebService Event Collector Context.

Role required: evt_mgmt_admin

JSON formatted event messages are sent from BMC TrueSight. The MID Server transforms the collected event messages by parsing them using the TransformEvents_bmcTrueSight script include, located here: Event Management > Event Listener (Push) > Listener Transform Scripts. In the Listener Transform Scripts page, click TransformEvents_bmcTrueSight.

The default format of the URL to push event messages from BMC TrueSight to the MID Server is http://<MID_Server_IP>:<MID_Web_Server_Port>/api/mid/em/inbound_event?Transform=TransformEvents_bmcTrueSight.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MID_Server_IP</td>
<td>IP address of the MID Web Server Extension.</td>
</tr>
<tr>
<td>MID_Web_Server_Port</td>
<td>Listening port of the MID Web Server Extension.</td>
</tr>
<tr>
<td>MID_Web_Server_User</td>
<td>Username for the MID Web Server Extension.</td>
</tr>
<tr>
<td>MID_Web_Server_Password</td>
<td>Password of the user of the MID Web Server Extension. However, encode the password in BASE64. For example, if the MID Web Server Extension password is admin, in this case use YWRtaW4= as the password for MID_Web_Server_Password. To determine the BASE64 value, you can use the utility at this website: <a href="https://www.base64encode.org/">https://www.base64encode.org/</a></td>
</tr>
</tbody>
</table>
The following procedure describes the collection of JSON formatted event messages using basic authentication. For more information about supported authentication methods, see Configure the MID Web Server extension.

1. In BMC TrueSight, set the MID WebService Event Collector as the target for BMC TrueSight notification, using these parameters:

   **Variables in the generic BMC URL**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>serverHost</td>
<td>Name of the BMC TrueSight server.</td>
</tr>
<tr>
<td>port</td>
<td>Number of the BMC TrueSight port.</td>
</tr>
</tbody>
</table>

2. In the message body and generic BMC URL, replace the parameters with the values in the preceding table and connect to BMC TrueSight. Use the BMC Publish-Subscribe REST approach to create a stream event subscription and send event messages in JSON format. The generic format of the BMC URL to create a stream event subscription is:

   For example: http://TrueSight1server:40/bppmws/api/stream/subscribe?dataType=event.

**Example of mapping event messages to event fields in the Event (em_event) table**

<table>
<thead>
<tr>
<th>Event field</th>
<th>Event message</th>
</tr>
</thead>
<tbody>
<tr>
<td>node</td>
<td>mc_host</td>
</tr>
<tr>
<td>type</td>
<td>mc_object_class</td>
</tr>
<tr>
<td>metric_name</td>
<td>mc_parameter</td>
</tr>
<tr>
<td>resource</td>
<td>mc_object</td>
</tr>
<tr>
<td>severity</td>
<td>severity</td>
</tr>
<tr>
<td>time_of_event</td>
<td>date_reception</td>
</tr>
<tr>
<td>description</td>
<td>msg</td>
</tr>
</tbody>
</table>

**Example, showing the message body.**

```json
{
  action: 'create',
  data:
  {
    mc_abstracted: [],
    itsm_operational_category3: '',
    mc_object_class: 'CPU',
    source: 'MySource',
    adapter_host: '',
    itsm_operational_category2: '',
    itsm_location: '',
    itsm_operational_category1: '',
    mc_abstraction: [],
    mc_tool_id: '',
    mc_original_priority: 'PRIORITY_1',
    event_handle: '3172',
    mc_modhist: [],
    mc_tool_class: '',
    mc_origin: '',
  }
}
```
Event collection from custom payloads

The MID WebService Event Collector enables you to collect event information from custom payloads in JSON, XML, or plain text format.

Role required: evt_mgmt_admin

The MID Server transforms the collected event messages and populates the Event table fields (em_table) in the instance. The collection of formatted event messages is described in this procedure using basic authentication. For information about supported authentication methods, see Configure the MID Web Server extension.

The format of the required MID Server URL is: http://{MID_Server_IP}:{MID_Web_Server_Port}/api/mid/em/inbound_event?Transform={Transform_script_name}. The name of the MID Server script include is composed by appending a suffix to the default TransformEvents_ prefix. For information about the collection of JSON v2 event messages, see Configure the MID WebService Event Collector Context.

Note: The URL in the format http://{MID_Server_IP}:{MID_Web_Server_Port}/api/mid/em/{transform_script_name} is also supported.

1. Configure the MID WebService Event Collector, see Configure the MID WebService Event Collector Context.

2. Start the MID WebService Event Collector.

Transformation of XML formatted event messages using the custom payload URL

Assume that XML formatted event messages are sent to the MID Server. Use this example to return an array of event objects from the collected event messages. The name of the MID Server script include is composed by appending a suffix to the default TransformEvents_ prefix. For the purposes of this example, the user supplied the xmlSample script include. Using these details, the name of the MID Server script include is TransformEvents_xmlSample. The MID Server transforms
the collected event messages by parsing the messages using the script include and then transmitting them to the instance.

### Data for the XML example

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>MID_Server_IP</td>
<td>10.218.64.27</td>
</tr>
<tr>
<td>MID_Web_Server_Extension_Port</td>
<td>8097</td>
</tr>
<tr>
<td>transform_script_suffix_name</td>
<td>xmlSample</td>
</tr>
</tbody>
</table>

Replace the variables in the URL with the values from the above table:

```text
http://10.218.64.27:8097/api/mid/em/xmlSample
```

**Note:** When copying and pasting the text below, hidden characters might also be copied and can cause unexpected results.

**Example showing XML formatted event messages:**

```xml
<records>
  <event>
    <source>My Source</source>
    <node>host1</node>
    <type>type1</type>
    <severity>3</severity>
    <description>Virtual memory usage exceeds 98%</description>
  </event>
  <event>
    <source>My Source</source>
    <node>host2</node>
    <type>type2</type>
    <severity>2</severity>
    <description>Virtual memory usage exceeds 90%</description>
  </event>
</records>
```

### Event collection using script

You can create a scripted integration with Event Management to push external events from monitoring tools. You can use the cURL command-line tool to send one or more events to a ServiceNow instance.

For Mac, cURL is automatically available.

For Unix, Linux, or Windows, make sure that the cURL command-line tool is installed. You can download it at [http://curl.haxx.se/download.html](http://curl.haxx.se/download.html).

**Role required:** evt_mgmt_integration

For scripted integration, no configuration is required. If your monitoring tool is a supported event source, you can instead select a connector and configure an instance to pull events using a MID Server. In either case, the system uses a web service API to add events to the Event (em_event) table, see [Event collection to MID Server using web service API](#).

1. Use a text editor to create a shell (.sh) file with event records.

```bash
curl -v -H "Accept: application/json" -H "Content-Type: application/json"
-X POST --data "{
```

"records": [
    {
        "source": "Simulated",
        "node": "nameofnode",
        "type": "High Virtual Memory",
        "resource": "C:",
        "severity": "5",
        "description": "Virtual memory usage exceeds 98%",
        "ci_type": "cmdb_ci_app_server_tomcat",
        "additional_info": "{\"name\":\"My Airlines\"}\"
    },
    {
        "source": "Simulated",
        "node": "01.myairlines.com",
        "type": "High CPU Utilization",
        "resource": "D:",
        "severity": "5",
        "description": "CPU on 01.my.com at 60%"
    }
]
" -u myUserID:myPassword https://<my-instance>.service-now.com/api/
global/em/jsonv2

2. Use the -H option. For the POST parameter, start the data block with an open bracket and
   delimit the data with backslashes. For example:

   POST --data "({"records":[{"source": [. . .]}})"

   Header parameters for use with -H option

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>String</td>
<td>The acceptable type for this message. The default value is application/json.</td>
</tr>
<tr>
<td>Content-Type</td>
<td>String</td>
<td>The content type for this message. The default value is application/json.</td>
</tr>
<tr>
<td>POST</td>
<td>String</td>
<td>The request type is POST with one or more trailing records.</td>
</tr>
</tbody>
</table>

3. Use the -u option and the instance URL with login credentials. For example:

   -u myUserID:myPassword "https://<my-instance>.service-now.com/api/
global/em/jsonv2"

4. Test the scripted integration.

Configure listener transform scripts
Configure a push connector to connect to an external event source, using custom script that
processes the collected event messages and transforms it to the required event format. Select
to send events either through the MID Server or the instance, in each case using the URL of the
required format.

Role required: evt_mgmt_admin
The listener transform script accepts event messages that are generated by external event sources.

Configure the connector to listen to an external event source. Using custom listener transform script, send the event messages through either the MID Server or the instance.

**Note:** You can use this generic JSON target URL to collect events: https://<<INSTANCE>>/api/global/em/inbound_event?source=genericJson. This URL can be used as-is and requires an event rule to be configured.

1. Navigate to **Event Management > Event Listener (Push) > Listener Transform Scripts**.
2. Click **New** or click the listener transform script that you want to modify, for example, AWS or Azure.
3. Fill in the fields in the form, as needed.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name for this listener for easy identification.</td>
</tr>
<tr>
<td>Description</td>
<td>Enter a description for the use of the listener transform script.</td>
</tr>
<tr>
<td>Header name</td>
<td>Specify the name of the header that you want the value for, such as Set-Header.</td>
</tr>
<tr>
<td>Header value</td>
<td>The value of the header name that you want the value for, such as Set-Header.</td>
</tr>
<tr>
<td>Type</td>
<td>Select to send events either <strong>Instance</strong> or <strong>MID</strong>. In each case, use the URL of the selected type. See the description of the <strong>URL parameter value</strong> field.</td>
</tr>
<tr>
<td>Active</td>
<td>Select to enable pulling events from this external event source.</td>
</tr>
<tr>
<td>Order</td>
<td>Order in which an event rule is evaluated when multiple rules are defined for the same type of event. Event rules are evaluated in ascending order.</td>
</tr>
<tr>
<td>URL parameter value</td>
<td>• Send events to the instance.</td>
</tr>
<tr>
<td></td>
<td>Use the URL in this format for Azure: https://&lt;&lt;INSTANCE&gt;&gt;/api/global/em/inbound_event_azure. Use the URL in this format for all connectors, other than Azure: https://&lt;&lt;INSTANCE&gt;&gt;/api/global/em/inbound_event?source={URL_parameter_value}</td>
</tr>
<tr>
<td></td>
<td>• Send events through the MID Server.</td>
</tr>
<tr>
<td></td>
<td>Use the URL in the format: http://(MID_Server_IP):(MID_Web_Server_Port)/api/mid/em/inbound_event?Transform={Transform_script}</td>
</tr>
</tbody>
</table>

**Note:** Sending events to the MID Server requires the prior configuration of the MID WebService Event Listener extension.
4. In the **Script** section:
   - If the value selected for the **Type** field is **MID**, the **Transform script** field appears. In this field, specify or search for the name of the MID script include that accepts event messages that the required external event source generates and that the script parses into the required event format. Use this naming convention for the script: `TransformEvents_<your_source>`
   - If the value selected for the **Type** field is **Instance**, the **Script** editor appears. In the **Script** editor, enter the customized script that accepts event messages that the required external event source generates and that the script parses into the required event format.

Example, showing fields that have been transformed, being added to an event form.

```javascript
(function process(/*RESTAPIRequest*/ request, body) {
/*Function that receives a JSON object, adding all its fields to the Additional information object. The field name is a concatenation of the field key and the parent field key if it exists.*/
function updateAdditionalInfo(event, field,jsonObject,additionalInfo) {
    for (var key in jsonObject) {
        var newKey = key;
        if (field != "") {
            newKey = field + '_' + key;
        }
        // You can do some transformation here and set fields on the event
        //if(key == "MySource")
        //    event.source = jsonObject[key];
        additionalInfo[newKey] = jsonObject[key];
    }
}
try
{
    gs.info("TransformEvents_generic received body:" + body);
    var jsonObject = JSON.parse(body);
    var event = new GlideRecord('em_event');
    event.source = "GenericJson"; //TODO: Need to define
    event.event_class = "GenericJsonClass"; //TODO: Need to define
    event.severity = "5";

    var additionalInfo = {};
    updateAdditionalInfo(event, "",jsonObject,additionalInfo);
    /*Iterates over Additional information JSON object and adds all nested objects' fields as fields of the Additional information object*/
    var notDone = true;
    while (notDone) {
        notDone = false;
        for (var key in additionalInfo) {
            if (Object.prototype.toString.call(additionalInfo[key])
                == '[object Object]') {
                notDone = true;
                updateAdditionalInfo(event,
                key,additionalInfo[key],additionalInfo);
                additionalInfo[key] = "";
            }
        }
    }
    gs.info("TransformEvents_generic generated additional information:" +
    JSON.stringify(additionalInfo));
    event.additional_info = JSON.stringify(additionalInfo);
    event.insert();
}
catch(er){

}
Integrate AWS platform as a data source
Integrate Amazon Web Services (AWS) with Event Management. To add AWS platform as a data source, configuration is required in the AWS platform.

Role required: evt_mgmt_admin

When an AWS platform alarm arrives, Event Management:

- Extracts information from the original AWS platform alarm to populate required event fields and inserts the event into the database.
- Captures the content in the additional_info field.

The AWS platform transform script is located in Event Management > Event Listener (Push) > Listener Transform Scripts. In the Listener Transform Scripts page, click AWS Events Transform Script.

**Note:** The AWS transform script that is provided in the base system handles AWS CloudWatch alarms only. To handle Simple Notification Service (SNS) alarms that are other than AWS CloudWatch, create a new script or customise the AWS transform script.

1. In the AWS platform console, select Simple Notification Service. If an SNS topic does not exist, create a new one.
2. Under the SNS topic, create a new subscription.
   a) Take Topic ARN from the topic that you created. The Amazon Resource Name (ARN) is necessary for binding an Event Management alert to a CI.
   b) Set Protocol to: https.
   c) Set Endpoint to: https://<username>:<password>@<instance-name>.service-now.com/api/global/em/inbound_event?source=AWS.

   If AWS platform Multi-Factor Authentication (MFA) is enabled, when signing in to the AWS platform website, the user name and password are prompted for, as well as an authentication code from the AWS platform MFA device of the user.
3. Wait until the subscription changes from Pending to Confirmed and the subscription ARN is populated.
4. Create alarms in AWS platform to send to Event Management. Link the alarms to the SNS topic that you created.

These event rules are provided with the base system:
Integrate Azure platform as a data source
Integrate Microsoft Azure with Event Management. To add the Azure platform as a data source, configuration is required in the Azure platform.

Role required: evt_mgmt_admin and web_service_admin

The Event Management integration with Azure supports the Azure Classic Metric Alert format, also known as Insights Alerts. For this format, Event Management provides a dedicated listener, **Azure Events Transform Script**, see Dedicated listener. Several event rules for this format are provided with the base system, see Azure event rules provided with the base system. For information about how to receive events from other Azure formats, see Receive event from other Azure formats.

Activate the inbound event azure endpoint to enable receiving Azure platform alerts in Event Management, which works without security authentication:

1. Navigate to System Web Services > Scripted Web Services > Scripted Rest APIs.
2. Locate and click the Inbound Event script.
3. In the Resources area, click inbound event azure.
4. Select Active and then click Update.

**Dedicated listener**
Configure a dedicated listener that supports the Azure Classic Metric Alert format, as follows:

1. Open the Azure platform transform script, navigate to Event Management > Event Listener (Push) > Listener Transform Scripts.
2. In the Listener Transform Scripts page, click Azure Events Transform Script.

You can select to send Azure alerts either through the instance or the MID Server.

**Azure event rules**
Azure event rules provided with the base system are:

<table>
<thead>
<tr>
<th>Event rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Azure host binding</td>
<td>Bind Azure platform alerts, on either the host or VM, to the host Hardware CI.</td>
</tr>
<tr>
<td>Azure vm binding</td>
<td>Bind Azure platform alerts, on either the host or VM, to the Virtual Machine Instance CI. To enable this rule, first disable the Azure platform host binding rule.</td>
</tr>
<tr>
<td>Azure MSSQL binding</td>
<td>Bind Azure platform MSSQL alerts to the Cloud database CI.</td>
</tr>
<tr>
<td>Azure database binding</td>
<td>Bind Azure platform database alerts, other than MSSQL, for example, NoSQL and Redis, to the Cloud database CI.</td>
</tr>
<tr>
<td>Azure WS binding</td>
<td>Bind Azure platform Web Server alerts to Cloud WebServer CI.</td>
</tr>
</tbody>
</table>

When an Azure platform alert message arrives, Event Management:
- Extracts information from the original Azure platform alert message to populate required event fields and inserts the event into the database.
- Captures specified content in the additional_info field.

1. In the Azure platform portal, create alert rules using the Alerts (Preview) interface. The definition of an alert rule in Azure platform portal has these parts:
   - Target: Specific Azure platform resource that is to be monitored.
   - Criteria: Specific condition or logic that, when seen in Signal, should trigger action.
   - Action: Specific call sent to a receiver of a notification - email, SMS, Webhook, and so on.

2. In the Webhook column, specify the endpoint URL in the format: https://<instance-name>.service-now.com/api/global/em/inbound_event_azure. For example:

   ```
   Webhook
   
   https://mist2.service-now.com/api/global/em/inbound_event_azure
   ```

**Receive events from other Azure formats** Event Management can receive events from other Azure formats, such as Azure Activity Alert (also known as audit log), and Azure log Alert (also known as unified log). Use this generic JSON target URL to collect events from other Azure formats:https://<<INSTANCE>>/api/global/em/inbound_event?source=genericJson. This generic URL can be used as-is, and requires an event rule to be configured to populate the correct fields in the alert.

Example of the **Transform and Compose Alert Output** section of an event rule to show the configuration to receive an alert when receiving alert rules from Azure in the Azure Activity Alert format.
Integrate Panopta as a data source

Integrate the Panopta cloud-based monitoring solution with Event Management. To add Panopta as a data source, configuration is required in Panopta.
Configure Panopta

To prepare Panopta as a datasource, follow the procedure described in this link: How do I integrate with ServiceNow.

When the Event Management integration is configured in Panopta, add the integration to any of your Panopta Alert Timelines so that the ServiceNow instance receives incident events accordingly.

Optional Event Management configuration

Configure an alert action rule for launch in context of Panopta. For more information, see Launch web application from alert and Create or edit an alert action rule.

Integrate Datadog as a data source

To add Datadog as a data source, configuration is required, both in Event Management and in Datadog.

The configuration tasks to collect events and incidents from Datadog includes:

Event Management configuration tasks

Datadog components are made available to Event Management users by selecting menu items. The menu functions are imported into Event Management through an update set. Perform these tasks in Event Management:

- Add the Datadog menu components.
- Configure the transform tables.

Datadog configuration tasks

In Datadog, configure the integration with Event Management and specify the required target interim table. Perform these tasks in Datadog:

- Configure the Event Management integration.
- Add the required credentials.
- Add the details for the target interim table.
- Test the integration.

Configure Event Management to add Datadog as a data source

Integrate Datadog with Event Management to collect event and incidents.

Role required: evt_mgmt_admin

Configure the Event Management environment for the collection of events or incidents from Datadog by importing the required XML Update Set. Enable the Datadog functions to be installed and then selected from the Event Management navigation pane.

1. In your local hard drive, create a temporary directory.
2. Import the DataDog-ServiceNow integration files into the temporary directory from GitHub https://github.com/DataDog/Datadog-Servicenow
3. Create an update set from the files in the temporary directory.
   For information about the procedure to create an update set, see Create a data source.
5. Under Related Links, click Import Update Set from XML.
6. In the **Import XML** form, select the Datadog update set XML file that you created in step 3, and click **Upload**.

7. In the **Retrieved Update Sets** form, click **Datadog**.

8. Click **Preview Update Set**. Ensure that there are no errors, then click **Commit Update Set**.

9. Grant yourself the `x_datad_datadog.user` user role.
   a) Navigate to **System Security > Users and Groups > Roles**.
   b) Search for `*datadog`.

10. In the search field of the **Application Navigation** pane, enter `datadog`. The Datadog menu items appear.
• Configure the transform tables.
• Perform the Datadog configuration tasks.

*Create a custom push connector*
You can create a customized listener to push event information to the instance or MID Server.

Customize script to enable Event Management to receive external events. By using a script to collect events, no further configuration is required. All other methods of collecting events require configuration.

• To collect event messages in the instance via web service API, see Event collection to the instance using web service API.
• To collect event messages using a script, see Event collection using script.

*Configure event collection for SNMP traps*
The SNMP listener runs on the MID Server, which acts as a collection endpoint for SNMP traps. The MID Server sends the traps to the ServiceNow instance for further processing as an event by Event Management.

Role required: evt_mgmt_operator

Ensure that the MID Server is assigned with either EventManagement or ALL applications.
Use the **MID SNMP Trap Listener** to listen for SNMP traps. In this configuration, the specified MID Server acts as a collection endpoint for SNMP traps.

1. Navigate to **Event Management > Event Listener (Push) > MID SNMP Trap Listener**.
2. Click **New**.
3. Complete the SNMP Trap Collector Context form:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Unique name for the SNMP Trap Collector.</td>
</tr>
<tr>
<td>Short description</td>
<td>Short description of the MID Server extension execution context.</td>
</tr>
<tr>
<td>SNMP version</td>
<td>Specify the SNMP version:</td>
</tr>
<tr>
<td></td>
<td>- v1 and v2c</td>
</tr>
<tr>
<td></td>
<td>- v3</td>
</tr>
</tbody>
</table>

**Minimum Security Level**

The valid security level values are:

- None - No security level value set.
- noAuthnoPriv - Communication without authentication and privacy
- authNoPriv - Communication with authentication and without privacy.
- authPriv - Communication with authentication and privacy.

**Note:** This field appears only when v3 is selected in the **SNMP version** field.

<table>
<thead>
<tr>
<th>UDP Port</th>
<th>UDP port for SNMP Trap Collector to receive SNMP Traps. The default value is 1,162. However, if the port is already in use, you can use any other free port instead.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Status</th>
<th>The status of the trap listener. This field is blank until the listener is run. After the listener has run, the value is automatically populated to one of these statuses:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- <strong>Started</strong>: The listener is running.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Stopped</strong>: The listener is not running.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Offline</strong>: The MID Server is down.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Error</strong>: The listener failed with an error.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Execute on</th>
<th>The MID Server location for running this listener. Select from:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- Specific MID Server</td>
</tr>
<tr>
<td></td>
<td>- Specific MID Server Cluster</td>
</tr>
</tbody>
</table>

The recommended setting is **Specific MID Server**.

Network hardware typically has to be configured to send to a specific IP address. For example, if the listener is moved to a different MID Server in the cluster, the trap would not be received.
ServiceNow    New York    IT Operations Management

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MID Server</td>
<td>Specify:</td>
</tr>
<tr>
<td></td>
<td>- The name of the designated MID Server when you select Specific MID Server in the Execute on field.</td>
</tr>
<tr>
<td></td>
<td>- The name of the designated MID Server cluster when you select Specific MID Server Cluster in the Execute on field.</td>
</tr>
<tr>
<td></td>
<td>If you selected Specific MID Server Cluster, a ServiceNow algorithm determines which server in the cluster runs the listener.</td>
</tr>
</tbody>
</table>

| Executing on        | The name of the MID Server on which the extension is running. This field shows the name of the MID Server even if the MID Server is down. If you stop the extension, this field is empty. |
|                     | This field is automatically populated.                                                                                                       |

4. Right-click the form header and select Save.
5. In the Credentials for SNMPs section, specify the required SNMP v3 credentials that the SNMP listener uses for authentication.

**Note:** The Credentials for SNMPs section appears only when v3 is selected in the SNMP version field.

6. In the Related Links section, click Test parameters.
7. Click Update.
8. Optional: If the MID Server fails to start, review the MID Server log errors.

In Related Links, these actions may be run against the SNMP traps listener:

**Commands available in the SNMP trap listener form**

<table>
<thead>
<tr>
<th>Related Link</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start</td>
<td>If it is currently not running, starts the listener. The listener is started on the configured MID Server and port number.</td>
</tr>
<tr>
<td>Stop</td>
<td>Stops the running listener on the configured MID Server. If the listener is not running, no action is taken.</td>
</tr>
<tr>
<td>Restart</td>
<td>Stops, then starts the listener on the configured MID Server and port number.</td>
</tr>
<tr>
<td>Test parameters</td>
<td>Tests that the port is a valid number.</td>
</tr>
<tr>
<td>Update parameters</td>
<td>If you make changes to the listener configuration, use this option to update the parameters of the currently running listener. First, the parameters are tested for validity. If the parameters are valid, the listener disconnects and reconnects with the new parameters.</td>
</tr>
</tbody>
</table>

**Note:** Updates to the SNMP trap listener take effect only after Restart or Update parameters are clicked.

Configure the SNMP traps listener to receive OEM traps
Configure the SNMP trap listener to receive traps from Oracle Enterprise Manager (OEM).
Role required: evt_mgmt_admin

Event Management can process Oracle Enterprise Manager Cloud Control SNMP traps as events. For the SNMP trap listener to receive traps from OEM, you must designate the MID Server that runs the SNMP trap listener as a recipient of the trap. Upon receiving an OEM trap, the MID Server sends the trap to the ServiceNow instance for further processing as an event by Event Management.

The OEM 12c Trap event rule is provided with the default base instance, as well as these alert action rules:
- Oracle EM Launch Target Status
- Oracle EM Launch View Event

1. Navigate to **Event Management > Event Listener (Push) > MID SNMP Traps Listener**.
2. Click **New**.
3. Fill in the fields, as described in **Configure event collection for SNMP traps**. For the **SNMP version** field, select: v1 and v2c.
4. Click **Submit**.

In Oracle Enterprise Manager Cloud Control, configure the MID Server as a trap listener target.

Configure SNMP Trap collection for high availability
For SNMP traps, the MID Server requires failover configuration for the trap listener.

You can configure two MID Servers for failover. Because the SNMP Trap listener on the MID Server receives inbound traffic on the IP address and port of the MID Server, you configure each MID Server to receive the same SNMP traps. Only one MID Server is active at any point in time, therefore Event Management does not receive duplicate traps.

**Configure event collection from email**
Configure an inbound email action to send email notifications when events and alerts are triggered.

Role required: evt_mgmt_admin

When you add an inbound email action to send email, Event Management uses inbound email actions to process inbound email in the same manner as any external event. The email content is used to generate and update events, use rules to generate alerts, or change event severity. The severity is updated after the impact calculation and stored in the em_impact_status table.

1. Navigate to **System Properties > Email Properties**.
2. In the **Inbound Email Configuration** section, in the **Email receiving enabled** option, select **Yes** to enable the collection of events from email.
3. To configure the email information to pass to Event Management for event and alert processing, navigate to **System Policy > Email > Inbound Actions** and in the list of Inbound Email Actions records search for and open the default **create event** form.

   a) In the **Inbound Email Actions** form, specify these values.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active</td>
<td>Select the check box to enable the email notification.</td>
</tr>
<tr>
<td>Description</td>
<td>Type a description for this email message.</td>
</tr>
<tr>
<td>Target table</td>
<td>Select <strong>Event (em_event)</strong>.</td>
</tr>
<tr>
<td>Action type</td>
<td>Select <strong>Record Action</strong>.</td>
</tr>
</tbody>
</table>

   b) Click the **Actions** tab and select these **Field Actions**.
For example, you can select **Subject** as the portion of the email to use.

4. To customize the inbound parameters and map the text to event variables, add a **Script**. For example:

```javascript
current.source = 'email';
current.event_class = 'email';
current.description = email.body_text;
current.time_of_event = new GlideDateTime();
current.insert();
```

5. From the instance, send an email that contains matching data, and then confirm that the event or alert information appears in Event Management. For more information sending email messages to create an instance, see **Inbound email actions**.

**Note:** Ensure that the user who sends the email has the role **evt_mgmt_integration**.

6. Click **Submit**.

The inbound email is sent to the em_event table and regular Event Management processes continue, for example, event rules and alert management rules run.

**Manage and monitor alerts**

An alert is a notification generated by Event Management for selected events that are considered to be important and require attention. The generation of alerts is based on event rules.

After alerts generate, the manner in which you can monitor and resolve alerts is based on alert configuration settings and properties, and alert impact calculation.

**Contextual search in alerts**

Use contextual search to search for and attach a knowledge base (KB) article from within an alert.

**Role required:** **evt_mgmt_user**

In an alert, search for related KB articles to provide additional information about the alert. You can preview the text of the article and optionally attach the article to the alert.

The search query is based on the contents of the short description of the alert. This search query comprises the following fields from the alert:

- Node
- Type
- Resource
- Description

When performing a search for related articles, a list of articles appears below the related search field. You can preview an article. If relevant, attach the KB article to the alert.

1. Navigate to **Event Management > All Alerts**.
2. In the Alerts list, select an alert.
3. In the alert form, click **Related Search Results**.
4. Review the list of suggested knowledge articles, and:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Preview the article</td>
<td>Click Preview next to the article. After reviewing the article in the pop-up window, click Attach to Alert if it is relevant, or click (X) to close the article.</td>
</tr>
<tr>
<td>Attach the article without previewing it</td>
<td>Click Attach next to the article.</td>
</tr>
</tbody>
</table>

When you attach an article, a URL to the KB article is added to the Work Notes field of the alert. Save the alert to keep the changes.

If performing a search for related articles and the short description of the alert is blank and when you need to search according to your own keywords:

- You can enter your search query in the Related Search text box.
- Click Related Search Results.

5. Review the list of suggested knowledge articles, as in step 4.

6. Click Update.

**Alert management rules for resolving alerts**

Configure Event Management to automatically respond to alerts. Create alert management rules to determine the required response, which might be to open an incident, knowledge base, open any kind of task, launch remediation action, and so on.

Alert management rules that are provided with the base system are available to assist you to respond to alerts. Use filters to specify conditions. The alert management rule takes the remedial action that is specified when the conditions are met. For example, to launch the required subflow or open an incident based on an alert. The alert is automatically updated to show the execution history, showing what actions were taken.

Users with the evt_mgmt_admin role can use the alert management rule designer to create and configure alert management rules that can act on the specified alerts. Define rules with complex filters to determine which alert the rule must apply to. Create rules to launch applications, URLs, subflows, remediation actions, or take other actions, for example, open an incident. For more information, see [Create an alert management rule](#).

Users with the evt_mgmt_operator role can manually run alert management rules.

**Alert management rule workflow**

The workflow to create and run an alert management rule is described in the following steps.
1. Create an alert management rule to respond to the alerts that you specify.
2. Configure a filter for the rule, to ensure that the rule applies only to those alerts that match the filter.
3. Configure the actions to be taken to resolve the alert.

Components of alert management rules

The components of an alert management rule are:

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alert Info</td>
<td>Create the rule.</td>
</tr>
<tr>
<td>Alert Filter</td>
<td>Specify a filter to determine to which alerts this rule must be applied to. Related list conditions can be specified.</td>
</tr>
<tr>
<td>Actions</td>
<td>Specify the response to the alert, for example, run a subflow, perform remediation action, launch an application, or launch a URL in a browser.</td>
</tr>
</tbody>
</table>

How rules are applied to updated alerts

Alert management rules run on all open alerts that have been updated. Rules do not run on closed alerts, even if they have been updated. Whether the actions that are configured in the rule are applied to the alert, depends on the conditional filters of the rule. For example, assume that a rule has a condition that an email message is sent when the severity of an alert changes to Major. This rule applies to an alert updated by a severity change from Warning to Major.

Use of filters and other actions

Create a filter so that the rule does not act on every update of the alert, only when the condition that you set occurs. For example, an entry in the Work notes field of an open alert is an update, but you can configure the rule so that updates that are not relevant do not cause the rule to run. Configure alert management rules to run only when the update is significant to the rule. Another example is to set a condition so that the alert management rule runs only when the alert severity is Critical.

You can:

- Specify a filter to determine which alerts the rule applies to.
- In the Related List Conditions section, configure further conditions, for example, with an Alert > Parent relationship, to filter for any alerts that were received today.
- Respond to alerts. For example, by using subflows and workflows, create incidents for primary alerts with critical severity, or open a search engine in a browser to search for data according to the description field of the alert.
- Apply remediation. Remediation is based on Orchestration workflows that can be scripted to perform remediation tasks such as gathering system information or rebooting a server.
Scheduled job that checks alert management rules

Alert management rules are checked every 11 seconds by the default Event Management - Evaluate Alert Management Rules scheduled job. The job then executes the required actions.

Migrate existing alert action rules

Existing alert action rules from an earlier release can be migrated to become alert management rules. Only after migrating an alert action rule to an alert management rule, can the rule be modified. For more information, see Migrate an alert action rule to an alert management rule. Create an alert management rule

Create an alert management rule to track alerts and resolve them by determining the required response, for example, to open an incident, or launch remediation action.

To enable remediation with a subflow, you can use a subflow that is available with the base system, or you can create your own subflow. To create a custom subflow, navigate to Flow Designer > Designer. In the Flow Designer window, click Subflows. Click Alert Management Template. The template opens in Flow Designer in read-only format. Click the more actions icon and select Copy subflow. In the New Subflow Name field, enter the name of the new subflow. If you want to limit the application scope of the subflow, in the Application field select the required application. Click Copy. In the Flow Designer editor, you can specify values for the fields, add actions, flow logic, and subflows. For example, click Action, select Alert Management Content and then select Update Execution With Task. Continue by entering information in the required fields and then click Done. To save the subflow in draft status, click Save. To save and publish the subflow so that it can be used in the alert management rule designer, click Publish. For more information about using Flow Designer, see Create a subflow.

To enable remediation with a workflow, create the workflow to remediate alerts.

Navigate to Workflow > Workflow Editor. In the Welcome tab of the Workflow Editor, click New Workflow. In the Table field, select Remediation Task (em_remediation_task).

After you finish configuring the workflow, make sure that you publish it. For information about creating a workflow, see Create a workflow.

Role required: evt_mgmt_admin

Use alert management rules to track and resolve alerts.

While working in the alert management rule designer, you can work in multiple sections without losing information in any section.
Create alert management rules that:
- Locate other alert management rules that have relevance to the selected alert.
- Determine when the execution of the rule takes place.

You can configure alert management rules to:
- Automatically generate and link incidents, tasks, or knowledge articles to alerts.
- Automatically apply a remediation workflow or enable users to manually run remediation.
- Automatically construct a URL that is created according to the value of specified fields in the alert.

To assist you, several alert management rules are provided with the base system. You can use them as presented or you can use them as examples to build custom alert management rules.

### Alert management rules provided with the base system

<table>
<thead>
<tr>
<th>Rule</th>
<th>Description</th>
<th>Active</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open sensor dashboard in PRTG</td>
<td>The sensor dashboard in the Paessler PRTG Network Monitor (PRTG) application opens.</td>
<td>Yes</td>
</tr>
</tbody>
</table>
| Oracle EM Launch Target Status and View Events | Launch Oracle Enterprise Manager to view:  
  - Target Status  
  - Event for alerts from source Oracle EM | Yes    |
| Drilldown to OMI                          | Drill down to the HP Operations Manager i (OMI) application.                 | Yes    |
| Create Incident on Primary Critical Alert | Create an incident for primary critical alerts. The incident can be created automatically or manually. | No     |
| Search Google for "description"          | Open Google Search in a browser to search for data according to the description that appears in the alert. | Yes    |
| Create Incident                          | Create an incident for all alerts that are not in maintenance state. The rule runs automatically on selective update. | No     |
| Create Incident Manually                  | Manually create an incident for alerts that are not in maintenance state.    | Yes    |
| Create Major Incident Candidate           | Create a major incident candidate for all alerts that are not in maintenance state and are not secondary alerts.  
  A major incident candidate can be promoted to become a major incident. | No     |
| Create Major Incident                     | Create a major incident for all alerts that are not in maintenance state and are not secondary alerts. | No     |

If your instance was upgraded from Kingston, the alert action rules that were provided with the Kingston base system are available to you. However, if you modified any of the rules, the changes made are not carried over.

1. **Navigate to** **Event Management > Rules > Alert Management.**
2. **Click** **New.**
3. On the form, fill in the fields.

**Alert Management Rule form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Unique name for the rule.</td>
</tr>
<tr>
<td>Active</td>
<td>Check box for enabling the rule.</td>
</tr>
<tr>
<td></td>
<td>If this check box is selected, you must specify:</td>
</tr>
<tr>
<td></td>
<td>- in the Alert Filter section, an alert filter</td>
</tr>
<tr>
<td></td>
<td>- in the Actions section, at least one of any of these actions:</td>
</tr>
<tr>
<td></td>
<td>- active subflow</td>
</tr>
<tr>
<td></td>
<td>- workflow</td>
</tr>
<tr>
<td></td>
<td>- quick response</td>
</tr>
<tr>
<td>Order</td>
<td>Order in which rules are evaluated when multiple rules are defined for the same alert. Alert management rules are evaluated in ascending order. The default value is 100.</td>
</tr>
<tr>
<td>Multiple alert rules</td>
<td>Instruction about whether to search for additional rules:</td>
</tr>
<tr>
<td></td>
<td>- Search for additional rules--execute the current rule then continue and execute other matching rules by the order of rule priority, where the lower number has the higher priority.</td>
</tr>
<tr>
<td></td>
<td>- Stop search for additional rules--execute only the current rule for the alert that matches the defined filter.</td>
</tr>
<tr>
<td>Description</td>
<td>Descriptive text to describe the rule.</td>
</tr>
</tbody>
</table>

4. Click **Alert Filter** and specify conditions for alerts that this rule is applied to.

5. On the form, fill in the fields.

**Alert Filter stage**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rule is activated when</td>
<td>Rule execution takes place when:</td>
</tr>
<tr>
<td></td>
<td>- <strong>Alert changes to filter</strong>—content changes to the alert cause the alert to match the filter. If the filter is matched on following update of the alert, the rule is not applied. If the alert was closed and then reopen, at the next update of the alert and the filter is matched, the rule is applied. Thereafter, when there is an update of the alert, the rule is no longer applied.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Alert matches filter</strong>—the content of the alert matches the filter. On following update of the alert and if the filter is matched, the rule runs and is applied to the alert. The rule remains applied for every matching update.</td>
</tr>
<tr>
<td>Alert filter</td>
<td></td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Preview</td>
<td>Function to preview alerts that match the specified condition. A hyperlink shows how many alerts match the filter.</td>
</tr>
<tr>
<td></td>
<td><img src="image" alt="Preview" /> <strong>13 records match condition</strong></td>
</tr>
<tr>
<td></td>
<td>If you click the hyperlink, the browser opens another tab that lists alerts in the Alerts (em_alert_list) table. The list shows which alerts match the rule, including closed alerts. Alerts that have already been run by the rule are not marked in any way. You can click any alert to view further details.</td>
</tr>
<tr>
<td>Conditions</td>
<td>Conditions that, if fulfilled, cause the filter to be applied. For more information about building conditions, see <a href="#">Using the condition builder</a>.</td>
</tr>
<tr>
<td></td>
<td>To add another condition, click <strong>New Criteria</strong>.</td>
</tr>
</tbody>
</table>
| Related List Conditions | Conditions to include a relationship with another table in the filter.  
1. Click **Table** and select the required table.  
2. Specify the conditions for this filter.  
For more information about creating related lists, see [Add related list conditions](#).                                               |

### 6. Click Actions.

In this section, you can configure these action types as a response to alerts or to remediate alerts:

- Remediation Subflows—Execute a subflow provided with the base system.
- Remediation Workflows—Execute a workflow that you previously published.
- Launch Applications—Open applications and browsers that you configure.

### 7. Optional: In the Remediation Subflows area, to add subflows:

a) Under **Subflow**, double-click the cell.

b) Click the search icon ![search icon](image).  
The list of subflows provided with the base system appears. For more information, see [Event Management subflows provided](#).  

c) From the subflow list, select a subflow.

d) Repeat, adding as many subflows as required.
e) If you want to specify when the subflow must be executed, under **Execution**, double-click the cell.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Automatic</td>
<td>The subflow is executed automatically when the rule is matched.</td>
</tr>
<tr>
<td>Manual</td>
<td>Execute the subflow if required when the rule is matched.</td>
</tr>
<tr>
<td>Both</td>
<td>When the rule is matched, the subflow is executed automatically and you can optionally execute the subflow again manually.</td>
</tr>
</tbody>
</table>

f) Under **Automatic executions limit**, double-click the cell and enter the required integer. Use this field to configure how many times the subflow is executed.

g) If you want to enable the subflow to be executed, under **Active**, double-click the cell and select `true`.

A link in the cell under **Link to Flow Designer** appears only after a subflow has been selected and the rule has been saved.

### Link to Flow Designer

`/flow-designer.do?sysparm_nostack=true#/sub-flow-designer/b1e21924937b0300415c74`
### Workflow execution options

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Automatic</td>
<td>The subflow is executed when the rule is matched.</td>
</tr>
<tr>
<td>Manual</td>
<td>When to execute the subflow when the rule is matched. For example, you can run the remediation from the <strong>Quick Response</strong> option. For more information, see <a href="#">Apply a quick response in an alert</a>.</td>
</tr>
<tr>
<td>Both</td>
<td>When the rule is matched, the subflow is executed automatically and you can optionally execute the subflow again manually.</td>
</tr>
</tbody>
</table>

- **e)** Optional: Double-click the cell under **Automatic executions limit** and enter the required integer.
  
  Use the **Automatic executions limit** field to configure how many times the workflow is executed. This value sets the maximum number of executions of the workflow as long as the alert is open. The counter is reset when the alert is closed.

- **f)** Optional: To enable the workflow to be executed, double-click the cell under **Active** and select true.
  
  For information about how to create a workflow, see [Create a workflow](#).

9. To add instructions to launch applications or to open browser windows, in the **Launch Applications** area:

   Any URL-based action can utilize the alert parameters and the URLs can refer to wikis, messaging services, REST APIs, and so on.

   - **a)** Under **Display Name**, double-click the cell.
     
     Specify a name for the link.

   - **b)** In the **URL** field, compose the URL using data from the alert in the format: `http://{source}.com:{port}/${cmdb_ci.name}

     The **Active** field is automatically updated.

10. Click **Submit**.

The alert management rule that was created is added to the list of available rules that can be used to resolve alerts.

**Event Management subflows provided**

In the Remediation Subflows area of alert management rules, the subflows provided with the base system are available.

**Subflows available**

Navigate to **Event Management > Rules > Alert Management** and click **New**. Click the **Actions** tab. In the Remediation Subflows area, double-click the **Insert a new row** field.
Click the search icon to add subflows. The list of subflows that are provided with the base system appears.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Acknowledge Alert</td>
<td>Subflow to mark the alert as being Acknowledged. Acknowledge an alert to show that further attention is required.</td>
</tr>
<tr>
<td>Attach Knowledge Article (legacy)</td>
<td>Subflow to attach a knowledge article to the alert. This subflow is provided for instances that are migrated from legacy releases (prior to the London release).</td>
</tr>
<tr>
<td>Change Alert to Maintenance Mode</td>
<td>Subflow to mark the alert as being in Maintenance.</td>
</tr>
<tr>
<td>Close Alert</td>
<td>Subflow to mark the alert as being Closed.</td>
</tr>
<tr>
<td>Create Incident</td>
<td>Subflow to create an incident. Fields from the alert are used to populate the matching fields in the incident that is created.</td>
</tr>
<tr>
<td>Create Major Incident Candidate</td>
<td>Subflow to create a major incident candidate. Fields from the alert populate the matching fields in the major incident candidate that is created. A major incident candidate can be upgraded to become a major incident.</td>
</tr>
</tbody>
</table>

**Note:** Add the Knowledge article column to the Alert Management Rules (em_alert_management_rule) table, and select an article to attach to an alert when the rule executes.

**Note:**
- If there is an existing incident that is attached to the alert, this subflow is not activated.
- If the alert is in Maintenance, an incident is not created.

**Note:**
- If there is an existing incident that is attached to the alert, this subflow is not activated.
- If the alert is in Maintenance, a major incident candidate is not created.
- If the Role in group is Secondary, the major incident candidate is not created.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Major Incident from Alert</td>
<td>Subflow to create a major incident from alert. Fields from the alert are used to populate the matching fields in the major incident that is created. Note: If there is an existing incident that is attached to the alert, this subflow is not activated. If the alert is in Maintenance, an incident is not created. If the Role in group is Secondary, the major incident candidate is not created.</td>
</tr>
<tr>
<td>Create Task (legacy)</td>
<td>This subflow uses a task template, if provided, or the EventMgmtCustomIncidentPopulator script for instances migrated from legacy releases (prior to the London release). If configured, apply the task template. Note: Add the Task template column to the Alert Management Rules (em_alert_management_rule) table, and select a task template and task to apply when the rule executes.</td>
</tr>
<tr>
<td>Overwrite Alert Template (legacy)</td>
<td>This subflow applies the alert template. This subflow is provided for instances that are migrated from legacy releases (prior to the London release). Note: Add the Task type column to the Alert Management Rules (em_alert_management_rule) table, and select an alert template to apply when the rule executes.</td>
</tr>
</tbody>
</table>

1. Select the subflow that you need.
2. To customize a subflow, see Create a custom subflow. This topic also describes the input parameters in a subflow.
3. To specify when the workflow must be executed, double-click the cell under Execution.
Create a custom subflow
You can create a subflow according to your requirements. You can then use the custom subflow to resolve alerts.

Role required: evt_mgmt_admin

Copy an existing subflow, and then customize it. Publish the custom subflow so that it is available to be used to resolve any alert. For more information, see Create a subflow.

Note: If your ServiceNow instance uses domain separation, you must ensure that the new custom subflow that you created operates only on the data of the designated domain.

For the purposes of explanation, the Create Incident subflow is used. For more information about how to customize a subflow, see this Knowledge Base article KB0722376.

1. Navigate to Flow Designer > Designer.
2. In the Flow Designer window, click Subflows.
3. Click Create Incident.

The Create Incident subflow opens in Flow Designer in read-only format. The inputs in the Create Incident subflow are described in the following table.

Create Incident input parameters

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>alertRuleName</td>
<td>The name of the alert management rule that specifies this subflow, for example IDD.</td>
</tr>
<tr>
<td>alertRuleId</td>
<td>The sys_id of the alert management rule, for example, 1ae122e84f5f1300b28392918110c71e.</td>
</tr>
<tr>
<td>alertGR</td>
<td>The alert record that matches the filter that is defined in the alert management rule, for example, Alert0027931</td>
</tr>
<tr>
<td>executionId</td>
<td>The ID of the execution to be retrieved, for example, 000182ebdb66630091187f1daf9619d4</td>
</tr>
<tr>
<td>userName</td>
<td>The current user’s name, for example, System Administrator</td>
</tr>
<tr>
<td>userDisplayName</td>
<td>The name that the current user specified to be displayed, for example, admin</td>
</tr>
</tbody>
</table>

For example, in an alert management rule that has processed alerts, in the Alert Executions area, click the Link to execution of the required alert.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
The Flow Designer opens. Click **Subflow Inputs and Outputs**. The input variable names of the subflow are displayed with their respective values.

![Subflow Inputs and Outputs](image)

<table>
<thead>
<tr>
<th>VARIABLE NAME</th>
<th>TYPE</th>
<th>RUNTIME VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>alertGR</td>
<td>Reference</td>
<td>Alert0027931</td>
</tr>
<tr>
<td>alertRuleId</td>
<td>String</td>
<td>1ae122e84f5f13</td>
</tr>
<tr>
<td>alertRuleName</td>
<td>String</td>
<td>IDD</td>
</tr>
<tr>
<td>executionId</td>
<td>String</td>
<td>000182ebdb666</td>
</tr>
<tr>
<td>userDispName</td>
<td>String</td>
<td>System Admin</td>
</tr>
<tr>
<td>userName</td>
<td>String</td>
<td>admin</td>
</tr>
</tbody>
</table>

4. In the subflow header, click more actions and select **Copy subflow**.

5. In the **New Subflow Name** field, enter the name of the new subflow.

6. To limit the application scope of the subflow, in the **Application** field, select the required application, otherwise select **Global**.

7. Click **Copy**.

The new subflow is created and is opened as a tab in the subflow designer editor. The inputs provided by the template appear.

In the editor, you can delete subflow inputs or outputs, as required.

8. To delete an input, click ![Trash Can](image).

9. To add an input, click ![Plus Sign](image).

A variable is added to the custom subflow.

a) Double-click the variable to give it a recognizable name, for example, `alertDescription`.

b) In the **Type** column, select the type variable that is being defined, for example, `String`.

c) To make the input a mandatory configuration option, select the **Mandatory** flag.

d) Click ![Down Arrow](image) to view the advanced options and define values.
Inputs provide advanced options based on their data type. All inputs have advanced options to add a hint or provide a default value. Use advanced options to guide flow designers through adding and configuring a subflow to a flow. For example, create a choice input to provide flow designers with a pre-defined list of configuration options to choose from. For more information about the configuration options available to particular data types, see field types.

10. Create subflow outputs by defining the names and data types.
   a) Click \( + \) to add output.
   b) Define the name and the data type.

11. To save the subflow in draft status, click Save.
12. To save and publish the subflow so that it can be used in the alert management rule designer, click Publish.

Include the modified subflow in an alert management rule to resolve alerts according to your customized requirements.

**Alert Executions Information**
Alert executions information provides a reference to the alert management rule actions that are performed. This information appears in the Alert Management Rule record only if an alert matches the filter in the rule and an action was performed. You can click any link in the Alert Executions list to open the referenced item.

**Alert Executions**
In the Alert Management Rule record, the Alert Executions list shows key related records for the rule. Among the

### Alert Executions list

- Alert0010009 Create Incident
  - \( /\text{flow-designer.do?sysparm_nostack=true#/operations/...} \)
- Alert0010008 Create Incident
  - \( /\text{flow-designer.do?sysparm_nostack=true#/operations/...} \)
Information in the Alert Executions list

The columns in the Alert Executions list are populated with details of the alerts that matched the alert management rule and the actions that were run. The alerts shown are the alerts that match the filter in the rule.

View alert execution information
You can click any link in the Alert Executions list to view the alert execution information of the referenced item. This information appears in the Alert Management Rule record only after an alert matched the filter in the rule and an action was performed.

Role required: evt_mgmt_admin
Among the information shown in the Alert Executions list is:

- The list of alerts that matched the filter of the rule.
- The tasks, including incidents, that were opened.
- Which remediation workflows ran and which subflows ran.

2. In the Alert Management Rules list, click the required rule.

If an alert matched the filter in the rule and an action was performed, the Alert Executions list displays in the Alert Management Rules record. This list is displayed irrespective of which stage of the alert management rule has been selected.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alert</td>
<td>Alert number of the alerts that matched this alert management rule.</td>
</tr>
<tr>
<td>Action name</td>
<td>Name of the action that was taken to resolve the alert (subflow or workflow).</td>
</tr>
<tr>
<td>Link to execution</td>
<td>Link to the action execution log that was created when the action was performed.</td>
</tr>
<tr>
<td>Related task</td>
<td>Link to the task that was created when the alert was resolved. For example, if the action for a rule is to create an incident, this field provides the incident number with a link to open the incident. A link is provided to the workflow remediation task that is created to monitor the remediation.</td>
</tr>
<tr>
<td>Log</td>
<td>Notice or information showing the result of the execution action, for example, how executions took place, &quot;1 out of 2 executions.&quot; This information does not indicate that the subflow was executed successfully, rather that the call to that subflow was successful and that the subflow is correctly configured.</td>
</tr>
<tr>
<td>Automatic run</td>
<td>Indication of how the action ran: automatically (true) or manually (false).</td>
</tr>
<tr>
<td>Created</td>
<td>Date and time that the entry was created.</td>
</tr>
</tbody>
</table>
Migrate an alert action rule to an alert management rule

Existing alert action rules from an earlier release can be executed, but cannot be modified. Alert action rules that have been migrated become alert management rules and all the definitions of the alert action rules are migrated to the alert management rule format. Migrated rules can be modified.

Role required: evt_mgmt_admin

Existing alert action rules are active, read-only rules. An alert action rule can be modified only after it is migrated to an alert management rule.

2. Select an alert action rule to migrate or delete.

3. Click Migrate.
   
   If you clicked Migrate, the list of migrated rules can be found, together with new alert management rules, by navigating to Event Management > Rules > Alert Management.

   After a successful migration, all the definitions of the alert action rules are migrated to the alert management rule format.

   When an alert action rule has been migrated successfully, the alert action rule can no longer be modified. However, the new alert management rule can be modified.

   If the alert action rule that was migrated had a task template, you can customize the alert management rule designer to display the task template name.

   1. In the header of the alert management rule, click Additional actions.
2. Select Configure > Form Layout.
3. In the **Available** pane, select **Task template** and move it to the **Selected** pane. Position it as required.

4. In the **Task template** field, select the required template.

5. In the Actions tab, in the Remediation Subflows area, select the Create Task (legacy) subflow to run the task template.

---

### Alert lifecycle configuration

Event Management provides various modules, templates, and properties for configuring alerts and the actions that execute for these alerts.

**Configure the alert active interval**

The active interval property determines how Event Management handles a new event that is similar to events that appear on an existing alert. Based on the active interval, event, and existing alert information, the event information is added to either the existing alert or a new alert.

Role required: evt_mgmt_admin

When the new event is received, Event Management compares the active interval time to the elapsed time between the **Time of event** and **Initial event time** field values on the alert. Then either the existing alert is updated or a new alert is created, as explained in the following table.

<table>
<thead>
<tr>
<th>Scenario</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>The new event occurs before the active interval elapses for the existing alert.</td>
<td>The alert is updated with the event information. The event is identified as a recurrence of an existing issue and its severity is copied to the alert. If the alert was closed before the active interval elapses, the alert is reopened and updated with the event information.</td>
</tr>
<tr>
<td>The new event occurs after the active interval elapses for the existing alert.</td>
<td>A new alert is created because the event is identified as a new issue. The event information is added to the new alert.</td>
</tr>
</tbody>
</table>

Change the active interval by editing the **Active interval (in seconds)**, within which a new event **reopens a closed alert** property value.

1. Navigate to **Event Management > Settings > Properties**.
2. Change the number of seconds for the **Active interval (in seconds)**, within which a new event reopening a closed alert property.

3. Click **Save**.

**Configure alert flapping**

You can set flapping properties to determine when an alert enters and exits the flapping state.

Role required: evt_mgmt_admin

Flapping condition that occurs when the event source continues to generate events even after its associated alert has been closed. Flapping causes the status of the resource to repeatedly fluctuate between an **Info** Severity and another severity that requires attention, for example, **Critical**.

An alert enters the flapping state when its current **Flap Count** value reaches or exceeds the given **evt_mgmt.flap_frequency** property value within the time period specified by the **evt_mgmt.flap_interval** property.

An alert exits the flapping state when the time interval between the latest occurrence of the event and the **Flap last update time** of the alert reaches or exceeds the **evt_mgmt.flap_quiet_interval** property value. An alert can also exit flapping in these conditions:

- When an incoming event arrives after the **flap_quiet_interval** time has elapsed. The new alert generates and its state value depends on the incoming event severity.
- After a background job, which runs every five minutes, verifies that no alert updates occurred and the **flap_quiet_interval** time has elapsed. If there are no updates, the alert shows the previous state value that it had before the background job ran.

1. Navigate to **Event Management > Settings > Properties**.

2. Edit the following properties, as appropriate.
   
   - **Minimum time in seconds before updating an alert for identical events**
     (**evt_mgmt.update_alert_restricted_fields_elapsed_time**)
   - **Flap interval (in seconds), within which an alert enters the flapping state**
     (**evt_mgmt.flap_interval**)
   - **Flap frequency, frequency an alert must reoccur to enter the flapping state**
     (**evt_mgmt.flap_frequency**)
   - **Flap quiet interval (in seconds), quiet time that must pass for an alert to exit the flapping state**
     (**evt_mgmt.flap_quiet_interval**)

3. Click **Save**.

You can monitor the **Event Management > All Alerts** list for alerts that are in the flapping state. For details, see [View alerts in the flapping state](#).

**Alert impact calculation**

Impact calculation shows the magnitude of an outage on CIs, services, alerts, and alert groups. As an alert generates, factors such as impact rules and CI relationships are used to calculate the severity. The alert severity is then displayed on the impact tree, application service maps, and dashboards.

Impact calculations are available for business services, application services, and alert groups. The following factors are used to calculate the overall impact of an outage.

- **Impact rules**.
- **Number of related active alerts**.
- **Past history of the affected CI**.
- **Relationships between CIs for a particular business service or application service**.

© 2020 ServiceNow, Inc. All rights reserved.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
- If the CI element includes a network or storage devices.
- If the CI is in maintenance. When CIs are in maintenance, alerts on the CI are excluded from impact calculation.

**Note:** CIs are considered to be in maintenance not only when an active change request is scheduled, but also when the Status field of the CI is set to **In Maintenance**. In both cases, the CI is excluded from impact calculation and alerts for the CI do not appear in the Alert console.

**Note:** When a child CI is put in maintenance, it also places the parent CI in maintenance.

If there is a connection between services, the impact of one service on the other is also calculated.

Impact calculations use information from various sources to set the alert severity.
How impact is calculated

Impact calculation varies depending on the CI relationships for a business service or application service. Additional factors, such as change requests, network paths, storage paths, and related CIs all affect impact calculation.

You can learn about the impact tree from the following video tutorial.

Business services

The following impact calculation flow operates for alerts where the outage does not affect a network or network storage. Event Management performs the following steps:

1. Create a business service map. Use the Service Configuration Item Associations (svc_ci_assoc) and CI Relationships (cmdb_rel_ci) tables to create child-parent relationships in the business service or application service.

2. If there is no CMDB path from the business service to the CI but an association appears in the svc_ci_assoc table, show a Depends-on relationship between the business service and the CI. Otherwise, show no connection.

3. For an application service, if the CIs assigned to the service are also connected to the service in the CMDB, the map keeps the hierarchy between CIs as they appear in CMDB. The CI service assignments appear in the Service Configuration Item Associations section of the Application service form. If there is no connection to the service in the CMDB, the CIs appear directly under the application service in the map.

4. Create the impact tree. Mark the magnitude of an outage by 100% down, 60% affected, 40% impaired, or 20% impaired. If the items in two or more clusters are affected, the impact is 100% down.

Change requests and the In Maintenance status

If an active change request is scheduled for the CI or if the Status of the CI is In Maintenance, all alerts on the affected CI are excluded from impact calculation. The Alerts tab and Alert console also temporarily hide all corresponding alerts. The impact tree shows the CI in green with a note of (In Maintenance). The impact tree and the business service map temporarily show CIs in green.

Note: CIs are considered to be in maintenance not only when an active change request is scheduled, but also when the Status field of the CI is set to In Maintenance. In both cases, the CI is excluded from impact calculation and alerts for the CI do not appear in the Alert console.

For a business service, all alerts on CIs in the business service are also hidden from the Alerts tab. The entire business service is shown in green on the impact tree. For a host with an active change request, the host applications are considered as one unit. All child applications are treated in the same manner as the host until the change request is no longer active. For additional information, see How alerts work with CIs in maintenance.

Network paths

To account for network redundancy, Event Management uses a separate impact calculation. You can see network topology or path changes in the business service. The following impact calculation flow operates for alerts where a network path is affected. Event Management performs the following steps:

1. Create a business service map for the affected network.
- Use the host ID and target IP information from the alert and the network path from the Network Paths (sa_network_paths) table.
- Use the elements in the network path that derive from the Configuration Item (cmdb_ci) table. Also, use the elements that are associated to the path, from the Infra Path To Elements (sa_infra_path_assoc) table.
- Set the relationships. The application CI has a Depends on::Used by relationship on an element in the path that is defined in the CI Relationship (cmdb_rel_ci) table. In the relationship, the application CI is the parent and the element in the network path is the child.

2. Calculate a separate severity for each regular element in the path. Each regular element in the path contributes its own severity to its ancestors up to the application CI where the path originated from.

3. Calculate all redundant elements in the path with the redundancy rule by reducing the severity on the impacted CIs by one level. For example, if the severity is Critical, the redundancy rule decreases severity by one level to Major.

4. Create the impact tree. Mark the magnitude of an outage by 100% down, 60% affected, 40% impaired, or 20% impaired. If the items in two or more clusters are affected, the impact is 100% down.

Storage paths

To account for storage device redundancy, Event Management uses a separate impact calculation. You can see impact tree updates when the network storage topology changes from the business service. Event Management performs the following steps for alerts that contain storage CIs:

1. Create a business service map for the affected storage device:
   - Use the storage device in the sa_fs_to_storage_path table. The storage device definition uses the file system information in the path.
   - Use the elements in the storage path that derive from the Configuration Item (cmdb_ci) table. Also, use the elements that are associated to the path from the Infra Path To Elements (sa_infra_path_assoc) table.
   - Set the relationships. The application CI has a Depends on::Used by relationship on an element in the path that is defined in the CI Relationship (cmdb_rel_ci) table. In the relationship, the application CI is the parent and the element in the storage path is the child.

2. Calculate a separate severity for each regular element in the path. Each regular element in the path contributes its own severity to its ancestors up to the original application CI the path.

3. Use the redundancy rule to calculate redundant elements in the path by reducing the severity on the impacted CIs by one level. For example, if the severity is Critical, the redundancy rule decreases by one level to Major.

4. Create the impact tree. Mark the magnitude of an outage by 100% down, 60% affected, 40% impaired, or 20% impaired. If the items in two or more clusters are affected, the impact is 100% down.

Related CIs

As alerts generate for a CI, additional impact calculations run for related CIs. For example, additional impact calculations run for a business service dependency to a CI that is not actually
part of the business service. These related CIs are not discovered as part of the service. Instead, the related CIs are specified by an infrastructure relationship definition.

The following impact calculation flow operates for alerts with CIs that have a dependency to related CIs which are considered outside the business service. Event Management performs the following steps:

1. Derive relationships between the business service CIs and related CIs. Use the relationships, impact rules, and other data from the Infrastructure Relations (em_impact_infra_rel_def) table.
2. Add related CIs to the impact tree and alert list on the Event Management dashboard.
   - Use data from the Infrastructure Relationship (em_impact_infra_rel_def) table to show containment links to the host.
   - Use the Impact Status (em_impact_status) and Alert History (em_alert_history) tables to determine the status.

Impact rules

Impact rules, which are used for impact calculation, estimate the magnitude or severity of an outage based on affected CIs.

The Impact Rule (em_impact_rule) table contains impact rules that show the applicable CIs, business services, and settings for impact. The following default impact rules are available.

**Application Cluster Member**

Determines how application cluster members affect the overall impact of the cluster. For example, if a three-member cluster requires 70% Influence to set the severity for the entire cluster to **Major**, each member has 23% Influence (70% divided by 3). The severity of the entire cluster can only change to **Major** when all three members have a severity of **Major**.

**Inclusion**

Determines the impact on entities with a Contains relationship. This rule is read-only.

**Infrastructure Dependencies**

Determines the definition of impact propagation for CIs in infrastructure relationships.

**CI Business Service**

Determines how impact applies to parent or child entities that are part of a business service.

**CI Impact**

Applies to application services. Determines the relationship between service members. The impact from child to parent CIs is always 100%. For example, the parent impact severity is derived from the child CI with the highest severity.

**CI Parent in Application**

Sets impact only on the parent entity.

**Network Path**

Determines how impact applies to parent or child entities that are part of a traditional network.

**OS Cluster Member**

Determines how host cluster members affect the overall cluster status based on a percentage or number of cluster members. For example, if a three-host cluster requires 50% Influence to set the severity of **Major**, each member has 17% Influence (50% divided by 3). The severity of the entire

cluster can only change to **Major** when two or more cluster members have a severity of **Major**. The entire cluster is also considered to be down.

**Storage Path**

Determines how impact applies to parent or child entities that are part of a storage network.

**Properties**

In addition to configuring impact rules, you can configure properties for impact calculation. Configure these properties, as appropriate:

- Enable alert group support (`evt_mgmt.impact_calculation.alert_group_support`)
- Minimum time in seconds for checking CI maintenance: checks both the Status field on the CI and any change request schedule for the CI (`evt_mgmt.impact_maintenance.sleep_time_sec`)

**View the impact tree**

The impact tree shows the relationships between CIs and the relative percentage impact for each child CI. This information is available for both discovered services and application services.

Role required: `evt_mgmt_admin`, `evt_mgmt_operator`, or `evt_mgmt_user`

The impact tree shows the result of impact rules on CI parent and child relationships. The tree represents a business service map with CIs from the Service Configuration Item Associations (svc_ci_assoc) table. When related CIs are connected but not part of the business service map, the impact for the related CIs can also appear in the impact tree.

The numbers or percentages on a parent CI summarize overall severity based on alerts from child CIs. The parent severity is based on impact rule computations.

You can also learn about the impact tree from the following video tutorial.
1. Open the business service map for the service from either the Event Management dashboard or the Application service list.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>From the Event Management dashboard</td>
<td>1. Navigate to Event Management &gt; Dashboard.</td>
</tr>
<tr>
<td></td>
<td>2. Double-click the tile of the service.</td>
</tr>
<tr>
<td>From the Application service list</td>
<td>1. Navigate to Event Management &gt; Services &gt; Application Services.</td>
</tr>
<tr>
<td></td>
<td>2. Click View Map next to the service.</td>
</tr>
</tbody>
</table>

2. On the business service map, click a CI that has a severity color.
3. Click the Impact tab.
4. From the Impact Tree tab in the side pane, expand the parent CI and click the CI that generated alerts.
5. Use the severity color to locate CIs that contain alerts:
   - **Critical (red)**: Immediate action is required. The resource is either not functional or critical problems are imminent.
   - **Major (orange)**: Major functionality is severely impaired or performance has degraded.
   - **Minor (yellow)**: Partial, non-critical loss of functionality or performance degradation occurred.
   - **Warning (blue)**: Attention is required, even though the resource is still functional.
   - **Info (green)**: An alert is created. The resource is still functional.
6. Do one or more of the following:
### Adjust impact rules

- **Description:**
  1. Click the **Impact** tab.
  2. Review and adjust the impact rules as necessary.

### Remediate an alert

- **Description:**
  1. Click the **Alerts**.
  2. Right-click the alert and select **Run remediation**.

---

### Adjust impact rules for a CI

Configure impact rules to customize the impact calculation. The impact rules update the overall alert and show the impact on related CIs. When you change impact rules, the updates apply to alert severity in places such as the Event Management alerts console and dashboard.

**Role required:** evt_mgmt_admin, evt_mgmt_operator, or evt_mgmt_user

You can view and adjust the impact rules of CIs from the business service map of a service.

1. Open the business service map from either the Event Management dashboard or the Application service list.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>From the Event Management dashboard</strong></td>
<td></td>
</tr>
<tr>
<td>1. Navigate to <strong>Event Management</strong> &gt; <strong>Dashboard</strong>.</td>
<td></td>
</tr>
<tr>
<td>2. Double-click the tile of the application service.</td>
<td></td>
</tr>
<tr>
<td><strong>From the Application Service list</strong></td>
<td></td>
</tr>
<tr>
<td>1. Navigate to <strong>Event Management</strong> &gt; <strong>Services</strong> &gt; <strong>Application Services</strong>.</td>
<td></td>
</tr>
<tr>
<td>2. Click <strong>View Map</strong> next to the application service.</td>
<td></td>
</tr>
</tbody>
</table>

2. On the business service map, click a CI.

3. Below the map, click the **Impact** tab and then adjust the impact rules accordingly.
Impact Rules

<table>
<thead>

</tr>
<tr>
<td></td>
<td>• Warning: Blue (lowest severity).</td>
</tr>
</tbody>
</table>

Review the changes on the impact tree. For example, if you changed a number or percentage influence for child CIs, review the impact tree updates accordingly.

**View alert impact on CIs in a service map**

The business service map shows active alerts for CIs and the relationships between CIs. The business service map is available for all application services.

Role required: evt_mgmt_admin, evt_mgmt_operator, or evt_mgmt_user

A business service map shows alerts with impacted CIs and CI interdependencies. For example, changes to a connection between a host and hypervisor appear on the business service map. As the business service map definition or the statuses of alerts change, the business service map, alert, and impact information updates accordingly. You can open a business service map from these places:

- From the Application services list, you can view business service maps for application services.
- From the Monitored services list, you can view business service maps for monitored services.
- From the Event Management dashboard, you can view business service maps for discovered services and application services.

The following icons are used in business service maps. The icon shapes are slightly different for application services.

**Business service map icons**

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="application_server_icon" /></td>
<td>The application server icon represents applications such as Microsoft IIS or SQL servers.</td>
</tr>
<tr>
<td><img src="image" alt="call_server_icon" /></td>
<td>The call server icon represents physical and VM computers and servers.</td>
</tr>
<tr>
<td><img src="image" alt="entry_point_icon" /></td>
<td>The entry point icon represents the network starting point. For example, Layer 3 devices appear toward the top of the map, and connected software and services appear near the end of the map.</td>
</tr>
<tr>
<td><img src="image" alt="redundancy_arrow_icon" /></td>
<td>The redundancy arrow shows the number of redundant CIs.</td>
</tr>
<tr>
<td><img src="image" alt="load_balancer_icon" /></td>
<td>The load balancer icon.</td>
</tr>
<tr>
<td><img src="image" alt="gray_connector_icon" /></td>
<td>The gray connector shows a relationship between CIs.</td>
</tr>
<tr>
<td><img src="image" alt="gray_box_icon" /></td>
<td>Each box represents a network CI. A gray box represents a CI with no active alerts. Information about the CI is hidden.</td>
</tr>
<tr>
<td><img src="image" alt="redundancy_icon" /></td>
<td>The redundancy icon hides multiple CIs that are designated as redundant.</td>
</tr>
</tbody>
</table>
An impacted CI displays the color that represents the severity of the alert associated with the CI.

- **Critical (red):** Immediate action is required. The resource is either not functional or critical problems are imminent.
- **Major (orange):** Major functionality is severely impaired or performance has degraded.
- **Minor (yellow):** Partial, non-critical loss of functionality or performance degradation occurred.
- **Warning (blue):** Attention is required, even though the resource is still functional.
- **Info (green):** An alert is created. The resource is still functional.
- **No color:** No active alerts.

The storage icon represents fiber channel, hard drives, or other data storage devices.

The web server icon represents related web services for the network such as NGINX or JBoss.

**Note:** Session timeout settings do not apply to this screen, so the session remains connected, even when there is no human interaction. If this setting is a concern, either log out or close the active tab in the browser.

1. Perform one of the following actions:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| To open a map of an application service or a business service | 1. Navigate to Event Management > Dashboard.  
2. Double-click the tile of the service. |

To open an application service map

1. Navigate to Event Management > Services > Application Services.  
2. Click View Map next to the service.  

Alternatively, if you are in the Map window in Service Mapping, click Monitor Service at the top of the window.

2. Do one or more of the following:

<table>
<thead>
<tr>
<th>Option</th>
<th>Action</th>
</tr>
</thead>
</table>
| View alerts for a CI by type and severity | In the business service map:  
1. Click a CI tile.  
2. Below the map, click the Alerts tab and review the listed alerts. |
<table>
<thead>
<tr>
<th>Option</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>View changes to a CI in a discovered service</td>
<td>In the business service map:</td>

<tr>
<td></td>
<td>1. Click a CI tile.</td>
</tr>
<tr>
<td></td>
<td>2. Below the map, click the Changes tab.</td>
</tr>
<tr>
<td>Show alert bindings to CIs</td>
<td>In the business service map:</td>
</tr>
<tr>
<td></td>
<td>1. Click a CI tile.</td>
</tr>
<tr>
<td></td>
<td>2. Click the menu icon, and turn on the Affected CI’s indicator.</td>
</tr>
<tr>
<td></td>
<td>3. Below the map, click the Affected CI’s tab.</td>
</tr>
<tr>
<td>View CI properties</td>
<td>In the business service map:</td>
</tr>
<tr>
<td></td>
<td>1. Click a CI tile.</td>
</tr>
<tr>
<td></td>
<td>2. In the side pane, click the Properties tab and review information about the CI.</td>
</tr>
<tr>
<td></td>
<td>3. If you want to view more detailed information, scroll to the end of the pane and click Detailed Properties.</td>
</tr>
<tr>
<td>Show impact rules for a CI</td>
<td>In the business service map:</td>
</tr>
<tr>
<td></td>
<td>1. Click a CI that has a severity.</td>
</tr>
<tr>
<td></td>
<td>2. Below the business service map, click the Impact tab and review the listed impact rules.</td>
</tr>
<tr>
<td>Show alert details for networks or storage for a business service</td>
<td>In the business service map:</td>
</tr>
<tr>
<td></td>
<td>1. Right-click a path between CIs.</td>
</tr>
<tr>
<td></td>
<td>2. Select Show network path or Show storage path.</td>
</tr>
<tr>
<td>Display additional information for CIs</td>
<td>In the business service map header:</td>
</tr>
<tr>
<td></td>
<td>1. Click the menu icon.</td>
</tr>
<tr>
<td></td>
<td>2. Turn on the Map Indicators for the additional information that you want to view.</td>
</tr>
<tr>
<td>Remediate a CI</td>
<td>In the topology, right-click the CI, and then select Remediation options.</td>
</tr>
</tbody>
</table>

Create an infrastructure relationship for related CIs
Infrastructures show CIs that are connected to a business service but are not necessary parts of the service. Infrastructure relationships are only available for business services.
Role required: evt_mgmt_admin

When you create a CI infrastructure relationship, the information is stored in the Infrastructure Relations (em_impact_infra_rel_def) table. When alerts generate, the related CI accompanies the business service information on the Event Management dashboard and in the impact tree. Additional information for the related CIs only appears on a related dependency view map for the business service. The following default infrastructure relationships are available.
### Default infrastructure relationships

<table>
<thead>
<tr>
<th>Infrastructure relationship</th>
<th>Impact rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmdb_ci_appl</td>
<td>OS Cluster Member</td>
<td>Shows alert impact between hardware and software applications.</td>
</tr>
<tr>
<td>cmdb_ci_esx_server</td>
<td>Infrastructure Dependencies</td>
<td>Shows alert impact between VCenter and ESX clusters.</td>
</tr>
<tr>
<td>cmdb_ci_kvm</td>
<td>Infrastructure Dependencies</td>
<td>Shows that alert impact on Linux Kernel-based Virtual Machine (KVM) connectivity.</td>
</tr>
<tr>
<td>cmdb_ci_vm_zones</td>
<td>Infrastructure Dependencies</td>
<td>Shows alert impact on the Solaris VM zones.</td>
</tr>
</tbody>
</table>

For example, based on the `cmdb_ci_vm_zones` infrastructure relationship definition, Event Management adds `ZoneServer@mmp1` to the business service. The Containment rule manages impact severity on alerts.
Related CIs appear on the BSM

1. Navigate to **Event Management > Settings > Infrastructure Relations**.
2. Click **New**.
3. Fill in the fields, as appropriate.

**Infrastructure Relations form**

<table>
<thead>
<tr>

</tr>
<tr>
<td></td>
<td>- <strong>Storage Path</strong>: Determines how impact applies to parent or child entities that are part of a storage network.</td>
</tr>
<tr>
<td></td>
<td>- <strong>CI Impact</strong>: Applies to application services. Determines the relationship between service members. The impact from child to parent CIs is always 100%. For example, the parent impact severity is derived from the child CI with the highest severity.</td>
</tr>
</tbody>
</table>

4. Click **Submit**.

*View impact of child service on parent service*

In the map view of a business service, the severity of a child service is propagated to its parent service.

Role required:
In the map view of an application or of a discovered service, you can see that the severity of a child service is propagated to the parent service.

A business service is affected by the severity of alerts that are directly associated with it and alerts on the CIs that are in the service. If the severity of a child service is higher than that of its parent service, on the map view the parent service shows the severity of the child service. In the map view, the **Impact Tree** list shows the CIs. The color of the CIs indicates the alert severity. The child service is also affected by business services that are under it.

![Example where the parent service shows the severity of the child service](image)

If a loop is created, for example, by connecting a parent service to a sub-service, this relationship can be viewed in the map view. The impact of this loop is not calculated and the Impact Tree does not display this relationship. For example, assume that there are three CIs, A, B, and C, where C is a sub-service to B and B is a sub-service to A. The relationship of the A connected service to C is displayed in the map view. However, this relationship is not shown in the Impact Tree.

**Note:** A message appears in the system error log in the following format, where the sys_id of the service and the node changes accordingly: Found loop in ServiceId:[sysId], and node:[sysId]. Removing this relation to avoid impact loops

For example, Found loop in ServiceId:409d4fd59f030200fe2ab0aec32e705c, and node:df5cf6159f030200fe2ab0aec32e70a2. Removing this relation to avoid impact loops

Click a service or CI to see the alerts that are associated with it. For example, if you click the high-level business service, the alerts that are associated with it are displayed in the alert area under the Map View. The alerts listed are those of the selected service. Alerts of child-services are listed when those services are selected.
Example of alerts listed under the Map View

In the Event Management dashboard, double-click the required application service or discovered service.

In the business service map, you can visually verify that the service health of the sub-service is rolled-up to the parent service. At the bottom of the icon of an impacted CI is a colored bar that represents the severity of the alert. This color bar also displays in the bottom bar of its parent service.

Alert group types

Alerts are correlated, or grouped, either automatically or manually into (R)ule-based, (A)utomated, (M)anual, or (C)MDB alert groups. Grouping alerts enables you to narrow down problems by focusing on the primary alerts in the correlated group.

You can learn about Event Management grouping of alerts from this video tutorial:

When evaluating incoming alerts to form alert groups, the types of group that alerts might potentially belong to, are considered in the following order. After an alert becomes part of a group, it is not available for any other group.

1. Rule-based
3. Automated
4. CMDB

You can view all alert groups by navigating to Event Management > Alert Console. The icon in the Group column denotes the alert group type. Alerts that do not have an entry in the Group column are not correlated with any group.

At any given time, an alert can only belong to a single alert group.

### Note:
The filter that defines Alert Groups should not be on fields that do not appear in the em_alert_history table because impact calculation is not calculated properly. This situation occurs because fields like Event Count, Priority, and Priority Group are not copied to the em_alert_history table for impact calculation.
### Alert group types

<table>
<thead>
<tr>

<td>CMDB alert groups</td>
</tr>
</tbody>
</table>

Double-click the **Group** column for an alert group to open its **Grouped Alerts** dialog box, where you can:

- Display all alerts in the group.
- Provide feedback about the usefulness of the group.
- Manually add or remove alerts from the group.

**View timeline for alert groups**

A timeline format that displays alerts and alert groups that correspond to the alerts and alert groups currently visible in the list view in the alerts console.

A line of blue dots at the top of the timeline view represent all the alerts displayed in the list view, and all the alerts that are included in the alert groups displayed in the list view. Alert groups and alert bubbles are displayed underneath across a timeline, according to the update time of the alerts.

1. Navigate to **Event Management > Alert Console**.
2. Enable **Group Timeline** and do any of the following:
   - Double-click a group name in an alert group in the timeline view to display the set of alerts within the group. For details about the alert form, see [View alert information](#).
   - Hover over a blue dotted alert, or over an alerts bubble in a group to display further details.
   - Zoom into alert groups to change the time granularity of the timeline. Drag the mouse over a collection of alert groups or blue dotted alerts to highlight the area of the timeline to zoom into.
   - Use one of the time presets to display alerts from a certain period such as alerts from the past 7 days.
   - Click an alerts bubble to open the **Grouped Alerts** dialog box which displays the individual alerts in the group. This view is equivalent to clicking a group in the list view.
   - Page through the list view to display the timeline for another set of alerts and groups.
Add alert to an alert group
After viewing the individual alerts in an alert group such as an automated alert group, you might conclude that there is another alert that should be added to the group. You can manually add an alert to an existing alert group so the group is more complete and useful in troubleshooting an incident.

Role required: evt_mgmt_operator

If the alert that you choose to add to an alert group already belongs to an alert group, the alert is automatically removed from its current alert group, thereby changing the alert group to which the alert belongs.

The addition of an alert to an alert group is registered as a form of feedback to alert groups. Later, when similar alert groups are formed, the Service Analytics Learner automatically repeats these additions which were previously done manually by the user.

Note: A closed alert cannot be assigned as a parent.

1. Navigate to Event Management > Alert Console.
2. Locate the group to which you want to add alerts, and click the group parent alert to open its Alert form.
3. Underneath the Related Links section, select the Alerts tab.
4. Click Add To Group, and then select the alerts to add to the group.
   The Alerts (Add To Group view) view displays all alerts which can be added to the alert group. Primary and closed alerts, for example, are not displayed.
   Alternatively, you can add an alert to an alert group by changing the alert’s parent. When you specify a new parent for an alert, the alert is added to the new parent’s alert group, and gets removed from its current alert group. You can specify a new parent by modifying the Parent field on an Alert form, or by modifying the value in the Parent column of an alert in the Alert Console.
5. To remove an alert, click Actions on selected rows, and then click Remove.
   After viewing the individual alerts in an alert group, you may decide to remove an alert from the group to improve the group’s accuracy and usefulness in troubleshooting an incident.
   If an alert group is left with one or no alerts after removing alerts, the group is deleted and no longer displays in alert group lists. The virtual primary alert that was added when the group was created is closed.

On the Alert form, verify that the newly added alerts appear in the Alerts tab.
Provide feedback for an alert group
As you view the details of an automated or CMDB alert group in the Alert Console, you can provide feedback about the accuracy and usefulness of the group. This feedback can help future analysis, and over time, accumulated feedback continues to improve the accuracy of alert aggregation.

Role required: evt_mgmt_user

Provide feedback in the form of a Yes/No response to the question of how accurate and useful the alert group is. This form of feedback for an alert group is provided for the primary alert of the group, as described in the following procedure.

Another form of feedback is user manipulation of manual alert groups and automated alert groups:

- The Alert Aggregation Learner tracks manual additions and removals of alerts from automated alert groups. In subsequent occurrences of the same types of alerts with similar time correlation - this form of feedback is applied. Alert aggregation and RCA automatically repeats the
addition or removal actions that were previously done manually. If you undo any previous alert additions or removals to those alert groups, the automatic process is adjusted accordingly.

You can review user additions and removals of alerts from an automated alert group, and undo any action so it is not automatically repeated by alert aggregation and RCA. See Edit feedback for an automated alert group for more information.

- The Alert Aggregation Learner also learns the patterns of alerts in manual alert groups. Later, when new streams of alerts arrive, alert aggregation and RCA automatically forms automatic alert groups according on these patterns.

To enable the application of this form of feedback during alert aggregation, set the property sa_analytics.agg.query_customer_feedback_enabled to true.

1. Navigate to Event Management > Alert Console.
2. Locate the group for which you want to provide feedback, and click its button to display the alerts included in the group.
3. Click the primary alert of the group to open its Alert form.
4. Based on your analysis of the accuracy and helpfulness of this group, set Feedback to Yes or No.
5. Click Update.

Edit feedback for an automated alert group
Modify which manual additions and removals of alerts are automatically applied to newly formed automated alert groups.

Event Management alert aggregation and RCA tracks your feedback of manually adding or removing alerts from automated alert groups. Later, when alert aggregation and RCA forms new automated alert groups, those additions and removals are automatically repeated.

You can edit this form of feedback by reviewing the list of user actions for the alert group, and then undoing specific alert additions and alert removals. Those additions and removals are not repeated when new automated alert groups are formed.

1. Navigate to Event Management > Alert Aggregation and RCA > Edit Feedback.
2. In the Grouped Alerts page:
   a) Click the alert group for which you want to edit feedback, and then click the user edit (Added or Removed) that you want to undo.
   b) Or, click the button next to the alert group for which you want to edit feedback. In the list of all user edits (Added and Removed), click the user edit that you want to undo.
3. Fill out the form and then click Submit.
   Most fields on the form are automatically populated according to the selected alert group and the user edit.

Grouped Alert form

</tbody>
</table>
Create a manual alert group
After you manually create a manual alert group, you can continue and manually add specific alerts to the group. The resultant manual alert group can contain many alerts and is useful in troubleshooting an incident.

Role required: evt_mgmt_operator

To initially create a manual alert group, select at least two alerts that do not belong to any alert group. Make one of those alerts the parent of the other alert. The new manual alert group appears in the Alert Console.

After manually creating a manual alert group, the Alert Aggregation Learner learns the group and generates a pattern based on the alerts in the group. Later, if alert aggregation and RCA detects a similar pattern in incoming streams of alerts, then alert aggregation and RCA forms automatic alert group according to the pattern.

Note: At any given time, an alert can belong only to a single alert group. A closed alert cannot be assigned as a parent.

1. Navigate to Event Management > Alert Console.
2. Clear the Correlated Alerts toggle. All alerts appear in the list, including open, primary, and secondary alerts.
3. Note the alert number of an alert that you want to set as the parent in a new alert. Ensure that the alert does not belong to any alert group. This alert is also known as the primary alert.
4. Click an alert that you want to set as the secondary alert in the new manual alert group. Ensure that the alert does not belong to any alert group.
5. In the Parent field of the selected alert, enter the alert number of the alert that is being configured as the primary alert.
6. Click Submit.

When the Alert Consolerefreshes, the primary alert that was selected, is denoted as being in the manual alert group. The alert, that is a member of the new manual alert group, is denoted as being the secondary alert.

In the Alert Console, you can add and remove other alerts to the manual alert group.

View reasons for alert groupings
As alerts are added to a group, a message is added to the alert’s Work notes field that indicates the reason for aggregating that alert into the group.

Ensure that the evt_mgmt.alert_groups_reasoning.enable_worknotes property is configured with Value = all. Configure this property by navigating to System Properties > All Properties. The default values in this property are configured in the Choices field and are listed in the following table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>All Alerts</td>
<td>Work note information is generated for all alerts.</td>
</tr>
<tr>
<td>Primary Alerts</td>
<td>Work note information is generated only for primary alerts.</td>
</tr>
<tr>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------------------------------------------</td>
</tr>
<tr>
<td>Secondary Alerts</td>
<td>Work note information is generated only for secondary alerts.</td>
</tr>
<tr>
<td>None</td>
<td>No work note information is generated.</td>
</tr>
</tbody>
</table>

By default Value = all, indicating that work note information is generated for all alerts.

Role required: evt_mgmt_admin

In an alert record, the Work notes field in the Activities tab provides information that enables you to better understand the group to which the alert belongs. You can view the list of alerts in:

- Event Management dashboard
- Alert Intelligence
- Alert Console
- All Alerts

When another alert is added to an alert group, this information is shown in the Work notes field of the selected alert. When an alert is removed from the group, this information is also shown in the Work notes field of the selected alert.

Information related to the following types of alert groups appears in Work notes fields:

- Secondary
- Automated
- Aggregated
- CMDB

1. Navigate to Event Management > All Alerts.
2. Click an alert record that is part of a group.
3. Click the Activities tab.
   In the Work notes field, you can see the reason for aggregating an alert into a group.
   The following example provides a sample explanatory note.

   2018-10-16 14:53:14 - System Administrator
   Alerts Alert0056912, Alert0056913 were grouped together due to pattern

   To see the patterns that caused the alerts to be grouped, you would click the pattern hyperlink.

Alert monitoring

Alert generation and remediation can be monitored from the Event Management dashboards, alert console, and alert timeline.

- The Alerts Console shows incoming alerts for discovered business services, application services, technical services, and alert groups.
- The Event Management Dashboard displays the health of services. It consolidates alert information about discovered business services, application services, technical services, automated alert groups, and other alert groups. Additional information is available on the business service map, impact tree, and timeline.
• The **Overview** dashboard displays reports on active alerts. You can drill down to individual alerts from these reports.

**Monitor service health**

On the Event Management dashboard, you can view alerts by business service, application service, technical service, and alert group. For services, you can also open a business service map to view relationships between CIs in the service.

Ask an administrator to create at least one business service, application service, technical service, or alert group if none of these items exist.

**Role required:** evt_mgmt_admin, evt_mgmt_operator, or evt_mgmt_user

The dashboard tiles represent a service, alert group, or CI. Tile sizes correspond to the selection in the **Prioritize by** field in the dashboard. A larger tile size represents the severity of the alerts. The tile color represents the overall alert severity.

You can learn about the Event Management basic components from this video tutorial:

**These tile icons are available:**

<table>
<thead>
<tr>
<th>Dashboard tile icons</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Icon" /></td>
</tr>
<tr>
<td><img src="image" alt="Icon" /></td>
</tr>
<tr>
<td><img src="image" alt="Icon" /></td>
</tr>
<tr>
<td><img src="image" alt="Icon" /></td>
</tr>
</tbody>
</table>

Each tile represents the highest severity of an alert for the service, alert group, or CI. For example, a tile appears in red if an alert is critical. A green tile indicates either information alerts or no currently active alerts. As the alert severities change, the dashboard updates accordingly. The following severities are available:

- **Red:** critical severity (highest severity). Immediate action is required. The resource is either not functional or critical problems are imminent.
- **Orange:** major severity. Major functionality is severely impaired or performance has degraded.
- **Yellow:** minor severity. Partial, non-critical loss of functionality or performance degradation occurred.
- **Blue:** warning severity (lowest severity). Attention is required, even though the resource is still functional.
- **Green:** informational. No severity. An alert is created. The resource is still functional.

To integrate with Operational Intelligence, activate the Operational Intelligence (com.snc.sa.metric) plugin and follow the steps in the [Get started with Operational Intelligence](#) topic. In the dashboard, double-click a discovered business service to drill down and reach the **topology map**. These Operational Intelligence buttons are available:
• **Click View metrics.** This view displays a canvas to which you can drag CIs and display metric charts on. The server CIs are listed in the device pane. Point to the CIs in the list to display a tooltip that notes if the CIs have no metric data. For CIs that do have metric data, you can drill down into that data. Use the View metrics button to switch between the map and metric chart viewer. You can drag a CI that has metric data into the canvas area in the map to create a chart. The metric data also appears on the timeline.

• The **Metrics** button is automatically selected when **View metrics** is clicked. In the device pane, select a server. All the CIs that are related to that server are listed and metric data is displayed for those CIs that have metric data. A circle that depicts the metric anomaly score appears to the right of each metric value, see Configure anomaly score thresholds. If it is within the green band range, Operational Intelligence does not track changes to an anomaly score. The colors of the dots at the upper left on the CI icons or the absence of a dot, signify:

  • Grey dot: Metrics are being tracked for the CI, but none of those metrics have ever had an anomaly.
  • Colored dot: Corresponds to the last recorded anomaly score according to the configuration of the color band ranges.
  • No dot: There are no metrics for the CI and there is no data to drill into.

• Items can be selected on the map to filter the list of CIs on the right.

• The time range for the graphs is tied to the timeline at the top of the service map.

For more information, see View metric values in the Insights Explorer.

**Note:** Session timeout settings do not apply to this screen, so the session remains connected, even when there is no human interaction. If this setting is a concern, either log out or close the active tab in the browser.

1. Navigate to **Event Management > Dashboard.**
2. Choose from:
   - To view alerts by business service, application service, technical service, or alert group, click **Services**.
• To view alerts in your business group only, click **Groups**.

3. **Do one or more of these actions:**

<table>
<thead>
<tr>
<th>Task</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Prioritize alerts</strong></td>
<td>Above the tile area:</td>
</tr>
<tr>
<td></td>
<td>1. Click <strong>Prioritize by list</strong>.</td>
</tr>
<tr>
<td></td>
<td>2. Select <strong>Severity</strong>, <strong>Business criticality</strong>, or <strong>Cost</strong>.</td>
</tr>
<tr>
<td></td>
<td>The filter values use the Dashboard filter dictionary attribute from the <code>cmdb_ci_service_auto.list</code> to prioritize alerts.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>View alert details for a service or group</strong></th>
<th>In the tile area:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1. Click the service or group tile.</td>
</tr>
<tr>
<td></td>
<td>2. Review the list of corresponding alerts under the <strong>Alerts</strong> tab.</td>
</tr>
<tr>
<td></td>
<td>3. To view the properties of an alert, double-click it.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Show or hide alerts by severity</strong></th>
<th>In the dashboard header, click the icon of the lowest severity that you want to view in the dashboard.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>You can also move the slider to the left of the icon. The dashboard appears only the severities that are to the right of the slider. For example, move the slider to the left of the red icon if you want to view only alerts with critical severity.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>View the properties of an alert</strong></th>
<th>Click <strong>Alerts</strong> or <strong>Correlated Alerts</strong>, then double-click the required alert number.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong> Alerts of type A (analytic alert group) do not show in the bottom alerts panel when <strong>Correlated Alerts</strong> is not selected.</td>
<td></td>
</tr>
</tbody>
</table>

| **View alerts from another service or group** | In the dashboard header, click the down arrow, and then select the service or group name. |

| **Show active alerts for a group**          | In the dashboard header, click **Service**. Then click the group name and review the alerts listed for it under the **Alerts** tab. |

| **Show alert CI relationships or bindings in a business service map** | On the dashboard, double-click a tile for the service. For more information on the business service map, click **View alert impact on CIs in a service map**. |

<p>| <strong>Show an aggregation of correlated alerts for services and alert groups</strong> | Below the dashboard tiles, click <strong>Correlated Alert</strong>. |</p>
<table>
<thead>
<tr>
<th>Task</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Remediate an alert</td>
<td>Under the <strong>Alerts</strong> tab, right-click the alert and then select <strong>Run remediation</strong>.</td>
</tr>
</tbody>
</table>

4. To reduce the number of alerts that display in the alerts panel, enable **Correlated Alerts**.

The alerts panel displays alert groups and alerts that have not been grouped.

![Correlated Alerts](image)

**Note:** The **Correlated Alerts** toggle also appears in the **Alerts Console**. When either the **Alerts Console** or the dashboard is opened, the **Correlated Alerts** toggle opens in the setting that was last selected.

---

**Create a customized dashboard view**

You can create a customized Event Management dashboard view and save it as a favorite link in the navigation tree.

**Role required:** evt_mgmt_admin, evt_mgmt_operator, or evt_mgmt_user

You can filter business services and save the customized dashboard view as a favorite link.

**Note:**
- The Dashboard View feature applies only to business services, and not to business service groups. The business service groups appear whether they do or do not match the filter, and whether they do or do not contain any services that match the filter.
- The Dashboard View filters services in the dashboard. However, alerts are not filtered. Alerts appear whether they do or do not match the filter.

1. Navigate to **Event Management > Settings > Dashboard Views**.
2. In the **Dashboard Views** screen, click **New**.
3. In the **Name** field, enter a descriptive name for the dashboard view.
4. Select **Active**.
5. Specify the filter conditions and click **Submit**.
6. Click the options menu in the title next to **Dashboard Views**.
7. In the context menu, click **Create Favorite**.

In the **Create Favorite** screen, the name that you specified for the view is displayed. You can optionally edit the name. Select a symbol and its color to display to the left of the dashboard view name.
8. Click **Done**.
   The dashboard view name and its symbol appear in the navigation tree.

9. In the navigation tree, click the required dashboard view name to show the customized dashboard.
   You can view a selected service group in the Event Management dashboard by pasting a link into a browser, using this format: `https://<instance_name>.service-now.com/nav_to.do?uri=%2F$sw_dashboards.do?sysparm_cancelable=true&amp;groupId=<GROUP_SYSID>&tree_state=open&amp;sysparm_bsid=<GROUP_SYSID>&openDirectGroup=true`.
   Replace the variables `<instance_name>` and `<GROUP_SYSID>` with the respective values of the selected service group. Copy and then paste the link into a browser to view the selected service group in an Event Management dashboard.

   For example, if the instance is named `asteroid` and the sys_id of the service group is `17f8dc780fd22300b678778ce1050eb4`, copy and paste this link into a browser:
   ```
   http://asteroid.service-now.com/nav_to.do?uri=%2F$sw_dashboards.do?sysparm_cancelable=true&amp;groupId=17f8dc780fd22300b678778ce1050eb4&amp;tree_state=open&amp;sysparm_bsid=17f8dc780fd22300b678778ce1050eb4&amp;openDirectGroup=true
   ```

**View monitored services**

View all services that Event Management supports, such as, alert groups, discovered services, application services, and technical services. According to the type of service, you can view service definition details or drill down into the service.

Role required: `evt_mgmt_user`

1. Navigate to **Event Management > Monitored services**.
2. Click **View Service** to open the view that is relevant to that service.
   When you drill down to the contents of the service, either a map, alert list, or CI list appears according to the type of service.
   For example, if you click **View Service**, for SNMP1000 you can drill down to the contents of the service and the related topology map appears.
3. To view service definition details of a service, click the name of the required service.

For example, in the Name column, click SNMP1000.

**Monitor and manage alerts**

Monitor and manage alerts in Alert Intelligence in Workspace. You can also monitor and manage alerts in the Alerts Console.
You can monitor and manage alerts in the following components:

- The alerts list in Alert Intelligence and in the Alerts Console shows incoming alerts for discovered business services, application services, technical services, and alert groups.
- The Event Management Dashboard displays the health of services. It consolidates alert information about discovered business services, application services, technical services, automated alert groups, and other alert groups. Additional information is available on the business service map, impact tree, and timeline.
- The Overview dashboard displays reports on active alerts. You can drill down to individual alerts from these reports.

Monitor incoming alerts

You can monitor incoming alerts in Alert Intelligence in Workspace. You can also monitor alerts in the Alerts Console.

You can learn about Event Management basics, including the Alerts Console, from the following video.

Role required: evt_mgmt_admin, evt_mgmt_operator, or evt_mgmt_user

1. Navigate to Event Management > Alert Intelligence.
2. You can also navigate to Event Management > Alert Console.

<table>
<thead>
<tr>
<th>Column heading</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Unique ID generated by Event Management to identify the alert.</td>
</tr>
<tr>
<td>Column heading</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| Group          | An entry in this column indicates that the associated alert is a member of an alert group. Alerts that do not have an entry in this column are ungrouped alerts.  
- **CMDB**: CIs without historical data that were aggregated by alert aggregation and RCA based on CI relationships in the CMDB.  
- **Manual**: This alert is a member of an alert group that is formed when right-clicking an alert and setting it as secondary to the selected primary alert.  
- **Secondary**: This alert is a component of an alert group. The alert at the head of the group is known as the primary alert. When **Correlated Alerts** is selected, the secondary alerts that are under the primary alert do not display, making the Alerts Console less cluttered and easier to review.  
- **Blank**: This alert is an ungrouped alert. To make an ungrouped alert become a member of a group, right-click it and select in the topic **Add to Groups**. Select the alert and click **Add Selected**.  
- **Automated**: Aggregated automatically by alert aggregation and RCA. A virtual alert is added to the group as the primary alert of the group.  
- **Rule**: Alert group created as a result of a user configured correlation rule. |
| Severity        | The severity of the event. The value for this field is copied from the event unless the event closes the alert, in which case the previous severity is retained for reporting.  
- **Critical**: Immediate action is required. The resource is either not functional or critical problems are imminent.  
- **Major**: Major functionality is severely impaired or performance has degraded.  
- **Minor**: Partial, non-critical loss of functionality or performance degradation occurred.  
- **Warning**: Attention is required, even though the resource is still functional.  
- **Info**: An alert is created. The resource is still functional.  
- **Clear**: No action is required. An alert is not created from this event. Existing alerts are closed. |
<p>| Priority group  | Indicates which alerts should be attended to first. Priority is calculated for each open alert and then mapped into one of four priority categories. |</p>
<table>
<thead>
<tr>
<th>Column heading</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Priority</td>
<td>Value providing a guide as to the priority of the alert, based on a number of accumulated categories. For example, alert state and business criticality.</td>
</tr>
<tr>
<td>Source</td>
<td>Event monitoring software that generated the event, for example, SolarWinds or SCOM. Optionally, you can enter a description, for example, Group Alert. This field has a maximum length of 100.</td>
</tr>
<tr>
<td>Description</td>
<td>The alert description.</td>
</tr>
<tr>
<td>Node</td>
<td>Node name, fully qualified domain name (FQDN), IP address, or MAC address that is associated with the event, such as IBM-ASSET. This field has a maximum length of 100.</td>
</tr>
<tr>
<td>Configuration item</td>
<td>JSON string that represents a configuration item. For example, {&quot;name&quot;:&quot;SAP ORA01&quot;,&quot;type&quot;:&quot;Oracle&quot;}. The CI identifier that generated the event appears in the Additional information field. This field has a maximum length of 1000. Click ![icon] to open the alert in dependency view.</td>
</tr>
<tr>
<td>Impacted Services</td>
<td>Indicates the number of business services affected by this alert group. For example, an alert with a severity status of <strong>Major</strong>, might affect eight business services. Whereas, an alert with a severity status of <strong>Critical</strong>, might affect one business service.</td>
</tr>
<tr>
<td>Metric Name</td>
<td>Unique name that describes which metrics are collected and for which this alert has been created.</td>
</tr>
<tr>
<td>Maintenance</td>
<td>Shows whether the resource affected by the alert is in maintenance. Valid values are <strong>true</strong> or <strong>false</strong>.</td>
</tr>
<tr>
<td>Task</td>
<td>The corresponding task for the alert, such as an incident, change, or problem.</td>
</tr>
<tr>
<td>Parent</td>
<td>Reference to a parent alert.</td>
</tr>
<tr>
<td>Initial event generation time</td>
<td>Time that the initial event occurred in the remote system.</td>
</tr>
</tbody>
</table>

If Operational Intelligence is activated, you can right-click an alert and click **View Metrics** to open the integrated Insights Explorer and Dependency Views map for the CI that is associated with the alert.

Manage alerts
Alerts can be managed in Alert Intelligence in Workspace. You can also manage alerts in the Alerts Console.

Role required: evt_mgmt_admin, evt_mgmt_operator, or evt_mgmt_user
1. Navigate to Event Management > Alert Intelligence

For information about how to manage alerts in Workspace, see Manage alert lists in Workspace.

2. To manage alerts, you can also navigate to Event Management > Alert Console.

3. In Alert Console list view, right-click the required alert record and select any of the following options.

<table>
<thead>
<tr>
<th>Alert right-click options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Copy URL to Clipboard</td>
<td>The URL is copied to your clipboard. For more information about the URL, see Launch web application from alert. On some browsers, you are prompted to manually copy the URL to the clipboard. The Now Platform frame around the dashboard is not included in the link.</td>
</tr>
<tr>
<td>Copy sys_id</td>
<td>The SYSId of the alert is copied to the clipboard.</td>
</tr>
<tr>
<td>Assign Tag</td>
<td>Create and assign tags to specific records to group and organize alerts.</td>
</tr>
<tr>
<td>Quick Response</td>
<td>Either apply remediation to the alert or launch a web application.</td>
</tr>
<tr>
<td>Acknowledge</td>
<td>Selects the Acknowledge check box on the Alert form to indicate that the alert is acknowledged.</td>
</tr>
<tr>
<td>Maintenance</td>
<td>Selects the Maintenance check box on the Alert form to indicate that the related CI is receiving maintenance. Selecting this check box does not change the Status field of the CI.</td>
</tr>
<tr>
<td>Close</td>
<td>Marks the alert as closed to indicate that the alert is resolved and requires no further action.</td>
</tr>
<tr>
<td>View Metrics</td>
<td>Opens a dependency views map in metrics mode for the CI that is associated with the alert. The metrics data of the CI is displayed, and you can use the Insights Explorer to build metric charts.</td>
</tr>
</tbody>
</table>

Note: You cannot report alerts directly on business services groups.
4. To view the alerts in a group, click the play icon next to a parent alert.

Monitor alerts for an application service

To view information for application services only, navigate to the Application service list. From this list, you can open business service maps to view and manage alerts for the CIs in each service.

Role required: evt_mgmt_admin, evt_mgmt_operator, or evt_mgmt_user

1. Navigate to Event Management > Services > Application Services.

2. In the row of the required application service, click View Map.

3. Do one or more of these actions:

<table>
<thead>
<tr>
<th>Option</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>View alert details for a CI</td>
<td>In the business service map:</td>
</tr>
<tr>
<td></td>
<td>1. Click a CI tile.</td>
</tr>
<tr>
<td></td>
<td>2. Below the map, click the Alerts tab and review the listed alerts.</td>
</tr>
<tr>
<td>View impact on the CI parent</td>
<td>In the business service map:</td>
</tr>
<tr>
<td></td>
<td>1. Click a CI tile.</td>
</tr>
<tr>
<td></td>
<td>2. Below the business service map, click the Impact tab and review the listed impact rules.</td>
</tr>
<tr>
<td></td>
<td>3. Adjust the impact rules as necessary.</td>
</tr>
<tr>
<td>Change the map display, map layout, or map indicators</td>
<td>In the business service map header:</td>
</tr>
<tr>
<td></td>
<td>1. Click the menu icon.</td>
</tr>
<tr>
<td></td>
<td>2. Configure the appropriate settings.</td>
</tr>
<tr>
<td>Option</td>
<td>Action</td>
</tr>
<tr>
<td>--------</td>
<td>--------</td>
</tr>
<tr>
<td>Navigate to another application service</td>
<td>In the business service map header: 1. Click the down arrow next to the service name or the folder icon for all services. 2. Search for and select another application service ( ). The icon color represents the highest impact or severity for active alerts on the application service. - <strong>Critical</strong>: Red (highest severity). - <strong>Major</strong>: Orange. - <strong>Minor</strong>: Yellow. - <strong>Warning</strong>: Blue (lowest severity).</td>
</tr>
</tbody>
</table>

**View properties for a CI**

<table>
<thead>
<tr>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>In the business service map: 1. Click a CI tile. 2. In the side pane, click the <strong>Properties</strong> tab and review information about the CI. 3. If you want to view more detailed information, scroll to the end of the pane and click <strong>Detailed Properties</strong>.</td>
</tr>
</tbody>
</table>

---

**Priority group**

For better triage and focus, alerts that have a higher priority are brought to the top of the alert list. This placement brings to your attention those alerts that require you to handle them at a higher priority than other alerts.

The priority group indicates which alerts should be attended to first. Priority is calculated for each open alert and then mapped into one of four priority categories.

**Thresholds**

Thresholds on the calculated priority are used to determine to which category the alert is mapped to. Alerts with a priority above the value of the `evt_mgmt.top_priority_group_threshold` property are categorized as **Urgent**, which is the highest priority. The default value of this threshold is 1M.

**Priority group categories**

The priority groups into which alerts fall are listed in the following table.

<table>
<thead>
<tr>
<th>Alert priority groups</th>
</tr>
</thead>
<tbody>
<tr>
<td>Priority group</td>
</tr>
<tr>
<td>Urgent</td>
</tr>
<tr>
<td>High</td>
</tr>
</tbody>
</table>
The value of the alert priority group is more meaningful than the alert severity on its own. For example, an alert with a severity of Major, may not be in need of resolution ahead of an alert whose priority is Critical. The combined group priority value takes the weight of each factor into account, giving you a better indication of which alert to attend to first.

The alert priority group is available in alert lists in the Dashboard, Alert Console, and All Alerts page. For example, in the All Alerts list, the alert priority group is displayed as depicted in the following image.

<table>
<thead>
<tr>
<th>Number</th>
<th>Group</th>
<th>Severity</th>
<th>Priority group</th>
<th>Priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>Demo0001011</td>
<td></td>
<td>Warning</td>
<td>Low</td>
<td>100</td>
</tr>
<tr>
<td>Demo0001006</td>
<td></td>
<td>Warning</td>
<td>Moderate</td>
<td>100</td>
</tr>
<tr>
<td>Alert0010004</td>
<td></td>
<td>Minor</td>
<td>High</td>
<td>200</td>
</tr>
</tbody>
</table>

**Triggers that cause recalculation**

Changes to open alerts trigger the recalculation of the priority and then the alert is again categorized into the relevant priority group. Closed alerts are not considered for alert priority group calculation.

**Alert priority**

Determine the order in which to handle alerts according to the alert priority score. Multiple factors determine the alert priority score and this value changes with changes to the underlying factors.

**Multi-factor decisions**

The value of the alert priority score is a composite of the value of the category and its relative weight. You can configure the factors that make up the score, as described in the following sections, according to Category order, Category value mapping, and CI type weight factor mapping. The categories are:

<table>
<thead>
<tr>
<th>Priority group</th>
<th>Icon</th>
</tr>
</thead>
<tbody>
<tr>
<td>Moderate</td>
<td><img src="image" alt="Moderate Icon" /></td>
</tr>
<tr>
<td>Low</td>
<td><img src="image" alt="Low Icon" /></td>
</tr>
</tbody>
</table>
- **Accumulated categories** - These categories accumulate items with different sub-types that may have a different status or weighing factor. For example, business services that are factored according to different business criticality or business services that are factored according to cost.

- **Choice-list categories** - A list of items. You can map any of the items to a different value, thereby changing the priority for that item. For example, critical severity, which has the value of 1 by default, can be mapped to 4 to give it a higher weight in the calculated alert priority score.

### List of categories

<table>
<thead>
<tr>
<th>Category</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Accumulated categories</strong></td>
<td></td>
</tr>
<tr>
<td>Number of impacted business-services</td>
<td>This category is factored by the business-criticality of the service. An alert that has an impact on one service has a lower priority score than an alert that has an impact on many services. For example, if a router is down, then it might affect many services and a higher priority ensures that this alert is handled before handling another alert that has an impact on fewer services. An alert that has an impact on many non-critical business services must be handled with priority. However, if an alert has an impact on only a few services, but they are critical services, then this alert has a higher priority.</td>
</tr>
<tr>
<td>CI type</td>
<td>This category distinguishes between various CI types. For example, an alert on a CI type that is a router or switch may have a higher priority than an alert on another CI type, like a server or application.</td>
</tr>
<tr>
<td>Number of Secondary alerts</td>
<td>Alerts that have characteristics similar to other alerts are usually grouped, for example, alerts with the same message key are grouped. A parent alert which has many secondary alerts has a higher priority than a parent alert that has only a few secondary alerts. All secondary alerts of a parent alert are counted. If a secondary alert is closed, it is no longer correlated to the parent alert. If a parent alert is closed, all secondary alerts are no longer correlated and their priority value is calculated accordingly.</td>
</tr>
<tr>
<td><strong>Choice-list categories</strong></td>
<td></td>
</tr>
<tr>
<td>Alert state</td>
<td>Priority score is not calculated for an alert that is in <strong>Closed</strong> state. The available states with their default values are:</td>
</tr>
<tr>
<td></td>
<td>- Open = mapping value 1</td>
</tr>
<tr>
<td></td>
<td>- Reopen = mapping value 2</td>
</tr>
<tr>
<td></td>
<td>- Flapping = mapping value 3</td>
</tr>
<tr>
<td>Alert severity</td>
<td>The priority score reflects the level of seriousness of the underlying alert, for example, an alert that has severity of <strong>Critical</strong> has a higher weighted value than an alert with a severity of <strong>Minor</strong>. Priority is not calculated for an alert that has a severity of <strong>Info</strong>. The available levels are:</td>
</tr>
<tr>
<td></td>
<td>- Critical</td>
</tr>
<tr>
<td></td>
<td>- Major</td>
</tr>
<tr>
<td></td>
<td>- Minor</td>
</tr>
<tr>
<td></td>
<td>- Warning</td>
</tr>
<tr>
<td>Category</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| Role     | The priority score reflects the role of the alert. The priority score is higher for an alert that has a role of Parent, next is the role of None, and the least weight is given to an alert with a role of Secondary. A parent alert that has many secondary alerts has a higher value than a parent alert that has less secondary alerts. The available roles are:  
|          | None  |
|          | Parent|
|          | Secondary |

**Structure of the alert priority score**

**Weighted value for each category**

Each category has its own placement in the alert priority score, according to its order and limit. You can configure the order and limit, see Modify the alert priority score. There are only positive numbers.

**Example constituents of alert priority score of 24302020.003**

<table>
<thead>
<tr>
<th>Category</th>
<th>Score</th>
</tr>
</thead>
<tbody>
<tr>
<td>Business services</td>
<td>(24.0, 1000000.0)</td>
</tr>
<tr>
<td></td>
<td>For example, if there are 24 impacted business services, the computed priority value is 24,000,000 (24 * 1000000.0)</td>
</tr>
<tr>
<td>Severity</td>
<td>(3.0, 100000.0)</td>
</tr>
<tr>
<td>CI type</td>
<td>(20.0, 100.0)</td>
</tr>
<tr>
<td>Role</td>
<td>(2.0, 10.0)</td>
</tr>
<tr>
<td>Secondary</td>
<td>(0)</td>
</tr>
<tr>
<td>State</td>
<td>(3.0, 0.001)</td>
</tr>
</tbody>
</table>

Using the scores from the preceding table, the alert priority score is computed as follows:

$$ (24 \times 1000000) + (3 \times 10000) + (20 \times 100) + (2 \times 10) + (0) + (3 \times 0.001) = 24302020.003 $$

Replacing the values of the categories from the preceding table into the formula:

$$ (24 \times 1000000) + (3 \times 10000) + (20 \times 100) + (2 \times 10) + (0) + (3 \times 0.001) = 24302020.003 $$

In the Priority Breakdown area of the Additional Information tab, the alert priority value is displayed as 24302020.003. In the Alerts list, this value is displayed as 24302.

**Effect of category limits**

Limits placed on categories enable overflow values to affect the next category that is ranked higher in priority order. Each accumulated category has a predefined limit. If the count goes above that limit, 1 is added to the next higher-order category. For example, if the number of CI types goes over the limit, then 1 is added to the next category (Severity) which is higher in priority: \( yyy - zzz \) becomes \( yy(y+1) - 000 \)
Display in All Alerts list

In the All Alerts list, the alert priority score value is displayed in the Priority column. For display purposes only, the actual calculated alert priority score is divided by 1000, while in the database, for calculation and sorting purposes, the full computed value is used. For example, for Alert0010002, the alert priority score displayed in the All Alert list is 20302, while in the Additional information tab, the actual value that is displayed in the Priority Breakdown field is 20302020.003, see the following images.

The detailed computation of the alert priority of the selected alert is displayed in the Priority Breakdown area Additional Information tab, as depicted in the image below.
Calculating the alert priority score

Priority is calculated for alerts that match these conditions:

- State not-equal to Closed
- Severity not-equal to Info

Alerts that are queued for priority calculation are listed in the `em_alert_trigger_queue` table. In the Scheduled Jobs table, there are two Event Management - Alert Priority Queue jobs. These two jobs can run in parallel. You can use Insert and Stay to create another job. The Event Management - Alert Priority Queue job runs once every minute and calculates priorities in batches of 1000 open alerts. There are multiple factors that determine the value of the priority of an alert. A change in severity triggers an immediate update of the alert priority score. In this case, only the severity-part of the priority is changed, together with severity information in the Priority Breakdown area of the Additional Information tab.

Triggers that cause recalculation

Triggers that can cause the alert priority score to be recalculated are:

<table>
<thead>
<tr>
<th>Trigger</th>
<th>Effect on the alert priority score</th>
</tr>
</thead>
<tbody>
<tr>
<td>New alert</td>
<td>The generation of a new alert is a trigger to calculate the alert priority score.</td>
</tr>
</tbody>
</table>
### Trigger

<table>
<thead>
<tr>
<th>Trigger</th>
<th>Effect on the alert priority score</th>
</tr>
</thead>
<tbody>
<tr>
<td>Existing alert that changes from closed to any other state</td>
<td>Priority is not calculated for a closed alert, so if the alert state is changed from its current state of closed to open, reopen, or flapping, that change is a trigger to recalculate the alert priority score.</td>
</tr>
<tr>
<td>Role change, between primary, secondary, or none</td>
<td>Changes in role are a trigger for the alert priority score to be recalculated. For example:</td>
</tr>
<tr>
<td></td>
<td>· An alert whose type has changed to Primary, triggers the alert priority score to be recalculated.</td>
</tr>
<tr>
<td></td>
<td>· An alert whose type has changed to None, triggers the alert priority score to be recalculated.</td>
</tr>
<tr>
<td></td>
<td>· An alert whose type has changed to Secondary, triggers the alert priority score to be recalculated.</td>
</tr>
<tr>
<td>CI type</td>
<td>When a CI becomes bound to alert, that change is a trigger to recalculate the alert priority score. This trigger to recalculate the priority occurs once only, when the CI is bound to the alert.</td>
</tr>
<tr>
<td>Change of number of secondary alerts</td>
<td>A change in the number of secondary alerts triggers the alert priority score to be recalculated.</td>
</tr>
<tr>
<td>Severity</td>
<td>A change in severity is a trigger to recalculate the alert priority score. For example, changing from Info to Major triggers the score to be recalculated. Unlike the other triggers listed above, a change in severity triggers an immediate update of the severity part of the alert priority score calculation.</td>
</tr>
</tbody>
</table>

### Modify the alert priority score

You can change the importance of some categories of the alert priority, by modifying their order and/or their weight, as described below. For example, if the CI type is higher in importance than the number of impacted business services, you can change their respective order. As a result, the number of business services is now multiplied by 100, while CI type is now multiplied by 1000000.

**Note:** The changes that you make, using this advanced procedure, changes the default method of calculating the alert priority score. Alerts that might otherwise not have a high score, by changing these configurable values, changes the way you determine the order in which to handle alerts.

### Changing category order

Navigate to the `em_alert_priority_category_order` table. In the **Order** column, you can change the order of the required category.

### Category value mapping

The `em_alert_priority_category_mapping` table shows the configuration value for each category choice. Each value in a drop-down list of categories can be remapped to a different value by configuring this table.

### CI type weight factor mapping

Navigate to the `em_alert_priority_ci_type` table. You can add a new CI, for example, `DualCoreCPU` and in the **Priority** column, you can change the priority of the required category.

In addition, you can edit existing Type and also change its priority value. This table is used to map the value of each CI type, for example, a mainframe that is CI_type: cmdb_ci_mainframe might
have a priority of 80, while a server with CI type: cmdb_ci_server might have a priority of 6 0. The mapping enables you to customize the priority of the various CI types.

**View discovered service history**
The discovered service history shows the frequency of discovered services for a particular time period.

Role required: evt_mgmt_admin, evt_mgmt_operator, or evt_mgmt_user

You can view the discovered services history by business service. The discovered services history is not available for application services. The discovered services history appears only when there are multiple discovered services that occur over a period. A discovered service is a business service that is discovered by Service Mapping. If no discovered services are generated for a particular business service, the discovered services history is hidden. The color corresponds to the discovered services severity, and the length of the bar in each color corresponds to how long the discovered services stayed at that severity.

**Discovered services history**

1. Navigate to **Event Management > Dashboard**.
2. Double-click a business service tile.
3. On the business service map, click a CI that has a severity color.
4. To change the information that appears on the discovered services history, click a history icon.

   - **Calendar icon**: Show information for currently active discovered services.
   - **H**: Show information for discovered services that occurred in the past hours.
   - **D**: Show information for discovered services that occurred in the past 24 hours.
   - **W**: Show information for discovered services that occurred in the past week.
   - **M**: Show information for discovered services that occurred in the past month.

**How alerts work with CIs in maintenance**

When a CI is in maintenance, the impact tree, the business service map, and Alerts tab are updated based on various factors.

A CI is in maintenance when:

- A change request is scheduled for the CI.
- The **Status** field on the CI record is set to **In Maintenance**.

**Note**: To customize how alerts work with CIs in maintenance, see **Create maintenance rules**.

You can learn about how alerts work with CIs from the following video tutorial.
How CIs in Maintenance appear in Event Management

<table>
<thead>
<tr>
<th>Description and the optimal time to resolve the alert</th>
</tr>
</thead>
<tbody>
<tr>
<td>An active change request has the following values:</td>
</tr>
<tr>
<td>• The State is Scheduled or Implement.</td>
</tr>
<tr>
<td>• The current time is between the Planned start date and Planned end date on the change request.</td>
</tr>
<tr>
<td>OR</td>
</tr>
<tr>
<td>• The current time is between the Actual start date and Actual end date on the change request.</td>
</tr>
<tr>
<td>You can monitor the progress of the change request. Wait until the change request moves to the Review or Closed state. Then you can address all alerts for the affected CI and any alerts that generated between start and end dates. Use the impact tree, topology, and Alerts tab to show the calculated impact severity.</td>
</tr>
</tbody>
</table>

Note: The Maintenance check box for an alert is selected when the Status field on the CI record is In Maintenance. This Maintenance check box indicates that the alert must be hidden from the Alerts tab and Alert console.

If an active change request is scheduled for the CI or if the Status of the CI is In Maintenance, all alerts on the affected CI are excluded from impact calculation. The Alerts tab and Alert console also temporarily hide all corresponding alerts. The impact tree shows the CI in green with a note of (In Maintenance). The impact tree and the business service map temporarily show CIs in green.

For a business service, all alerts on CIs in the business service are also hidden from the Alerts tab. The entire business service is shown in green on the impact tree. For a host with an active change request, the host applications are considered as one unit. All child applications are treated in the same manner as the host until the change request is no longer active.
How CIs in Maintenance appear in Event Management

Description and the optimal time to resolve the alert

An inactive change request has the following values:
- The State is New, Assess, Authorize, Review, Close, or has no changes at all.
- The State is Scheduled or Implement. However, the current time is before or after the planned or actual date ranges on the change request.

You can monitor the progress of the change request. When a CI has an inactive change request, you can address the corresponding alerts as appropriate.

CI with no active change request and not in maintenance

When there is no active change request for a CI and when the CI is not in maintenance, impact calculation resumes. The impact tree, the business service map, and Alerts tab show the calculated impact severity for alerts.

Alert similarity

Finding alerts that are similar to the alert that you are currently investigating can help save troubleshooting time by seeing how similar alerts were resolved.

Finding similar alerts

Alert similarity applies natural language processing (NLP) based on Now Platform machine learning (ML) as implemented in Predictive Intelligence.

ML logic filters out irrelevant information and provides further information to help you understand the cause of alerts. You can view solutions used to resolve similar alerts and the probable root cause.

ML helps find similar alerts based on text found in these alert record fields:
- Description
- Short description
- Source
- Type
- Resource
- Metric name
Additional alert information

In the Alert Workspace, select the required alert and click **Insight** to view additional information about the alert.

In the Alert Console, select the required alert and use the group of tabs on the right, the "alert insight tabs," in the alert record to view additional information and insight about the alert. For example, you can view the top recent alerts for the current CI and similar CIs to find the most suitable solution to remediate and resolve the alert.

The alert insight tabs are:

- Repeated Alerts
- Similar Alerts
- CI Incidents
- CI Change Requests
- CI Problems
- Related Incidents
- Related Change Requests
- Related Problems

For more information about the alert insight tabs, see [Alert insight information](#).

Find similar alerts

You can find alerts similar to the alert currently being investigated. Save troubleshooting time by reviewing similar alerts to see how they were resolved.

Ensure that the Predictive Intelligence plugin is activated. To activate this plugin, see [Activate a plugin](#).

Ensure that the `evt_mgmt.similarity_use_ml` property is set to `true`.

Role required: evt_mgmt_admin

Save time in resolving the current alert by reviewing how similar alerts were resolved. Provide resolution consistency by resolving similar alerts in the same way.

1. Navigate to **Event Management > All Alerts**.
2. In the list of alerts, click the alert record that you want to investigate.
3. In the alert record, click the **Similar Alerts** tab.
   *Alerts that are similar to the alert that is being investigated are listed.*
By default, up to 10 similar alerts are listed. You can modify this value by setting the `evt_mgmt.similarity_max_similar_alerts_shown` property.

4. If you configured a threshold, in the Related links area, click **Show Similarities Details**.

The Sys ID and confidence level of each similar alert is displayed. The Confidence level is an indication of how the similar alert matches the parameters that you set. As an example, a high confidence percentage value indicates a higher likelihood of similarity of the alerts to the values that you set.

You can modify the value of the threshold by setting the `evt_mgmt.similarity_use_threshold` property.

**Similarity solutions**

Similarity solutions enable you to use Machine Learning (ML) to compare the text in a resolved alert record to an open alert record to reuse its resolution approach.
Training a similarity solution

To train a similarity solution, you collect words to compile a collection that Machine Learning (ML) can use to compare text in the **Short Description**, **Description**, **Source**, **Type**, **Resource**, and **Metric Name** fields in a resolved alert to see whether the words in the set match words in an open alert. The resolved alert, which is similar to an open alert, provides an example to show how the open alert can be resolved.

To train a solution, the filter must return at least one record. If your filter returns no records, update it.

**Note:** The preferred number of records for training a solution is between 30,000 records and 300,000. If you submit more than 300,000 records, the most recent 300,000 records are used to train the solution. Use only authentic records from the database.

- Ensure that the records you train are not too old and that they are relevant to your business needs. Keep the words in the collection current.
- Do not use hard-coded dates as filters because these filters are not updated when you retrain solutions unless you update them manually before every retraining. Instead, use relative date filters, for example, the last 3 months, last 6 months, or last 12 months.
- Perform training as needed until it provides an acceptable similarity solution. This practice provides you time to review and update your solution definition.

Fields to include in the solution

Record the fields that are likely to contain words and phrases that help the system identify similar records for your solution.

The similarity fields that you select should be a subset of your input field selections. For example, if you select fields from incident records that are in Open state, do not select **Close note** as a similarity field. Because open records do not include **Close note** fields, the text cannot be similar.

The similarity fields are available to users when they create records.

About the similarity score

The similarity score is a measure from 0-100 of the degree of similarity between two alert records. Alert records that have a similarity score higher than the threshold that you specify is returned by the solution.

Review similarity examples and their scores using the **Show training progress** feature to determine whether to either increase or decrease the solution threshold. You can change the threshold value in the **Threshold for Similarity Score** field.

View training solution progress

Training times vary based on the number of records and classes within the training set. The more records and classes you use, the longer the training can take. For example, a data set containing 100,000 records and several hundred classes can take around five hours to complete.

To show the training solution progress, the ML solution automatically performs the following activities when you select **Show training progress** on the Solutions page. For more information, see **View solution training progress**.
Solution training activities

<table>
<thead>
<tr>
<th>Activity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fetching files for training.</td>
<td>The system downloads the training records and sends them to the nearest training service.</td>
</tr>
<tr>
<td>Preparing the data.</td>
<td>The system removes duplicate records from the training set.</td>
</tr>
<tr>
<td>Training the solution.</td>
<td>The training service trains the solution.</td>
</tr>
<tr>
<td>Uploading the trained solution.</td>
<td>The training service uploads the solution as attachment records.</td>
</tr>
</tbody>
</table>

Create an Event Management similarity solution
Create and train a solution that applies machine learning to a collection of words to target and suggest similar alerts in your instance dataset. For example, you can compare the text in a resolved alert record to an open alert record to reuse its resolution approach.

Role required: evt_mgmt_admin

The encryption scheme that you use can affect whether you can train solutions.
- If your data is encrypted by Full Disc Encryption (FDE), you can train solutions.
- If the field you are using for training is encrypted using Platform Encryption, ensure that the shared service worker user has the correct encryption context role that has been used for encryption.
- If you are using Edge Encryption, training is not supported.

Note: This feature supports only English language processing.

1. Navigate to Predictive Intelligence > Similarity > Solution Definitions.
2. Click New.
3. On the form, fill in the fields.

ML Solution Definition form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Solution Template</td>
<td>Use to define a word collection.</td>
</tr>
<tr>
<td>Label</td>
<td>Unique name for the similarity solution.</td>
</tr>
<tr>
<td>Name</td>
<td>Field that is auto-populated with a system-assigned name that is similar to the label name when the solution is created.</td>
</tr>
<tr>
<td>Table</td>
<td>Table that contains the records to use for the word collection, for example, the Incident table or the Asset table. When you assign a table value, a link appears that shows the number of records that match your current conditions.</td>
</tr>
<tr>
<td>Filter</td>
<td>Conditions that you want to apply to the training records. To train a solution, the filter must return at least one record. If your filter returns no records, update it.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Input Fields</td>
<td>Record the fields that contain the text and context that you want to include in your word collection. The field data type can be a string, reference, choice, or HTML, such as Short description and Description.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Journal type is not a supported data type. Good candidates for your input fields have text that is relevant to the solution. For example, if you are configuring a solution to find similar incident records, you can select the Short Description, Description, Resolution notes, and Close notes fields.</td>
</tr>
<tr>
<td>Training Frequency</td>
<td>Training is performed once by the system, by default. Because your data can age over time and degrade the accuracy of recommendations, consider invoking scheduled trainings once your solution definition is fairly stable.</td>
</tr>
<tr>
<td>Domain</td>
<td>On instances where domain separation is active, select the domain whose target records you want to use for your word collection. Create a separate similarity solution definition record for each domain whose field values you want to use for your word collection.</td>
</tr>
<tr>
<td>Similarity Fields</td>
<td>Record fields that are likely to contain words and phrases that help the system identify similar records for your solution. To change your Similarity Field choices, click the Lock icon ( ) to open the field and make your updates. Click the icon again to close the field and save your updates.</td>
</tr>
<tr>
<td>Similarity Window</td>
<td>The period in which you want to look for similar records. If you have a smaller number of total incoming records, a larger window might be best. However, if the window is too large, you may retrieve records that are not as useful. If the window is too small, you might not retrieve enough similar records. For example, if you are looking for similar incident records that are open, you can select Last 1 day. This selection targets the most recent records, many of which could still be open.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>Similarity Window Filters</td>
<td>Filter conditions for your similarity window. These filters define the dataset conditions under which your similarity results are determined. For example, if you are looking for similar incident records that are open, you can filter your search by creating conditions such as: (Incident state) (is) (In progress) These filters are applied in addition to the Input Field filters.</td>
</tr>
<tr>
<td>Window Refresh Frequency</td>
<td>Frequency to refresh the similarity window. For example, if your window contains incident records that are open, you can select a refresh frequency value of Every 15 minutes. New incidents typically occur frequently throughout the day so this frequency increases the likelihood that newly opened records are included in the refresh. Note: If your similarity window is composed of records such as Knowledge article records, which are typically not created often, you can choose a larger refresh frequency such as Every 1 day.</td>
</tr>
</tbody>
</table>

4. Click **Save** to save the solution definition record so you can return to it later, or click **Submit & Train** to create the solution definition record and train it.

5. If you submitted the solution for training, click **OK** on the **Training Activation** window to confirm.

The system schedules the solution for training with the nearest training service. You and other users subscribed to the Predictive Intelligence Notifications category receive a notification when the training completes, including any errors that might have occurred in the training. When training is complete, the system uploads the solution as an Attachment record.

Review the trained similarity solution examples in the **Similarity Examples** related link on your ML Solution Definition form.

View Event Management solution training progress

View solution training progress or statistics to determine whether a solution is available or how long the next training cycle might take to complete.

Role required: evt_mgmt_admin

1. Navigate to **Predictive Intelligence > Similarity > Solutions**.
2. In the ML Solutions list, select the solution whose progress or statistics you want to view.
3. Click the **Show training progress** related link.

The ML solution automatically performs activities that appear in the Training Progress pop-up window.

The system shows a Training Progress pop-up window. In the following example, the progress failed.
If the training is a success, all bars would be fully blue and the progress for each step would show 100%.

See Review Event Management similarity examples. Review Event Management similarity examples
Review the similarity examples and scores that the system provides during solution training to see how the selected alert record compares to existing alert records. For example, you can modify the similarity score threshold to increase the accuracy of your similarity recommendations.

Train a similarity solution in a ServiceNow datacenter. For more information, see Create an Event Management similarity solution.

Role required: evt_mgmt_admin

Adjust the current threshold to provide useful results. For example, a low similarity score has more coverage but less precision.

1. Navigate to Predictive Intelligence > Similarity > Solutions.
2. In the ML Solutions list, locate your solution and click the Information icon (i).
3. Click Open Record.
4. Click the Similarity Examples related link.
5. Review the similarity examples and their threshold scores to determine the accuracy and coverage levels you want applied to your solution similarity results. The higher the similarity score, the more precise it is and the less coverage it offers. The lower the similarity score, the more coverage it has and the less precision it offers.

6. Based on your review, determine whether to increase or decrease the similarity score threshold value for your similarity solution. If the current threshold is not providing useful results, adjust the threshold value.

7. Navigate to Predictive Intelligence > Similarity > Solutions.

8. In the ML Solutions list, locate your solution and click the Reference icon.

9. Click Open Record.

10. In the Solution Statistics tab, enter a new value in the Similarity Score Threshold field. For example, suppose that the current score is 80. Based on your similarity example review, you might want to update the field by entering a higher score of 90, which will return fewer results but ones that are more similar to the alert record under review. A lower similarity score has more coverage but less precision.

11. Right-click in the form header and click Save. Your solution uses the new similarity threshold value. In the example, the solution returns similar results that have a score higher than 90.

Activate Event Management solution version
The system activates the most recent version of the solution, but you can activate any previously trained Event Management solution version if it is more appropriate.

As you might have created more than one solution, activate the solution that is most appropriate.

Role required: evt_mgmt_admin

1. Navigate to Predictive Intelligence > Similarity > Solutions.

2. In the ML Solutions list, click the Reference icon for the trained solution that you want to activate.

3. Click Open Record. You can assign a title to the solution using the evt_mgmt_similarity_solution_title property. The default value is ml_x_global_alert_similarity. This property changes the value in the Solution Name field.

4. In the solution record, click Activate.
The system activates this solution version and deactivates any other solution version.

Alert and CI remediation

Alert and configuration item (CI) remediations help troubleshoot and resolve underlying problems that generate alerts. Remediation is based on Orchestration workflows that can be scripted to perform remediation tasks such as gathering system information or rebooting a server.

Event Management provides a framework for configuring and implementing a system-wide remediation plan to resolve, minimize, or prevent problems that generate events and alerts. Configure alert management rules to remediate alerts and CI remediation rules to remediate a set of CIs.

Alert remediation

Use alert management rules to associate specific alerts with a remediation workflow. You can apply a workflow to alerts manually. Alternatively, you can configure the alert management rule that executes a workflow automatically for alerts that match the rule criteria. The workflow can also be scripted to request user approval before executing subsequent workflow tasks. The workflow is paused for user approval, even if it was automatically triggered.

CI remediation

Configure remediation more comprehensively by creating CI remediation rules to manually apply remediation to specific CIs.

Remediation tasks

When a remediation workflow is executed, a remediation task is created to capture details such as the time that the workflow started to run, the alert that triggered the remediation workflow (if relevant), and the CI that was remediated. View these tasks to track remediation activities in the organization.

Apply alert remediation

If an alert meets the criteria of an alert action rule that enables manual remediation, you can manually apply remediation to resolve the alert.

Ensure that the alert matches an alert action rule that enables manual remediation.

Role required: evt_mgmt_admin

When an alert is initially created, you can select which remediation to run from a list of all applicable remediations.

1. Find the alert that you want to remediate.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| From the Event Management dashboard         | Navigate to Event Management > Dashboard. You have these options for selecting an alert:  
  - Select an alert from the list at the bottom of the dashboard.  
  - Click a business service tile and select an alert from the list at the bottom of the service map.  
  - Click a technical service tile and select an alert from the technical service object list, or select an alert from the Alerts tab.                                                                                                                                                                                                                                                                                                                                                             |
| From the Alerts Console                     | 1. Navigate to Event Management > Alerts Console.  
  2. Select an alert from the list.  
  2. Right-click the alert, and select Quick Response.  
  3. In the Quick Response dialog box, select the link to the remediation workflow that you want to apply.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

Create or edit CI remediation
Create a CI remediation rule that lets users manually apply an Orchestration workflow for resolving issues with specific CIs associated with alerts. Define these CIs in the CI filter conditions of the rule.

Create the workflow to remediate CIs. In the workflow settings, select Remediation Task (em_remediation_task) in the Table field.

Then submit the workflow definition, and add the following conditions to the workflow properties:

- (Run Remediation)(is)(true)
- (Workflow)(is)(&lt;name of the new workflow that you just created&gt;)
  For example, if the name of the workflow is CI remediation, add this condition:
  
  (Workflow)(is)(CI remediation)

After you finish configuring the workflow, make sure that you publish it. For more details, see Create a workflow.

Role required: evt_mgmt_admin

A CI remediation rule associates a set of CIs that might experience problems with a remediation workflow. The remediation workflow can either resolve the underlying problem or help troubleshoot the problem that generated the alert. For example, you can proactively configure a workflow with the appropriate response actions for predictable alerts. For more details, see the Event Management Remediation short video.

2. Click New, or select a CI remediation to edit.  
3. Fill in the fields, and click Submit or Update.

<table>
<thead>
<tr>
<th>Control</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CI filter</td>
<td>Conditions to match the CIs that you want to apply this remediation to.</td>
</tr>
</tbody>
</table>
In service maps that are opened from the Event Management dashboard, this remediation can be applied to any CIs that match the filter conditions. For more information, see Apply CI remediation.

**Apply CI remediation**

You can apply remediation to a CI that matches the conditions in a CI remediation rule. The specified remediation workflow is then executed to perform tasks that help resolve or troubleshoot a problem that the CI is experiencing.

Ensure that the CI matches a CI remediation rule.

Role required: evt_mgmt_admin

1. Navigate to Event Management > Dashboard.
2. Double-click the tile of the service that includes the CI.
3. On the service map, right-click the CI and select Remediation options.
4. In the Remediation options dialog box, select the remediation that you want to apply and click Run.

The remediations list includes remediations in which the CI matches the filter of a CI remediation rule, and remediations configured in alert action rules for which alerts that are associated with the CI, match the filter.

**View remediation tasks**

Event Management automatically creates a remediation task to capture every remediation that was applied to a CI or to an alert. It gives you an overall view of remediation activities in the organization.

Role required: evt_mgmt_user

Navigate to Event Management > Remediation Tasks.

<table>
<thead>
<tr>

**Use the Event Management overview dashboard**

The Event Management overview module uses Performance Analytics to present data from your instance for you to better visualize and understand your processes and drive continual improvement.
The default number of rows that are allowed to be fetched from an Indicator Source is 50,000. To modify this number, edit the com.snc.pa.dc.max_row_count_indicator_source property that is located here: **Performance Analytics > System > Properties**.

Role required: evt_mgmt_admin, evt_mgmt_operator, or evt_mgmt_user

With the Event Management administration role, you can add, delete, and rearrange report widgets. The other Event Management roles can view and refresh report widgets.

Note: Event Management does not support mobile devices.

1. Navigate to **Event Management > Overview**.
   
   The default display of the Event Management Overview dashboard depends on whether the base instance is an upgrade from an earlier release and which plugins are activated:
   
   - Event Management upgraded from an earlier release or is activated in the instance, see **Event Management Overview dashboard**.
   - Event Management and the Performance Analytics - Content Pack - Event Management (com.snc.pa.em) plugin are activated, see **Event Management Insight dashboard**.

   Note: If Event Management is upgraded from an earlier release and Performance Analytics - Content Pack - Event Management (com.snc.pa.em) plugin is also activated, see **Event Management Scorecards**.

2. Move or add widgets as needed.
3. Click elements within widgets to obtain more information.

**Event Management Insight dashboard**

The Event Management Insight dashboard is available to be displayed when both the Event Management plugin (com.glideapp.itom.snac) and the Performance Analytics - Content Pack - Event Management (com.snc.pa.em) plugin are activated.

**Event Management Insights dashboard**

Note: Event Management does not support mobile devices.

1. Navigate to **Event Management > Overview** to view the overview module.
2. Select Event Management Insights from the drop-down list.

The tabs available in the Event Management Insights dashboard are:

- Data Quality
- Services Criticality Monitor
- Impact Time Severity Monitor
- Alert Lifecycle

You can click elements within widgets to obtain more information.

**Data Quality**

The Data Quality tab provided in the base instance displays:

- Open Alerts older than 7 days by severity and state
- Open alerts not updated in the last 5 days by severity and state
- Open alerts where related INT is not updated in the last 3 days
- % of alerts in un-acknowledge
- % of un-grouped alerts
- % of alerts without assigned task
Open Alerts older than 7 days by severity and state

</table>
Self-health monitors for Event Management

Use the Event Management self-health monitors to track Event Management features and resolve issues.

Monitor Event Management to detect and resolve issues

Enable the self-health feature to help detect and troubleshoot Event Management health issues. Some configuration is required before the self-health feature can display meaningful data. Once configured and the related scheduled jobs are enabled, the Event Management dashboard displays data that is automatically collected and calculated on a recurring schedule.

The self-health feature creates CIs in the CMDB to represent the components of the self-health service. Use the provided monitors to monitor and track the health of business services and Event Management features.

Event Management self-health can:

- Trigger alerts when there is an issue with Event Management.
- Display the ServiceNow Event Management application service on the Event Management dashboard. Use the dashboard to view alerts by business service, application service, technical service, and alert groups. You can double-click a tile to view a map representation of the service.
- View a map representation of the ServiceNow Event Management application service to see the relationships between CIs in the ServiceNow Event Management application service.
Set up

Ensure that the Event Management — self-health monitoring (evt_mgmt.self_health_active) property is set to Enable to use the Event Management features that handle issues with the Event Management application itself. For more information, see Start or stop self-health monitoring.

Self-health monitoring process workflow

After the Event Management — self-health monitoring property is enabled:
1. The **ServiceNow Event Management** application service is automatically created.
2. Jobs are automatically scheduled to run scripts that configure what must be monitored.
3. The Monitoring States (em_monitor_state) table is updated after each event run that the configuration scripts trigger.
4. Monitor the alerts that are generated. The business service displays the status of the monitored entity. For example, alerts are displayed in the Event Management dashboard or Alert Console.
5. Resolve the alerts according to the underlying issue, for example, using **Quick Response**.

### Jobs scheduled to process scripts

The jobs scheduled to run by default after the **Event Management — self-health monitoring** property is enabled are:

- The **Event Management - Insert Health Monitor** scheduled job which runs the scripts. Determine what must be monitored by adding to, or modifying the script in this job which runs once every hour. After the job has run, you can view the **ServiceNow Event Management** application service.

- The **Event Management - Update Health Monitor** scheduled job which runs the update scripts. This job runs once every minute.

### Start or stop self-health monitoring

You can control the starting or stopping of the self-health monitor feature by configuring the self-health monitoring property. The first time that the self-health monitoring property is enabled, it automatically creates the **ServiceNow Event Management** application service.

**Role required:** evt_mgmt_admin

Configure the self-health monitoring property to monitor and track application services and Event Management.

1. Navigate to **Event Management > Settings > Properties**.
2. Locate the **Enable Event Management self-health monitoring (evt_mgmt.self_health_active)** property.
   Select one of these values:
### Enable Event Management self-health monitoring property

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enabled</td>
<td>The ServiceNow Event Management application service is created and set to monitor self-health. Events are received and alerts are generated.</td>
</tr>
<tr>
<td>Alerts Only</td>
<td>The ServiceNow Event Management application service and the CIs related to it are not created. Alerts are created but are not bound to a CI.</td>
</tr>
<tr>
<td>Disabled</td>
<td>The ServiceNow Event Management application service is not operational. Events are not received, and alerts are not generated.</td>
</tr>
</tbody>
</table>

3. **Click Save.**

The ServiceNow Event Management application service is set according to the value selected for the `evt_mgmt.self_health_active` property.

**Monitor self-health with domain separation**

Use domain separation to enable self-health to display Event Management health issues that are based on data, rules, and settings from the logged-on user domain. The selected domain must not contain any child domains.

Ensure that the Domain Support — Domain Extension Installer (com.glide.domain.msp_extensions.installer) plugin is activated and that the MID Server you are connecting to is configured for Event Management.

**Role required:** `evt_mgmt_admin`

Self-health monitoring is domain aware. If the Domain Support — Domain Extension Installer (com.glide.domain.msp_extensions.installer) plugin has been activated, then self-health displays health issues based on data, rules, and settings from the logged-on user domain. If rules and settings are not defined for a child domain, then the settings of the parent are applied, recursively.

When the Domain Support — Domain Extension Installer (com.glide.domain.msp_extensions.installer) plugin is not activated, adding, or removing a connector or MID Server is immediately reflected in the map.

When the Domain Support — Domain Extension Installer (com.glide.domain.msp_extensions.installer) plugin is activated, updates are done periodically according to the interval specifications of the Event Management — Insert Health Monitor scheduled job.

1. Navigate to **System Scheduler > Scheduled Jobs**.
2. In the **Schedule** list, locate and select the Event Management — Insert Health Monitor job.
3. In the Event Management — Insert Health Monitor job, under Related Links, click **Configure Job Definition**.
4. Set the required periodic update time in the **Repeat Interval** field by specifying the required values. The default interval is one hour.
5. Click Update.

Further configuration is required for CI creation, receipt of events, and alert generation. The `sys_id` of the domain must be specified in the Value field of the `evt_mgmt.domain_self_monitoring` property.

1. Navigate to System Properties All Properties.
2. Locate and select the `evt_mgmt.domain_self_monitoring` property.
3. In the Value field, specify the `sys_id` of the domain.
4. Click Update.

Configure a self-health monitor

You can configure a self-health monitor to track Event Management components and see that they do not exceed the specified threshold.

Role required: `evt_mgmt_admin`
The Monitoring Configurations (em_monitor_conf) table lists the records that determine which Event Management components are being monitored. Each record contains the health monitor script that is relevant to what you are monitoring. If you intend to create a new health monitor script, you must configure a monitor to match the purpose of the custom script. You can configure the monitoring configuration records to track the items that are important to you. For example, you can modify the threshold aspect in the Connector’s Idle state monitoring record, by specifying that the monitoring job frequency is 90 seconds instead of 120 seconds.

**Note:** Each of the monitoring configuration records can be disabled.

If a monitoring configuration specifies a threshold, the configuration value determines what alert severity to display. Threshold values specify the delay time values in units of minutes.

**Note:** Additional self-health information appears on the Event Management Overview dashboard.

After the Event Management - self-health monitoring property is enabled, these jobs are automatically scheduled to run scripts that configure what must be monitored:

- **The Event Management - Insert Health Monitor** scheduled job runs the scripts. Determine what must be monitored by adding or modifying the script in this job, which runs once every hour.
- **The Event Management - Update Health Monitor** scheduled job runs the update scripts. This job runs once every minute.

Use the following procedure to configure whether a monitoring configuration can run and set the frequency of the monitoring job. You can specify the threshold values that, if exceeded, trigger an alert.

1. **Navigate to Event Management > Settings > Self-Health configuration.**
2. From the Monitoring Configurations list, select a monitoring configuration record and modify the required field. On the form, fill in the fields.

### Monitoring Configuration form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active</td>
<td>Check box for enabling the monitoring configuration to be active.</td>
</tr>
<tr>
<td>Monitoring job frequency (seconds)</td>
<td>Frequency that the monitoring job is run.</td>
</tr>
<tr>
<td>Critical Threshold</td>
<td>Any point above the value is considered a critical consequence.</td>
</tr>
<tr>
<td>Major Threshold</td>
<td>Any point above the value, but below the value of the Critical Threshold, is considered a major consequence.</td>
</tr>
<tr>
<td>Minor Threshold</td>
<td>If exceeded, the value is considered a minor consequence.</td>
</tr>
<tr>
<td>Warning Threshold</td>
<td>If the value is exceeded, a warning is issued.</td>
</tr>
</tbody>
</table>

3. **Click Update.**

The values in the modified monitoring configuration record are compared to the actual values as they occur in events that are received. Alerts are created according to the configuration settings.
Example 1: Use the following procedure to modify the Critical Threshold field of the Connector’s Idle state monitoring monitor from 30 seconds to 35 seconds. This field determines the number of seconds that pass before an alert is generated when the Critical Threshold idle state value of a connector is exceeded. In this example, the Critical Threshold field is modified from 30 seconds to 35 seconds.

1. Navigate to Event Management > Settings > Self-Health configuration.
2. From the Monitoring Configurations list, select Connector’s Idle state monitoring.
3. In the Critical Threshold field, modify the value to 35.
4. Click Update.

Result The threshold value of the Critical Threshold field is increased from 30 to 35, thereby increasing the number of seconds that pass before an alert is generated for this threshold.

Example 2: This example describes the configuration of the severity threshold when using the Connectors Status monitor. The Connectors Status monitor has a true (= value 1) or false (= value 0) configuration for the severity threshold. For this monitor, where a threshold has the value 1, then that severity is displayed. Only one severity threshold can have the value 1. This example assumes that the required severity displayed is Minor.

1. Navigate to Event Management > Settings > Self-Health configuration.
2. From the Monitoring Configurations list, select Connectors Status.
3. In the Minor Threshold field, specify the value 1.
4. Click Update.

Result The monitor issues an alert if the threshold value of the Minor Threshold field is exceeded.

Create a customized monitor. A template is provided to assist you to create script that can monitor the specified components. For more information, see Create a self-health monitor to use custom health monitor script.

Create a self-health monitor to use custom health monitor script
You can create a self-health monitor to use custom health monitor script to monitor specified Event Management components.

Role required: evt_mgmt_admin

To augment the self-health monitors that are provided with the base system, you can create a self-health monitor to monitor the components that you specify. The health monitor scripts that are provided with the base system are listed in the following table.

Health monitor scripts provided with the base system

<table>
<thead>
<tr>
<th>Health monitor script</th>
<th>Used by a monitor to:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Check delay in event processing</td>
<td>Monitor the duration of events (in minutes) that remain in Ready state and are not processed.</td>
</tr>
</tbody>
</table>
### Health monitor script

<table>
<thead>
<tr>
<th>Health monitor script</th>
<th>Used by a monitor to:</th>
</tr>
</thead>
</table>
| Connectors Monitor    | Monitor:  
  - Whether the time that a connector in idle state surpassed the threshold (in minutes) configured.  
  - The active status of connectors. |
| Get Event Processing state | Monitor the time that events are in Ready state. Alerts are sent when this time exceeds the threshold. |
| MID Server Threshold Alerts | Monitor MID Server health. Events are sent when changes in MID Server state are detected. |

You can create alert management rules to respond to and remediate the issues detected by self-health. Alerts are generated based on the specified severity and threshold. Navigate to **Event Management > Settings > Self-Health configuration** for the monitors that are provided with the base instance to monitor the issues detected by self-health, which are:

<table>
<thead>
<tr>
<th>Monitor</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connector’s idle state monitoring</td>
<td>Monitor to verify whether any of the connectors were in idle state that surpassed the threshold (in minutes) that was configured. Health Monitor script selected: Connectors Monitor.</td>
</tr>
<tr>
<td>Connectors Status</td>
<td>Monitor to track the active status of the connectors. Select only one threshold to configure which severity to invoke using 1 to select the threshold field or 0 to ignore the threshold field. For more information, see Connector status example. Health Monitor script selected: Connectors Monitor.</td>
</tr>
<tr>
<td>Delay in event processing</td>
<td>Monitor to track the duration of events (in minutes) that remain in Ready state and were not processed. This duration period initiates an alert for the event processing CI with severity according to the configured thresholds (minutes). Health Monitor script selected: Check delay in event processing.</td>
</tr>
<tr>
<td>Event Processing job</td>
<td>Monitor the state of the event processing jobs. An alert is generated when the idle time of a job exceeds the configured threshold. Health Monitor script selected: Get Event Processing state.</td>
</tr>
<tr>
<td>MID Server Threshold Alerts</td>
<td>Monitor MID Server health. Events are sent when issues with MID Server availability and resource thresholds are detected. Health Monitor script selected: MID Server Threshold Alerts.</td>
</tr>
</tbody>
</table>

**Note:** To prevent a self-health monitor from detecting the connector status, at any time you can clear the **Active** check box of the monitor and then click **Update**.

1. Navigate to **Event Management > Settings > Self-Health configuration**, and click **New**.  
2. On the form, fill in the fields.
### Monitoring Configuration form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Descriptive and meaningful name for the monitor.</td>
</tr>
<tr>
<td>Description</td>
<td>Text narrative that describes the monitor.</td>
</tr>
<tr>
<td>Active</td>
<td>Check box to enable the monitor.</td>
</tr>
<tr>
<td>Monitoring job frequency (seconds)</td>
<td>Frequency that the monitoring job should run. Default: 120 seconds.</td>
</tr>
<tr>
<td>Last Run</td>
<td>Last run date and time. These values are automatically updated.</td>
</tr>
<tr>
<td>Script</td>
<td>Monitoring script. Click the search icon. The existing scripts are listed in the Health Monitor Scripts screen, or click <strong>New</strong> to create a custom health monitor script. For more information about creating a custom health monitor script, see step 3.</td>
</tr>
</tbody>
</table>

**Note:** Regarding all the following threshold configuration fields: All monitored values are compared against the thresholds. If a monitored value exceeds a threshold, an alert with the appropriate severity is issued.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Critical Threshold</td>
<td>Any point above the value is considered a critical consequence.</td>
</tr>
<tr>
<td>Major Threshold</td>
<td>Any point above the value, but below the value of the Critical Threshold, is considered a major consequence.</td>
</tr>
<tr>
<td>Minor Threshold</td>
<td>If exceeded, the value is considered a minor consequence.</td>
</tr>
<tr>
<td>Warning Threshold</td>
<td>If the value is exceeded, a warning is issued.</td>
</tr>
<tr>
<td>Additional information</td>
<td>Further information about the monitor.</td>
</tr>
</tbody>
</table>

3. To create a custom health monitor script, on the Monitoring Configuration form, next to the **Script** field, click the search icon to open the Health Monitor Scripts form, and click **New**.

4. On the form, fill in the fields.

### Health Monitor Script form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active</td>
<td>Check box to enable the monitor.</td>
</tr>
<tr>
<td>Description</td>
<td>Text narrative that describes the custom script.</td>
</tr>
<tr>
<td>Name</td>
<td>Descriptive and meaningful name for the custom script.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Script</td>
<td>Custom script to run when called from a monitor. A script template is provided as a guide.</td>
</tr>
<tr>
<td></td>
<td>You can use the <a href="https://service-now.com">Health monitor scripts provided with the base system</a> as examples of how to author the script, and use the <a href="https://service-now.com">script editor tools</a>.</td>
</tr>
<tr>
<td></td>
<td>Ensure that the custom script includes:</td>
</tr>
<tr>
<td></td>
<td>Run the monitor function, which is called according to the “monitoring job frequency” setting runUpdateHealthMonitorScripts(scriptId). Add this function to run the monitoring logic.</td>
</tr>
<tr>
<td></td>
<td>Specify the configuration function that is called every hour runInsertHealthMonitorScripts(scriptId). Add the configuration logic and add a CI if needed. In the navigation pane search field, enter em_monitor_state.list. In the Monitoring States (em_monitor_state) table, specify the initialization of the monitor record in the required record.</td>
</tr>
<tr>
<td></td>
<td>Use the helper functions defined in EvtMgmtHealthMonitorCommon and EvtMgmtEventAlertGenerator script includes:</td>
</tr>
<tr>
<td></td>
<td>· EvtMgmtHealthMonitorCommon</td>
</tr>
<tr>
<td></td>
<td>· healthMonitorCommon.shouldRun</td>
</tr>
<tr>
<td></td>
<td>· healthMonitorCommon.calculateSeverity</td>
</tr>
<tr>
<td></td>
<td>· EvtMgmtEventAlertGenerator</td>
</tr>
<tr>
<td></td>
<td>· openAlert</td>
</tr>
<tr>
<td></td>
<td>· closeAlert</td>
</tr>
</tbody>
</table>

You can use the Monitoring Configurations (em_monitor_conf) table for self-health monitoring configuration, the Health Monitor Scripts (em_monitor_scripts) table for scripts, and Monitoring States (em_monitor_state) table for displaying the results of the monitor, as initialized inside runInsertHealthMonitorScripts.

For more information about script includes and APIs, see:
- Script includes that are installed with Event Management
- [APIs and scripts](https://service-now.com)

5. **Click Submit.**

To monitor the Event Management components that you specify, you can configure a self-health monitor that uses the custom health monitor script that you created.

*View the Event Management self-health application service map*

You can view Event Management application service maps to have a visualization of the data on configuration items (CIs) that comprise this service, and the relations and connections between these CIs.

Role required: evt_mgmt_admin
The Event Management application service topology map only displays MID Servers that have passed validation and connectors that are active.

The Event Management components that are monitored by the self-health application service are listed in the following table:

<table>
<thead>
<tr>
<th>Component</th>
<th>What is monitored</th>
</tr>
</thead>
<tbody>
<tr>
<td>Event connectors</td>
<td>For each connector:</td>
</tr>
<tr>
<td></td>
<td>· Status: Success or Error</td>
</tr>
<tr>
<td></td>
<td>· Delay: Elapsed time from ‘last run time’ (above threshold)</td>
</tr>
<tr>
<td>Event processing jobs</td>
<td>For each event processing job:</td>
</tr>
<tr>
<td></td>
<td>· Number of actual jobs executed compared to the number of jobs configured to run.</td>
</tr>
<tr>
<td></td>
<td>· Delay of any of the event processing jobs above the time set as threshold.</td>
</tr>
<tr>
<td></td>
<td>· Duration of events in Ready state compared to the specified threshold.</td>
</tr>
<tr>
<td></td>
<td>· Delay of event rule processing above the set threshold. If there is a delay, an alert is generated and the event rule is disabled.</td>
</tr>
<tr>
<td>MID Servers</td>
<td>MID Servers that have been validated are displayed. The MID Server status and the Ecc_agent_issue table are monitored. An event is triggered whenever this table is updated. The MID Server status is displayed, either Up or Down.</td>
</tr>
</tbody>
</table>

For information about MID Server health, see [MID Server heartbeat](#).

1. Navigate to Event Management > Dashboard.
2. On the Event Management dashboard, double-click the ServiceNow Event Management application service tile, or navigate to Event Management > Services > Application Services.

3. In the application service screen, locate ServiceNow Event Management and click View Service.

Displayed in the map are the related MID Servers and the Event Management object, as depicted in the following image; these MID Servers have an Up status. MID Servers are updated when they are created or deactivated.
Under the Event Management object is Event Processing, Alert Processing, and Event Sources (for example, connectors). Only **Active** connectors are shown; when a connector is created, the connector is displayed only after it has been activated. The status of active connectors is updated and the status of non-active connectors is not displayed.

In the preceding image, the health of Event Management components is displayed. The omniConnector component has a red bar, indicating that a critical alert has occurred that affects this connector. In addition, this critical alert impacts the parent Alert Processing object, which as a result, has a red bar.

You can select the configuration item that has a critical alert and change the impact from parent to business service.
View event processing statistics

Extract statistics from your instance to ensure that performance is not affected and extract metrics related to event processes to monitor event processing status.

Ensure that the Event Management - Collect xmlstats job is active. Configure this scheduled job by navigating to System Definition > Scheduled Jobs.

You can control the processing of event statistics using these properties:

- `evt_mgmt.enable_event_processing_stats`. For information about configuring this property, see Enable processing of event process statistics.
- `evt_mgmt.event_processing_stats_period`. For information about configuring this property, see Configure statistics processing period.

Role required: evt_mgmt_operator

You can view key metrics from the instance to ensure that performance is not affected and monitor the status of the processing of events. For more information about viewing self-health monitoring statistics, see View self-health monitoring statistics for Operational Intelligence.

1. In a browser where the instance is running, run the XML Stats script by appending the following text to the instance URL: `xmlstats.do?include=XMLStatsEm`
2. Press Enter.
3. Monitor the event processing metrics that are reported to ensure that events are processed according to accepted benchmark values.

Sample output after running the XML Stats script

```
<xmlstats created="Tue Oct 23 04:01:25 PDT 2018"
   includes="XMLStatsEm" version="2">
   <itom_event_management>
   <event_processing>
   <processed count="47" max_process_time="10"
      mean_process_time="5" record_time="2018-10-23 11:00:41"/>
   <ready count="7" oldest_ready_event="37" record_time="2018-10-23 11:00:41"/>
   <error count="5" record_time="2018-10-23 11:00:41"/>
   <total_created count="5" record_time="2018-10-23 11:00:41"/>
   </event_processing>
   </itom_event_management>
</xmlstats>
```

The event processing metrics in the report are described in the following table.

```
<table>
<thead>
<tr>
<th>Metric</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Event processing statistics</td>
<td></td>
</tr>
<tr>
<td>processed count=n</td>
<td>Number of events processed by the instance.</td>
</tr>
<tr>
<td>max_process_time=n</td>
<td>Longest time taken by the instance to process an event.</td>
</tr>
</tbody>
</table>
```

Note: The default processing cycle is events created in the last hour and updated in the last minute.
### Metric | Description
--- | ---
`mean_process_time=n` | Average time taken by the instance to process the events in this cycle.  
**Event ready statistics**

`ready count=n` | Number of events that are in Ready state and are available to be processed.  
Default processing cycle: events created in the last hour and updated in the last minute.  

`oldest_ready_event=n` | Longest time taken by an event to remain in Ready state. If this metric has a value that is bigger than your benchmark figure, investigate the event further to determine what is impeding the processing.  
Default processing cycle: events created in the last hour.  

**Other processing statistics**

`error count=n` | Number of events for which errors were reported.  
Default processing cycle: events created in the last hour and updated in the last minute.  

`total_created count=n` | Overall number of events that were processed during this event processing cycle.  
Default processing cycle: events created in the last hour.

---

**Enable processing of event process statistics**

Enable the processing of event process statistics.

Role required: `evt_mgmt_admin`

Use the `evt_mgmt.enable_event_processing_stats` property to enable the XMLStatsEm script to run and collect event processing statistics. You can disable the running of the XMLStatsEm script, for example, to alleviate a performance issue.

1. Navigate to **System Properties > All Properties**.
2. Search for the `evt_mgmt.enable_event_processing_stats` property.
3. Either configure the value of an existing `evt_mgmt.enable_event_processing_stats` property to enable the XMLStatsEm script to run or create a new property if it does not exist already:
   - If the property exists, set the property to **Enable** to enable the XMLStatsEm script to collect event processing statistics and click **Update**.
   - If the property does not exist, click **New**, fill in the form, and click **Update**.
### System property fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the property you are creating.</td>
</tr>
<tr>
<td>Description</td>
<td>Narrative that describes the property and its function.</td>
</tr>
<tr>
<td>Choices</td>
<td>Comma-separated values for a choice list. If you need a different choice list label and value, use an equal sign (=) to separate the label from the value. For example, Blue=0000FF, Red=FF0000, Green=00FF00 displays Blue, Red, and Green in the list, and saves the corresponding hex value in the property value field.</td>
</tr>
<tr>
<td>Type</td>
<td>Data type, that is selected from a list (for example, integer, string, or true</td>
</tr>
<tr>
<td>Value</td>
<td>Desired value for the property. When retrieving properties using the gs.getProperty() method, treat the results as strings. For example, a true</td>
</tr>
<tr>
<td>Read roles</td>
<td>Roles that have read access to this property.</td>
</tr>
<tr>
<td>Write roles</td>
<td>Roles that have write access to this property.</td>
</tr>
</tbody>
</table>

### Configure statistics processing period

Set the time period, in seconds, for collecting event processing statistics. For example, you can set a time period twice as long as the default 60 seconds to collect more statistics.

Role required: evt_mgmt_admin

Use the `evt_mgmt.event_processing_stats_period` property to configure the XMLStatsEm script time to collect event processing statistics. Set the property values to run the script over a longer or shorter period. For example, set a shorter period of statistics collection so fewer CPU resources are used.

1. Navigate to System Properties > All Properties.
2. Search for the `evt_mgmt.event_processing_stats_period` property.
3. Either configure the value of an existing `evt_mgmt.enable_event_processing_stats` property to run the XMLStatsEm script over a shorter or longer time period or create a new property if it does not exist already.
   - If the property exists, set the property to the required time period to enable the XMLStatsEm script time to collect event processing statistics and click Update.
   - If the property does not exist, click New, fill in the form, and click Update.
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>Narrative that describes the property and its function.</td>
</tr>
<tr>
<td>Choices</td>
<td>Comma-separated values for a choice list. If you need a different choice list label and value, use an equal sign (=) to separate the label from the value. For example, Blue=0000FF, Red=FF0000, Green=00FF00 displays Blue, Red, and Green in the list, and saves the corresponding hex value in the property value field.</td>
</tr>
<tr>

### Alert management

As alerts generate, you can view more information about them, acknowledge them, and take action to resolve them. You can also manually create alerts to track issues that did not generate an event or alert.

You can respond to an alert in the following ways:

- Manually remediate the alert.
- Acknowledge an alert that requires attention.
- Create an incident or security incident.
- Create a case.
- Close the alert.
- Resolve any incident that is related to the alert.
- Reopen the alert.

**Note:** Business rules that are written for alert tables (em_alert) must be highly efficient or they may result in performance degradation.

**View alert information**

View a list of all alerts for business services and application services, and then manage individual alerts as necessary.

Role required: evt_mgmt_admin, evt_mgmt_operator, or evt_mgmt_user
Multiple related events may correlate into a single alert. Event Management only creates alerts when one or more events meet the conditions defined in event rules, alert action rules, and alert configuration settings.

1. Navigate to Event Management > All Alerts.
2. To view or manage an alert, click the alert number.
3. Review the information on the Alert form.
   You can click tabs on the form for further information.
   - To view flapping information, click the Flapping tab.
   - To view alert history, click the History tab.

### Alert form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>If an alert was created as a result of the event, this field contains the unique ID that Event Management generates to identify the alert.</td>
</tr>
<tr>
<td>Source</td>
<td>Event monitoring software that generated the event, such as SolarWinds or SCOM. This field has a maximum length of 100 digits.</td>
</tr>
<tr>
<td>Node</td>
<td>Node name, fully qualified domain name (FQDN), IP address, or MAC address that is associated with the event, such as IBM-ASSET. This field has a maximum length of 100 digits.</td>
</tr>
<tr>
<td>Type</td>
<td>Pre-defined event type, such as high CPU, which is used to identify an event record. This field has a maximum length of 100 digits.</td>
</tr>
<tr>
<td>Resource</td>
<td>Node resource that is relevant to the event. For example, Disk C, CPU-1, the name of a process, or service. This field has a maximum length of 100 digits.</td>
</tr>
<tr>
<td>Configuration item</td>
<td>JSON string that represents a configuration item. For example, {&quot;name&quot;:&quot;SAP ORA01&quot;,&quot;type&quot;:&quot;Oracle&quot;}. The CI identifier that generated the event appears in the Additional information field. This field has a maximum length of 1000 digits. Note: Reference pop-ups and click-throughs are hidden by default for read-only fields. For Configuration item and other read only fields, you can optionally change the read-only setting. For more information, see Configure pop-ups on read-only fields. Click to open the alert in dependency view.</td>
</tr>
<tr>
<td>Task</td>
<td>The corresponding task for the alert, such as an incident, change, or problem.</td>
</tr>
<tr>
<td>Metric Name</td>
<td>Unique name that describes which metric data is collected.</td>
</tr>
<tr>
<td>Description</td>
<td>The alert description.</td>
</tr>
<tr>
<td>Message key</td>
<td>Unique event identifier to identify multiple events that relate to the same alert. If this value is empty, it is generated from the Source, Node, Type, Resource, and Metric Name field values. This field has a maximum length of 1024 digits.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Severity</td>
<td>The severity of the event. The value for this field is copied from the event unless the event closes the alert, in which case the previous severity is retained for reporting.</td>
</tr>
<tr>
<td></td>
<td>* Critical: Immediate action is required. The resource is either not functional or critical problems are imminent.</td>
</tr>
<tr>
<td></td>
<td>* Major: Major functionality is severely impaired or performance has degraded.</td>
</tr>
<tr>
<td></td>
<td>* Minor: Partial, non-critical loss of functionality or performance degradation occurred.</td>
</tr>
<tr>
<td></td>
<td>* Warning: Attention is required, even though the resource is still functional.</td>
</tr>
<tr>
<td></td>
<td>* Info: An alert is created. The resource is still functional.</td>
</tr>
<tr>
<td></td>
<td>* Clear: No action is required. An alert is not created from this event. Existing alerts are closed.</td>
</tr>
<tr>
<td>State</td>
<td>The state of the alert.</td>
</tr>
<tr>
<td></td>
<td>* Open: The alert requires user action.</td>
</tr>
<tr>
<td></td>
<td>* Reopen: The previously closed alert requires additional user action.</td>
</tr>
<tr>
<td></td>
<td>* Flapping: After the alert has been closed, it receives a high frequency of identical events from the same source that causes many alert reopenings. User action is required.</td>
</tr>
<tr>
<td></td>
<td>* Closed: The alert is closed and no further user action is required.</td>
</tr>
<tr>
<td>Acknowledged</td>
<td>Select to show that a user has acknowledged the alert.</td>
</tr>
<tr>
<td>Maintenance</td>
<td>A check box that shows whether the resource is affected by the alert is in maintenance.</td>
</tr>
<tr>
<td>Updated</td>
<td>The most recent time that the alert information was updated.</td>
</tr>
<tr>
<td>Parent</td>
<td>If this field is blank, you can specify an alert number. The current alert becomes a secondary alert to this parent alert.</td>
</tr>
<tr>
<td></td>
<td>If an alert number is displayed, then the current alert is already a secondary alert to this current alert, which is the parent alert.</td>
</tr>
<tr>
<td>Feedback</td>
<td>This field appears in alert forms only if the alert being modified is a parent alert. Your response provides feedback about the accuracy and usefulness of the group. Possible values are:</td>
</tr>
<tr>
<td></td>
<td>* None - No value was selected.</td>
</tr>
<tr>
<td></td>
<td>* No Feedback - There is no feedback for this alert.</td>
</tr>
<tr>
<td></td>
<td>* Yes - The alert group is accurate and useful.</td>
</tr>
<tr>
<td></td>
<td>* No - The alert group is not accurate and not useful.</td>
</tr>
<tr>
<td>Knowledge article</td>
<td>The knowledge article associated with the alert, if any.</td>
</tr>
</tbody>
</table>
## Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Overall Event Count</td>
<td>The counter is increased every time an event is bound to the alert. The count value is kept even after the actual event has been purged. Primary alerts (virtual alerts) are updated based on their secondary alerts. The actual number of events that affected the alert is displayed.</td>
</tr>
<tr>
<td>Source instance</td>
<td>The name of the machine or software that generated the event. For example, SolarWinds on 10.22.33.44.</td>
</tr>
<tr>
<td>User name and role</td>
<td>The user and role of the person who made the most recent alert updates.</td>
</tr>
<tr>
<td>Acknowledged</td>
<td>The <strong>Acknowledged</strong> check box value after the most alert recent update.</td>
</tr>
<tr>
<td></td>
<td>• <strong>True</strong>: The <strong>Acknowledged</strong> is selected.</td>
</tr>
<tr>
<td></td>
<td>• <strong>False</strong>: The <strong>Acknowledged</strong> check box is cleared.</td>
</tr>
<tr>
<td>Correlated Alerts section</td>
<td>The secondary alerts that are correlated with this alert, where this alert is the primary alert. For more information, see Alert correlation rules.</td>
</tr>
<tr>
<td>Primary Alerts section</td>
<td>The primary alert that is correlated with this alert, where this alert is a secondary alert. For more information, see Alert correlation rules.</td>
</tr>
<tr>
<td>Impacted Services tab</td>
<td>The impacted services that are related to this alert are listed. For more information, see View the impact tree.</td>
</tr>
<tr>
<td>Flap count</td>
<td>The number of times the alert has flapped—that is, has fluctuated between a closed and a non-closed state—within the flap interval since the start time in the Flap start window.</td>
</tr>
<tr>
<td>Flap start window</td>
<td>The initial start time to measure the flapping occurrences.</td>
</tr>
<tr>
<td>Flap last update time</td>
<td>The last time flapping occurred. This time is the ServiceNow processing time, not the source system time.</td>
</tr>
<tr>
<td>Flap last state</td>
<td>The state before the alert entered the flapping state.</td>
</tr>
<tr>
<td>Initial event generation time</td>
<td>The time when the event that generated the alert first occurred. This time is the ServiceNow processing time, not the source system time.</td>
</tr>
</tbody>
</table>

**Note:** Do not create an Alert Group based on Event Count. Where an Alert Group is based on Event Count, the impact of the group does not calculate properly because the Event Count field is not copied to the em_alert_history table for impact calculation.

**Additional tabs.**

</tr>
<tr>
<td>Activity</td>
<td>The additional notes about the alert.</td>
</tr>
<tr>
<td>More Information tab</td>
<td>Displays the computation of the alert priority score.</td>
</tr>
<tr>
<td>Priority Breakdown</td>
<td>A JSON string that gives more information about the event. The JSON data is supported for String values only, other value types are not supported. You must convert numbers to String values by enclosing them in double quotes. For example, this value is not supported: <code>{&quot;CPU&quot;:100}</code> while this value is supported: <code>{&quot;CPU&quot;:&quot;100&quot;}</code>. Another example of a valid JSON string is: <code>{&quot;evtComponent&quot;:&quot;Microsoft-Windows-UpdateClient&quot;,&quot;evtMessage&quot;:&quot;Installation Failure: Windows failed. Error 0x80070490&quot;}; This information can be used for third-party integration or other post-alert processing. Values in the **Additional information** field of an Event that are not in JSON key/value format are normalized to JSON key/value format when the event is processed. For example, assume that the following plain text is in the **Additional information** field &quot;Connection instance is successful&quot;. When the event is processed, all this plain text becomes one JSON string and might not be useful within an alert. In the resultant alert, this string is in the **Additional information** field in JSON key/value format, containing the data: </code>{&quot;additional_content&quot;:&quot;Connection instance is successful&quot;}`.</td>
</tr>
</tbody>
</table>

For more information about the Calculate Related Tasks command and the alert insight tabs, see [View alert insight information](#).

You can respond to the alert in the following ways:

#### Alert response options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Submit</td>
<td>Save the modifications that were made to the form and return to the <strong>Alerts</strong> list.</td>
</tr>
<tr>

</tbody>
</table>

Alert execution information
Alert execution information provides a reference to the actions that have been performed concerning the alert. Among the information presented is which alert management rules ran on the alert, incidents that were opened, and which remediation workflows ran.

**Alert Executions**
In an alert form, the Alert Execution tab shows key related records for the alert. For example, it shows which actions were performed and which alert management rules were run. If an incident was opened, the related tasks are shown.

### Alert Executions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alert</td>
<td>Reference to the alert that ran under this rule.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Action name</td>
<td>Indicates how the alert was resolved.</td>
</tr>
<tr>
<td>Link to execution</td>
<td>Link action that was taken to resolve the alert.</td>
</tr>
<tr>
<td>Related task</td>
<td>Link to the incident that was created when the alert was resolved.</td>
</tr>
<tr>
<td>Log</td>
<td>Link to the log that details the actions taken to resolve the alert.</td>
</tr>
<tr>
<td>Automatic run</td>
<td>Indicates if the rule was automatic (true) or manual (false).</td>
</tr>
</tbody>
</table>

**Action name**

This indicates what occurred, for example, if an incident was created.

**Log**

The log reveals which alert management rule initiated the action. It shows, for example, automatic execution 1 out 3, or manual execution, 2 out of 4.

**Alert insight information**

Alert insight aids faster alert triage, enabling a quicker way to find a solution and expose the probable root cause of the selected alert.

**Use alert insight to find a solution and help find the root cause of the alert**

Results from data analysis provide further information about the alert, beyond that of the alert form. This aids faster alert triage, enabling a quicker way to find a solution and expose the probable root cause of the alert.

Information shown is from repeated alerts, similar alerts, incidents, problems, and change requests on the same CI, similar CIs, and other CIs that are related by CMDB relations and business service (BS) relations, or grouping. For more information about the alert insight tabs in the alert form, see [View alert insight information](#).

**View alert insight information**

In the alert form, in the alert insight tabs, view calculated insight information on the alert and the CI, based on history and analysis of CMDB and ITSM data. Use alert insight information to show how to resolve the alert and help find what the root cause is.

**Role required: evt_mgmt_user**

The alert insight tabs contain insights on the alert and the related CIs based on history and analysis of CMDB and ITSM data. The alert insight information can help to find a solution for the alert and expose the probable root cause of the alert.

Domain separation is supported. For more information, see [Domain separation and Event Management](#).

1. Navigate to **Event Management > All Alerts**.
2. Click the required alert number.
3. Review the alert insight information on the alert form in the tabs that appear in the red frame in the following image:
## Alert insight tabs in the alert form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>When calculated</th>
</tr>
</thead>
<tbody>
<tr>
<td>Repeated Alerts</td>
<td>List of alerts that have the same message key as that of the selected alert CI and that are in closed state. Use this insight information to find a solution for the alert. Timeframe: Alerts that are up to 30 days old are retrieved.</td>
<td>When the alert form is refreshed.</td>
</tr>
<tr>
<td>Similar Alerts</td>
<td>List of similar alerts that have the same CI type as that of the selected alert CI, as well as the same source, resource, metric name, and so on. Use this insight information to find a solution for the alert and to see similar alerts that were resolved. Timeframe: Alerts that are up to 30 days old are retrieved. For a list of other configurable similar fields, see the description of the <code>evt_mgmt.alert_insight_alert_same_as_filter</code> property in the <a href="#">Alert insight properties</a> topic.</td>
<td>When the alert form is refreshed.</td>
</tr>
<tr>
<td>CI Incidents</td>
<td>List of incidents that have the same CI as that of the selected alert CI. Timeframe: Incidents that were created up to 7 days before the alert was created are retrieved.</td>
<td>When the alert form is refreshed.</td>
</tr>
<tr>
<td>CI Change Requests</td>
<td>List of change requests that have the same CI as that of the selected alert CI. Change requests are only retrieved for these states: implement, closed, and review. Use this insight information to find the root cause of the alert. Timeframe: Incidents that were created up to 7 days before the alert was created are retrieved.</td>
<td>When the alert form is refreshed.</td>
</tr>
<tr>
<td>CI Problems</td>
<td>List of problems that have the same CI as that of the selected alert CI. Use this insight information to find the root cause of the alert. Timeframe: Incidents that were created up to 7 days before the alert was created are retrieved.</td>

<tr>
<td></td>
<td>· Use the value in the <strong>Affiliation Type</strong> column to see the CI relationships. For more information, see <a href="#">Affiliation Type column</a>.</td>
<td></td>
</tr>
<tr>
<td>Related Change Requests</td>
<td>List of change requests on CIs that have a level of relationship with the selected alert CI. Use the insight information to find the root cause of the alert.</td>
<td>Calculated on demand by clicking Calculate Related Tasks.</td>
</tr>
<tr>
<td></td>
<td>Timeframe: Change requests that are up to 7 days old from the creation time of the alert are retrieved.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>When the Related Change Requests tab is selected:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>· Use the value in the <strong>Score</strong> column to see which task might be more relevant as the root cause for the alert. For more information, see <a href="#">Score column</a>.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>· Use the value in the <strong>Affiliation Type</strong> column to see the CI relationships. For more information, see <a href="#">Affiliation Type column</a>.</td>
<td></td>
</tr>
<tr>
<td>Related Problems</td>
<td>List of problems on CIs that have a level of relationship with the selected alert CI. Use this insight information to find the root cause of the alert.</td>
<td>Calculated on demand by clicking Calculate Related Tasks.</td>
</tr>
<tr>
<td></td>
<td>Timeframe: Problems that are up to 7 days old from the creation time of the alert are retrieved.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>When the Related Problems tab is selected:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>· Use the value in the <strong>Score</strong> column to see which task might be more relevant as the root cause for the alert. For more information, see <a href="#">Score column</a>.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>· Use the value in the <strong>Affiliation Type</strong> column to see the CI relationships. For more information, see <a href="#">Affiliation Type column</a>.</td>
<td></td>
</tr>
</tbody>
</table>

**Related CIs**

For further information about the various relations in the **Related Incidents**, **Related Change Requests**, and **Related Problems** columns, see the following table.
CI affiliation type relationship

<table>
<thead>
<tr>
<th>Value</th>
<th>Relationship</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>CMDB dependent relationship rules</strong></td>
<td>• Regular CMDB relation rules</td>
</tr>
<tr>
<td></td>
<td>• Metadata rules (these rules help identify dependent CIs):</td>
</tr>
<tr>
<td></td>
<td>• Containment rules—these rules represent configuration hierarchy of CIs, describing which CI contains which other CIs</td>
</tr>
<tr>
<td></td>
<td>• Hosting rules—these rules represent the placement of CIs in a business definition and describes what the CIs run on</td>
</tr>
<tr>
<td></td>
<td>• Suggested rules</td>
</tr>
<tr>
<td>Business service</td>
<td>CIs that are in the same business service.</td>
</tr>
<tr>
<td>Alert group</td>
<td>CIs of alerts within the same group as that of the selected alert.</td>
</tr>
</tbody>
</table>

The **Score** column in the **Related Incidents**, **Related Change Requests**, and **Related Problems** columns indicate which task might be more relevant as the root cause for the alert. The higher the value of the score, the more relevant that task is as the root cause of the alert. The value is the level of relationship in CMDB or business service, plus its value if it exists in the same alert group.

The score value is calculated as follows:

- The CI found in level 1 has a score of 3.
- The CI found in level 2 has a score of 2.
- The CI found in level 3 has a score of 1.
- The CI that is found in the alert group (the alert group that contains the alert CI) has a score of 2.

For example, if a CI at level 3 is found in the alert group and it has a relationship with the alert CI, the score value is the alert group score plus the level value of the CI. In this example, the score is 1 plus 2 = 3 (the task level plus the alert group score).

The **Affiliation Type** column in the **Related Incidents**, **Related Change Requests**, and **Related Problems** columns show the type of relationship that the alert CI and the CI have. To see affiliation type relationships, navigate to **Configuration > Identification/Reconciliation > Metadata Editor**.

The parent-child relationship between configuration items is considered:

- Containment rules represent configuration hierarchy of CIs, describing which CI contains which other CIs.
- Hosting rules represent the placement of CIs in a business definition and describes what the CIs run on.

For further information, see **CMDB dependent relationship rules**.

Use properties to configure alert insight. For more information, see **Alert insight properties**.

**Alert insight properties**

Use these properties to configure alert insight.

- The role required: evt_mgmt_admin
- The following alert_insight properties are under sys_properties.
<table>
<thead>
<tr>
<th>Property</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time Frame</td>
<td></td>
</tr>
<tr>
<td>evt_mgmt.alert_insight_alert_history_min</td>
<td>Set the time frame (in minutes) to retrieve repeated and similar alert data. Default 43200 (30 days)</td>
</tr>
<tr>
<td></td>
<td>Note: Alerts are retrieved regardless of their state (open / reopen / flapping / closed).</td>
</tr>
<tr>
<td>evt_mgmt.alert_insight_closed_alert_window</td>
<td>Set the time frame (in minutes) to retrieve alerts that were already closed. It is the time after the alert last updated date. Default: 4320 (3 days)</td>
</tr>
<tr>
<td>Similarity</td>
<td></td>
</tr>
<tr>
<td>evt_mgmt.alert_insight_alert_same_as_filter</td>
<td>This property is a comma-separated string that defines which of the alert fields is used to consider alerts to be similar. Default: source, type, resource, metric_name</td>
</tr>
<tr>
<td>Related CIs</td>
<td></td>
</tr>
<tr>
<td>evt_mgmt.alert_insight_related_cis_topology_levels</td>
<td>The relationship types are:</td>
</tr>
<tr>
<td></td>
<td>· CMDB based (metadata rules and suggested relations)</td>
</tr>
<tr>
<td></td>
<td>· Within business services</td>
</tr>
<tr>
<td></td>
<td>· Within alert groups</td>
</tr>
<tr>
<td></td>
<td>For ‘Within business service’ relationship type, this property sets the depth or the maximum level of relationship of retrieved CIs. Default: 3</td>
</tr>
<tr>
<td>Score</td>
<td></td>
</tr>
<tr>
<td>evt_mgmt.alert_insight_group_mapping</td>
<td>This property sets the score for within alert group relations. Default: 2</td>

<tr>
<td>evt_mgmt.alert_insight_level_1_mapping</td>
<td>This property sets the score for level 1 relationship. Default: 3</td>
</tr>
<tr>
<td>evt_mgmt.alert_insight_level_2_mapping</td>
<td>This property sets the score for level 2 relationship. Default: 2</td>
</tr>
<tr>
<td>evt_mgmt.alert_insight_level_3_mapping</td>
<td>This property sets the score for level 3 relationship. Default: 1</td>
</tr>
<tr>
<td>Maximum related tasks</td>
<td>Maximum related tasks to retrieve for alert insight. Default: 10</td>
</tr>
</tbody>
</table>

**Metadata rules consideration**

The parent-child relationship of CIs is considered. Dependent relationship rules consist of hosting and containment rules, each type modeling the data from a different perspective of the CI.

To manage dependent relationship rules:

- To access rules at the class level and use the CI Class Manager. Navigate to **Configuration > CI Class Manager**.
To access grouped rules, use the Metadata Editor. Navigate to Configuration > Identification/Reconciliation > Metadata Editor.

Containment rules represent configuration hierarchy of CIs, describing which CI contains which other CIs.

Hosting rules represent placement of CIs in a business definition, describing what CIs run on.

Modify the alert insight properties to configure the way alert information and analysis appears in the Alert Insight pane.

**Related CIs configuration**

The following properties control which CMDB relationships to consider for related CIs. The CMDB relationships include regular CMDB relation rules, metadata rules (containment rules and hosting rules), and suggested relations.

<table>
<thead>
<tr>
<th>Property</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>evt_mgmt.related_cis_get_all_relation_types</td>
<td>Get all relation types, not including metadata rules. Default: false</td>
</tr>
<tr>
<td>evt_mgmt.related_cis_use_containment_rules</td>
<td>Use metadata containment rules. Default: true</td>
</tr>
<tr>
<td>evt_mgmt.related_cis_use_hosting_rules</td>
<td>Use metadata hosting rules. Default: true</td>
</tr>
<tr>
<td>evt_mgmt.related_cis_use_suggested_relations_rules</td>
<td>Use suggested relations rules. Default: false</td>
</tr>
<tr>
<td>evt_mgmt.related_cis_validate_relation_rules</td>
<td>This property controls whether to validate relation of CI according to metadata rules. Default: true</td>
</tr>
</tbody>
</table>

**Score**

Scores are configured per relation type or depth. Scores are accumulated. The higher the score, the more relevant is the related CI to the current CI.

**Example:** For a CI that was found at level 2 in the same business service of the current CI, the score is 2. The same CI is in the same alert group, so there is an extra score of 3. The accumulated score is therefore $2 + 3 = 5$.

**Affiliation type**

The Affiliation Type column in the Related Incidents, Related Change Requests, and Related Problems tabs shows the type of relationship that the CI of the selected alert and the related CI have.

To see affiliation type relationships, navigate to Configuration > Identification/Reconciliation > Metadata Editor.

The parent-child relationship between configuration items is considered.

**Alert process flow**

Alert management rules and alert correlation rules run on the Alert (em_alert) table.
Alert process flow

Actions are taken on alerts according to this process flow:

- Match the alert management rule to an alert.
  - If the source of the event matches the source specified in an existing rule, then a rule is matched. You can define any kind of condition, on the source of the alert or any other field, and combination of fields.
  - If multiple alert management rules are defined for the same type of alert, use the rule **Order** to determine the order of rule application.
- Match the alert correlation rule to an alert.

![Alert process flow diagram](image-url)
Task/Incident fields that are populated from the alert by default

- `alert.description` is copied to `incident.short_description` and `incident.description`
- `alert.cmdb_ci` is copied to `incident.cmdb_ci`
- `alert.severity` is transformed into `incident.urgency`

For automatically opened incidents:
- `Alert value` is copied to `incident.contact_type`
- `sys_user value` is copied to `incident.caller_id`

Business Rules/Jobs that perform the alert processing actions

<table>
<thead>
<tr>
<th>Action</th>
<th>Name of Business Rule/Job</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Apply alert template</td>
<td>Apply overwrite rule and validate</td>

<tr>
<td>Close Alert by closed incident</td>
<td>Event Management - create/resolved incidents by alerts</td>
<td>Scheduled job</td>
</tr>
<tr>
<td>Close incident by closed Alert</td>
<td>Close associated incident</td>
<td>Business rule</td>
</tr>
</tbody>
</table>

Invoke domain separation through subflows

Event Management supports domain separation in both its out-of-the-box and customized subflows. After customizing a subflow, add it to the Domain Separation Subflows White List table (`em_ds_subflow_white_list`).

Only out-of-the-box subflows in the Domain Separation Subflows White List table (`em_ds_subflow_white_list`) are verified for domain separation. When customizing subflows, an admin user must verify that the subflows support domain separation before adding them to the Domain Separation Subflows White List table (`em_ds_subflow_white_list`).

View alerts in the flapping state
You can view alerts that are specifically in the flapping state.

Before starting this procedure, ask your administrator to configure alert flapping properties.

Role required: `evt_mgmt_admin`, `evt_mgmt_operator`, or `evt_mgmt_user`

Flapping condition that occurs when the event source continues to generate events even after its associated alert has been closed. Flapping causes the status of the resource to repeatedly fluctuate between an Info Severity and another severity that requires attention, for example, Critical.
The frequency of events from an identical source within a given time interval determines whether an alert is in a flapping state or a new issue has occurred. Based on the `evt_mgmt.flap_frequency` and `evt_mgmt.flap_interval` property values:

- If the same issue is recurring, Event Management associates the new event with the existing alert and the state of the alert is set to **Flapping**.
- If the issue occurs after the time interval expires, Event Management creates an alert.

For example, you can respond to an alert by rebooting a problematic server. After no events are generated for several minutes, it is assumed that the issue is fixed and the alert is closed. If the reboot did not actually fix the issue, this server can generate more events later. Then additional alerts are generated for the same issue.

1. Navigate to **Event Management > All Alerts**.
2. Click the number of an alert that is in the **Flapping** state.
3. On the alert, click the **Flapping** tab.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Flapping tab</td>
<td></td>
</tr>
<tr>
<td>Flap count</td>
<td>The number of times the alert has flapped—that is, has fluctuated between a closed and a non-closed state—within the flap interval since the start time in the Flap start window.</td>
</tr>
<tr>
<td>Flap start window</td>
<td>The initial start time to measure the flapping occurrences.</td>
</tr>
<tr>
<td>Flap last update time</td>
<td>The last time flapping occurred. This time is the ServiceNow processing time, not the source system time.</td>
</tr>
<tr>
<td>Flap last state</td>
<td>The state before the alert entered the flapping state.</td>
</tr>
</tbody>
</table>

4. If the **Parent** field is empty, address this alert as a new issue.

**View all alerts by the maintenance status**

The **Maintenance** status indicates that the CI is under maintenance. For example, there is a software upgrade, and the issues can result from that activity, therefore all maintenance alerts are discarded.

Role required: `evt_mgmt_admin`, `evt_mgmt_operator`, or `evt_mgmt_user`

The alert maintenance status can change due to any of these reasons:

- A user selected the **Maintenance** check box on the alert, or selected the alert from the list view, and then clicked the **Maintenance** UI action.
- A new alert that had been bound to a CI whose status is in maintenance status on the CMDB table.
- If all previous events associated with the alert are in maintenance, the alert **Maintenance** field can automatically be set to **true** showing maintenance is in progress. However, if an alert **Maintenance** field is **false** but the related CI status is changed to **In Maintenance** after the alert was created, any subsequent events do not put the alert into maintenance. For example, if an alert is generated for a router and later the router is taken down for maintenance, it is still assumed that there was a problem before maintenance started and the issue must not be ignored.
Note: If a maintenance flag was set on an alert in Geneva, after upgrading to Helsinki it affects the impact as a regular alert. However, it is seen in the alert console only when a new event arrives.

1. Navigate to Event Management > All alerts.
2. Review the Maintenance column for each alert.
   A value of true indicates that the CI is under maintenance.

Note: If the Maintenance field is not visible on the Alert form, personalize the list to add the field. For more information, see Personal lists.

Create maintenance rules
Use maintenance rules to mark CIs in maintenance status. When in maintenance status, these CIs are excluded from impact calculation.

Role required: evt_mgmt_admin

You can define rules to mark CIs that match the specified criteria as being in maintenance status. The marked CIs populate the Impact Maintenance CIs (em_impact_maint_ci) table.

Note: When running maintenance rules, the cmdb_ci status of matching CIs is not changed. However, matching CIs are flagged in the em_impact_maint_ci table by these rules and this status is considered for impact and alert calculations.

The field flagged by this rule as being in maintenance status is the CMDB status field.

Note: To activate a maintenance rule, select the Active field in the maintenance rule. To deactivate a maintenance rule, clear the Active field.

The maintenance rules provided with the base instance are:
### Default maintenance rule

**CI in Change Window**

Where the CI has an active change window, the matching CIs are marked as being in maintenance status.

The rule runs a query against the change request (change_request) table to determine whether the rule is applied. All these conditions in the change_request table must be met:

- **State** is one of these options: Scheduled, Implement, Work in Progress, or Open/New (state in (-2, -1, 1, 2)).
- **Approval** is Approved (approval = 'approved').
- The change request window is active, that is, the current time is between Planned start date and Planned end date, or the current time is between Actual start date and Actual end date.
- The change request record is not an on-hold record (on_hold='false').

**Note:** All these conditions must be present for the CI to be placed in maintenance status by this rule. For example, if the State of the change request approval status is Change is waiting for approval, then the change is not added to the em_impact_maint_ci table.

### Maintenance status of CI

CIs whose CMDB status field is **In Maintenance** are flagged by this rule as being in maintenance status.

By default, retired CIs are not included in CIs that are **In Maintenance**. To include retired CIs:

1. Navigate to **All Properties**.
2. Select **New**.
3. Configure the **evt_mgmt.maintenance_rule_include_retired** property with **Value = true**.

**Note:** Including thousands of retired CIs may decrease system performance.

1. Navigate to **Event Management > Rules > Maintenance Rules**.
2. Click **New**.
3. Fill in the fields, as appropriate.

<table>
<thead>
<tr>
<th>Column heading</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The maintenance rule name.</td>
</tr>
<tr>
<td>Active</td>
<td>Select to activate the maintenance rule.</td>
</tr>
<tr>
<td>Advanced</td>
<td>Select to enable the optional script section to display.</td>
</tr>
<tr>
<td>Column heading</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Description</td>
<td>Information that describes this maintenance rule.</td>
</tr>
<tr>
<td>Flag CIs that run on this host</td>
<td>Select to flag all applications running on the recognized host as being in maintenance.</td>
</tr>
<tr>
<td>Table</td>
<td>Select the table that contains the CI that you require.</td>
</tr>
<tr>
<td>Filter</td>
<td>Specify how to select the data.</td>
</tr>
<tr>
<td>CI field name</td>
<td>Select the CI from the list. The list is populated according to your selection in the Table field. If a CMDB table, or a table derived from CMDB, was selected, specify <code>sys_id</code> for the CI field name. Otherwise, specify the required CI field that you want to use. See the examples.</td>
</tr>
</tbody>
</table>

4. **Click Submit.**

Example of a maintenance rule using a CMDB table.

Assume that a company defines a CI as being in maintenance when the Operational Status of the CI is either **Repair in Progress** or **DR Standby**.
Example of a maintenance rule using a table other than CMDB.

Assume that a company uses Incident records to track maintenance. Any maintenance request is translated to an incident when it has a description that starts with “Performing maintenance on CI”. As long as the status of such an incident is open, this status indicates that the maintenance is in progress. For the CI field name field, specify a CI name from the table that was chosen, in this case Incident.
Example of a maintenance rule that uses the advanced script feature.

In the Maintenance Rule page, select the **Advanced** option. Customize the provided example script:

```javascript
var gr = new GlideRecord('cmdb_ci');
gr.addQuery('name', 'your_name_here');
gr.query();
while (gr.next()){
  result.push(gr.sys_id + '');}
```

The return value for this example script is a text string that represents an array of CI IDs, for example, `['sys_id1', 'sys_id2', 'sys_id3']`.

You can use this script as an example to prepare your own customized script.
Place an alert into maintenance
You can manually place any alert into maintenance to hide it from the alert console and the Alerts tab.

Role required: evt_mgmt_admin, evt_mgmt_operator

Placing the alert in maintenance does not place the CI into maintenance. The Status field on the CI record remains the same.

1. Navigate to Event Management > All Alerts.
2. Perform one of the following actions:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>To put multiple alerts into maintenance</td>
<td>Select the check boxes next to each alert, and then click the Maintenance UI action at the top of the list.</td>
</tr>
<tr>
<td>To put one alert into maintenance</td>
<td>Open the alert, and either select the Maintenance check box and click Update, or click the Maintenance UI action at the top of the list.</td>
</tr>
</tbody>
</table>

Collaborate from within an alert
You can collaborate with colleagues and write work notes while working in an alert.

Role required: evt_mgmt_admin, evt_mgmt_operator, or evt_mgmt_user

You can select to work either in a compact view of Connect that overlays the standard user interface or in a full-screen workspace. The conversations are not copied into the alert.

1. Navigate to Event Management > All Alerts.
2. Click the required alert.
3. In the alert screen, click Follow.
The label of the button changes to **Following**, showing the current connection to collaboration status.

4. To view the Connect sidebar in a full window, click the down arrow in the **Follow** button and select **Open Connect Full**.

   You can write text in the **Worknote** field. This text is not copied into the alert.

5. To collaborate with colleagues or with support, click the **Add User** icon.

6. To conclude the Connect collaboration session, click **Following**.

**Manually create an alert**

An alert can be automatically generated or you can manually create an alert. After creating the alert, an event is also created in the Event (em_event) table. Alerts that are manually created are useful for testing purposes.

**Role required: evt_mgmt_admin or evt_mgmt_operator**

1. Navigate to **Event Management > All Alerts**
2. Click **New**.
3. Fill in the fields, as appropriate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>If an alert was created as a result of the event, this field contains the unique ID that Event Management generates to identify the alert.</td>
</tr>
<tr>
<td>Source</td>
<td>Event monitoring software that generated the event, such as SolarWinds or SCOM. This field has a maximum length of 100 digits.</td>
</tr>
<tr>
<td>Node</td>
<td>Node name, fully qualified domain name (FQDN), IP address, or MAC address that is associated with the event, such as IBM-ASSET. This field has a maximum length of 100 digits.</td>
</tr>
<tr>
<td>Type</td>
<td>Pre-defined event type, such as high CPU, which is used to identify an event record. This field has a maximum length of 100 digits.</td>
</tr>
<tr>
<td>Resource</td>
<td>Node resource that is relevant to the event. For example, Disk C, CPU-1, the name of a process, or service. This field has a maximum length of 100 digits.</td>
</tr>
<tr>
<td>Configuration item</td>
<td>JSON string that represents a configuration item. For example, ({&quot;name&quot;:&quot;SAP ORA01&quot;,&quot;type&quot;:&quot;Oracle&quot;}). The CI identifier that generated the event appears in the Additional information field. This field has a maximum length of 1000 digits. <strong>Note:</strong> Reference pop-ups and click-throughs are hidden by default for read-only fields. For <strong>Configuration item</strong> and other read only fields, you can optionally change the read-only setting. For more information, see <a href="#">Configure pop-ups on read-only fields</a>.</td>
</tr>
<tr>
<td>Field</td>

<tr>
<td>Additional tab</td>
<td></td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Additional information</td>
<td>A JSON string that gives more information about the event. The JSON data is supported for String values only, other value types are not supported. You must convert numbers to String values by enclosing them in double quotes. For example, this value is not supported: {&quot;CPU&quot;:100 } while this value is supported: {&quot;CPU&quot;:&quot;100&quot;}. Another example of a valid JSON string is: {&quot;evtComponent&quot;:&quot;Microsoft-Windows-WindowsUpdateClient&quot;,&quot;evtMessage&quot;:&quot;Installation Failure: Windows failed. Error 0x80070490&quot;}. This information can be used for third-party integration or other post-alert processing. Values in the Additional information field of an Event that are not in JSON key/value format are normalized to JSON key/value format when the event is processed. For example, assume that the following plain text is in the Additional information field: &quot;Connection instance is successful&quot;. When the event is processed, all this plain text becomes one JSON string and might not be useful within an alert. In the resultant alert, this string is in the Additional information field in JSON key/value format, containing the data: {&quot;additional_content&quot;: &quot;Connection instance is successful&quot;}.</td>
</tr>
</tbody>
</table>

4. Click **Submit**.

You can respond to the alert in the following ways:

**Alert response options**

| Option                                    | Description                                                                                                                                                                                                 |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---|
| Submit                                    | Save the modifications that were made to the form and return to the **Alerts** list.                                                                                                                         |  |
| Acknowledge the alert.                    | Click **Acknowledge**. If the alert is reopened, this button reappears so you can reacknowledge the alert.                                                                                                       |  |
| Create an incident.                       | Click **Create incident**. For more information, see **Create an incident or security incident from an alert**.                                                                                               |  |
| If Security Incident Response is activated, create a security incident response. | Click **Create Security Incident**.                                                                                                                                                                         |  |
| Designate that the alert is in maintenance.| Select the **Maintenance** check box. For more information, see **View all alerts by the maintenance status**.                                                                                            |  |
| Close the alert.                          | Click **Close**. For more information, see **Close an Event Management alert**.                                                                                                                             |  |

Create an incident or security incident from an alert
When an alert must be escalated and assigned to someone who can resolve the underlying issue, you can open an incident.

Role required: evt_mgmt_admin, evt_mgmt_operator, or evt_mgmt_user

If Security Incident Response is activated, a security incident can be created.

You can manually create incidents and security incidents from the Alert form. To prevent duplicate tasks, the system checks the conditions of all task templates before creating an incident.

You can customize the created incident using the `EvtMgmtCustomIncidentPopulator.populateFieldsFromAlert` script include. The customization includes mapping fields from the alert to the incident or aborting the incident creation according to customized conditions. For more information, see Custom alert fields.

You can populate incident fields using custom alert fields values that were populated from additional information fields. Use the `EvtMgmtCustomIncidentPopulator` script include to copy the values to the incident after copying the data to the alert. For more information, see Custom alert fields.

**Note:** If Security Incident Response is activated, the base system includes an alert action rule called Create security incidents for critical alerts. This alert action rule creates security incidents when critical security events are reported.

1. Navigate to Event Management > All Alerts.
2. Click the alert Number.
3. To create an incident:
   - To create an incident, click Quick Incident.
   - To create a security incident, click Create Security Incident. You must install the Security (secops) plugin to enable this option.
4. Click Update.

The created incident appears in the Task field of the Alert form.

Resolve an incident related to an alert
When you resolve an incident that is associated with an alert, the alert can also close according to the `evt_mgmt.incident_closes_alert` property.

Role required: evt_mgmt_admin, evt_mgmt_operator, or evt_mgmt_user

When you close an incident by clicking Resolve Incident on an open incident, the corresponding alert is closed, resolved, or left alone as specified by the `evt_mgmt.incident_closes_alert` system property.

Launch web application from alert
You can launch a web application from an alert that matches the conditions set in an alert action rule.

Create an alert action rule that is configured to prepare a URL when the conditions that you stipulate are met. For example, based on the results when the alert parameters are resolved, this feature can open a Knowledge Base article or construct a URL.

Role required: evt_mgmt_admin, evt_mgmt_operator, or evt_mgmt_user

Right-click an alert in any screen to use this feature, for example, in the Alert Console, All Alerts, or the Alert list in the Event Management Dashboard, and choose Quick Response. Click the
required link to launch the web application that was configured in the alert action rule. For further information, see Migrate an alert action rule to an alert management rule.

1. Navigate to Event Management > Alerts Console.
2. Right-click the required alert and select Quick Response.
   A window appears with a list of available web applications that were configured in the alert action rule and the filter that matches the alert. To see the target URL, point to the cursor over the application name.

   **Note:** If one or more of the alert action rule parameters cannot be resolved, the related application name appears in black. When the alert parameters are resolved, then the application name becomes a link.

3. Click the name of an application to open the URL in another tab or window in your browser.

   A common use case is launch in context to the source management system.

   Other examples include to search in knowledge bases, not only within ServiceNow, but externally as well. Any URL-based action can utilize the alert parameters and the URLs can refer to wikis, messaging services, REST APIs, and so on.

Close an Event Management alert
Close an alert by an event or a user action. Closing an alert also closes any related incident that is not already resolved or closed.

Role required: evt_mgmt_admin, evt_mgmt_operator, or evt_mgmt_user

By closing an alert, any related incident that is not already resolved or closed is closed. This default behavior can be configured by changing the value of the evt_mgmt.alert_closes_incident property.

1. You can close an alert from the Alert form or the Event Management dashboard.
   - To close an event from the Alert form, navigate to Event Management > All Alerts. In the All Alerts list, click the required alert.
   - To close an event from the Event Management dashboard, navigate to Event Management > Dashboard. In the Alerts panel, click the required alert.

2. In the Alert Properties view, click Close.
   When you click Close, the alert is closed without confirmation.

   If the alert has any resolved or closed incidents, a work note is added to the incident indicating that the related alert was closed.

   If the alert has an open incident that is not related to any other open alerts, the incident is closed, resolved, or left alone as specified by the evt_mgmt.alert_closes_incident property.

Reopen an alert
Additional events can cause reopening of alerts, or you can reopen an alert by changing its state. When an alert reopens, any associated incidents can also be updated or reopened according to the incident state and the evt_mgmt.alert_reopens_incident property.

Role required: evt_mgmt_admin, evt_mgmt_operator, or evt_mgmt_user

When an alert is reopened, the related incident is processed as follows:

- If the incident is not Resolved or Closed, a work note is added to indicate that the related alert was reopened.
- If the incident is Resolved or Closed, the incident is reopened, a new incident is created, or nothing is done, depending on the evt_mgmt.alert_reopens_incident property value.
• If the incident is reopened, work notes are added to the incident.
• If a new incident is created, any matching alert management rule, alert action rule, and task template applies to the incident. If there is no matching alert action rule or template, fields from the existing incident are copied to a new incident.

1. Navigate to Event Management > All Alerts.
2. Search by alert number.
3. In the State field, click Reopen.
4. Click Update.

Apply a quick response in an alert
In an alert, use the Quick Response feature to apply remediation to the alert or to launch a web application.

Role required: evt_mgmt_operator, evt_mgmt_admin

Quick Response is a feature that enables you to perform a quick action on the selected alert. The action is to apply remediation or to launch an application. If you have upgraded from Istanbul or earlier, this feature is a combination of the Remediation and Launch an application features.

Right-click an alert, for example, in the Alert Console, All Alerts, or the Alert list in the Event Management Dashboard, and you can choose Quick Response to perform a quick action. If you select a remediation link, a workflow is executed according to the criteria specified in the alert management rule. Click a launch application link to launch the web application that was configured in the alert management rule. For further information, see Migrate an alert action rule to an alert management rule.

1. Navigate to Event Management > All Alerts.
2. In the Alerts list, right-click the required alert and select Quick Response.

Quick Response for Alert0110004

Click the appropriate link either to run remediation or to launch a web application.

Run Remediation

Remediation - Get Running Processes

Launch Application

Google
H!
ServiceNow docs

3. In the Quick Response page, click the required link to perform the required action. If the link that you require is not available, perform one of these actions:
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| For Remediation, define a remediation task using an Alert rule based on the selected alert | 1. Navigate to Alert Rules.  
2. Select the required alert management rule to edit.  
3. Click Remediation.  
4. Click Enable Remediation.  
5. In the Execution field, select either Automatic or Manual.  
6. In the Orchestration workflow field, specify the remediation workflow.  
   - For Orchestration, in the workflow settings, select Remediation Task (em_remediation_task) in the Table field.  
   - After you finish configuring the orchestration workflow, publish it.  
7. Click Update.  
  
For further information, see Migrate an alert action rule to an alert management rule. |
| For Launch Application, create a web application link using an Alert rule based on the selected alert | 1. Navigate to Alert Rules.  
2. Select the required alert management rule to edit.  
3. Click Launcher.  
4. Click Enable.  
5. In the Display Name field, specify a name for the link.  
6. In the URL field, compose the URL using data from the alert in the format: ${source}.com:${port}/ ${cmdb_ci.name}  
7. Click Update.  
  
For further information, see Migrate an alert action rule to an alert management rule. |

To create a remediation task or web application link, see Migrate an alert action rule to an alert management rule.

**Alert intelligence**

Alert intelligence is implemented in the multi-tab interface of Agent Workspace. You can manage alerts in Workspace in the Event Management implementation of Agent Workspace.

**About alert intelligence in Workspace**

In Workspace, you can work on an alert record without navigating out of the interface. You can maintain context while opening and working in several tabs and respond to alerts without leaving the form. In the Workspace navigation pane, from the list of alerts sorted in order of smart priority, you can drill down to see key information relevant to the alert. For example, you can see the
priority of the alert, key indicators, and a time-line together with information from other alerts that are part of the alert group.

This implementation is intended for the Network Operations Center (NOC) operator. Its purpose is to enable the operator to resolve alerts in a more efficient and effective way. The operator can examine and diagnose alerts in an intuitive manner using insights (for example, past incidents, similar, or repeated alerts), access to relevant KB articles, graphic time-line of alert groups, and it enables the operator to perform actions (for example, create an incident) that can speed alert resolution.

Note: Do not activate the Alert Intelligence plugin manually. If this plugin must be activated, contact your ServiceNow account manager.

An alert is a notification generated by Event Management for selected events that are considered to be important and require attention. The generation of alerts is based on event rules. After alerts generate, the manner in which you can monitor and resolve alerts is based on alert management rules. If the alert generated an incident, you can click the incident and see the incident details.

For more information about Agent Workspace, see Agent Workspace.

Agent Assist is integrated into the Workspace interface. This feature enables you to perform contextual search, refer to relevant Knowledge Base articles, and save a link to the information found in the alert form. For more information about Agent Assist, see Using Agent Assist in Agent Workspace.

Browser support for workspaces

Do not use Internet Explorer 11 to access any workspaces. If you are on the New York release and you are using Internet Explorer 11 with any workspace, such as Service Owner Workspace, Vendor Manager Workspace, or any other type workspace, you must migrate to a modern browser before you upgrade to future releases. Internet Explorer 11 will not be supported for workspaces after the New York release. See KB0683275 for more information on Internet Explorer 11, and see Generally supported browsers for more information about browsers and what you can use across the platform.

Open Alert Intelligence in Workspace

The Event Management implementation of the Workspace interface can be reached in a number of ways.

Open Alert Intelligence in Workspace

Various ways to open Alert Intelligence in Workspace are:

- In the navigation pane, navigate to Event Management > Alert Intelligence.

- In a browser, add /workspace to the instance URL and press Enter.

- Open an alert in the Event Management Dashboard, the Alert Console, or the All Alert list. In the alert record that opens, click Open in Workspace.
From the right-click menu of an alert from the Event Management Dashboard, the Alert Console, or the All Alert list, select **Open in Workspace**.

**Navigate in Workspace**

When Workspace is open, to see how to navigate, using Agent Workspace as an example, see [Navigating Agent Workspace](#).

**Manage alert lists in Workspace**

Lists that are specific to Event Management alerts in Workspace are provided in the base system and are located in the Lists panel.
Alert lists in Workspace

Filtered lists

In the base system, Event Management provides lists that are filtered into various categories. Click the required filtered list to display the alerts that you need.

1. In the Workspace navigation bar, click .

   The list panel displays the categorized lists.

2. In the Lists panel, under Alerts, the filters provided in the base system are:

   Provided alert filters

<table>
<thead>
<tr>
<th>Filter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Top Priority</td>
<td>List of open alerts that are in the highest Priority group category.</td>
</tr>
<tr>
<td>Top Severity</td>
<td>List of open alerts that have the highest Severity.</td>

<tr>
<td>All Alerts</td>
<td>List of open and closed alerts.</td>
</tr>
</tbody>
</table>

Create a custom list
You can create a list that is filtered according to your requirements, and you can save the list using an easy-to-identify name.

1. In the Workspace navigation bar, click **My Lists**.
2. At the bottom of the Lists panel, click **New list**.
3. On the form, fill in the fields.

   **New List form**

<table>
<thead>
<tr>
<th>Filter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>List name</td>
<td>Name for the custom list.</td>
</tr>
<tr>
<td>Table</td>
<td>Database table from which the alert list fields are to be populated.</td>
</tr>
<tr>
<td>Conditions</td>
<td>Conditions that you define to select the required fields for the alert list.</td>
</tr>
<tr>
<td>Columns</td>
<td>Columns to be displayed in the alert list, chosen from the selected database table.</td>
</tr>
</tbody>
</table>

4. Click **Save**.
   In the Workspace navigation bar, the new custom filtered list appears in the **My Lists** pane.

**Alert list functions**

You can select one or more alerts on the alert list and click the relevant button on the top of the form:

<table>
<thead>
<tr>
<th>Button Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Acknowledge</td>
<td>Acknowledge the alerts to indicate that they require attention.</td>
</tr>
<tr>
<td>Maintenance</td>
<td>Place the alerts in maintenance to indicate that the alert's CI is in the Maintenance state.</td>
</tr>
<tr>
<td>Close</td>
<td>Close the alerts.</td>
</tr>
</tbody>
</table>

**Update alerts in an alert list**

By default, alerts in the alert lists are automatically updated (auto-refresh) whenever an action is performed on an alert. You can configure the amount of time, in seconds, after which the alert list refreshes when an action is performed.

You can also disable auto-refresh and configure how often the alert list is to be updated. You may want to invoke this parameter when a large number of alerts are being processed continuously, so that the list is not constantly refreshing.

1. In the navigation pane, enter `sys_properties_list.do` in the search field.
2. To change the alert list refresh time, modify these properties:

   **Properties to configure alert list refresh**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>evt_mgmt.ai_refresh_time_to_wait_after_manual_action</code></td>
<td>Alert list refresh time after a manual action has been performed on the alert.</td>
</tr>
</tbody>
</table>
### Property and Description

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>evt_mgmt.ai_refresh_time_interval</code></td>
<td>Amount of time after which alert list refreshes, whether or not any action was performed on the alerts.</td>
</tr>
<tr>
<td><code>evt_mgmt.disable_lists_auto_refresh</code></td>
<td>Select to disable auto refresh of alerts in Workspace.</td>
</tr>
</tbody>
</table>

You can create a new list on the **Alert Lists Auto Refresh** page (enter `em_alert_lists_auto_refresh.list` in the navigation pane), and clear the **Enable Refresh** option so that the list does not refresh automatically.

### Open an alert from a list

You can open an alert from any of the list categories. For example, in the Lists panel, click **All Alerts** and then click the required alert.

### Actions you can perform in lists

From the list of alerts in Workspace, you can perform the following actions.

#### Search the list
Search just within the list you have open. The list search automatically searches all the columns in the list.

**Note:** If any records are hidden or removed due to security access restrictions, you see a message with the number of records that were hidden.

### Sort columns

Click the column headings to determine the sort order of a column. The arrow next to the column name indicates the current sort order. A downward pointing arrow indicates that the column is sorted in descending order. Only the primary sort order is indicated. The system remembers the most recent sort order that you choose for a specific column.

Column sorting follows the same default behavior as the platform. If a column is not currently sorted, it sorts ascending unless the column data type is a Date. Dates are sorted as descending by default.

### Change the number of rows per page

In the list footer, click the <Number> rows per page button and select the number of rows you want to display.

### Open a record

Click anywhere in the row to open a record. The list closes and the record opens in a new tab.

### Tab levels in an alert form

There are two levels of tabs in the alert form in the Workspace page.

#### Highest tab level

The alert number of the open alert displays in the highest tab level. The alert number of each subsequent alert that you open displays in its own tab. A maximum of 10 tabs can be opened.

#### Secondary tab level

In the alert form, click an object to open it in a secondary level tab. In the second level, you can have tabs that show, for example, details of the alert; related task (Incident) of the alert; related CI of the alert.
Alert state

If an alert is in **Closed** state, and is now changed to **Open**, after saving the alert and refreshing the alert record, the **Actions** button shows in the alert ribbon.

A user with the role of **evt_mgmt_admin** can change the state of an alert.

1. To change the state of an alert from Closed to Open, select the required alert in the alert list.
2. In the Details tab, in the State area, select Open and click **Save**.
   
   **Actions** now shows in the alert ribbon.

View a topology service map

You can view a topology map of all services affected by an alert. Click the **Actions** button for the alert and select **Dependency View**. For details on the topology map, see [View monitored services](#).

Create a major incident from an alert

When an alert meets the criteria set in the Alert Filter tab (on the legacy UI), you can create a major incident for the alert. Click the **Actions** button for the alert and select **Major Incident**. For details on managing major incidents, see [Major incident management](#).

View alert record details

To view the details of an alert record, click an alert in an alert list.

The following graphic depicts the details of an alert that is in Open state.
The areas on the alert form are described in the following table.

**Alert form areas**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(A) Tab</td>
<td>Each record you click opens in a new tab within Workspace. A tab view of records makes it easier to navigate work in your queue.</td>
</tr>
<tr>
<td>Feature</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>(B) Details tab</td>
<td>The Details tab includes form fields, where you can save and complete forms similar to the platform.</td>
</tr>
<tr>
<td></td>
<td>The header in the details tab includes these details:</td>
</tr>
<tr>
<td></td>
<td>• Description: The text from the Description field of the alert is displayed.</td>
</tr>
<tr>
<td></td>
<td>• Updated: Date and time when the alert was updated.</td>
</tr>
<tr>
<td></td>
<td>• Source: The text from the Source field of the alert is displayed.</td>
</tr>
<tr>
<td></td>
<td>• Overall Event Count: The total overall number of events related to this alert.</td>
</tr>
<tr>
<td></td>
<td>• Role in group (None/Primary/Secondary): The role that the selected alert has in the alert group.</td>
</tr>
<tr>
<td></td>
<td>• Group (None/CMDB/Manual/Automated): The group that the selected alert is a member of.</td>
</tr>
<tr>
<td>(C) Form</td>
<td>The following components make up a form:</td>
</tr>
<tr>
<td></td>
<td>• A header, which gives a quick glance of alert details and priority information.</td>
</tr>
<tr>
<td></td>
<td>• A ribbon, which shows additional alert information. The ribbon includes two widgets:</td>
</tr>
<tr>
<td></td>
<td>• Alert and Alert Group Timeline.</td>
</tr>
<tr>
<td></td>
<td>• The alert body, which gives a complete view of the alert information.</td>
</tr>
<tr>
<td></td>
<td>• Related lists, which show additional related information at the bottom of the form.</td>
</tr>
<tr>
<td>(D) Agent Assist attachment panel</td>
<td>Agent Assist displays relevant knowledge base (KBs) articles for the current alert to find information that might help in solving the alert. Use contextual search to find relevant knowledge base articles. Add the knowledge base articles as attachments to the alert, for example, supporting information to a customer issue.</td>
</tr>
<tr>
<td>(E) Details area</td>
<td>The details of the alert record are displayed in this area.</td>
</tr>
<tr>
<td></td>
<td>Included in the details is the Overall Event Count: The total overall number of events related to this alert. The Overall event count may be different when compared to the number of events, as the overall count includes historic events related to this alert but are no longer kept in the events table.</td>
</tr>
</tbody>
</table>

**Alert section of the information ribbon**

The Alert widget displays on the left-hand side of the information ribbon and is depicted in the following image.
Alert widget contents

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Priority</td>
<td>Priority group category of the alert. For more information about priority groups, see Priority group.</td>
</tr>
<tr>
<td>CI or Node</td>
<td>The CI or node that is bound to the alert. Click the CI or node to open it in a sub-tab.</td>
</tr>
<tr>
<td>Severity</td>
<td>Display the severity status of the alert.</td>
</tr>
<tr>
<td>Actions</td>
<td>Displays actions that were defined in Alert Management. For more information about actions to resolve alerts, see Apply a quick response in an alert.</td>
</tr>
<tr>
<td>Feedback</td>
<td>Submit your feedback about the usefulness of the alert group. Feedback can help future analysis and, over time, accumulated feedback continues to improve the accuracy of alert aggregation.</td>
</tr>
<tr>
<td>Task</td>
<td>Open the underlying incident, change request, or problem. The task opens in a sub-tab.</td>
</tr>
</tbody>
</table>

Timeline section of the information ribbon

The Timeline widget, which displays on the right-hand side of the information ribbon, shows the Alert Group Timeline. For further information about the Alert Group Timeline, see Timeline information.

Collapse information ribbon

Click the to toggle the display of the alert and timeline ribbon.

Functions at the top of the alert form

Actions that can be performed in the alert form are listed in the following table.

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Insight</td>
<td>Retrieve and display Alert Insight details. For more information about Alert Insight, see View alert insight information in Workspace</td>
</tr>
<tr>
<td>Save</td>
<td>Update the selected alert.</td>
</tr>
<tr>
<td>Quick Incident</td>
<td>Create an incident that is linked to the selected alert.</td>
</tr>
<tr>
<td>Close</td>
<td>Close the selected alert.</td>
</tr>
<tr>
<td>Inform Customer Service</td>
<td>Create an internally reported case.</td>
</tr>
<tr>
<td></td>
<td>Toggle the display of the Agent Assist sidebar. For more information about Agent Assist, see Using Agent Assist in Agent Workspace.</td>
</tr>
</tbody>
</table>

Alert Management Executions

The entries in this section provide a reference to the actions that have been performed concerning alert management rules. For more information about alert executions, see Alert executions information.
Remediation Tasks

A remediation task is automatically created to capture every remediation that was applied to a CI or to an alert. For more information, see View remediation tasks.

Post comments in the Activity area

In the Activity area of alerts in Workspace, you can post comments or attach a solution.

1. In the Activity area of an alert, select Additional comments to make your entry visible to customers, or select Work notes to keep the entry internal.

2. In the selected comment field, write a comment or attach a solution and then click Post.

Priority group in Workspace

Alerts that require you to handle them at a higher priority than other alerts are brought to your attention by listing alerts with a higher priority at the top of the alert list. This leads to better triage and focus.

The priority group indicates which alerts should be attended to first. Priority is calculated for each open alert and then mapped into one of four priority categories.

The priority group of the selected alert is prominently displayed in the alert section of the ribbon. For example, the following graphic depicts that the selected alert has a High priority, indicating that it should be resolved ahead of alerts that have a lower priority.

For more information about priority groups, see Priority group.

Timeline information

The Alert Group Timeline tracks alert groups and displays them as points on a timeline.
Information displayed in the timeline

Each point in the timeline represents an alert at the time of the event generation.

Click an alert point to open the alert in a new tab.

If multiple alerts are generated at the same time, only the alert with the highest severity is displayed on the timeline.

An alert point on the timeline that is surrounded by a blue frame indicates that it represents the current alert.

Hover over an alert point to show a tooltip that includes these details:

- CI or Node
- Alert number
- Event Generation Time
- Alert priority group category
Filter alerts on the timeline

Click **Show legend** to display the timeline legend and filter. The color of the alert point represents the severity of the alert.

To filter out the display of alerts on the timeline, in the legend, click the alert point type that is not required to be displayed.

To close the display of the timeline legend, click **Hide Legend**.

Zoom into a time range

To focus on the time range of an alert point, on the timeline you can zoom in the required area. Zoom by dragging the mouse over the required section of the timeline.

Release the mouse to show the time range on the timeline. The highlighted area is brought into focus.
To return the timeline to its previous state, click ![Reset zoom](image).

**Alert insight information**
Alert insight aids faster alert triage, enabling a quicker way to find a solution and expose the probable root cause of the selected alert.

**Use alert insight to find a solution and help find the root cause of the alert**

Results from data analysis provide further information about the alert, beyond that of the alert form. This aids faster alert triage, enabling a quicker way to find a solution and expose the probable root cause of the alert.

Information shown is from repeated alerts, similar alerts, incidents, problems, and change requests on the same CI, similar CIs, and other CIs that are related by CMDB relations and business service (BS) relations, or grouping. For more information about the alert insight tabs in the alert form, see [View alert insight information](#).

**View alert insight information in Workspace**
View insight information on the alert and the CI based on history, analysis of CMDB, and ITSM data.

Role required: evt_mgmt_user for alert insight information and evt_mgmt_admin for all actions, for example, resolve the alert.

Alert insight provides further information about the alert, for example, to show how similar alerts were resolved and provide further insight into the root cause of the alert. View relevant data in Workspace in the context of the alert and the CI as well as in the context of related alerts and CIs.

The various sections in this feature contain insight data analysis on the alert and the related CIs based on history, analysis of CMDB, and ITSM data. You can, for example, see repeated or similar alerts and this information can help you to investigate problems further. The information in the **Repeated alerts** tab is relevant, while the information in all the other tabs provide suggestions that might be relevant to the selected alert.

**Note:** Secondary alerts that have any of the following settings are not displayed:
- Severity is Info
- State is Closed
- Maintenance is selected.
Domain separation is supported. For more information, see Domain separation and Event Management.

1. In Workspace, navigate to List > All Alerts.
2. Click the required alert.
3. Optional: You can click **Actions**.

Select an action to resolve the alert, such as Launch Application, or Remediate.
- If you select a remediation link, a workflow is executed according to the criteria specified in the alert management rule.
- If you click launch application link, it launches the web application that was configured in the alert management rule.
- If you clicked subflow, the selected subflow is executed according to the criteria specified in the alert management rule.

4. The Alert Group Timeline depicts the time of occurrence of the alert in the group it belongs to. Alert groups are displayed across a timeline according to the update time of the alerts. For more information, see Timeline information.

5. To view in-depth alert analysis, in the Details panel, click Insight.
The alert insight details open on the second-level row of tabs. Subsequent actions are displayed on this level as well.

6. Review the alert insight information on the selected alert record.
In each alert insight block, drill down to see if the solution or root cause can be determined.

- View current CI and similar CIs to find the most suitable solution to remediate and resolve this alert.
- Probable root cause is based on machine learning analysis. Review results to find the top Incidents, Changes, and Problems for the current CI. For related CIs, find the most likely probable root cause for the selected alert.

### Alert insight in Workspace

<table>
<thead>
<tr>
<th>Alert insight block</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Top Alerts</strong></td>
<td></td>
</tr>
<tr>
<td>Repeated alerts</td>
<td>List of alerts that have the same message key as the insight alert CI and the alerts which are in closed state. Use this insight information to find a solution for the alert. Timeframe: Alerts that are up to 30 days old are retrieved.</td>
</tr>
<tr>
<td>Similar alerts</td>
<td>List of similar alerts that have the same CI type as the insight alert CI, as well as the same source, resource, metric name, and so on. Use this insight information to find a solution for the alert and to see similar alerts that were resolved. Timeframe: Alerts that are up to 30 days old are retrieved.</td>
</tr>
<tr>
<td><strong>Top Incidents</strong></td>
<td></td>
</tr>
<tr>

</tr>
</tbody>
</table>

Use properties to configure alert insight. For more information, see [Alert insight properties](#).

**Alert correlation rules**

Alert correlation rules enable you to manually classify alerts into primary and secondary, and establish a relationship between them. Use alert correlation rules to group alerts that are related.

For example, if a server in your organization goes offline, you do not need to see additional alerts that show that the virtual machines or applications running on the server are also down. Instead, these additional alerts, or secondary alerts, are grouped under the root alert called the primary alert. You can see these grouped alerts in the alert list in Alert Intelligence.

**Note:** Event Management alert aggregation and RCA provides alert groups for an automated correlation of events and alerts. These alert management rules give you full manual control of alert correlation. For more information on the alert aggregation and RCA feature, see [Automated alert groups](#).

**Primary and secondary alerts**

- A primary alert identifies the root cause of an event.
- A secondary alert is another alert that the same event generates, but is considered less important than the primary alert.

The purpose of specifying secondary alerts is to identify which alerts to suppress, so you can reduce the amount of alert noise and focus on the primary alert. You are able to see both types of alerts, but the secondary alerts are grouped under the primary alert. You can see these groups in the alert list in Alert Intelligence.

**How primary and secondary alert management rules work**

Primary and secondary alert management rules are simply filters that specify which kinds of alerts are classified as primary and which kinds are classified as secondary. The filter criteria runs against the Alert (em_alert) table.

An alert can belong to more than one group, but only one level of secondary alerts is allowed under a primary alert. For example, if secondary alert A is grouped under secondary alert B, both alerts become secondary alerts under the same primary alert. See [alert hierarchy](#) for more information.

**Alert relationships**

Alert correlation rules enable you to specify what type of relationship the primary and secondary alerts must have for the rule to match. These relationships depend on the relationships between the CIs in the CMDB:
- **No Relationship**: Ignore the relationship when looking for a match.
- **Same CI or Node**: Relate both alerts with the same CI. If the CI field is blank, then the alerts must have the same Node value.
- **Primary is Parent**: The relationship is in the direction of parent (primary) to child, as described in the CI Relationship Types table (cmdb_rel_ci).
- **Primary is Child**: The relationship is in the opposite direction, child (primary) to parent, as described in the CI Relationships table (cmdb_rel_ci).

### When correlation rules run

Alert correlation rules run when an alert is created or reopened. The alert is checked to determine if it matches being primary or secondary.

When the primary alert severity is changed to **Closed**, the secondary alerts are also set to **Closed** unless they are part of other groups where the primary alert is not yet set to **Closed**.

### Alert hierarchy

Only one level of secondary alerts is permitted. In situations where a secondary alert has its own secondary alert, the Event Management application flattens the hierarchy to preserve only two levels.

For example, assume alert A is the primary alert and alert B is the secondary alert. If alert C becomes a secondary alert for alert B, the application flattens the hierarchy so that A remains the primary and B and C become sibling secondary alerts, one level below A.

As another example, assume that there are three correlation rules that produce the following results:

1. Rule 1 (with an Order value of 1): B becomes a primary alert for A.
2. Rule 2 (with an Order value of 2): A becomes a primary alert for C and D.
3. Rule 3 (with an Order value of 3): E becomes a primary alert for A.

When alerts B, C, D, and E are triggered, they all appear in the alert list separately because there are no correlations between them.

When alert A is triggered:

1. Rule 1 makes A a secondary alert under alert B.
2. Rule 2 makes both C and D secondary alerts under alert A.
3. Rule 3 makes A a secondary alert under E, giving alert A two primary alerts above it in the hierarchy.

Therefore, if all alerts are triggered, only B and E appear in the alert list, indicated as primary alerts.

**Note**: A secondary alert can be correlated with more than one primary alert, and vice versa.

### View correlated alerts

You can view primary alerts on the alert console and see correlated alerts on a primary alert record.
Role required: evt_mgmt_admin or evt_mgmt_operator

1. Navigate to Event Management > Alert Console. The Group column contains an icon indicating that an alert is a primary alert that has one or more secondary alerts correlated with it.

2. Ensure that Correlated Alerts is selected.

3. Click the primary alert number to open the record for the primary alert. The Correlated Alerts section shows a list of all the secondary alerts that are correlated with this primary alert.

Correlated alert example

Create an alert correlation rule
Create an alert correlation rule to specify a primary alert and a related alert that is of secondary importance.

Role required: evt_mgmt_admin

Note: If you delete an alert correlation rule, the existing correlation groupings on the alert console are not removed.

2. Click New.
3. On the form, fill in the fields.
## Alert Correlation Rule form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Descriptive name to identify the correlation rule.</td>
</tr>
<tr>
<td>Order</td>
<td>The priority for rule evaluation. Rules with lower-order values are given priority. An alert is checked against every alert action rule until a match is found.</td>
</tr>
<tr>
<td>Active</td>
<td>Select to activate the rule.</td>
</tr>
<tr>
<td>Advanced</td>
<td>Select to display the script field. This option enables you to script the event correlations.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the rule.</td>
</tr>
<tr>
<td>Primary Alert</td>
<td>The filter condition to identify the alert that is the primary alert, or most important alert, in a set of related alerts.</td>
</tr>
<tr>
<td></td>
<td>This field does not appear when Advanced is selected.</td>
</tr>
<tr>
<td>Secondary Alert</td>
<td>The filter condition to identify the alert that is related to the primary alert, however it is of lesser importance.</td>

<tr>
<td><strong>Relationship</strong></td>
<td>Description of the CI relationship between primary and secondary, for example, Allocated from::Allocated to or Allocated to::Allocated from. This field displays only if either Primary is Parent or Primary is Child is selected for the Relationship Type.</td>
</tr>
<tr>
<td><strong>Relationship Type</strong></td>
<td>Primary is Child</td>
</tr>
<tr>
<td><strong>Relationship</strong></td>
<td>Allocated from::Allocated to</td>
</tr>
</tbody>
</table>

4. Click Submit.
An alert group is created when a new alert was generated or the status of an alert changed from close or flapping to open or reopen and the filter is matched.

**Alert aggregation and RCA**

The alert aggregation and root cause analysis (RCA) capability enhances Event Management with alert data analysis and alert aggregation. It also provides root cause analysis (RCA) for automated alert groups, and CMDB alert groups.

Use alert aggregation and RCA to do the following:

- Aggregate alerts to create **automated alert groups**.
  
  Correlate alerts according to timestamps and CI identification to create automated alert groups. Alert correlation helps organize incoming real-time alerts and reduce alert noise.
- Apply RCA to automated alert groups and to CMDB alert groups.
- Correlate alerts based on CIs' relationships in the CMDB to create **CMDB alert groups**.
- Generate a pattern for a **manual alert group** and then create an automated alert group according to that pattern.

**Alert aggregation**

Alerts are grouped based on the CI that is associated with the alerts. Event Management groups alerts that are similar, but not necessarily identical, and also based on how close in time the alerts were created.

Alert aggregation has these components:

**Alert Aggregation Learner**

An offline job that runs once a day to process past alerts. The Alert Aggregation Learner identifies patterns of related alerts using a combination of pattern-based and probabilistic techniques. If the CMDB property used for grouping alerts in alert aggregation (**sa_analytics.agg.learner_group_by_property**) is set, then before processing starts, the Alert Aggregation Learner groups alerts by the specified CMDB property. For example, setting the property's value to **location** indicates that the property takes the CMDB location into account when grouping alerts.

**Note:**

- When configuring this property, ensure that you use the column name (in this example, **location**), and not the column label (**Location**).
- Configuring this property causes patterns to be created only for alerts within individual groups, and not across groups. You must ensure that the CMDB property used for grouping alerts in alert aggregation (**sa_analytics.agg.learner_group_by_property**) does not contain overly unique values (such as **name**, **sys_id**, and so forth. If it does, the number of alerts created in a group is limited, which prevents the job from creating a pattern.

**Real-Time Query**

A scheduled job that runs every minute and updates alert aggregation groups. It tries to match real-time alerts with alert patterns stored in the alert knowledge base.

**Aggregation reasoning work notes**
Work notes in the alert display the reason for the creation of the alert group. For example, if the alert was created due to a pattern, a link to the pattern is given.

If the `evt_mgmt.alert_groups_reasoning.enable_worknotes` property is set to `none`, work notes are not written.

RCA for automated alert groups

If you set the Enable root cause analysis for automated (pattern-based) groups property (`sa_analytics.agg.learner_rca_detection`) to `true`, Event Management applies RCA algorithms to automated alert groups. RCA identifies the root cause alert within the automated alert group. RCA helps to direct resources to the root cause CI of a problem. Root cause alerts are displayed in the timeline of alerts in Alert Intelligence.

RCA for CMDB alert groups

If the Enable CMDB Correlation for Alert Aggregation (`sa_analytics.agg.query_cmdb_correlation_enabled`) property is set to `true` and the Enable root cause analysis for CMDB groups (`sa_analytics.agg.query_cmdb_rca_enabled`) property is set to `true`, Event Management applies RCA algorithms to CMDB alert groups. RCA identifies the root cause alert within the CMDB alert group. RCA helps to direct resources to the root cause CI of a problem. Root cause alerts are displayed in the timeline of alerts in Alert Intelligence.

Specify and manage pattern identifier attributes for alert aggregation

Alert aggregation learns the alerts and then forms patterns based on a set of alert and CI attributes. You can specify the set of CI and alert attributes that will be used as the pattern identifier attributes for learning patterns, that will result in alert groups that are meaningful in your environment.

The default attribute used for forming patterns is `metric_name`. Navigate to Event Management > Alert Aggregation and RCA > Manage Pattern Identifier to view which pattern identifier attributes are currently in effect, to choose a different set of attributes to deploy, or to define a new set of pattern identifier attributes.

To ensure that the specified pattern identifier attributes used for forming patterns is effective, a sufficient number of alerts must have the respective attributes populated. Therefore, if you specify a new set of pattern identifier attributes, do the following to ensure meaningful analysis:

- Create an event rule that populates the respective attributes.
- If a large number of existing alerts do not have values for the new set of pattern identifier attributes, ensure to run the Service Analytics Attribute Populator for Historical Alerts job which uses the appropriate event rule to populate attributes in historical alerts. Properties originating from the CMDB CI using dot walking are not populated.
- Choose effective identifiers:
  - Ensure that the set of pattern identifier attributes is not too unique (for example, the date field is unique for every alert), because it will be impossible to identify any pattern.
  - Ensure that the set of pattern identifier attributes is not too common, because it will not be possible to create distinct groups, as everything would be included in the same group.

When an alert pattern is discovered based on a set of identifier attributes, the alerts are considered to be related to each other and therefore are grouped together into a Learned Pattern. For example, if you configure identifier attributes to create a pattern based on alerts with the same Priority Group and Resource, if a group of alerts match those attributes, they are
grouped into a pattern which displays on the Learned Patterns report (Event Management > Alert Aggregation and RCA > Learned Patterns).

Only one set of pattern identifier attributes can be active at a time. A new set of pattern identifier attributes is not automatically implemented until you deploy it. When you deploy a new set of attributes, the current set of attributes that is in effect becomes inactive. Subsequent queries use the active pattern identifier attributes to perform alert aggregation.

1. Navigate to Event Management > Alert Aggregation and RCA and then click Manage Pattern Identifier.
2. On the SA Alert Aggregation Pattern Attributes page click New.
3. Click the Feature Identifier Attributes icon and move attributes from the Available list to the Selected list.
   The Configuration Item attribute is automatically included as an identifier with all selections.
4. Click Submit.
5. Optionally, activate the newly specified pattern identifier attributes by selecting the pattern identifier attributes that you want to activate and clicking Deploy.

After specifying a new set of pattern identifier attributes, ensure that a matching event rule exists that populates the respective alert attributes. Also, run the Service Analytics Attribute Populator for Historical Alerts job to populate the respective attributes of historical alerts, if values are missing in existing alerts.

Automated alert groups

Event Management alert aggregation and RCA aggregates alerts into automated alert groups that represent the underlying event data. Automated alert groups are displayed in the Alert Console and in the Event Management dashboard.

To enable creating automated alert groups, set the Enable alert aggregation (sa_analytics.aggregation_enabled) property to true. For troubleshooting, ensure that the Service Analytics group alerts using RCA/Alert Aggregation scheduled job is running.

If Domain Support - Domain Extensions Installer is activated, then alert aggregation is applied at the domain level that is specified in the sa_analytics.agg.learner_domain_level property. By default, this property is set to 2, which is the second domain level in the domain hierarchy.

To create automated alert groups, aggregation algorithms rely partly on historical data in the alert knowledge base from similar past alerts and processes. As alerts continue to be generated and processed, data is collected and incorporated into the alert knowledge base for future processes and analysis.

Automated alert groups provide these capabilities:

Predictive alerts

If an automated alert group pattern contains at least four alerts, then alert aggregation uses the information of these existing alerts to generate predictive alerts. Each predicted alert is associated with a probability percentage number which represents the confidence in this alert actually being generated in the future. Predicted alerts with probability above the value of the Alert Prediction Minimum Confidence Score (%) Threshold property, are then displayed in the Group Timeline view in the Alert Console.

Root Cause Analysis

Alert aggregation applies Root Cause Analysis (RCA) to automated alert groups, to identify a root cause alert within the group. Identified root cause alerts are then displayed with a star, in the Group Timeline view in the Alert Console. If a root cause alert is identified for an automated alert group, then that alert is designated as the primary alert of the group.
View automated alert groups

View automated alert groups from the Event Management dashboard, the Alert Console, or a business service map. Automated alert groups are displayed in a list view, and are included in the timeline view in the Alert Console. When displaying an automated alert group that is associated with services, the impacted services are displayed and you can view the root cause CI if applicable.

Role required: evt_mgmt_user

In the Alert Console, from each automated alert group in the list view or in the timeline view, you can drill down to view all the alerts that are included in that group. The overall severity of an automated alert group corresponds to the highest alert severity within the alert group. The color that is associated with a automated alert group represents its severity.

The Event Management dashboard does not let you drill down to view further details of an automated alert group.

1. To display all automated alert groups:
   a) Navigate to Event Management > Alert Console.

In the list view, automated alert groups are noted by an icon in the Group column, and the value is Automated.

b) Click the icon for a parent alert to open the hierarchical list of alerts for an automated alert group.

For details about the alert form, see View alert information

2. To display automated alert groups that are associated with the services displayed on the Event Management dashboard:
   a) Navigate to Event Management > Dashboard.
   b) Enable Correlated Alerts.
   c) In the list view, automated alert groups are noted by an icon in the Group column.

- Click on a parent alert to open its alert form and provide feedback about the accuracy and helpfulness of the automated alert group.
- Add or remove alerts from the group.
- View root cause alert for an automated alert group.

View predicted alerts

Alert correlation analyzes existing alerts in an automated alert group, to predict future alerts for that group. Predicted alerts can indicate future problems with the associated services. By viewing those predicted alerts in the Alert Console, you can take measures to prevent any anticipated problems.

Enable creating predicted alerts by setting the (sa_analytics.pred.cl_enabled) property to true by performing the following steps:
1. Navigate to Event Management > Alert Aggregation and RCA > Properties.
2. Select the Enable alert prediction check box.
If necessary, change the default threshold for creating predicted alerts, which is controlled by the (sa_analytics.pred.cl_min_conditional_probability) property:

1. Navigate to Event Management > Alert Aggregation and RCA > Properties.
2. Change the value in the Confidence score threshold (%) after which alert prediction is generated field.

Predicted alerts are generated only if an automated alert group pattern contains at least four alerts and each of these alerts occurs on at least two CIs. Only the three predicted alerts with the highest probability numbers are displayed, all of which must be higher than the value of the property that controls the threshold for creating predicted alerts. The default threshold for creating predictive alerts is 10. Predicted alerts are distinguished from actual alerts by the color gray.

1. Navigate to Event Management > Alert Console.
2. Enable the Group Timeline view.

Only alerts for which probability meets or exceeds the threshold value are displayed.

Predicted alerts are displayed as gray dots on the group timeline, along with actual alerts. You can point to a predicted alert to display details such as the probability that was calculated for this alert, and the CI it is associated with.

View root cause alert for an automated alert group

If root cause analysis (RCA) is applied to automated alert groups, then you can view the identified root cause alert within the group. This helps identify the root cause CI when troubleshooting a problem.

Ensure that the (sa_analytics.agg.learner_rca_detection) property is set to true by performing the following steps:

1. Navigate to Event Management > Alert Aggregation and RCA > Properties.
2. Select the Enable root cause analysis for Automated (pattern-based) groups check box.

To enable RCA for automated alert groups.

1. Navigate to Event Management > Alert Console.
2. Enable the Group Timeline view.
3. Identify the automated alert group for which you want to view root cause alert.

In the list view, automated alert groups are noted by an icon in the Group column, and the value is Automated.

4. Click to open the hierarchical list of alerts in the group.

Root cause alerts are noted as a star on the timeline.

CMDB alert groups

Alerts are grouped by Event Management alert aggregation and root cause analysis (RCA) using different methods of correlation. For CIs without historical data, alerts are correlated based on those CIs relationships in the CMDB. CMDB alert groups are displayed in the alert list in Alert Intelligence and in the Event Management dashboard.

To correlate alerts into groups, alert aggregation and RCA learns from historical alert data and then forms alert patterns. Alert aggregation and RCA then attempts to match new alerts with these patterns to correlate alerts and create alert groups. However, in some situations, such as,
with a new implementation, or with a new set of CIs, there is no historical data to learn from.
In these situations, alert aggregation and RCA can automatically correlate alerts based on CI relationships. This correlation is based on hosting rules, containment rules, and suggested relationships. For example, the alerts for the CIs in the following relationships can be correlated into a CMDB alert group:

- A server hosting a computer
- Processes that are running on a specific server

**Note:** The hosting and containment relationships that are used for CMDB-based grouping are used only if the number of connections between the CIs is small. If two CIs are related through many connections, the connection is considered to be too weak for CMDB-based grouping.

You can view all alert groups by navigating to Event Management > Alert Intelligence. The icon in the Group column denotes the alert group type. Alerts that do not have an entry in the Group column are not correlated with any group.

If your ServiceNow instance uses domain separation, domain names are considered when forming groups.

**RCA for CMDB alert groups**

Alert aggregation and RCA apply RCA to identify a root cause alert within the CMDB alert group if the following properties are set to true:

- Enable CMDB Correlation for Alert Aggregation ([sa_analytics.agg.query_cmdb_correlation_enabled](#))
- Enable root cause analysis for CMDB groups ([sa_analytics.agg.query_cmdb_rca_enabled](#))

If the `true` property is set to true and CMDB alert groups are forming, then identified root cause alerts are then displayed with a star in the Alert Group Timeline view in Alert Intelligence.

**RCA indicator on alerts timeline**

If a root cause alert is identified for a CMDB alert group, that alert is designated as the primary alert of the group.

**Configure automatic creation of CMDB alert groups**

Use the properties listed in this table to control which alerts are automatically included in CMDB alert groups. For more information about Event Management properties, see Components installed with Event Management.
Properties to control CMDB alert groups

<table>
<thead>
<tr>
<th>Property</th>
<th>Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable CMDB Correlation for Alert Aggregation</td>
<td>sa_analytics.agg.query_cmdb_correlation_enabled&lt;br&gt;Enable to allow alert aggregation and RCA to automatically use CI relationships to correlate alerts and form CMDB alert groups.</td>
</tr>
<tr>
<td>Enable Suggested Relations for CMDB Correlation</td>
<td>evt_mgmt.related_cis_use_suggested_relations_rules&lt;br&gt;Enable to use any suggested relationship that is defined in the system when forming CMDB alert groups.</td>
</tr>
<tr>
<td>CMDB Groups: Relationship level</td>
<td>sa_analytics.agg.query_cmdb_graph_walk_nodes&lt;br&gt;Set the number of levels to use for dot-walking. Dot-walking provides access to fields on related tables from a form, list, or script. For more information, see Dot-walking examples.&lt;br&gt;The setting for this property impacts the application of CMDB hosting rules, containment rules, and endpoints to CMDB group formation during alert aggregation.</td>
</tr>
<tr>
<td>evt_mgmt.related_cis_use_containment_rules</td>
<td>to disable CMDB alert groups from forming when using hosting and containment relationships. To add this property to your instance, navigate to System Properties &gt; All Properties and click New. Specify these details:&lt;br&gt;- Name: sa_analytics.agg.query_cmdb_containment_enabled&lt;br&gt;- Type: true</td>
</tr>
<tr>
<td>sa_analytics.agg.ignore_cmdb_applicative_flow</td>
<td>to prevent CMDB groups from forming due to applicative flow relations. To add this property to your instance, navigate to System Properties &gt; All Properties and click New. Specify these details:&lt;br&gt;- Name: sa_analytics.agg.ignore_cmdb_applicative_flow&lt;br&gt;- Type: true</td>
</tr>
<tr>
<td>sa_analytics.agg.query_cmdb_rca_enabled</td>
<td>to cause analysis for CMDB groups. This property is enabled by default.&lt;br&gt;To access this property, navigate to Event Management &gt; Alert Aggregation and RCA &gt; Properties. Then select the Enable root cause analysis for CMDB groups check box.</td>
</tr>
</tbody>
</table>

View root cause alert for a CMDB alert group
View the identified root cause alert within the group to identify the root cause CI when troubleshooting a problem.

Ensure that the (sa_analytics.agg.query_cmdb_rca_enabled) property that supports root cause analysis for CMDB groups is enabled:

1. Event Management > Alert Aggregation and RCA > Properties.<br>2. Ensure that the Enable root cause analysis for CMDB groups check box is selected.

The Enable CMDB Correlation for Alert Aggregation property must be set to true to enable the formation of CMDB alert groups.
Role required: evt_mgmt_admin

1. Navigate to Event Management > Alert Intelligence.

2. In the Lists pane, click All Alerts.

<table>
<thead>
<tr>
<th>Number</th>
<th>Group</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alert0010002</td>
<td>Automated</td>
<td>Spectrum: RadWare CHASSIS DOWN IP:10.0.0.0</td>
</tr>
<tr>
<td>Alert0010003</td>
<td>CMDB</td>
<td>Demo Hardware hosting</td>
</tr>
<tr>
<td>Alert0010004</td>
<td>None</td>
<td>monitor value: 5</td>
</tr>
</tbody>
</table>

3. Click the alert that has the CMDB group for which you want to view root cause alert. For the purposes of example, Alert0010003 is opened.

Root cause alerts are noted as a star on the timeline. The root cause of the alert can be viewed on the timeline.

**Root cause CIs for business services**

For alerts associated with discovered business services and application services, Event Management alert aggregation and RCA can apply root cause analysis (RCA). RCA identifies the CI that is the underlying root cause in a business service.

If Domain Support - Domain Extensions Installer is activated, then RCA is domain aware. Alerts are analyzed within the context of the domain that business services or application services belong to. RCA for a business service or application service runs on the MID Server that is in the
same domain as the business service or application service. If there is no MID Server for a specific domain, then the MID Server from the global domain is used.

**Root cause analysis**

The ongoing operations of an application can generate many events and alerts which can become overwhelming when problems arise. If the system is experiencing a problem, the application service of assessing the impact of the alerts and identifying the underlying cause might require extensive resources and be lengthy.

To identify underlying problems, RCA algorithms prioritize alerts, group them in the context of impacted services, and identify *root cause CIs*. The root cause CI is a CI in a business service from which the root alert for an incident originated and which subsequently triggered additional alerts.

RCA has these components:

**RCA Learner**

An offline job that runs once a day to process past alerts. It collects information about frequent alert patterns within a service context, and stores this information in the alert knowledge base. Based on past alerts and on the impact model, the RCA Learner creates a probability model that can be used to answer cause and effect queries.

**Real-Time Query**

A scheduled job that runs every minute to group alerts and to update root cause CIs. It queries past lists of root cause recommendations to get the probability score for real-time alerts associated with other open alerts within the service.

For discovered business services and for application services, the Learner collects and analyzes data from past alerts. For new alerts, the Learner applies existing knowledge from similar past alerts, and continues to capture and analyze data from new alerts. As more alerts are encountered and resolved, the alert knowledge base grows and the precision of diagnosing the root cause CI improves.

Business services are discovered by Service Mapping and are represented internally in the system by a service model. The service model of the business service is used for identifying CIs related to the root cause CI.

When the root cause CI in a service is known, operators can create a single incident ticket and engage only the needed IT operator to expedite remediation. The IT operator can direct troubleshooting efforts to remove the root cause problem, and stop the recurrence of undesirable events.

**RCA-related properties**

By default, RCA is not applied for business services and for application services. You can enable RCA and modify other RCA-related behavior by changing the settings of the `sa_analytics.aggregation.include_service` and `sa_analytics.rca_enabled` properties.

**RCA configurations**

RCA uses an RCA configuration that filters and scopes the alerts to be analyzed. The base system includes pre-defined RCA configurations which might not be optimal in every environment. See RCA configurations for more information.
Confidence score

To help you decide how to invest troubleshooting efforts, RCA algorithms calculate a confidence score for the identified root cause CI. The confidence score is based on the Learner data and expresses the confidence in the identification. For example, a confidence score of 75% means that there is a certainty of 75% in the identification of the root cause CI. If more than one cause is possible, you can investigate the most likely root cause before investigating less likely root causes.

By default, RCA groups with any confidence scores are listed. To limit what groups are listed, change the `sa_analytics.rca.query_probability_threshold` property to a percentage that the RCA group confidence score must meet to be listed. If a root cause CI has a confidence score that is lower than the specified percentage, alert aggregation and RCA does not treat that CI as the root cause.

View root cause CIs

You have these options for viewing root cause CIs in the Event Management dashboard.

<table>
<thead>
<tr>
<th>UI access</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>In a business service map</td>
<td>Displays root cause CIs highlighted in a business service map, and the relationships between the root cause CI, alerts, and related CIs in business services.</td>
</tr>
<tr>
<td>In impacted services</td>
<td>Displays all automated alert groups that are associated with business services. You can drill down to view details about the alerts in the group, and the root cause CI if it exists. Double-click a group, and then click the Impacted Services tab to display the services and root cause CIs if applicable.</td>
</tr>
</tbody>
</table>

RCA configurations

Event Management alert aggregation and RCA uses an RCA configuration to determine which alerts to include in its root cause analysis. The RCA configuration is used in learning the conditional probability of how a particular state of CI impacts other CIs. Multiple RCA configurations can be defined, but only a single configuration is in effect at any point of time for a given domain.

There are two types of RCA configurations, and the base system includes a pre-defined RCA configuration for each type:

- Rule-based model: Considers the severity of the alert, and maps any severity level (Critical, Major, Minor, Warning) into a state. For example, a binary-state configuration maps into two possible states:
  - 0 – No alert for the CI
  - 1 – Alerts exist for the CI

  Each configuration consists of one or more rules that define the set of alerts to be included in the RCA, such as all alerts with the severity of critical. You can define custom RCA configuration using the rule-based model, adding rules to map alerts according to CI and alert attributes to various states.

  The base system includes the predefined RCA configuration Default Binary Model Config, which is the default RCA configuration.

- Multi-state model: Based on the combination of the Resource and the Metric Name alert columns to learn the model, and it is not associated with any rules. The multi-state model combines the Metric Name and Resource alert columns into a string, and then aggregates
such strings from multiple alerts into a single state string. The number of resulting states is determined by the number of unique state strings for a particular CI.

The base system includes the predefined RCA configuration Default Multi State Config, which you can use in a comparison test of RCA configurations. There are no variations for this default configuration, and therefore you cannot create a custom RCA configuration that is based on the multi-state model.

There is no single RCA configuration that is the most optimal in every environment. Therefore, in addition to the default configurations, you can create custom rule-based RCA configuration. A custom RCA configuration can use additional CI and alert attributes, such as a location attribute to scope the analysis to a specific data center. User can add rules that define how to map alerts for different CIs to various states.

You can compare the RCA results on actual business data, between any two RCA configurations allowing you to select the optimal configuration in your environment. A comparison simulates analysis on historical data, and the RCA Configs Comparison report displays the results of the comparison.

Create an RCA configuration
Event Management alert aggregation and RCA uses an RCA configuration to determine which set of alerts from the sa_analytics_alert table to use for RCA. You can create a custom rule-based RCA configuration, compare it with another RCA configuration and decide how efficient and helpful it is. You can then choose the RCA configuration that is most suitable in your environment, and configure RCA to use that configuration in its analysis.

Role required: evt_mgmt_admin
Each rule-based RCA configuration consists of one or more rules. If an RCA configuration has multiple rules, then the rules’ filters are applied to alerts according to their priority order.

If the Domain Support - Domain Extensions Installer plugin is activated, then alerts are processed according to the domain of the associated business service.

1. Navigate to **Event Management > Alert Aggregation and RCA > RCA Configs**
2. Click **New**, and fill out the SA RCA SMC Config Base form.

### RCA Configuration form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Configuration name.</td>
</tr>
<tr>
<td>Description</td>
<td>Description for the configuration.</td>
</tr>
<tr>
<td>Domain</td>
<td>Domain that this configuration applies to.</td>
</tr>
<tr>
<td>Config deployed</td>
<td>Read-only field, which is automatically computed by the system. It is selected (true) if at least one version of the configuration has been deployed.</td>
</tr>
<tr>
<td>Created</td>
<td>Date and time that this configuration was created.</td>
</tr>
<tr>
<td>Created by</td>
<td>User that created this configuration.</td>
</tr>
<tr>
<td>Updated</td>
<td>Date and time that this configuration was updated.</td>
</tr>
<tr>
<td>Updated by</td>
<td>User that updated this configuration.</td>
</tr>
</tbody>
</table>
3. Right-click on the form title, and click **Save**.

4. Add rules to a rule-based RCA configuration:
   a) Click **SA RCA SMC Rule Bases** at the bottom of the form.
   b) Click **New**, and fill out the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the RCA configuration rule.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the RCA configuration rule.</td>
</tr>
<tr>
<td>Configuration id</td>
<td>The RCA configuration that this rule is associated with.</td>
</tr>
<tr>
<td>Order</td>
<td>An integer that represents the priority of the rule within the rest of the rules for the configuration. Lower numbers have higher priority.</td>
</tr>
<tr>
<td>Created by</td>
<td>User name.</td>
</tr>
<tr>
<td>Created</td>
<td>Time created.</td>
</tr>
<tr>
<td>Updated by</td>
<td>User name.</td>
</tr>
<tr>
<td>Updated</td>
<td>Time updated.</td>
</tr>
<tr>
<td>Domain</td>
<td>Domain that this rule applies to.</td>
</tr>
<tr>
<td>% Alert Coverage</td>
<td>System generated percentage of alerts in the sa_analytics_alert table that match the rule's filter.</td>
</tr>
<tr>
<td>Rule filter</td>
<td>Conditions to filter alerts for this rule.</td>
</tr>
</tbody>
</table>

5. Select the check box for the new rule and click **Alert Coverage** to calculate the rule's % Alert Coverage.

- Compare the new RCA configuration with another configuration, and decide which configuration is most helpful and should be deployed in the next RCA Learner cycle.
- After modifying a configuration, or when there is a significant number of new alerts, select any rules and click **Alert Coverage**. This recalculates the % Alert Coverage for the selected rules.

Compare and deploy RCA configurations

Compare the results of root cause analysis between two RCA configurations on actual alerts, then choose the optimal configuration in your environment, and deploy it.

Select any two RCA configurations and a business or an application service for the comparison. The comparison simulates analysis on historical data from the business or application service,
while applying the two RCA configurations. The RCA Config Comparison report displays the comparison results.

When you compare one RCA configuration to another RCA configuration, alert aggregation and RCA stores a current snapshot of the definitions of the RCA configurations that are being compared. An RCA configuration can end up having several versions, each one created when it is used in a comparison.

Review the comparison results, and decide which RCA configuration is most efficient, and then deploy that configuration. The deployment request is registered, and will take effect at the next cycle of the RCA Learner. The version of the configuration that was used for the comparison will be deployed.

1. Navigate to Event Management > Alert Aggregation and RCA > RCA Configs.
2. Click on one of the two configurations that you want to compare, and on the configuration form click Run Comparison.
3. In the Run Comparison dialog box, select a second configuration for the comparison from the Compare with Configuration list.
4. Select a business or an application service from the Run comparison on list to use for the comparison.
5. Click Run.
6. Navigate to Event Management > Alert Aggregation and RCA > RCA Configs Comparison, and select a comparison to review.
   Ensure that the status of the comparison is Completed.
7. Decide which configuration you want to deploy, and click the configuration link in the comparison that you are reviewing.
8. On the configuration form, click Deploy.

View root cause CIs in a business service map
For alerts associated with discovered business services or application services, you can view root cause CIs in a business service map on the Event Management dashboard.

Role required: evt_mgmt_admin, evt_mgmt_operator, or evt_mgmt_user

When you select a root cause CI, the business service map displays the business or application services that are impacted by the root cause CI.

**Note:** Session timeout settings do not apply to this screen, so the session will remain connected, even when there is no human interaction. If this is a concern, either log out or close the active tab in the browser.

1. Navigate to Event Management > Dashboard.
2. Double-click the tile of the business or application service for which you want to view root cause CIs.
3. Underneath the map, click Root Cause CI and select a root cause CI to highlight in the business service map.

The list of root cause CIs associated with the selected business service displays the following details:

<table>
<thead>
<tr>
<th>Root Cause CI details</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Field</strong></td>
</tr>
<tr>
<td>Root Cause CI</td>
</tr>
<tr>
<td>Related Alerts</td>
</tr>
</tbody>
</table>
4. Double-click a root cause CI to display the alerts within this alert group.
5. Select any alert to highlight the CIs that it is associated with, and view additional details about the alert.

**Alert aggregation and RCA reports**

Event Management alert aggregation and RCA generates several reports to help you assess the efficiency and depth of analysis.

You can access alert aggregation and RCA reports by navigating to **Event Management > Alert Aggregation and RCA**.

**RCA Config Comparison Report**

This report displays the results of a comparison between two RCA configurations defined for root cause analysis. Evaluate and score the comparison results. Then choose the RCA configuration that appears most efficient in your environment, and deploy it.

In addition to the default RCA configurations, you can create custom rule-based RCA configurations, and you can compare any two configurations (ConfigA and ConfigB). For each configuration that is being compared, RCA algorithms are applied using real historical alerts from the past 7 days. The RCA Config Comparison Report displays the RCA results for each configuration, if it would have been used during the past 7 days. Once you start a comparison, wait for the report to show that the status is **Completed**.

To display the report, navigate to **Event Management > Alert Aggregation and RCA > RCA Configs Comparison**, which requires the evt_mgmt_admin role. The report has 3 sections, each section provides further details for a selected item in the previous section.

**Comparison summary list**

This section lists summaries of recent comparisons, with the following details:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start time</td>
<td>Time the comparison started.</td>
</tr>
<tr>
<td>Run Name</td>
<td>System created unique ID for the comparison run, prefixed by ‘RUN’.</td>
</tr>
<tr>
<td>Status</td>
<td>Status of the comparison, ensure it is completed before reviewing the details.</td>
</tr>
<tr>
<td>Config (A)</td>
<td>The first RCA configuration used in the comparison.</td>
</tr>
<tr>
<td>Config (B)</td>
<td>The second RCA configuration used in the comparison.</td>
</tr>
<tr>
<td>Score (A)</td>
<td>Sum of user assigned scores for all automated alert groups analyzed by Config (A).</td>
</tr>
<tr>
<td>Score (B)</td>
<td>Sum of user assigned scores for all automated alert groups analyzed by Config (B).</td>
</tr>
<tr>
<td>Column</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Service</td>
<td>Discovered business service or application service for which alerts were used in this comparison.</td>
</tr>
</tbody>
</table>

Actions:
- Select a comparison for which to display further details about RCA results for Config (A) alongside Config (B).
- Deploy an RCA configuration:
  1. Click the link for the RCA configuration that you want to deploy in the **Config (A)** or **Config (B)** column.
  2. On the configuration form, click **Deploy**.

**RCA results for Config (A) and Config (B) per comparison**

This section displays a comparison of root cause analysis for Config (A) and Config (B), for the selected comparison in the previous section. Displaying the following details:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Grouping Time</td>
<td>Time that the group was created.</td>
</tr>
<tr>
<td>Root Cause</td>
<td>Comparison of the root cause CI being identified by Config (A) and Config (B). Both configurations have either identified the <strong>Same</strong> root cause CI, or a <strong>Different</strong> one.</td>
</tr>
<tr>
<td>Score (A)</td>
<td>User assigned score of RCA results for this automated alert group, as it was analyzed by Config (A).</td>
</tr>
<tr>
<td>Score (B)</td>
<td>User assigned score of RCA results for this automated alert group, as it was analyzed by Config (B).</td>
</tr>
<tr>
<td>Probability % (A)</td>
<td>Confidence in the accuracy of the root cause CI identified by Config (A).</td>
</tr>
<tr>
<td>Probability % (B)</td>
<td>Confidence in the accuracy of the root cause CI identified by Config (B).</td>
</tr>
<tr>
<td>Group Name (A)</td>
<td>Automated alert group created by Config (A).</td>
</tr>
<tr>
<td>Group Name (B)</td>
<td>Automated alert group created by Config (B).</td>
</tr>
<tr>
<td>Related Alerts (A)</td>
<td>Summary of alerts within the automated alert group created by Config (A), broken down by alert severity.</td>
</tr>
<tr>
<td>Related Alerts (B)</td>
<td>Summary of alerts within the automated alert group created by Config (B), broken down by alert severity.</td>
</tr>
</tbody>
</table>

Actions:
- Select an automated alert group to display further details about all the alerts within that group.
- Score results:
1. Select the group and the configuration that you want to score, in either *Score (A)* or *Score (B)* column.

2. Double-click the score value, enter a numeric score, and then click the green check-mark. The new group score value is aggregated into the summary score for *Score (A)* or *Score (B)* in the comparison summary row for this comparison.

- Toggle between different display options for the automated alert groups:
  - **Same**: Displays only the automated alert groups for which RCA results for Config (A) and Config (B) are identical.
  - **Different**: Displays only the automated alert groups for which RCA results for Config (A) and Config (B) are different.
  - **All**: Displays all automated alert groups for which there are RCA results for either Config (A) or Config (B).

**Correlated alert group details per config**

This section displays details of all related alerts within an automated alert group selected in the previous section. Displaying the following details for both Config (A) and Config (B):

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Alert ID.</td>
</tr>
<tr>
<td>Severity</td>
<td>Severity of the alert.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the alert.</td>
</tr>
<tr>
<td>Configuration Item</td>
<td>CI that the alert is associated with.</td>
</tr>
<tr>
<td>Updated On</td>
<td>Last time that the alert was updated.</td>
</tr>
</tbody>
</table>

**Learned Patterns Report**

This report displays metrics associated with learned patterns such as the frequency of occurrence and the number of occurrences of the pattern identifier attributes in learned patterns (CI/MetricName by default). You can sort the learned patterns by pattern score, pattern frequency, and pattern size. This report helps you identify higher-frequency occurring alert patterns.

For each alert, Event Management alert aggregation and RCA combines the associated pattern identifier attributes that represent the alert. It then groups all the pattern identifier attributes for alerts that occur together, to create a learned pattern. The same combination of pattern identifier attributes can exist in multiple learned patterns. Typically, a learned pattern indicates a single problem. The report displays metrics in table format, grouped by learned patterns.

To display the report, navigate to **Event Management > Alert Aggregation and RCA > Learned Patterns**.

You can use this report to:

- Allocate resources to the higher frequency occurring alerts to reduce the time for closing a large number of alerts.
- Allocate resources to larger learned patterns of lower frequency.

**Actions:**

- Expand a pattern group to display details about all the identifier attributes that are associated with the pattern.
<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configuration Item</td>
<td>The configuration item used for the combined pattern identifier attributes.</td>
</tr>
<tr>
<td>Feature Identifier</td>
<td>The feature identifier used for the combined pattern identifier attributes.</td>
</tr>
<tr>
<td>Frequency</td>
<td>The number of times that the combined pattern identifier attributes occur in the data set.</td>
</tr>
</tbody>
</table>

- Sort within each pattern by Configuration Item and Feature Identifier.
- View the following information for each pattern:
  - **Size**: The number of combined pattern identifier attributes occurrences in a learned pattern.
  - **Frequency**: The number of times that a learned pattern occurs in the data set.
  - **Score**: Combined calculation of frequency and size, using the formula:
    \[ \text{Frequency} \times (\text{Size} + 1) \]
- Click on a CI link in the Configuration Item column to display the CI form.

**Event Management Operator Tutorial**

As an Event Management operator, your role is to find alerts, analyze them, and take action to help resolve the underlying issue.

**Take the tutorial**

Before you can work as an operator, you should take a tutorial to become familiar with several Event Management concepts and understand what operators typically do on a regular basis.

Start the tutorial by clicking the first lesson:

<table>
<thead>
<tr>
<th>Lesson</th>
<th>Lesson title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lesson 1</td>
<td>An overview of events and alerts</td>
</tr>
<tr>
<td>Lesson 2</td>
<td>An overview of business services</td>
</tr>
<tr>
<td>Lesson 3</td>
<td>Event management operator workspaces</td>
</tr>
<tr>
<td>Lesson 4</td>
<td>What operators do</td>
</tr>
</tbody>
</table>

**An overview of alerts for Event Management operators**

As an Event Management operator, you need to understand how an alert is generated from an event, what to look for in an alert, and how alerts can be grouped together.

This is the first lesson in the Event Management tutorial.

<table>
<thead>
<tr>
<th>Lesson</th>
<th>Lesson title</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lesson 1</td>
<td>An overview of events and alerts</td>
</tr>
<tr>
<td>Lesson 2</td>
<td>An overview of business services</td>
</tr>
</tbody>
</table>
Your organization already has an event monitoring tool in place, such as Microsoft System Center Operations Manager (SCOM), Nagios, SolarWinds, and so on. When an issue occurs on your network, such as a computer going down or a database failure, these event monitoring tools send events to your ServiceNow instance. The Event Management application processes these events according to the settings that your administrator configured, and then it generates alerts. An alert is an indicator that the issue requires some type of action.

That is where you come in as an Event Management operator. Your role is to view alerts and, depending on how Event Management is implemented in your organization, take some sort of action to help resolve the underlying issue or notify someone else who can. Later in this tutorial, you can see the phases of a typical alert management process.
Alert priority and severity

The two most common characteristics of an alert are the priority and the severity.

- The **priority** of an alert is a score that helps you determine how important the impact is to business services. Multiple factors determine the alert priority score. Your Event Management administrator can configure the algorithm that Event Management uses to calculate priority.
- The **severity** of an alert is an indicator of how serious the underlying issue is. The event monitoring tool in your organization usually sends severity values as part of the event, which then gets carried over as part of the alert. These are the default severity types that you can see in this tutorial:

<table>
<thead>
<tr>
<th>Severity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Critical</td>
<td>The resource is either not functional or critical problems are imminent.</td>
</tr>
<tr>
<td>Major</td>
<td>Major functionality is severely impaired or performance has degraded.</td>
</tr>
<tr>
<td>Minor</td>
<td>Partial, non-critical loss of functionality or performance degradation occurred.</td>
</tr>
<tr>
<td>Warning</td>
<td>Attention is required, even though the resource is still functional.</td>
</tr>
<tr>
<td>Info</td>
<td>No severity. An alert is created. The resource is still functional.</td>
</tr>
<tr>
<td>Clear</td>
<td>The alert no longer needs action.</td>
</tr>
</tbody>
</table>

Correlated alerts

Some alerts are related to each other. For example, if an issue occurs like a router going down, several separate alerts could be generated, one for each server connected to the router. All of these alerts are actually related, or **correlated**. To help you manage these correlated alerts, Event Management can automatically group them together and establish a two-level hierarchy with one root alert, called the **primary alert**, at the top, and other related alerts, called **secondary alerts**, under the primary alert. When you view alerts, primary alerts stand out by default so you know which alert to focus on without being distracted by the secondary alerts.

In our example, if a router goes down on your network, network communication is also affected for connected servers, assuming they cannot reach any other routers. The router outage becomes the primary alert and the alerts generated on the server are secondary alerts that should be correlated under the router alert.
Depending on your organization’s Event Management implementation, alerts might be grouped automatically based on correlation rules that your administrator sets up. Your ServiceNow instance can also learn how to improve the way it automatically correlates alerts based on these rules and feedback that you can give. As an operator, you should still verify the accuracy of the correlation and, if necessary, manually correlate additional alerts with the primary alert. Later in the tutorial, you will learn how to do this.

In this tutorial, you will learn how to manually correlate alerts. In an advanced topic, you will learn how to give feedback to the system, so that your system can improve the automatic alert correlation process.

**Alert flapping**

An alert can flap, meaning that it gets multiple open-close events in rapid succession. Flapping indicates that Event Management does not know if the underlying events are genuine or not. The events could indicate small issues with the way CIs are configured, or larger issues, like network outages.
For example, if a server that hosts a web service has too many active processes, it might trigger an event about excessive CPU usage. Since CPU usage can fluctuate rapidly depending on the requests made through the web service, several events might be triggered, leading to the alert being put in the flapping state. As an operator, you might need to create an incident to have the server restarted, or someone might have to reconfigure the CPU, or possibly make a hardware change on the device.

As another example, consider a loose network cable that causes momentary, repeated network outages. The thresholds that your administrator configures might not be optimal for this kind of alert and Event Management considers it a flapping alert.

Continue the tutorial

Proceed to the next lesson: Business services for Event Management operators.
Business services for Event Management operators

As an Event Management operator, you need to understand what business services are. This is the second lesson in the Event Management tutorial.

| Lesson 1 | ✓ | An overview of events and alerts |
| Lesson 2 | ☐ | An overview of business services |
| Lesson 3 | ☐ | Event management operator workspaces |
| Lesson 4 | ☐ | What operators do |

A business service is a collection of components, such as network devices, computers, and applications, that offer a service to your organization. These services can be something like an email system or a website that tracks orders or requests in a database. Your administrator should have already specified the business services in your ServiceNow instance.

Each component that makes up a business service is referred to as a configuration item or CI. This is a visual representation of a business service on a business service map:
In this example, you can see a Web Portal business service with these CIs:

- **PS Apache03**: An Apache web server that hosts a company website.
- **PS LinuxApp01** and **PS LinuxApp02**: Two Linux servers that share the workload from the web server.
- **PS ORA01**: A database server that both Linux servers need to access.
- **Storage Area Network 001**: A mass storage device on which the other CIs depend.

You can see business service maps like this from the Event Management Dashboard. Later in this tutorial, you will learn about the dashboard and what business services look like when an alert is associated with a CI.

**Types of business services**

Event Management classifies business services into the following types:

**Technical services**
A technical service is a dynamic grouping of CIs, based on some common criteria. For example, a technical service could be comprised of all web servers or all Oracle databases for a specific location, like North America.

**Application services**

An application service is an ad-hoc business service that your administrator puts together by selecting each CI separately and choosing the relationship between them.

**Discovered services**

A discovered service is business service that [Service Mapping](#) finds (if your organization uses it).

**Alert groups**

Alerts that are grouped together, either manually or automatically.

**Alert impact**

Business services are critical to the operations of your organization, so if an issue occurs on one CI, the entire business service can be impacted. Part of your role as an operator is to analyze alerts on CIs and see how they impact the business service as a whole, and then take some sort of action to help remediate or solve the underlying issue. Your administrator can configure impact rules that go into calculations for the severity of an alert.

Later on, when you learn how to use the Event Management Dashboard, you will learn how to view an impact tree for a business service so you can understand the relationship between the severity of an alert and the overall business service.

In this example, you can see how a **Major** alert on an Oracle database (PS ORA01) also causes a major alert on its parent CIs and on the Web portal business service itself.
Continue the tutorial

Proceed to the next lesson: Event Management operator environment.

Event Management operator environment

As an Event Management operator, your primary work environment is the Event Management dashboard and Alert Intelligence.

In this, the third lesson in the Event Management tutorial, you are given an overview of the workspaces in which you work, so you know how to find the information you need.

<table>
<thead>
<tr>
<th>Tutorial lessons</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Lesson 1</td>
<td><em>An overview of events and alerts</em></td>
</tr>
<tr>
<td>Lesson 2</td>
<td><em>An overview of business services</em></td>
</tr>
<tr>
<td>Lesson 3</td>
<td>Event Management operator environment</td>
</tr>
<tr>
<td>Lesson 4</td>
<td><em>What operators do</em></td>
</tr>
</tbody>
</table>
The Event Management dashboard

Your main area of work is the Event Management dashboard, which provides an application-service centric view of all alerts. From here, you can drill into each application service to see the affected CIs and get an understanding of the overall impact of whatever caused the alert.

The main sections of the dashboard are:
The banner contains controls that show or hide application services based on the criteria you select:

- Use the application service selector to choose a specific application service to display in the main body of the dashboard.

- Use the severity slider to show or hide application services based on the alerts associated with them.

- From the Prioritize by choice list, order the application services by Severity, Criticality, or Cost.

  **Note:** Your administrator assigns an application criticality and cost value to your application services. You do not have to configure these.

- Select Groups to show the application service groups that your administrator set up or select Services to show application services separately.

**Application services**

On the main part of the Event Management dashboard are tiles, each of which is an application service. Each tile has a color, which represents the severity of the alerts that are associated with the application service, and a size, which represents the priority of the alerts.
Click an application service tile to show only the alerts associated with that application service. A gray box outlines the tile and the alerts appear in the Alerts list at the bottom.

### Alerts

All active alerts appear in the Alerts list under the dashboard. You can also filter or sort the list to find the alert you are looking for:

Sort by any alert details, such as the **Priority**, which considers multiple factors for how serious the alert is, or the **Severity**, which is value provided by the event monitoring tool.
Click the **Correlated Alerts** switch to the off position to show all alerts, regardless of whether they are secondary alerts that are already correlated with a primary alert. By default, the switch is in the on position, grouping correlated alerts under the primary alert.

Open any alert by clicking the number.

You will learn about what each of the columns means for an alert later on when you analyze an alert.

**Application service map views on the Event Management Dashboard**

Double-click the name of an application service tile to open one of the application service map views. The view that you see depends on the type of application service.

*For a manual or standard application service, this view appears:*
The application service map that you were introduced to in a previous lesson appears in the main panel. This is what you can do from this view:

Click any of the CIs to see the alerts only for that CI and to display the details about that CI in the Properties pane.
Click **Impact Tree** to see the state of all the CIs and how they affect each other when receiving an alert. You will learn more about the impact tree later on in the tutorial.

Open any alert from the **Alerts** list at the bottom by clicking the number.
For a technical application service, this view appears:

This is what you can do from this view:
Click any CI to view details about it.

<table>
<thead>
<tr>
<th>Name</th>
<th>Severity</th>
<th>Class</th>
<th>Child</th>
</tr>
</thead>
<tbody>
<tr>
<td>PS ORA01</td>
<td>Major</td>
<td>Database</td>
<td></td>
</tr>
<tr>
<td>lawson_db</td>
<td>Critical</td>
<td>Database</td>
<td>lawson_db_100</td>
</tr>
<tr>
<td>MySQL-16011</td>
<td></td>
<td>Database</td>
<td></td>
</tr>
<tr>
<td>bond_trade_ny</td>
<td></td>
<td>Database</td>
<td></td>
</tr>
<tr>
<td>SAP ORA01</td>
<td></td>
<td>Database</td>
<td></td>
</tr>
<tr>
<td>bond_trade_aus</td>
<td></td>
<td>Database</td>
<td></td>
</tr>
</tbody>
</table>

Open any alert from the Alerts list at the bottom by clicking the number.

Alert intelligence

In the navigation pane, navigate to Event Management > Alert Intelligence.

Alert intelligence provides insight data analysis on the alert and related CIs based on history, analysis of CMDB, and ITSM data. You can, for example, see repeated or similar alerts and this information can help you to investigate problems further.

For more information, see View alert insight information in Workspace.

Continue the tutorial

Proceed to the next lesson: What Event Management operators do.
What Event Management operators do

As an Event Management operator, your typical workflow involves three phases: analyzing an alert and its effect on business services, taking some type of action, and making sure the alert is finally closed.

This is the last lesson in the Event Management tutorial. In this lesson, you will run through the three phases of a typical operator day-to-day workflow.

| Lesson 1 | An overview of events and alerts |
| Lesson 2 | An overview of business services |
| Lesson 3 | Event management operator workspaces |
| Lesson 4 | What operators do |

Your organization will have specific policies and procedures that may differ from the phases outlined in this topic. In addition, your administrator might have customized the Event Management application so that some of these phases are automated and do not actually require any action on your part.

For the purposes of this tutorial, we will walk you through each phase and allow you to perform the tasks manually.

<table>
<thead>
<tr>
<th>Phase 1</th>
<th>Analyze and acknowledge an alert</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>In this phase, you will find an alert to work on, analyze the details, and acknowledge it so that other operators know it is a legitimate alert.</td>
</tr>
<tr>
<td>Phase 2</td>
<td>Triage an alert</td>
</tr>
<tr>
<td></td>
<td>In this phase, you take an action to help remediate the issue that caused the alert. The most common action to take is to create an incident and assign it to someone who can solve the underlying issue.</td>
</tr>
<tr>
<td>Phase 3</td>
<td>Close an alert</td>
</tr>
<tr>
<td></td>
<td>In this phase, you will verify that the alert is resolved, and then close the alert.</td>
</tr>
</tbody>
</table>

Start here

Start out by learning how to *Analyze and acknowledge an alert*.

*Operator phase 1: Analyze and acknowledge an alert*

As an Event Management operator, the first thing you should do is access alerts and then find the ones you want to focus on. You can open the Alert form to analyze the details, and then acknowledge it to let other operators know that the issue causing the alert should be addressed in some way.
You must understand both of your operator environments: the Event Management Dashboard and Alert Intelligence. Review Event Management operator environment if you have not already done so. This tutorial uses the Event Management dashboard.

1. Navigate to Event Management > Dashboard.
   All the alerts are listed at the bottom of the dashboard under the business services.
2. Find the alerts you want to focus on by clicking a business service, or by using any of the filtering and sorting options in the banner.
3. Click the alert number to open it.
   In this example, we are focusing on the Web Portal business service and the alert with the highest severity.

4. Review the important fields and related lists on the form. These are described below:
The Alert form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>This is the automatically generated alert number that you saw in the list of alerts on the Event Management Dashboard or the Alert console.</td>
</tr>
<tr>
<td>Node</td>
<td>The name of the CI with which the alert is associated. The event that generated the alert occurred on this CI. You might see a computer name, or an IP address or MAC address of a device.</td>
</tr>
</tbody>
</table>

© 2020 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resource</td>
<td>The object on the node that caused the event. You might see values like the name of a hard disk, a CPU, or the name of a process or a service. You can add information to this field if necessary.</td>
</tr>
<tr>
<td>Configuration item</td>
<td>The CI in your database to which this alert applies. If the Node field is filled in but this field is empty, and if you know which CI the node represents, you can enter the CI in this field to manually associate the alert with it.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Your administrator can configure rules that automatically bind CIs to an alert, usually based on what is in the Node field. However, it is possible that the system is unable to find the correct CI to bind the alert to. In this case, you might need to manually select a CI. For the purposes of this tutorial, we assume that the correct CI is bound to the alert.</td>
</tr>
<tr>
<td>Task</td>
<td>Any existing task that is associated with the alert, such as an incident, change request, or problem, is shown in this field. When you first look at an alert, this field is blank. You can associate a task when you triage the alert. You associate an incident to an alert and assign the incident to someone at a later stage in this tutorial.</td>
</tr>
<tr>
<td>Description</td>
<td>A description of the alert that came from the alert monitoring software in your organization. You can add information if necessary.</td>
</tr>
<tr>
<td>Severity</td>
<td>The severity value that is copied from the event:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Critical</strong> indicates that immediate action is required. The CI is not functional or critical problems are imminent.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Major</strong> indicates that major functionality is severely impaired or performance has degraded.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Minor</strong> indicates that there is a partial, non-critical loss of functionality, or that performance had degraded.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Warning</strong> indicates that attention is required, even though the resource is still functional.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Info</strong> Indicates some type of informational message, but the resource is still functional.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Clear</strong> indicates that no action is required.</td>
</tr>
<tr>
<td>State</td>
<td>Indicates the processing state that the alert is in. A newly generated alert is in the <strong>Open</strong> state. Other states are:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Reopen</strong> indicates that a previously closed alert is open again, and it requires your attention.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Flapping</strong> indicates that the alert is receiving a high frequency of identical events from the same source, which can cause many alerts to re-open even after it is closed.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Closed</strong> indicates that the alert is closed and does not require any further action. You will close an alert as part of the last stage in this tutorial.</td>
</tr>
</tbody>
</table>
### Field Description

- **Acknowledged**: Indicates that an operator verified that the alert is genuine and is triaging it. You acknowledge the alert at a later stage in this topic.
  
  Your Event Management administrator can also have alerts automatically acknowledged immediately after they are generated. If this is the case, the **Acknowledged** check box on the Alert form might already be selected.

- **Maintenance**: Indicates that the alert does not need to be worked on and is hidden from the list of alerts in the Event Management Dashboard and the Alert Console. In this example, we do not want to put the alert in maintenance.

- **Parent**: Displays a value only for secondary alerts. The value indicates the alert number of the parent alert. The field is empty for primary alerts (alerts with no parent alert).

- **Knowledge article**: Any existing knowledge base (KB) article that is associated with the alert. When you first open an alert, this field is blank. You can associate a KB article when you triage the alert.

### Instructions

5. **Navigate to back to** **Event Management > Dashboard**.
6. **Double-click the business service tile for the Web portal**.

In this example, the business service is an application service, not a technical service, so the business service map appears.
Notice that the major severity indicator in orange is displayed on several CIs. It starts with the Oracle database (PS ORA01) and propagates up to all CIs that depend on the database. From this, you can surmise that the alert with the highest level of severity on the Oracle database indicates the root cause of the issue.

This does not necessarily mean that the system generated separate alerts for each CI, but it is possible. When you triage an alert, you can see if alerts on other CIs should be correlated under a primary alert.

7. Click the **Impact Tree** tab and review the impacts on each CI.

The percentages next to each CI in the impact tree show you the affect on each CI. In this example, each CI is impacted 100% by the alert, which means the underlying issue that led to the alert is serious enough to impact the functionality of the business service.
8. Open the alert on the Oracle database that you first opened above.
9. Click the **Acknowledge** button at the top of the form.

Acknowledging the alert does not assign it to you, nor does it create a task like an incident or change request. It simply lets other operators know that you are aware of the issue. After you acknowledge it, you will take further action during the triage stage.

10. Navigate back to the Event Management Dashboard or the Alert Console, and look for the alert that you acknowledged. You can see that the **Acknowledged** value is true.

Go to **Operator phase 2: Triage an alert**.

**Operator phase 2: Triage an alert**

After you analyze and acknowledge an alert, you must triage it. The triage phase involves verifying alert correlation and taking some sort of action to help resolve the issue that caused the alert. This topic covers the most common triage task: creating an incident from an alert.

---

© 2020 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
1. Before you start to work on the alert, check if other alerts need to be correlated with the one you just reviewed:
   a) Navigate to **Event Management > Dashboard**.
   b) Click the same business service tile and review the alerts in the **Alerts** list.
   c) If multiple alerts are present, open one to determine if it is related to the other alert, or if the underlying issue is the same in both alerts. For example, if an alert is associated with a web server and there is already an alert for the database issue, correlate the web server alert as a **secondary** alert with the database alert as the **primary** alert.
   d) Open the secondary alert, click the lookup icon (🔍) in the **Parent** field, and then select the primary alert. This creates a primary (parent) / secondary (child) relationship between the two alerts.
   e) Repeat this process to correlate as many secondary alerts as necessary.
   f) Navigate back to the Event Management Dashboard and verify that the primary alert displays an icon in the **Group** column.
2. Open the primary alert.
3. On the Alert form, click Create Incident. If your organization uses Security Incident Response, the button is named Create Security incident.

4. Fill in the form fields (see table below):

Note: Your administrator can set up rules that lets the system automatically correlate alerts so that you do not need to do so manually. In that case, a Feedback field appears on the Alert form and you can select Yes if the system correlated the alert correlated correctly, or No if it was not.
Incident INC0010004

- **Number**: INC0010004
- **Caller**: EM Operator
- **Category**: Database
- **Subcategory**: -- None --
- **Business service**: Web portal
- **Configuration item**: PS ORA01

**Short description**: Database issue

**Description**: Database issue

**Watch list**: [Lock] [Unlock]

**Work notes**: The Oracle Database service should be restarted or checked for other issues.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Caller</td>
<td>Click the lookup icon and then select your name. The caller is the person who discovered the issue that led to the incident.</td>
</tr>
<tr>
<td>Category and Subcategory</td>
<td>Select a category that best describes this alert. In this example, Database is the best choice.</td>
</tr>
<tr>
<td>Business service</td>
<td>Select the business service to which the CI belongs. In this example, the business service is Web portal.</td>
</tr>
<tr>
<td>Configuration item</td>
<td>If it is not already populated automatically, select the CI. In this example, the Oracle database (PS ORA01) is automatically populated into the field.</td>
</tr>
<tr>
<td>Impact and Urgency</td>
<td>Select the impact and urgency levels that you think is appropriate.</td>
</tr>
<tr>
<td>Assignment group Assigned to</td>
<td>Click the lookup icons ( ) for both or either of these fields, and then select the group or the individual that can handle the issue.</td>
</tr>
</tbody>
</table>

5. Click **Submit** on the Incident form to create the incident. The Alert you are working on reappears.

On the Alert form, the incident is populated in the **Task** field. You can also see the incident number in the Task column on the Event Management Dashboard.

There are other tasks you perform as part of the triage stage:

- **Run a remediation workflow on an alert** if your Event Management administrator already set up a workflow in your ServiceNow instance and your policies allow you to trigger it from the alert.
- **Launch a web application from an alert** to open a website or an event monitoring tool that provides more information about the alert.
- **Put an alert into maintenance** to temporarily hide it from the Alert Console and Event Management Dashboard if the alert does not require action at this time.
- **Associate a knowledge base article with an alert** if there is existing information about the alert that might help resolve the underlying issue.

If you do not need to perform any other triage actions, proceed to **Phase 3: Close an alert**.

Run a remediation workflow on an alert

As an Event Management operator, you can also run a workflow on your ServiceNow instance that helps remediate the alert. For example, you might run a workflow that automatically restarts a server on your network, which might resolve an alert about CPU usage.

Role required: evt_mgmt_operator

Phase 1: Analyze and acknowledge an alert
### Phase 2
- **Triage alerts**

### Phase 3
- **Close an alert**

**Note:** You can run a remediation workflow if your administrator already set up workflows for you to choose from. You should be familiar with your organization’s policies regarding triaging of alerts.

1. From the alert console or the Event Management Dashboard, open the alert that you acknowledged in Phase 1: Analyze and acknowledge an alert.
2. On the Alert form, click **Quick Response**.
3. In the Quick Response window, click the name of the remediation under **Run Remediation**.

There are also other tasks you can take as part of the triage stage:
- **Launch a web application from an alert** to open a website or an event monitoring tool that provides more information about the alert.
- **Put an alert into maintenance** to temporarily hide it from the Alert Console and Event Management Dashboard if the alert does not require action at this time.
- **Associate a knowledge base article with an alert** if there is existing information about the alert that might help resolve the underlying issue.

If you do not need to perform any other triage actions, proceed to **Phase 3: Close an alert**.

Launch a web application from an alert

As an Event Management operator, you can also launch a web application from an alert. The web application could be a console for the event monitoring tool that your organization uses, or any external website that provides additional information you might need about the alert.

<table>
<thead>
<tr>
<th>Phase 1</th>
<th>Analyze and acknowledge an alert</th>
</tr>
</thead>
<tbody>
<tr>
<td>Phase 2</td>
<td>Triage alerts</td>
</tr>
<tr>
<td>Phase 3</td>
<td>Close an alert</td>
</tr>
</tbody>
</table>

You can launch a web application if your administrator already set up a link to the application. You should be familiar with your organization’s policies regarding triaging of alerts.

1. From the alert console or the Event Management Dashboard, open the alert that you acknowledged in Phase 1: Analyze and acknowledge an alert.
2. On the Alert form, click **Quick Response**.
3. In the Quick Response window, click the name of the application under **Launch Application**.
There are also other tasks you can take as part of the triage stage:

- **Run a remediation workflow on an alert** if your Event Management administrator already set up a workflow in your ServiceNow instance and your policies allow you to trigger it from the alert.
- **Put an alert into maintenance** to temporarily hide it from the Alert Console and Event Management Dashboard if the alert does not require action at this time.
- **Associate a knowledge base article with an alert** if there is existing information about the alert that might help resolve the underlying issue.

If you do not need to perform any other triage actions, proceed to **Phase 3: Close an alert**.

**Associate a knowledge base article with an alert**

As an Event Management operator, you can associate a knowledge base (KB) article with the alert to capture additional information about the alert. This might include a procedure that someone has to follow to resolve the underlying issue on your network, or a best practice to prevent the issue from reoccurring.

<table>
<thead>
<tr>
<th>Phase 1</th>
<th>Analyze and acknowledge an alert</th>
</tr>
</thead>
<tbody>
<tr>
<td>Phase 2</td>
<td>Triage alerts</td>
</tr>
<tr>
<td>Phase 3</td>
<td>Close an alert</td>
</tr>
</tbody>
</table>

This task assumes that your organization uses the Knowledge Base application in your ServiceNow instance.

1. From the alert console or the Event Management Dashboard, open the alert that you acknowledged in Phase 1: Analyze and acknowledge an alert.
2. On the Alert form, click the lookup icon (🔍) next to the **Knowledge article** field.

3. Filter the list of existing KB articles by first selecting a field, such as **Short Description**, and then entering related text into the search text field. You can use the `contains (*)` operator to search for articles that contain keywords. For example, entering `*oracle` in the short description filters the KB articles that contain the word `oracle` somewhere in the short description.

4. If you cannot find any related KB articles, you can click **New**, create a new one, and then click **Submit**.

The KB article number appears in the **Knowledge article** field on the Alert form.

5. Click **Update** on the Alert form to save the information.

There are also other tasks you can take as part of the triage stage:

- **Run a remediation workflow on an alert** if your Event Management administrator already set up a workflow in your ServiceNow instance and your policies allow you to trigger it from the alert.
- **Launch a web application from an alert** to open a website or an event monitoring tool that provides more information about the alert.
- **Put an alert into maintenance** to temporarily hide it from the Alert Console and Event Management Dashboard if the alert does not require action at this time.

If you do not need to perform any other triage actions, proceed to **Phase 3: Close an alert**.

Put an alert into maintenance
As an Event Management operator, you can put an alert into maintenance if the alert does not require any further action, but you still want to keep the alert active. Putting the alert into
maintenance hides it from the Alert Console and Event Management Dashboard so that other operators do not need to access it, but it does not close the alert.

<table>
<thead>
<tr>
<th>Phase 1</th>
<th>Analyze and acknowledge an alert</th>
</tr>
</thead>
<tbody>
<tr>
<td>Phase 2</td>
<td>Triage alerts</td>
</tr>
<tr>
<td>Phase 3</td>
<td>Close an alert</td>
</tr>
</tbody>
</table>

1. From the alert console or the Event Management Dashboard, open the alert that you acknowledged in Phase 1: Analyze and acknowledge an alert.
2. Select the Maintenance check box and click Update, or click the Maintenance button at the top of the list.
3. Click Update.

Notice that alerts in maintenance are not visible in the list by default. The filter excludes alerts, where Maintenance | = | true.

If the issue that led to the alert still needs further attention later on, navigate to Event Management > All Alerts, open the alert, and then clear the Maintenance check box and click Update. From there you can then perform other triage actions.

There are also other tasks you can take as part of the triage stage:

- Run a remediation workflow on an alert if your Event Management administrator already set up a workflow in your ServiceNow instance and your policies allow you to trigger it from the alert.
- Launch a web application from an alert to open a website or an event monitoring tool that provides more information about the alert.
- Associate a knowledge base article with an alert if there is existing information about the alert that might help resolve the underlying issue.

If you do not need to perform any other triage actions, proceed to **Phase 3: Close an alert**.

**Operator phase 3: Close an alert**

After you take action on an alert, you can verify several items on an alert and then close it.

<table>
<thead>
<tr>
<th>Phase 1</th>
<th>Analyze and acknowledge an alert</th>
</tr>
</thead>
<tbody>
<tr>
<td>Phase 2</td>
<td>Triage alerts</td>
</tr>
<tr>
<td>Phase 3</td>
<td>Close an alert</td>
</tr>
</tbody>
</table>
1. Navigate to Event Management > Alert Console.
2. Find the alert you want to close. If the alert does not appear in the list for any reason, such as because it is in maintenance, click the filter icon and change the filtering options as needed.
3. Click the alert number in the Number column to open the Alert form.
4. Review key information about the alert in the main part of the Alert form:

   a) On the Task field, click the preview icon to see a small summary of the incident or task you created. You can also click Open Record to see the full task.
If the task is not assigned or is still in a Draft or Work in Progress state, you might not want to close the alert, per your organization’s policies. You can even select another task, such as another incident, a change request, or a problem to replace the existing one.

In this example, we assume everything is correct with the incident that you already created.

b) On the Knowledge article field, click the preview icon to see a small summary of a KB article and verify that captures the necessary information about the alert. You can also click Open Record to see the full article.

In this example, we assume the KB contains the necessary information.

5. Review information about business services in the Impacted Services related list. If you need more information about a business service and want to see the business service map, click View Service. In this example, the Web portal business service is visible.
6. Look at the alerts related to this one, and modify the correlation if necessary. This process is different if you are viewing a primary alert or secondary alert:

- On a primary alert, the secondary alerts that are correlated with the primary appear in the Alerts related list. In this example, the alert is a primary and the secondary alert that you already correlated with it during the triage stage appears:

Typically, you do not have to do anything with the secondary alerts, unless you want to add more secondary alerts, or remove the correlation altogether.

**Note:** When you close a primary alert, the secondary alerts are automatically closed by default.

- On a secondary alert:

  The alert number of the primary alert appears in the Parent field. You do not have to do anything with the parent alert, unless you want to re-correlate this secondary alert with another primary alert, or remove the correlation altogether by clearing the field.
When you are sure the underlying issue causing the generation of the event and corresponding alert has been rectified, click Close. If you think that the alert needs attention, put it into maintenance by clicking Maintenance instead of closing it.

You are finished with the Event Management Operator tutorial, which covers a basic workflow of analyzing alerts, triaging them, and closing them out.

After you close an alert, you might need to follow up on these items:

**If you need to reopen an alert**

You can also manually change the state of an alert to Reopen if you think it requires further action. When an alert reopens, any associated incidents can also be updated or reopened according to the incident state and the rules that your administrator configured. Always go through the triage and close phases again any time you open an alert.

**Alerts in the flapping state**

In some cases, the same event that created the alert you just closed could be triggered again, even repeatedly, in a short amount of time. If this occurs, the State of the alert you just closed changes to Reopen, and eventually to Flapping depending on settings that your administrator configures.

See *Handle alerts in the flapping state* for more information on what to look for.

Also see *Advanced tasks for the Event Management operator* for a summary of other tasks that you might need to perform at some time.

**Advanced tasks for the Event Management operator**

As an Event Management operator, you might need to perform additional tasks that are outside of your typical workflow, or tasks that you need to perform only once.

<table>
<thead>
<tr>
<th>Advanced task</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Customize your Event Management Dashboard view</strong></td>
<td>Get to the alerts you need to analyze as soon as possible.</td>
</tr>
<tr>
<td><strong>Handle alerts in the flapping state</strong></td>
<td>If an alert is in the flapping state, it means that the underlying issue keep reoccurring. You should triage the alert again and look for another solution.</td>
</tr>
<tr>
<td><strong>Handle alerts while CIs are in maintenance</strong></td>
<td>Learn how to handle alerts on a CI that is in the maintenance state, which means it is undergoing some type of change.</td>
</tr>
<tr>
<td>Advanced task</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Adjust alert impact while triaging an alert</td>
<td>You can change impact rules, which affects how alert impact is calculated and alert severity.</td>
</tr>
</tbody>
</table>

**Customize your Event Management Dashboard view**

You can create one or more customized dashboard views that show only the information pertinent to you. For example, you might want to focus only on the alerts for business services in a specific location, or only the alerts for business services of high criticality.

1. Navigate to Event Management > Settings > Dashboard Views.
2. In the Dashboard Views screen, click New.
3. In the Name field, enter a descriptive name for the dashboard view.
4. Keep the Active option selected to use the dashboard view.
5. Specify the filter conditions, and then click Submit.

**Note:** The Dashboard View feature applies only to business services, and not to business service groups. The business service groups appear whether or not they match the filter, and whether or not they contain any services that match the filter.
In this example, the only alerts that can appear on your customized dashboard are those that belong to the most critical or somewhat critical business services in the U.S. datacenter.

6. Navigate to Event Management > Dashboard and verify that the view works as expected.

Handle alerts in the flapping state
If an alert is in the flapping state, you might need to triage the alert again.

If an event repeatedly triggers the same alert in a short amount of time, the alert is put into the flapping state, even if an operator closed it previously. The event can also be fluctuating between severity levels, such as Info and Critical. You should triage the alert again, and take action to try to prevent the event from reoccurring.
Note: Your Event Management administrator can configure several settings that determine when to mark an alert as flapping, and other settings that determine what action you can take. This topic covers a generic example.

1. Find alerts in the flapping state:
   a) Navigate to Event Management > Alert console.
   b) Modify the list of alerts by clicking the filter icon ( ) and specifying criteria to find flapping alerts. For example, you can specify: State is Flapping.
   c) Click Run to get the list of alerts in the flapping state.

2. Click the alert number to open it.
3. On the alert, click the Flapping tab and review the information:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Flap count</td>
<td>The number of times the alert started flapping since the time in the Flap</td>
</tr>
<tr>
<td></td>
<td>start window field.</td>
</tr>
<tr>
<td>Flap start window</td>
<td>The time that flapping started.</td>
</tr>
<tr>
<td>Flap last update time</td>
<td>The last time flapping occurred. This time is the ServiceNow instance</td>
</tr>
<tr>
<td></td>
<td>processing time, not the source system time.</td>
</tr>
<tr>
<td>Flap last state</td>
<td>The state of the alert before it entered the flapping state.</td>
</tr>
</tbody>
</table>

4. Decide what action to take based on how often flapping has occurred. You can do any of the following, depending on what your organization's standard operating procedures are and what your Event Management administrator configured:
   - Run a remediation workflow that might do something like reboot a server or reset a router.
   - Access a web application, like the application for your event monitoring software on your network.
   - Modify an associated incident or a KB article to include additional information or steps.

5. After you are certain that the underlying issue is addressed, close the alert.

Handle alerts while CIs are in maintenance
When an alert occurs on a CI that itself is in a maintenance state, the alert state is also changed to maintenance. You should find and monitor the states of these alerts and, when any changes on the CI are complete, finish triaging the alert and close it.

Before completing this task, familiarize yourself with basic form configuration in a ServiceNow instance. You might need to add fields and related lists to forms.

The example in this topic assumes a network administrator opened a change request to reconfigure a problematic web server.

1. Find alerts in maintenance:
   a) Navigate to Event Management > Alert Console.
b) Modify the list of alerts by clicking the filter icon ( ) and specifying criteria to find alerts in maintenance. For example, you can specify:

State | is | Maintenance.

c) Click Run to get the list of alerts in the maintenance state.

2. In the list of alerts, find an alert with a value in the Configuration Item column. This is the CI on which the alert occurred.

3. Click the CI name to open the form that displays information about the CI.

4. Configure the form layout and the related lists to add the Status field and the Change Request related list.

Verify that the Status field appears in the position you put it, and that Change Request related lists appears at the bottom.
In this example, the status of the web server is **In Maintenance** and there is a change request scheduled so that someone can reconfigure it.

5. At this point, you should not modify the alert associated with this CI. You can open the change request to see if a schedule is attached, or coordinate with your team to find out when the CI will no longer be in maintenance.

6. After you verify that the **Status** field on the CI is not **In Maintenance**, open the alert again and clear the **Maintenance** check box.

7. Continue to **triage the alert**.

### Adjust alert impact while triaging an alert

As an Event Management operator, you might need to modify the impact that an alert has on CIs in a business service and on the business service itself. Do this when you think that the impact on a business service does not accurately represent what you see in your network environment and so other operators and administrators see the correct impact information.

Before you make any modifications to impact calculations, make sure that you understand how the business services and the CIs involved are actually functioning in your organization. This might require you to perform tests on network infrastructure or to contact personnel who can do so.

1. Navigate to **Event Management > Dashboard**, and then double click the name of the business service that has the alerts you want to modify.

2. Click the **Impact Tree** button.

3. Analyze the business service to see if the impact of the alerts is accurately reflected in the Impact Tree based on what you know about the CIs involved.

   In this example, a critical alert indicates a serious issue with a Linux server that is part of a Web portal business service.
Notice that the impact on the Web portal itself is red, meaning critical, even though only one of the Linux servers that it relies upon actually has a critical alert. The other Linux Server does is not impacted by the alert. Assume for this example that the Linux servers perform different roles for the web service, and that even though PS LinuxApp02 has a critical alert, the PS LinuxApp01 server can adequately provide all the necessary services to keep the business service operational.

4. Click the PS Apache03 CI, and then click the Impact button under the business service map to display the impact rules for that CI.

By default, the CI impact rule appears, showing you this information:
• The **Impact On** and **Influence** columns show you that the CI (PS Apache03) should inherit 100% of the impact of all child CI impact, which in this case includes the critical impact on the **PS LinuxApp02** server. This setting is why the **PS Apache03** web server, and the business server as a whole, inherits the impact 100%.

• The **Critical** column shows you that a critical alert (red) is inherited as critical alert (red).

5. Change the **Influence** value to 0 since the web server is still operational, and then change the **Critical** column to indicate that a critical impact status (red) should be inherited as a non-impact (green).

6. Wait for the dashboard to update automatically, or click **Event Management > Dashboard** and double-click the same business service to get an updated business service map.

Notice that the influence on the Apache web server is 0% and the impact status is green. Also notice that the critical alert status (red) remains unchanged, even though the impact changed to green.
7. Navigate back to the Event Management Dashboard. Notice that the business service is now green, indicating that the overall business service is operational. The critical alert still displays at the bottom in the Alerts list, indicating that there is still an issue that you or other operators can address.
Your administrator might configure additional impact rules that display when you click on a CI in the business service map. You can make adjustments to the **Influence** fields on any impact rule to get the most accurate impact tree.

**Mobile experience for Event Management**

You can manage Event Management alerts and business services from anywhere using the Event Management mobile application.

The mobile interface displays alerts and services, each of which is organized by top and high severity and top and high priority. You can also view alert and service details, perform various actions on alerts and services, create incidents, and add work notes.

To work with the Event Management mobile app, you must configure the app on your mobile device. You can also view and configure mobile settings within the app.

The Event Management mobile app works on both Android and IOS devices. The app runs on the ServiceNow Agent app, which you install from the App Store. For details, see [ServiceNow mobile app configuration](#).
If you encounter incidents that are not available on the mobile app, ensure that you have installed the ITSM mobile plugin (com.sn_itsm_mobile). For information on plugins, see ServiceNow plugins.

Event Management mobile functionality is also available on the Event Management instance.

**Connect to an instance using the mobile app**

After installing the mobile app, you must configure an instance from which the app measures alerts. When connecting to an instance using the mobile app, you can access and manage Event Management alerts.

Role required: evt_mgmt_operator or evt_mgmt_admin

1. Configure the Event Management mobile app. For more information, see ServiceNow mobile app configuration.
2. In the ServiceNow AgentEvent Management mobile app, click the plus icon to add a new instance.
3. Select the instance you want to configure.
4. Log in with either user, operator, or admin credentials.

Monitor alerts or services in the mobile app, as described in Work with Event Management alerts using the mobile app and Work with Event Management services using the mobile app.

**Work with Event Management alerts using the mobile app**

You can perform a variety of actions on Event Management alerts in the Event Management mobile app.

*Acknowledge an alert using the mobile app*

Acknowledge an alert on your mobile device to indicate that the alert needs to be addressed.

Role required: evt_mgmt_operator or evt_mgmt_admin

1. Open the mobile app and select Event Management. The home page appears.
2. Tap one of the alert groups.
   The relevant grouping of alerts appears, displaying the following alert details:
   - Number
   - Description
   - Severity
   - Priority
   - Time of update
3. **Slide an alert to the left and tap Ack on the right side of the alert.**
   The alert's Acknowledged state is set to True.

---

Place an alert into maintenance using the mobile app
Place an alert into maintenance on your mobile device to indicate that the alert's CI is in the Maintenance state.

Role required: evt_mgmt_operator or evt_mgmt_admin

1. Open the mobile app and select Event Management. The home page appears.

2. Tap one of the alert groups. The relevant grouping of alerts appears, displaying the following alert details:
   - Number
   - Description
   - Severity
- Priority
- Time of update

**Note:** The procedure for working with priority and severity alerts is the same.

3. Slide an alert to the right and tap **Maint** on the left side of the alert.
The alert is set to the Maintenance state and displays with both a blue indicator in the left margin and diagonal lines running through the alert. After refreshing the page, this alert no longer appears in the list of alerts.

**View repeated alerts using the mobile app**
You can check whether the issue tracked by your alert on your mobile device has occurred multiple times in the system to help determine how urgently the alert needs to be dealt with. Repeated alerts have the same source and the same severity as a particular alert.

**Role required:** evt_mgmt_user

1. Open the mobile app and select Event Management.
   The home page appears.

2. Tap one of the alert groups.
The relevant grouping of alerts appears, displaying the following alert details:

- Number
- Description
- Severity
- Priority
- Time of update
Note: The procedure for working with priority and severity alerts is the same.

3. Select an individual alert.
4. Tap the More Options icon (•••) and select **Repeated Alerts**. A list is displayed containing the alerts with the same source and severity as the selected alert.

*View similar alerts using the mobile app*
Check whether the CI tracked by your alert on your mobile device has occurred multiple times in the system to help determine how urgently the alert needs to be dealt with. Similar alerts are alerts with the same CI as a specified alert but do not necessarily match all aspects of the alert. Similar alerts are identified by Machine Learning (ML) discovering similar text in alert fields.

**Role required:** evt_mgmt_user

1. Open the mobile app and select Event Management. The home page appears.
2. Tap one of the alert groups.
   The relevant grouping of alerts appears, displaying the following alert details:
   - Number
   - Description
   - Severity
   - Priority
   - Time of update
3. Select an individual alert.

Note: The procedure for working with priority and severity alerts is the same.
4. Tap the More Options icon ( ■ ) and select **Similar Alerts**. A list is displayed containing alerts similar to the selected alert.

*View incidents related to alert CIs using the mobile app*

Viewing a list of alert CIs for which an incident is open helps determine which CIs are problematic in your Event Management environment.

**Role required:** evt_mgmt_user

1. Open the mobile app and select Event Management. The home page appears.
2. Tap one of the alert groups.
   The relevant grouping of alerts appears, displaying the following alert details:
   - Number
   - Description
   - Severity
   - Priority
   - Time of update
Note: The procedure for working with priority and severity alerts is the same.

3. Select an individual alert.
4. Tap the More Options icon (⋮) and select **CI Incidents**. A list of the CIs of the alert that have related open incidents appears.

*View change requests related to an alert CI using the mobile app*

When viewing an alert in a mobile environment, you can view any change requests that exist on the CI associated with the current alert. A change request indicates when a specific CI will be unavailable.

**Role required:** evt_mgmt_user

Change requests provide a method to implement a controlled process for the addition, modification, or removal of approved and supported configuration items (CIs). A change request records the detailed information about the change, such as the reason of the change, the priority, the risk, the type of change, and the change category.

1. Open the mobile app and select Event Management.
   The home page appears.
2. Tap one of the alert groups.
   The relevant grouping of alerts appears, displaying the following alert details:
   - Number
   - Description
   - Severity
   - Priority
   - Time of update
Note: The procedure for working with priority and severity alerts is the same.

3. Select an individual alert.
4. Tap the More Options icon ( ) and select **CI Change requests**.
A list of the change requests that exist on the alert’s CI appears.

*View alert executions using the mobile app*
You can view alert executions for an alert in the mobile environment. Alert executions track the history of an alert by displaying actions performed on the alert, and the alert management rules executed on the alert either manually or automatically.

Role required: evt_mgmt_user

1. Open the mobile app and select Event Management.
The home page appears.
2. Tap one of the alert groups.
   The relevant grouping of alerts appears, displaying the following alert details:
   - Number
   - Description
   - Severity
   - Priority
   - Time of update
3. Select the relevant group to display a list of alerts.
4. Select an alert.

**Note:** The procedure for working with priority and severity alerts is the same.
5. Tap the Related tab and select Alert Executions to view the alert management rules executed for the alert.

The number next to the Alert Execution link indicates the number of alert management rules executed on the alert.
View secondary alerts using the mobile app

When viewing an alert in a mobile environment, you can also view any secondary alerts in the specified alert's group. The alert containing a group of secondary alerts is called the primary alert.

Role required: evt_mgmt_user

1. Open the mobile app and select Event Management. The home page appears.

2. Tap one of the alert groups. The relevant grouping of alerts appears, displaying the following alert details:
   - Number
   - Description
- Severity
- Priority
- Time of update

Note: The procedure for working with priority and severity alerts is the same.
3. Select an individual alert.
4. Tap the Related tab and select Secondary Alerts to view the secondary alerts for the primary alert's group.

The number next to the Secondary Alerts link indicates the number of secondary alerts that are grouped with the specified alert.
Manage alert actions using the mobile app
When viewing alerts on your mobile device, you can track actions performed on the alert and log additional actions by adding work notes.

Role required: evt_mgmt_user

1. Open the mobile app and select Event Management. The home page appears.

2. Tap one of the alert groups. The relevant grouping of alerts appears, displaying the following alert details:
   - Number
   - Description
   - Severity
• Priority
• Time of update

Note: The procedure for working with priority and severity alerts is the same.

3. Select an alert to view its information.
The **Details** tab is selected by default and displays details on the alert.

**Alert0010140**

**JVM Memory usage exceeds 89%**

**Critical**

2019-05-13 17:50:08

**Description**

JVM Memory usage exceeds 89%

**State**

Open

**Source**

Nanios

[Close Alert]

[Quick Incident]
4. Tap the **Activity** tab to view work notes or other activities associated with the alert. You can also tap the green plus sign to add a new work note or perform an activity on the alert, such as adding an attachment.

5. Tap the green plus sign icon to add a new work note or perform an activity on the alert.
Your text appears in the list of Work notes.

View services impacted by alerts using the mobile app
Alerts impact business services, which can affect the way those services run in your environment. You can view the business services impacted by alerts that your mobile device monitors.

Role required: evt_mgmt_user

1. Open the mobile app and select Event Management. The home page appears.

2. Tap one of the alert groups. The relevant grouping of alerts appears, displaying the following alert details:
   - Number
- Description
- Severity
- Priority
- Time of update
Note: The procedure for working with priority and severity alerts is the same.

3. Select an individual alert.
4. Tap the More Options icon (⋮) and select **Impacted Services**.
   The services impacted by the alerts appear.
   For details on how alert impact is calculated, see [Alert impact calculation](#).

**Create an incident for a mobile alert**
When viewing an alert on your mobile device, you can create an incident for the alert.

Role required: evt_mgmt_operator or evt_mgmt_admin

1. Open the mobile app and select Event Management.
   The home page appears.
2. Tap one of the alert groups.  
The relevant grouping of alerts appears, displaying the following alert details:

- Number
- Description
- Severity
- Priority
- Time of update
Note: The procedure for working with priority and severity alerts is the same.

3. In the group’s list, select an alert to view its information.
The Details tab appears by default with details on the alert.

4. Tap Quick Incident to create an incident from the alert with the setting Severity = Major.
Close an alert using the mobile app

If an alert on your mobile device has already been handled or is no longer relevant, you can choose to close it.

Role required: evt_mgmt_operator or evt_mgmt_admin

1. Open the mobile app and select Event Management. The home page appears.

2. Tap one of the alert groups. The relevant grouping of alerts appears, displaying the following alert details:
   - Number
   - Description
   - Severity
- Priority
- Time of update

Note: The procedure for working with priority and severity alerts is the same.

3. Select an alert to view its information.
The Details tab appears by default with details on the alert.

4. Tap Close Alert to close the alert.
Work with Event Management services using the mobile app

You can view services and perform actions on services using the Event Management mobile app.

View service alerts and details using the mobile app

You can use the mobile app to view a service’s alerts, as well as its severity, priority, name, owner, and class.

Roles required: evt_mgmt_user, evt_mgmt_admin or evt_mgmt_operator

1. Open the mobile app and select Event Management.
2. Tap one of the Services groups.

The services in the selected group are listed with the following information:

- Name
- Owner
3. Tap a service to view further details.

4. Tap the Alerts button to view the alerts associated with the service. The service's current alerts are displayed.

**Note:** The mobile app displays only alerts from the em_alert table, which have not yet undergone impact calculation. Therefore, alert lists might be different on the mobile app than in the instance, where the list includes alerts from the em_history_alert table that have undergone impact calculation.
Receive push notifications for a service using the mobile app
You can choose to receive an update when a service’s status changes to Urgent or High. A notification will be displayed in the Event Management mobile app.

Role required: evt_mgmt_user

1. Open the mobile app and select Event Management.
2. Select the bell icon ( ) at the bottom of the home page.
   The Enable Notifications indicator appears.

3. Slide the notification indicator to the right to enable receiving notifications of services whose status changes to Urgent or High.

Operational Intelligence

ServiceNow® Operational Intelligence provides the ability to capture, and then explore and analyze operational metrics data, identifying and indicating anomalies. Operational Intelligence generates anomaly alerts that can be promoted to IT alerts and appear on the Alert Console and service health dashboard. You can leverage this analysis to prevent potential service outages.

Starting with the New York release, Operational Intelligence is part of ITOM Health in the IT Operations Management product.

Explore

Understanding Operational Intelligence

Use Operational Intelligence to identify and prevent potential service outages. Operational Intelligence, based on historical metric data, indicates anomalous behavior of CIs which events might not capture. Anomaly alerts can be promoted to regular IT alerts and appear on the Alert Console and service health dashboard for preventive actions.

Starting with the New York release, Operational Intelligence is part of ITOM Health in the IT Operations Management product.

Anomaly detection

Metric data is collected by various data sources such as SCOM, SolarWinds monitoring system, or Nagios XI server (some partially configured for metric collection by default). These monitoring systems collect metric data from the source environment regularly. Operational Intelligence captures the raw data from these monitoring systems, and uses event rules and the CMDB identification engine to map data to existing CIs and their resources. The data is then analyzed to detect anomalies and to provide other statistical scores.

Operational Intelligence uses historical metric data to build statistical models. These models facilitate projection of expected metric values along with upper and lower bounds. Operational Intelligence then uses these projections to detect statistical outliers and to calculate anomaly scores. Anomalies are scored on a range of 0-10. High anomaly scores for CI metrics can indicate that a CI is at risk of causing a service outage.

After processing, the Insights Explorer shows metric statistics and charts, and the Anomaly Map shows correlated scores for CIs with the highest anomaly scores, across a timeline.

Operational Intelligence is available when you activate the Operational Intelligence (com.snc.sa.metric) plugin.

Terms used with Operational Intelligence

Source metric type

A metric such as ‘% Free Space’ or ‘Current Bandwidth’ that can be measured by a data source for a CI. For each data source, you can choose which of all possible source metric types are processed. For example, there are about 380 source metric types that are active by default for the SCOM data source.

Anomaly
Data that is outside the control bounds is considered a statistical outlier. These outliers are used to compute an anomaly score, which is a value between 0–10 that indicates the degree to which the metric appears unlikely. When an anomaly score is above a threshold, an anomaly alert is generated. Anomaly alerts are reported separately from regular IT alerts.

**Resource**

A component of a CI that consists of multiple individual components of similar type, where each subcomponent can be monitored separately. For example, individual Web pages, or specific disks such as 'Disk C:' and 'Disk D:'.

**Time series**

A series of values (such as metric values) over a time range, associated with a CI and a metric type. Because an anomaly score is evaluated for each metric, the series of anomaly scores over a period of time are also a time series. Time series are computed by the statistical model built for a metric data series, and are used with metric data values, anomaly scores, and upper and lower control bounds.

**Statistical models**

Operational Intelligence jobs learn from past metric data (up to 32 days old). A model training process analyzes historical data to construct a model that projects future values. Typically, models are in effect until the next time the model learning process runs. These models are used to calculate upper and lower bounds. Incoming values that are beyond those bounds, and that deviate with statistical significance from expected values, generate anomalies. Each model is uniquely patterned and is labeled with a classifier that illustrates the general behavior of the model. This classification determines if anomaly detection can be applied. For most models, it is possible to project which future values deviate from expected values. Such models are associated with control bounds and anomaly detection can be applied (if enabled).

However, for some models, there is insufficient data to determine which values are anomalous and anomaly detection cannot be applied without additional information (even if anomaly detection is enabled).

The learned data models are stored in the Metric Time Series Models (sa_time_series) table.

The following statistical models and classifiers are used in anomaly detection:

**Time Series statistical model**

After it is established, a time series model does not adjust to changes in the incoming metric data. Therefore, if the pattern of incoming data changes, those changes are likely to be identified as anomalous. Upper and lower control bounds, after they are learned, persist until the next time the learning process runs (data is learned every day).

**Weekly**

Data with a pattern that repeats itself over weekly intervals (seasonal model).

Requires a minimum of 15 days of data in the series, as set by the `weekly_model_min_days` configuration setting.
Daily

Data with a pattern that repeats itself over a daily interval (seasonal model).

Requires a minimum of 3 days of data in the series, as set by the `daily_model_min_days` configuration setting.

---

Trendy

Data that has a linear trend with some slope and with some noise.

Requires a minimum of 30 data points in the series, as set by the `corrupt_data_count_threshold` configuration setting.

---

Noisy

Typical noisy data that is a basic pattern classification in a data model. The pattern cannot be identified with a specific trend or seasonality.
Requires a minimum of 30 data points in the series, as set by the `corrupt_data_count_threshold` configuration setting.

**Positive clipped noisy**

Similar to the noisy classifier other than the lower bound that is fixed on 0.

Requires a minimum of 30 data points in the series, as set by the `corrupt_data_count_threshold` configuration setting.

**Centered noisy**

Noisy data that typically spreads symmetrically between user-specified upper and lower bounds. The formula that is used to set bounds and width values, ignores the statistical data, and the lower and the upper widths have an identical value.

Requires that the number of data points in the series is zero.

See [Specify custom upper and lower metric bounds](#) for more information.
Skewed noisy

Noisy data that is not evenly spread between user-specified upper and lower bounds, but instead tends to concentrate closer to one of the bounds. The median of the data is used to separately compute an upper width and a lower width.

Requires a minimum of one data point in the series.

See Specify custom upper and lower metric bounds for more information.

Accumulator

Data pattern similar to the trendy classifier but with a monotonous increase and without noise. For this classifier, there is no data model and no anomaly detection.

Requires a minimum of 30 data points in the series, as set by the corrupt_data_count_threshold configuration setting.
Near Constant

Nearly constant data, in which most values are a specific constant value. For this classifier, there is no data model and no anomaly detection.

Requires a minimum of 30 data points in the series, as set by the `corrupt_data_count_threshold` configuration setting.

![Graph showing nearly constant data](image)

Multinomial

Data pattern in which all values are one of a relatively small number of values. For example, values are always 100 or 99.9. For this classifier, there is no data model and no anomaly detection.

Requires a minimum of 400 data points in the series, calculated as 10 times the value of the `multinomial_count_threshold` configuration setting.

![Graph showing multinomial data](image)

Corrupt

Data has insufficient data points to identify a pattern. For this classifier, there is no data model and no anomaly detection.

Requires that the number of data points in the series is less than the value of the `corrupt_data_count_threshold` configuration setting (30 by default).

![Graph showing corrupt data](image)

Kalman Filter statistical model

Add on to the time series statistical model and applicable only to the noisy and positive noisy classifiers. This model is a general method of estimating model parameters from a stream of data where level is the only parameter in the model. The Kalman Filter model can adjust to new values...
in incoming metric data. When there are no clear patterns in the noise or if there is too much noise, the Kalman Filter model is not used.

Local level
When incoming data clusters around a new value according to the current control bounds, the Learner adjusts the data model to accommodate a permanent change. This clustering is detected as a new value in the data model so that most incoming data is again within the control bounds rather than anomalous. Such change detection is useful when for example, cores or memory are added to a server, which impact the baselines.

Requires a minimum of 30 data points in the series, as set by the `corrupt_data_count_threshold` configuration setting.

Unrecognized
When data does not fit the local level classifier, time series classifiers are used. This happens when it is not possible to adjust the variance ratio in a learned local level model to reasonable values.

Non-Parametric statistical model
Add on to the positive noisy classifier. In the nonparametric model, noise distribution is not symmetrical and does not fit any seasonal pattern. The nonparametric model creates control bounds that better fit the actual data, and once learned, the control bounds persist until the next learning cycle. This model does not adjust itself to changes in the data, and it takes longer for a deviation to be identified as an anomaly.

Stationary Non-Parametric
Data that is not time-dependent meaning that there is no significant shift in parameters such as mean and variance when shifting data in time.

Requires a minimum of 5000 data points in the series, as set by the `snpm_minimum_data_count` configuration setting.
Unrecognized
When data does not fit the stationary classifier, time series classifiers are used.

Get started with Operational Intelligence

Complete the following setup and initial configuration steps to start using Operational Intelligence.

Raw metric data, collected by data sources (such as SCOM) needs to reach the Operational Intelligence MID Server, where Operational Intelligence can process and analyze it. You can set up Operational Intelligence to receive raw metric data from external data sources using either pull or push mechanism.

Using either method (pulling or pushing) requires the configuration of the Operational Intelligence Metrics MID Server extension. The main roles of this extension are to normalize the raw data, and to detect any anomalies. The normalized data and anomalies (if above the specified threshold), are then transmitted to the instance.

Some of the steps for setting up Operational Intelligence, must be completed regardless of the method used. Other steps depend on the method used for transmitting data between the data source and the MID Server:

Pulling
This method requires using a connector that is configured to pull data from a specific data source that is collecting raw metric data. You can use a pre-defined connector such as SCOM (which was previously defined for pulling events from SCOM), Azure platform, or AWS, or configure a new custom connector specifically for the external source that is used in your environment.

Pushing
This method uses web service APIs and is based on client-side tools that push the raw data from the external source to the MID Server. This method requires that the Operational Intelligence Metrics extension is configured with the Enable REST Listener option enabled.

You also need to configure the Web Server extension, which starts a Web Server on the MID Server. Request handlers are added on the Web Server that listen to any incoming metric data that was pushed from the external source.

Watch the Event Management | Collecting Events and Metrics short video about using MID Servers for pulling and pushing metric data.
In an initial setup, you can use an automated setup to automate many of the setup tasks. For example, to create a MID Server distributed cluster that contains a single Operational Intelligence MID Server. The following video describes the manual steps for setting up Operational Intelligence.

Operational Intelligence guided setup provides a sequence of tasks that help you configure Operational Intelligence on your ServiceNow instance. To open Operational Intelligence guided setup, navigate to Guided Setup > ITOM Guided Setup, and click Continue. Then scroll to Operational Intelligence, and click Continue. For more information about using the guided setup interface, see Using guided setup.

Alternatively, you can complete the following procedure.

1. **Activate the Operational Intelligence plugin.**
2. Prepare a MID Server to be configured for Operational Intelligence. For information, see MID Server and MID Server distributed cluster for Operational Intelligence.
3. Use the Automated Operational Intelligence setup.
4. To configure for pushing:
   a) Create the client scripts that push the raw data from the external source to the MID Server.
5. To configure for pulling, for each data source that you want to use for collecting metric data:
   a) Navigate to Event Management > Connector Definitions to determine if there is a pre-defined connector definition for the data source, and then create a new connector definition if need to (The pre-defined SCOM connector for example — is configured for pulling events from SCOM).
   b) Configure a metric connector instance for the data source (For a SCOM connector for example — see Configure the SCOM connector instance).
6. **Choose and configure metrics to monitor.**
7. Create event rules to map raw metric data to specific CI types and Create an event rule to bind metric events to host CIs.
8. About 10 minutes after the Operational Intelligence Metrics extension has started, run the quick start tests for Operational Intelligence to verify functionality.

Request Operational Intelligence

Operational Intelligence plugin (com.snc.sa.metric) requires a separate subscription and must be activated by ServiceNow personnel. This plugin includes demo data and activates related plugins if they are not already active.

See Get started with Operational Intelligence for the high level steps of setting up Operational Intelligence.

Role required: admin

To purchase a subscription, contact your ServiceNow account manager. The account manager can arrange to have the plugin activated on your organization’s production and sub-production instances, generally within a few days.

If you do not have an account manager, decide to delay activation after purchase, or want to evaluate the product on a sub-production instance without charge, follow these steps.

1. From your instance, navigate to System Definition > Plugins.
2. On the All Applications page, click Request Plugin to open the request form on HI.
3. On HI, select to be redirected to the HI Service Portal Service Catalog.
4. On the Activate Plugin request form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target Instance</td>
<td>Instance on which to activate the plugin.</td>
</tr>
<tr>
<td>Plugin Name</td>
<td>Name of the plugin to activate.</td>
</tr>
<tr>
<td>Specify the date and time you would like this plugin to be enabled</td>
<td>Date and time must be at least two business days from the current time.</td>
</tr>
<tr>
<td>Reason/Comments</td>
<td>Information that would be helpful for the ServiceNow personnel who are activating the plugin. For example, if you need the plugin activated at a specific time instead of during one of the default activation windows, specify it in the comments.</td>
</tr>
</tbody>
</table>

5. Click Submit.

**MID Server and MID Server distributed cluster for Operational Intelligence**

Using Operational Intelligence requires at least one MID Server distributed cluster which contains at least one MID Server that is configured for Operational Intelligence.

Even if using a single Operational Intelligence MID Server, that server must be added to a MID Server distributed cluster, and any additional MID Servers in that cluster, must be configured for Operational Intelligence. All Operational Intelligence MID Servers must be members of a MID Server distributed cluster. The first MID Server that is added to a distributed cluster, is designated as the Cluster Leader.

To support the specified throughput, create a distributed cluster with a single MID Server that meets the Operational Intelligence MID Server requirements. To support high availability, create a distributed cluster with two such MID Servers.

See [Get started with Operational Intelligence](#) for the high level steps of setting up Operational Intelligence.

**MID Server distributed clusters**

Activating Operational Intelligence (com.snc.sa.metric), automatically activates MID Server Distributed Cluster (com.snc.agent.distributed.cluster). MID Server Distributed Cluster supports the Distributed MID Server cluster type which is used exclusively with Operational Intelligence.
In a distributed cluster type, the MID Servers in the cluster communicate with each other to distribute and balance the work load. This communication requires that all MID Servers in a distributed cluster are able to communicate with each other. Ensure that the specified ports are open and that there are no firewalls that block communication.

**Operational Intelligence MID Server**

The Operational Intelligence MID Server supports the Operational Intelligence feature by processing data and detecting anomalies. The MID Server transmits batches of processed data to the instance. If an anomaly is detected, then information about the anomaly along with the raw data is sent immediately to the instance, regardless of the regular 10-minute cycle.

Each Operational Intelligence MID Server must be configured with the following settings:

- OperationalIntelligence as a supported application
- the Metrics capability
- running the Operational Intelligence Metrics extension

The OperationalIntelligence application that the Operational Intelligence MID Server is configured with, lets you add additional supported applications to the same MID Server. By default, Operational Intelligence is included in the definition of the MID Server ALL option. For information about modifying the behavior of the ALL option when selecting supported applications, see [Configure applications included in ALL Applications](#).

If Domain Support - Domain Extensions Installer is activated, then you can configure a MID Server with the Metrics capability, per domain. In this case, metrics for a business service are processed on the MID Server that is in the same domain as the business service. Otherwise, a MID Server from the global domain is used.

Ensure that the MID Server that you want to configure for Operational Intelligence:

- Is validated. For more information, see [Validate a MID Server](#)
- Is in running state
- Meets all software, hardware, and configuration requirements

### Hardware requirements for the virtual machine/host on which the MID Server runs (scaled for 5000 CIs with 100 metrics per CI)

<table>
<thead>
<tr>
<th>Requirement</th>
<th>Supports approximately up to a total of 1.2 million metrics (12,000 CIs with 100 metrics per CI).</th>
<th>Supports approximately up to a total of 1.7 million metrics (17,000 CIs with 100 metrics per CI).</th>
</tr>
</thead>
<tbody>
<tr>
<td>Three MID Servers, each has:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>- Memory: 12 GB</td>
<td></td>
<td></td>
</tr>
<tr>
<td>- Processor: 4 cores</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Three MID Servers, each with:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>- Memory: 24 GB</td>
<td></td>
<td></td>
</tr>
<tr>
<td>- Processor: 8 cores</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Software requirements

<table>
<thead>
<tr>
<th>Software</th>
<th>Supported versions</th>
<th>Additional requirements</th>
</tr>
</thead>
</table>
| Windows  | 32-bit and 64-bit versions:  
- Windows 2008 R2  
- Windows Server 2012 R2  
- Windows Server 2016 | 32-bit or 64-bit version of the MID Server |
| Linux    |  
- Red Hat Enterprise Edition Linux 6.6 or later  
- CentOS Linux 6.6 or later | 32-bit or 64-bit version of the MID Server |

Configuration requirements

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Requirement</th>
</tr>
</thead>
</table>
| MID Server service logon user (required only for pulling) | Must be set to a user with read access to the SCOM database (OperationsManagerDW).  
1. On the MID Server, open the MID Server Properties dialog box.  
2. Click the Log On tab.  
3. Select This account, and enter credentials for a user with the required access.  
4. Click Apply. |

Configuration Override

Update the wrapper-override.conf file in folder ../agent/conf:

- Add the following code at the bottom of the file:

  ```
  # GC
  wrapper.java.additional.5=-XX:+AlwaysPreTouch
  wrapper.java.additional.6=-XX:+UseG1GC
  wrapper.java.additional.7=-XX:+ScavengeBeforeFullGC
  wrapper.java.additional.8=-XX:+DisableExplicitGC
  # IP4
  wrapper.java.additional.9=-DpreferIPv4Stack=true
  ```

- Optionally, if a server has additional RAM available, for example 16 GB RAM, you can replace 4096 with 8192 in: wrapper.java.maxmemory=4096.

Automated Operational Intelligence setup

When you initially set up Operational Intelligence, you can automate many of the setup steps. For example, the automated setup configures a MID Server for Operational Intelligence and creates a MID Server distributed cluster which contains that MID Server.

Role required: evt_mgmt_admin
When the following conditions are met, the related link **Setup Operational Intelligence** appears on the MID Server form, enabling automated setup:

- The MID Server has been validated.
- The MID Server is in a running state.
- The property `sa.metric.display.mid.setup.action` is set to true (default value).

The Operational Intelligence automated setup performs the following setup tasks:

1. Configures the MID Server with the **OperationalIntelligence** application
2. Adds the **Metrics** capability to the MID Server
3. Creates a new MID Server cluster of type ‘distributed’ set with a default port of 47100 for Apache Ignite
4. Adds the MID Server to the new MID Server distributed cluster
5. Creates an Operational Intelligence Metrics Extension and starts it
6. Opens the Operational Intelligence Metrics Context form. On this form, you can click the **Setup REST Listener** UI action to create the MID Web Server extension configured with the ‘Enable REST Listener’ option and default port 8097

Use the **Setup Operational Intelligence** link only to create the first MID Server distributed cluster that contains a single MID Server, with default values. After the automated setup completes, you have to manually create any additional MID Server distributed clusters or add Operational Intelligence MID Servers.

1. Navigate to **MID Server > Servers**.
2. Click the MID Server that you want to configure as an Operational Intelligence MID Server.
3. On the MID Server form, click **Setup Operational Intelligence** in the Related Links section.
4. In the newly created Operational Intelligence Metrics Extension form, wait for **Status** to be ‘Started’. Then, if configuring the MID Server for pushing click the UI action **Setup REST Listener**. A notification appears about the MID Web Server extension being created. The **MID Web Server Extension** field appears and **Enable REST Listener** is checked. You can preview the MID Web Server Extension record to verify that its **Status** is ‘Started’.

**Manually configure a MID Server for Operational Intelligence**

To use Operational Intelligence, configure at least one MID Server with Operational Intelligence as a supported application, with the Metrics capability, and which runs the Operational Intelligence Metrics extension. Then, add that Operational Intelligence MID Server as a member to a MID Server distributed cluster.

Ensure that the MID Server meets all software, hardware, and configuration requirements to be configured for Operational Intelligence.

Role required: To access the MID Server - mid_server. To configure a MID Server in an instance (for example, to add a supported application), refer to the MID Server documentation.

1. Navigate to **MID Server > Servers**.
2. Click the MID Server that you want to configure for Operational Intelligence.
3. Add the **OperationalIntelligence** application:
   a) At the center of the MID Server form, click **Supported Applications**.
   b) In the **Supported Applications** section, click **Edit**.
   c) In the slushbucket, select **OperationalIntelligence** and click the > add button.
d) Click **Save**.

4. Add the Metrics capability:
   a) At the center of the MID Server form, click **Capabilities**.
   b) In the **Capabilities** section, click **Edit**.
   c) In the slushbucket, select **Metrics** and click the ‘>’ add button.
   d) Click **Save**.

5. Click **Update**.

Create a MID Server distributed cluster, and add the Operational Intelligence MID Server as a member to that cluster.

**Manually create a MID Server distributed cluster**

After creating at least one Operational Intelligence MID Server, create a MID Server distributed cluster for Operational Intelligence to contain that MID Server.

Role required: evt_mgmt_admin or agent_admin can manage cluster records

**Note:** If you used the related link Setup Operational Intelligence on a MID Server form, then you might not need to perform this procedure. If the automated setup completed successfully, then a MID Server distributed cluster which contains an Operational Intelligence MID Server, already exists. Use this procedure to manually create a MID Server distributed cluster and to add to it an Operational Intelligence MID Server. See ‘Automated setup of MID Server distributed cluster’ in this topic for more details.

Operational Intelligence uses two ports on each MID Server distributed cluster:

- One port for Discovery
- One port for communications

When deploying multiple Operational Intelligence MID Servers on the same physical server, allocate two ports for each additional MID Server. If for example, you deploy two Operational Intelligence MID Servers on the same physical server, then four ports are required.

1. Navigate to **MID Server > Clusters**.
2. Click **New**.
3. Fill out the MID Server Cluster form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the cluster.</td>
</tr>
<tr>
<td>Type</td>
<td>Cluster type which must be set to <strong>Distributed</strong>.</td>
</tr>
</tbody>
</table>

4. Right-click the form banner and select **Save**.
5. Additional fields appear on the MID Server Cluster form. Review the details, and then click **Update** if you modified any fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Distributed Cluster</td>
<td>Indicates that the cluster type is distributed.</td>
</tr>
<tr>
<td>Status</td>
<td>The cumulative status of the cluster, which can be Started, Stopped, Error, or Warning.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Error Message</td>
<td>The most recent error message that was generated for the cluster.</td>
</tr>
<tr>
<td>Port</td>
<td>Starting port in the port range to use for communication with other Operational intelligence MID Servers in the distributed cluster. Default value is 47100.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> If the same virtual machine/host server runs multiple Operational Intelligence MID Servers, and if those MID Servers are communicating with different ServiceNow instances or are part of a different distributed cluster on the same ServiceNow instance, then use separate ports for each cluster.</td>
</tr>
<tr>
<td>Port count</td>
<td>The number of ports to use for communication with other Operational Intelligence MID Servers in the MID Server distributed cluster. Port count is used with Port to determine a range of ports. If the value of Port is 47100, and the value of Port count is four, the ports 47100 - 47103 are used for communication. Default value is four. Do not modify this value if only a single MID Server is configured on a physical server. Otherwise, increase this value by two for each additional MID Server that is implemented on a single physical server.</td>
</tr>
</tbody>
</table>

6. In the Includes MID Servers related list, click Edit to add MID Servers to the cluster.
7. Use the slushbucket to add only MID Servers that were configured for Operational Intelligence. Then click Save.
8. On the MID Server Cluster form, click Update.

**Note:** The Operational Intelligence MID Servers do not join the MID Server distributed cluster until you configure the Operational Intelligence extension, which is the next step in setting up Operational Intelligence.

Parameters of MID Server distributed cluster
The following MID Server parameters support the MID Server Distributed cluster type.

You can access these parameters in the Configuration Parameters related list of a MID Server. To add and set any of these parameter, see Add a MID Server parameter.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mid.distributed.cluster.striped.threadpool.size</td>
<td>Size of striped threadpool in MID Server distributed cluster.</td>
</tr>
<tr>
<td></td>
<td>• Type: integer</td>
</tr>
<tr>
<td></td>
<td>• <strong>Default value</strong>: Number of cores on the virtual machine or server.</td>
</tr>
<tr>
<td>mid.distributed.cluster.log.level</td>
<td>Logging level for MID Server distributed cluster, which can help troubleshooting. However, logging impacts the performance of Operational Intelligence.</td>
</tr>
<tr>
<td></td>
<td>An empty value designates no logging.</td>
</tr>
<tr>
<td></td>
<td>• Type: integer</td>
</tr>
<tr>
<td></td>
<td>• <strong>Default value</strong>: none</td>
</tr>
<tr>
<td></td>
<td>• Other possible values: info, debug, trace</td>

</tbody>
</table>

**Scheduled jobs included with MID Server distributed cluster**

The following MID Server scheduled job is included with the MID Server Distributed cluster type.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Validate MID distributed cluster</td>
<td>Validates status of the cluster node for each MID Server in the cluster. For a MID Server that is down and its status is not stopped, updates the node status to stopped.</td>
</tr>
<tr>
<td></td>
<td>Also, validates overall status of the cluster. During this validation, the job stops the cluster if there are multiple sub-clusters in a single cluster.</td>
</tr>
</tbody>
</table>
Manually configure the Operational Intelligence extension

Configure the MID Server Operational Intelligence extension to enable the MID Server to pull raw metrics from external systems, to detect anomalies and report anomalies to the instance along with raw data. This MID Server Operational Intelligence extension is required and must be running in order for your system to be able to collect Operational Intelligence data.

See [Get started with Operational Intelligence](#) for the high level steps of setting up Operational Intelligence.

Role required: evt_mgmt_admin

The MID Server Operational Intelligence extension normalizes the raw data and then transmits the data to the instance. If the extension detected any anomalies above a specified threshold, they are sent to the instance. The extension runs for as long as it is enabled. This provides a persistent connection to the MID Server to constantly listen for raw Operational Intelligence data from external systems.

The MID Server Operational Intelligence extension:

- Receives raw metric data, batches them and sends them to the instance at specified intervals.
- Detects anomalies and sends a report to the instance.
- The information that is sent to the ServiceNow instance is relevant for Operational Intelligence, so data processing is efficient.

The MID Server Operational Intelligence extension does not provide any API calls. However, when the **Enable REST Listener** option is selected, the extension adds a handler for the supported REST APIs.

**Note:**

- Only upon configuring the Operational Intelligence extension, the Operational Intelligence MID Servers actually join the distributed cluster for Operational Intelligence.
- After the initial configuration, the first metric is not included in the metrics data.
- There is a delay of one minute in receiving metric information from the synchronization of the instance with the MID Server.

1. Navigate to **MID Server > Extensions > Operational Intelligence**.
2. In the Operational Intelligence Metrics Contexts list, click **New**.
3. Fill in the fields, as appropriate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name for this extension for easy identification.</td>
</tr>
<tr>
<td>Short description</td>
<td>A description of this extension.</td>
</tr>
</tbody>
</table>
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| Status         | This field is auto-populated with the status of the extension. The field is blank until the extension is started. After issuing a command to the extension, one of the following values is displayed:  
- **Started**: The extension is running.
- **Stopped**: The extension is not running.
- **Offline**: The MID Server is down.
- **Error**: The extension failed with an error (the error message is displayed in Error Message).  
- **Warning**: A run-time exception has occurred. The extension continues to work. |
| Error Message  | Message describing any error that causes a command, such as Start or Stop, to fail. This field appears when the value in the Status field is Error and also when the value in the Status field is Warning. |
| Execute on     | Location for running this extension. When configuring this option for use with Operational Intelligence, set to Specific MID Server. Then specify the MID Server with Operational Intelligence as a supported application and the Metrics capability. |
| MID Server     | The name of the designated MID Server, which is configured with Operational Intelligence as a supported application and the Metrics capability. |
| Executing on   | (Read-Only) The name of the MID Server on which the extension is running. This field shows the name of the MID Server even if the MID Server is down. If the user stops the extension, this field is empty. |

4. When using the Push method for collecting Operational Intelligence data, the MID Server Operational Intelligence extension must be configured with the Enable REST Listener enabled. This option enables a listener so that a REST endpoint can receive raw metric data. The raw metric data is then placed in the regular data flow where the data is sent to the instance and the anomaly detector looks for anomalies. When selected, it adds a handler to the web server to listen for any metrics that are pushed to the MID Server. When this option is selected, the Web Server extension, which starts a Web Server on the MID Server, must also be configured. For more information, see Configure the MID Web Server extension.

5. Right-click the form heading and select Save.

6. Under Related Links click Start to save the Operational Intelligence data in this extension and start the extension.

#### Commands available in the MID Server Operational Intelligence extension

<table>
<thead>
<tr>
<th>Related Link</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start</td>
<td>Starts the extension on the configured MID Server if it is currently not running.</td>
</tr>
</tbody>
</table>
### Manually configure MID Web Server for metric data

Configure the MID Web Server extension to enable external clients to push metric data to the MID Server. This extension is used to listen for raw metric data as well as external events and it provides options for authentication and data security.

- Deploy and start a MID Server.
- The **Enable REST Listener** option must be selected in the Operational Intelligence Metrics extension. For more information, see [Manually configure the Operational Intelligence extension](#).
- If the **Secure Connection** option is going to be selected, first obtain a server certificate. For more information, see [Setup certificate for secure connection](#).

Role required: evt_mgmt_admin

You can configure the MID Web Server to collect raw metric data by the MID Server and then transmit it to the instance. The MID Web Server extension runs for as long as it is enabled. The extension starts a web server on the MID Server to serve web requests from external systems. The raw data is pushed to the extension from a client or by using customized script.

1. Configure a MID Web Server. For more information, see [Configure the MID Web Server extension](#).
2. Configure the authentication and secure connection settings, as required.
   - **Authentication type** can be set to the more advanced option — **Keybased**.
   - **Secure Connection** lets you choose whether incoming and outgoing data is secured when transmitted. If you choose the more advanced secured option, it requires that you obtain a certificate from a well-known certificate authority, and then provide the **Keystore Certificate Alias** and the **Keystore Password**.
3. Click **Save** to save the Operational Intelligence data.
4. Under **Related Links** click **Start** to start the collector.

#### Commands in the MID Web Server form

<table>
<thead>
<tr>
<th>Related Link</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stop</td>
<td>Stops the running extension on the configured MID Server. No action is taken if the extension is not running.</td>
</tr>
<tr>
<td>Restart</td>
<td>Stops, then starts the extension on the configured MID Server.</td>
</tr>
<tr>
<td>Test</td>
<td>The test is not relevant to Operational Intelligence. Parameters are not tested or validated when <strong>Test</strong> is run.</td>
</tr>
<tr>
<td>Update parameters</td>
<td>Sends the latest saved parameters to the extension.</td>
</tr>
<tr>
<td>Related Link</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Test parameters</td>
<td>The test is not relevant to Operational Intelligence. Parameters are not tested or validated when Test is run.</td>
</tr>
<tr>
<td>Update parameters</td>
<td>Stops and then starts the MID Web Server with new parameters. If none of the parameters are modified, no update is made.</td>
</tr>
</tbody>
</table>

Create an authentication token to be sent with each request (Keybased authentication type).

**Method:** Create a token by constructing a string using defined elements of the HTTP/HTTPS request. Then create an HMAC (Hash Message Authentication Code) of the string by signing the generated string with the auto-generated secret key that is displayed in the Secret Key. This key is unique per context. Send this authentication token in the request header Authorization.

Data for the example:

**Keybased authentication data**

<table>
<thead>
<tr>
<th>Item</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Path to a web service API for sending raw data</td>
<td>URL format: https://&lt;MID Server IP address&gt;:&lt;port number&gt;/api/mid/sa/metrics Use a port number that matches one of the port numbers setup in the Web Server extension. Example: <a href="http://10.10.10.10:8097/api/mid/sa/metrics">http://10.10.10.10:8097/api/mid/sa/metrics</a></td>
</tr>
<tr>
<td>Request type</td>
<td>POST</td>
</tr>
<tr>
<td>Date format</td>
<td>yyyy-MM-dd'T'HH:mm:ss.SSS'Z'</td>
</tr>
<tr>
<td>For example:</td>
<td>2016-06-08T20:54:58.917Z</td>
</tr>
<tr>
<td>Content-Type</td>
<td>application/json</td>
</tr>
</tbody>
</table>

Use the following request elements to generate the required string: HTTP-Verb, Content-Type, Date, and request path. Specify these elements and place them in this order:

- HTTP-Verb + "\n" +
- Content-Type + "\n" +
- Date + "\n" +
- Request-Path

For this example, the request string is:
For the timestamp requirement, a valid timestamp that uses HTTP date header is required for authenticating the request. Ensure that the timestamp is within 15 minutes of the MID Server.

**Example, using Java, that describes how to generate the HMAC of the string that uses defined elements of the HTTP/HTTPS request.**

```java
package sample;
import com.glide.util;
import java.security.SignatureException;
import javax.crypto.Mac;
import javax.crypto.spec.SecretKeySpec;

public class AuthUtil {

private static final String HMAC_SHA1_ALGORITHM = "HmacSHA1";

    /**
     * Generates base64-encode the HMAC(Hash Message Authentication Code) of input data
     *
     * @param data
     * @param key
     * @return
     * @throws java.security.SignatureException
     */
    public static String signData(String data, String key) throws java.security.SignatureException {
        String result;
        try {
            // get an hmac_sha1 key from the raw key bytes
            SecretKeySpec signingKey = new SecretKeySpec(key.getBytes(), HMAC_SHA1_ALGORITHM);

            // create hmac_sha1 Mac instance and initialize with the signing key
            Mac = Mac.getInstance(HMAC_SHA1_ALGORITHM);
            mac.init(signingKey);

            // compute the hmac on input data bytes
            byte[] rawHmac = mac.doFinal(data.getBytes("UTF-8"));

            // base64-encode the hmac
            result = Base64.encode(rawHmac);
        } catch (Exception e) {
            throw new SignatureException("Failed to generate HMAC : " + e.getMessage());
        }
        return result;
    }
}
```

**Setup certificate for secure connection**

To use a secure connection, obtain and configure a server certificate.
You must import the server certificate before you can add it to the Java KeyStore.

1. Add a server certificate to the Java KeyStore.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you have the RSA private key in the Java KeyStore and generated the certificate from that key.</td>
<td>keytool -import -alias keyname -file server.cert -storetype JCEKS -keystore webserver_keystore.jceks -storepass pwd</td>
</tr>
</tbody>
</table>

If you have a PKCS12 file that contains the RSA key and the certificate.

| Description | keytool -importkeystore -destkeystore webserver_keystore.jceks -deststoretype jceks -srckeystore <PKCS12 filename> -srckeystore pkcs12 |

Ensure that the private key password is the same as the Java Keystore password.

To change the password, use this command:

    keytool -keypasswd -keystore webserver_keystore.jceks -alias <key alias>

For testing, you can use this command to generate a self-signed certificate.

    keytool -genkeypair -alias webserver -dname cn=localhost -validity 365 -keyalg RSA -keysize 1024 -keypass mykeypass -storetype jceks -keystore webserver_keystore.jceks -storepass mykeypass

2. Save the webserver_keystore.jceks file under the /keystore directory.

The user must provide the certificate alias and password when configuring the MID Web Server extension. For more information, see Configure the MID Web Server extension.

**Quick start tests for Operational Intelligence**

Validate that Operational Intelligence still works after you make any configuration change such as apply an upgrade or develop an application. Copy and configure these quick start tests to pass when using your instance-specific data.

Operational Intelligence quick start tests require activating the Operational Intelligence plugin (com.snc.sa.metric).
<table>
<thead>
<tr>
<th>Test</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OI: Health Metrics Collection</td>
<td>An individual test that verifies the following:</td>
</tr>
<tr>
<td></td>
<td>· There is at least one Operational Intelligence Metrics extension that is running.</td>
</tr>
<tr>
<td></td>
<td>· There are entries for the ‘Health Metrics’ in the Metric to CI table.</td>
</tr>
<tr>
<td></td>
<td>· For each of the Operational Intelligence Metrics extensions that are currently running, that there is data stored in MetricBase.</td>
</tr>
<tr>
<td></td>
<td>If the test initially fails, wait until the Operational Intelligence Metrics extension runs for at least 10-15 minutes. Then try again.</td>
</tr>
</tbody>
</table>

**Components installed with Operational Intelligence**

Several types of components are installed with activation of the Operational Intelligence (com.snc.sa.metric) plugin, including tables, scheduled jobs, and properties.

*Note:* To view all other components that install with this application, see the Application Files table. For instructions on how to access this table, see Find components installed with an application.

**Scheduled jobs installed**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operational Intelligence — Metric Learner job</td>
<td>Runs daily and builds the statistical models used for anomaly detection.</td>
</tr>
<tr>
<td>Operational Intelligence — Purge old metric schemas and anomaly scores</td>
<td>Cleans up the sa_metric_anomaly_score and the sa_metric_schema_definition tables.</td>
</tr>
<tr>
<td>Operational Intelligence — Sync metric schema to mid</td>
<td>Synchronizing data from the instance to the MID Server in the metric schema table sa_metric_schema_definition.</td>
</tr>
<tr>
<td>Operational Intelligence — Sync tables with mid</td>
<td>Synchronizing data from the instance to the MID Server in tables.</td>
</tr>
<tr>
<td>Operational Intelligence — Table cleanup</td>
<td>Cleaning up tables related to various deletion operations.</td>
</tr>
<tr>
<td>Operational Intelligence — Observation Interval Learner job</td>
<td>Calculates the observation interval using collected data points for all data series.</td>
</tr>
<tr>
<td>Operational Intelligence — Process Stale Anomaly Score – Daily</td>
<td>Daily job that cleans stale anomaly scores, for a specified window of time, in the Metric Anomaly Score (sa_metric_anomaly_score) table. Uses the properties sa_metric.anomaly_score_stale_interval_in_days and sa_metric.anomaly_score.next_stale_interval_in_days to calculate the window of time for cleaning.</td>
</tr>
<tr>
<td>Operational Intelligence — Sync CI Anomaly Scores</td>
<td>Keeps anomaly scores up to date with any deletion of metrics.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>

<td>Operational Intelligence — Local level kalman filter model learner job</td>
<td>Builds local level kalman filter model learner job which runs when user clicks Run Anomaly Test.</td>
</tr>
<tr>
<td>Operational Intelligence — Anomaly Model Test</td>
<td>On-demand scheduled job which runs when user clicks Run Anomaly Test.</td>
</tr>
<tr>
<td>Operational Intelligence — Update Metric CI Type Map</td>
<td>Goes through the different data sources that are used in Advanced Insights Explorer and synchronizes the CI Type to Metric Type Mapping for each of these sources. Runs daily.</td>
</tr>
</tbody>
</table>
| Operational Intelligence — Validate MID Distributed cluster | 1. Checks the status of the cluster node. If status is Started and the status of the Operational Intelligence extension is not any of Started/Starting/Warning (warning with specific errors), then the job changes the status of the cluster node to Stopped. This happens when MID Server stops unexpectedly without notifying the instance that it is stopping.  
2. Checks the status of all cluster nodes on all MID Servers in the cluster.  
   - If the status of all nodes is Stopped and the status of the cluster itself is Started, then the job changes the status of the cluster to Stopped.  
   - If the status of the cluster is Stopped but there are MID Servers with a cluster node that is running, then the job changes the status of the cluster to Started.  
3. Checks the number of Cluster Leaders: If two are detected, then the job stops the entire cluster. This happens when MID Servers are not able to connect with other members of the cluster and form multiple sub-clusters. |
<p>| Event Management - process metric binding events (1000-1020) | Process Operational Intelligence metric binding events separately from Event Management events (bucket range 1000-1020). |

### Create or configure data source registration

Operational Intelligence uses various data sources to collect raw metric data which is later processed and analyzed. These data sources must be registered in the system. For example, you can configure the pre-defined SCOM data source registration to control some aspects of how it processes raw data, or register a new data source.

Role required: evt_mgmt_admin

If raw data is pushed or pulled from a data source that is not registered, Operational Intelligence automatically registers that source and adds a record in the SA Metric Type Registration table. By default, Registration Mode is set to Active, Type Default Mode is set to Active, and Generate Missing CIs is set to false in the new record.

1. Navigate to **Operational Intelligence > Configure > Data Source Registration**. All existing registered data sources are displayed.
2. Click an existing data source to edit, or click **New** to create a new one.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source</td>
<td>Source of metric data.</td>
</tr>
</tbody>
</table>
| Registration Mode | Determines how to process an unknown metric type for the data source that is detected in raw data:  
• **Active**: A new metric is automatically generated based on the unknown metric.  
• **Inactive**: The unknown metric is discarded.  
For SCOM, value is set to **Inactive** by default. |
| Type default mode | Determines if a metric that is automatically generated by the system, is set to be active or inactive.  
For SCOM, value is set to **Inactive** by default. |
Choose and configure metrics to monitor

Operational Intelligence uses data sources that can be monitoring hundreds of metrics for all CIs. Choose for each data source type which details are important for which CIs, and then activate or deactivate the respective monitor type to control the amount of data that is being processed.

See [Get started with Operational Intelligence](#) for the high level steps of setting up Operational Intelligence.

Role required: evt_mgmt_admin

The SCOM data source, available by default, collects about 400 metric types from discovered devices such as '% Available Memory' and '% of Free Space'. Processing data from all metric types can overload the system and impact performance. It might be necessary to deactivate selected metric types for selected CIs to reduce that load.

The overall number of metrics that can be processed, depends on the number of MID Servers and their hardware configuration. For details about hardware requirements and metrics scalability, see [MID Server and MID Server distributed cluster for Operational Intelligence](#).

**Note:** The Active setting (true or false) for a metric in the Monitoring System Metric Types (sa_source_metric_type) table takes precedence over the setting for the corresponding metric in the Metric To CI Mappings (sa_metric_map) table. If a metric type in the Monitoring System Metric Types (sa_source_metric_type) table is disabled, all records related to the corresponding metrics are removed from the Metric To CI Mappings (sa_metric_map) table.

1. Navigate to Operational Intelligence > Configure > Metric Types.
   The Monitoring System Metric Types displays the metric types that are being collected per data source, per CI type.
2. Review the Monitoring System Metric Types list, and set the value in the Active column to false or true as necessary.

<table>

</tbody>
</table>

**Metric binding**

After metric data is collected, Operational Intelligence identifies the CIs and the resources to bind the data to.

The data that is collected on the MID Server is raw and does not relate to any specific CI or resource in the CMDB. To be useful, the data goes through a normalization process that uses CMDB identification rules and event rules to uniquely identify CIs, and to map and bind them to the raw data. Raw data can also be mapped and bound to resources, if binding to a CI is successful and if resource binding is configured.

Records for mapping raw data to CIs are automatically generated and remain in effect for a specified length of time determined by the properties:

- **sa.metric.map.with.ci.expiration.sec**: If the mapping to the CI was found. Set by default to be valid for five days.
- **sa.metric.map.without.ci.expiration.sec**: If mapping to the CI was not found. Set by default to be valid for 24 hours.

When similar metric data arrives within that time period, the existing mapping is used to match the data to CIs. At the end of the time period, metric-to-CI records expire. Also, a change in the event rules triggers an immediate expiration of the respective metric-to-CI records. Next time that raw metric data arrives, it will be normalized again. When Discovery adds or removes CIs, mappings are adjusted to reflect these changes at the next cycle.

**Metric binding to resources**

Bind metrics to resources to simplify metric events binding by enabling binding to resources such as specific disks or web pages, in addition to binding to CIs.

Operational Intelligence models metric series in either of the following methods:

- Binding a metric series to a CI and to the metric being monitored for that CI using a 'CI/Metric' format. For example, 'win_server_001/response_time_mean'.
- Binding a metric series to a CI, a resource within that CI, and the metric being monitored for that resource, using a 'CI/Resource/Metric' format. For example, 'win_server_001/Disk — C/disk_usage'. This method is referred to as 'resource binding'.

The first method enables modeling, storing, aggregating, and querying data at the CI level. However, resource binding creates resource records for specific monitored entities, such as an individual web page or a disk. Therefore, resource binding is more efficient when there are multiple resources of similar types within a CI, and metrics applicable to a category of these resources are mapped to these resources.

Use cases:

- Common examples are disks, processors, and network interfaces. In cases in which these entities are being monitored but do not exist in the CMDB, using resources for metric binding is useful.
- Some monitoring solutions capture metric data within services such as KPIs for individual web pages in an application. In such cases where the entity being monitored is not a configuration item, metric binding to resources can be helpful.
In those situations, using resource binding results in more meaningful aggregations across similar metrics (such as: avg disk_usage for a host across all disks).

**Resource binding process**

The MID Server generates metric binding events that are processed by the instance. When processing a metric binding event, there is an attempt to identify the CI to which this metric binding event belongs. If this attempt is successful, then the metric binding event is bound to the identified CI and binding to a resource is attempted. The following steps describe the attempt to bind a metric binding event to a resource:

1. Identify the CI class of the CI that was bound to the metric binding event.
2. Locate the resource class which is mapped to that CI class (using the CI Type To Resource Class \(sa\_ci\_type\_to\_resource\_class\) table).
3. Read the **resource_path** attribute value in the **additional_information** field in the metric binding event.
4. Check if a resource record exists in the resource class table, in which **name** is equal to **resource_path** and **cmdb\_ci** is equal to the CI that was bound to the metric binding event.
5. If such resource record exists, then the metric binding event is bound to that resource. Otherwise, a new resource record is created with the preceding values and the metric binding event is bound to the newly created resource.

**Configure resource binding**

- Ensure that the **sa\_metric\_use\_resource\_binding** system property is set to true (default).
- For series intended to be bound to resources, ensure that the **resource_path** attribute is populated by doing either step:
  - Use an event rule to add the **resource_path** attribute to the **Additional information** field in events. For more information, see [Create an event rule to map metrics to specific CI](#).
  - Populate the **resource_path** attribute as a part of the respective CI identifier when data is sent to the MID Server for processing.
- Review the default mappings in the CI Type To Resource Class \(sa\_ci\_type\_to\_resource\_class\) table and adjust as needed. It is critical that mappings are set as desired prior to data processing.

  Managing the CI Type To Resource Class table requires the evt_mgmt_admin role.

**Resource tables**

Resource binding uses an underlying hierarchy structure of resources which is a subset of the (cmdb\_ci) hierarchy. Operational Intelligence installs the following resource tables:

- CI Resource (ci\_resource) (parent table):
- Tables that extend CI Resource (ci\_resource):
  - ci\_resource\_hardware
  - ci\_resource\_appl
  - ci\_resource\_service
  - ci\_resource\_vm\_object
Mapping CIs to resources

Mappings of CI classes to resource classes are stored in the CI Type To Resource Class (sa_ci_type_to_resource_class) table. This table is installed with Operational Intelligence, and is used during metric binding to resources.

<table>
<thead>
<tr>
<th>CI class</th>
<th>Resource class</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmdb_ci_hardware</td>
<td>ci_resource_hardware</td>
</tr>
<tr>
<td>cmdb_ci_appl</td>
<td>ci_resource_appl</td>
</tr>
<tr>

<td>ci_resource_service</td>
</tr>
<tr>
<td>cmdb_ci_database</td>
<td>ci_resource_database</td>
</tr>
<tr>
<td>cmdb_ci_vm_object</td>
<td>ci_resource_vm_object</td>
</tr>
</tbody>
</table>

Create an event rule to map metrics to specific CI

Create event rules to map incoming raw metric data to specific CIs, to optionally modify metric names, and to populate the resource_path attribute for resource binding.

The system generates events for every new raw metric data for which there are no CI binding specifications. You can create event rules that filter those events to map the incoming metric data to specific CIs. In such event rules, you can for example define a filter that is based on the monitoring object (such as SCOM).

To use resource binding, the resource_path attribute of events must be populated. You can configure an event rule to ensure that the resource_path attribute is included in the Additional information field in events. For more information about configuring and using resource binding, see resource binding.

For example, in the Event Rule designer you can update the event rule SCOM IIS Web Server as follows:

- On the Event Filter tab, define filter to match only IIS Web Servers.
- On the Binding tab, set Class to Microsoft IIS Web Server.

Create an event rule to bind metric events to host CIs

Create event rules to explicitly allow binding of metric events to host CIs.

Role required: evt_mgmt_admin

Starting with the London release, Operational Intelligence no longer relies on the default Event Management binding workflow which binds nodes to host CIs. Event Management is configured to apply the default host binding algorithm when an event rule cannot find a CI to bind to, based on event data. In Operational Intelligence, with a given event rule and two different events, there can be a situation where one event binds to the correct CI and another event cannot bind. In this case, the same metric types would be created for the selected CI and for the host level CI, causing confusion.

For example: With an event rule that binds the disk percentage metric to a storage disk, one event can find a disk CI and another event cannot. This results in the disk percentage metric being created for a disk CI and for a host CI.
To avoid this confusion, Event Management default host binding is disabled for metric events in the base system. To allow host binding for metric events, explicitly create the following event rule in the Event Management event rule designer. The underlying binding functionality of the event rule designer is used to map metrics to CIs.

1. Navigate to Event Management > Rules > Event Rules to open the event rule designer.
2. Click New and ensure that the rule is set to Active.
3. On the Event Rule Info tab:
   a) Set Source to the data source that this rule applies to.
   b) Enter a Description such as Bind metrics at host level.
4. On the Event Filter tab, set All of these conditions must be met to Classification is Metric.
5. Click Save.

Disable a metric for a CI

Operational Intelligence can be configured to collect significant amounts of data, some of which might not be necessary. To improve performance, you can disable a specific metric for a specific CI to stop processing data related to the specified metric and CI.

Role required: evt_mgmt_admin

![Note: The Active setting (true or false) for a source metric in the Monitoring System Metric Types (sa_source_metric_type) table takes precedence over the setting for the corresponding metric in the Metric To CI Mappings (sa_metric_map) table. If a source metric type in the Monitoring System Metric Types (sa_source_metric_type) table is disabled, all records related to the corresponding metrics are removed from the Metric To CI Mappings (sa_metric_map) table.](image)

1. Navigate to Operational Intelligence > Configure > Metric to CI.
2. Locate the record for the metric/CI that you want to disable, and set its Active column to false.

Disable event collection

For performance reasons, you might want to disable the collection of events from a data source from which metric data is also collected. You can disable event collection for data sources such as Nagios XI server, SolarWinds monitoring system, and Zabbix server.

Role required: evt_mgmt_admin

![Note: To restart event collection after it has been disabled, you will need to restore the connector's original script.](image)

1. Navigate to Event Management > Event Connectors (Pull) > Connector Instances.
2. Select a connector instance for the data source for which to disable event collection. For example, select a connector instance for Nagios, SolarWinds, or Zabbix.
3. Set Event collection schedule (seconds) to a large value such as 20,000,000. Such setting avoids unnecessary communication with the MID Server, optimizing performance.
4. Click Update.
5. Navigate to **MID Server > Script Includes** and extend the connector's script (such as **NagiosMetrics_JS**, **SolarWindsJS**, or **ZabbixJS**) by overriding the **execute** method. Add a code snippet such as the following, and then click **Update**:

**Snippet for Nagios**

```javascript
var NagiosJSCustom = Class.create();

// Extending Nagios default script
NagiosJSCustom.prototype = Object.extendsObject(NagiosJS, {
    // Override execute method
    execute: function() {
        var retVal = {};
        retVal['status'] = SUCCESS.toString();
        retVal['error_message'] = "Disabled by custom Class, 'Last event collection status' will be 'error' and this is normal. To achieve success status, enable event pull in custom class(NagiosJSCustom)";
        return retVal;
    };
});
```

For the **SolarWinds** connector use:

```javascript
var SolarWindsJSCustom = Class.create();

// Extending solarwinds default script
SolarWindsJSCustom.prototype = Object.extendsObject(SolarWindsJS, {
//
});
```

For the **Zabbix** connector use:

```javascript
var ZabbixJSCustom = Class.create();

// Extending zabbix default script
ZabbixJSCustom.prototype = Object.extendsObject(ZabbixJS, {
//
});
```

### Configure anomaly score thresholds

Operational Intelligence scores anomalies on a range 0-10. This range is broken down to the five levels of event severities, each represented by a different color in the Insights Explorer and in the Anomaly Map. You can configure the anomaly score threshold for each level of severity.

Role required: **evt_mgmt_admin**

Anomaly score thresholds are defined in the table **Anomaly Score to Event Severity Map** (`sa_metric_anomaly_score_to_event_severity_map`). For example, by default, anomaly scores from 8 through 9 are severity 2 (Major), and are displayed by dark orange color in the Insights Explorer and in the Anomaly Map.

1. Navigate to **Operational Intelligence > Settings > Anomaly Score to Severity Mapping**.
2. In the **Metric Anomaly Score to Event Severity Maps** list view, double-click the event severity that you want to modify.
3. Modify the range of anomaly scores that map to the respective event severity.
4. Click **Update**.
Configure metric connector instances

Use Operational Intelligence connector definitions to create connector instances that pull metric data from event collection systems. Operational Intelligence then analyses metric data to detect anomalies and provide statistical scores.

Operational Intelligence plugin (com.snc.sa.metric) must be activated for the Operational Intelligence connectors to appear in the base system. In addition, each connector requires a credential that lets the instance access the data collection system accounts. You can use an existing credential or create a new one as needed.

Event Management and Operational Intelligence share some connector definitions and connector instances when pulling events and metric data from the same data source. Therefore, if a connector instance for a specific data source already exists, configure that connector instance to also pull metric data instead of creating another connector instance. Create a new connector instance for a data source only if such connector instance does not exist.

Supported connectors specific to Operational Intelligence

<table>
<thead>
<tr>
<th>Connector to</th>
<th>Supported versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Web Service (AWS)</td>
<td>NA</td>
</tr>
<tr>
<td>Microsoft Azure platform</td>
<td>NA</td>
</tr>
</tbody>
</table>

Supported connectors shared between Operational Intelligence and Event Management

<table>
<thead>
<tr>
<th>Connector to</th>

</tr>
</thead>
<tbody>
<tr>
<td>Nagios XI server</td>
<td>5.4.0</td>
</tr>
<tr>
<td>SolarWinds monitor</td>
<td>NPM 12.0, SAM 6.2.1</td>
</tr>
<tr>
<td>Zabbix server</td>
<td>3.0, 3.2</td>
</tr>
</tbody>
</table>

Create an Azure metric connector instance

Operational Intelligence provides the Azure connector definition which you can use to create a connector instance to pull metric data from the Microsoft Azure platform. Operational Intelligence then analyses metric data to provide statistical scores and detect anomalies.

Operational Intelligence plugin (com.snc.sa.metric) must be activated for the Operational Intelligence connectors to appear in the base system. In addition, the Azure connector requires an Azure Service Principal type credential that lets the instance access Azure platform accounts. You can use an existing credential or create a new one.

Role required: evt_mgmt_admin

After you configure the Azure connector, you can run a test to ensure that the MID Server can authenticate itself to the Azure platform account.

1. Navigate to Event Management > Event Connectors (Pull) > Connector Instances.
2. Click **New**.
3. Fill out the Connector Instance form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name for the connector instance record, such as the name of event source host.</td>
</tr>
<tr>
<td>Description</td>
<td>Any optional information that the administrator wants to use to identify this record.</td>
</tr>
<tr>
<td>Connector definition</td>
<td>Vendor and protocol used to gather metric data from the external source. Select <strong>AzureConnector</strong>.</td>
</tr>
<tr>
<td>Host IP</td>
<td>Not used for this connector. Therefore any value such as 1.1.1.1, is valid.</td>
</tr>
<tr>
<td>Metrics collection</td>
<td>Designates collection of metric data for Operational Intelligence.</td>
</tr>
<tr>
<td>Metrics collection last run time</td>
<td>The date and time of the most recent metric data collection. The value of this field is automatically populated.</td>
</tr>
<tr>
<td>Last metrics collection status</td>
<td>Status of the metric data collection activity. The value of this field is automatically populated.</td>
</tr>
<tr>
<td></td>
<td>This option appears only if the connector definition that is selected supports metric collection (such as SCOM) and if the <strong>Metrics collection</strong> option is selected.</td>
</tr>
<tr>
<td>Metrics collection schedule (seconds)</td>
<td>The time, in seconds, to repeat the metric data collection scheduled job.</td>
</tr>
<tr>
<td></td>
<td>This option appears only if the connector definition that is selected supports metric collection (such as SCOM) and when the <strong>Metrics collection</strong> option is selected.</td>
</tr>
<tr>
<td>Credential</td>
<td>A valid credential of the Azure Service Principal type, to the Microsoft Azure platform data source host. Click the <strong>Lookup using list</strong> icon to select a credential, or to create a new one.</td>
</tr>
<tr>
<td>Last error message</td>
<td>Last error message received by the connector. If the test connector fails, an error message appears in this field.</td>
</tr>
</tbody>
</table>

4. In the MID Servers for Connectors related list, click **Insert a new row** and then select an Operational Intelligence MID Server to send metric data to.
5. Right-click the form header and select **Save**.
6. In the Connector Instance Values related list, for each name, double-click the **Value** column and enter values as follows:
<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>max_fetch_interval_min</td>
<td>Maximum time in minutes to go back to for retrieving data. Example value: 180</td>
</tr>
<tr>
<td>offset_min</td>
<td>Number of minutes to shift the time interval back by. Used to offset a delay in the availability of data on external systems. For example, data for 12PM is available only at 12:00:30 which is a 30 seconds delay. offset_min ensures reading that data, which otherwise might have been missed. Example value: 5</td>
</tr>
<tr>
<td>subscription_id</td>
<td>A unique GUID for your subscription to Azure services. To obtain your subscription ID: 1. Log on to the Azure portal. 2. In the left navigation panel, click Subscriptions to list your subscriptions and the subscription ID.</td>
</tr>
</tbody>
</table>

7. Click Test connector to verify that the MID Server can communicate with the external server host.
   
   If the test fails, follow the instructions on the page to correct the problem and then run another test. The description of the reason for failure is shown in the MID Server log, according to the type of error, such as Events, Metrics, or Bi-Directional.

8. After a successful test, select the Active check box and then click Update.

Create an AWS metric connector instance

Operational Intelligence provides the AWS CloudWatch connector definition which you can use to create a connector instance to pull metric data from Amazon Web Service (AWS). Operational Intelligence then analyses metric data to provide statistical scores and detect anomalies.

Operational Intelligence plugin (com.snc.sa.metric) must be activated for the Operational Intelligence connectors to appear in the base system. In addition, the AWS connector requires an AWS Credentials type credential that lets the instance access AWS accounts. You can use an existing credential, or create a new one.

Role required: evt_mgmt_admin

After you configure the AWS CloudWatch connector, you can run a test to ensure that the MID Server can authenticate itself to the AWS account and read data from the account.

1. Navigate to Event Management > Event Connectors (Pull) > Connector Instances.
2. Click New.
3. Fill out the Connector Instance form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name for the connector instance record, such as the name of event source host.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Description</td>
<td>Any optional information that the administrator wants to use to identify this record.</td>
</tr>
<tr>
<td>Connector definition</td>
<td>Vendor and protocol used to gather metric data from the external source.</td>
</tr>
<tr>
<td></td>
<td>Select AWS CloudWatch.</td>
</tr>
<tr>
<td>Host IP</td>
<td>Not used for this connector. Therefore any value such as 1.1.1.1, is valid.</td>
</tr>
<tr>
<td>Metrics collection</td>
<td>Designates collection of metric data for Operational Intelligence.</td>
</tr>
<tr>
<td>Metrics collection last run time</td>
<td>The date and time of the most recent metric data collection. The value of this field is automatically populated.</td>
</tr>
<tr>
<td>Last metrics collection status</td>
<td>Status of the metric data collection activity. The value of this field is automatically populated. This option appears only if the connector definition that is selected supports metric collection (such as SCOM) and if the <strong>Metrics collection</strong> option is selected.</td>
</tr>
<tr>
<td>Metrics collection schedule (seconds)</td>
<td>The time, in seconds, to repeat the metric data collection scheduled job.</td>
</tr>
<tr>
<td></td>
<td>This option appears only if the connector definition that is selected supports metric collection (such as SCOM) and when the <strong>Metrics collection</strong> option is selected.</td>
</tr>
<tr>
<td>Credential</td>
<td>A valid credential of the AWS Credentials type, to the AWS metric data source host. Click the <strong>Lookup using list</strong> icon to select a credential, or to create a new one.</td>
</tr>
<tr>
<td>Last error message</td>
<td>Last error message received by the connector. If the test connector fails, an error message appears in this field.</td>
</tr>
</tbody>
</table>

4. In the MID Servers for Connectors related list, click **Insert a new row** and then select an Operational Intelligence MID Server to send metric data to.

5. Right-click the form header and select **Save**. The Connector Instance Values related list appears.

6. In the Connector Instance Values related list, for each name, double-click the **Value** column and enter values as follows:

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>account_id</td>
<td>The AWS account identification.</td>
</tr>
<tr>
<td>max_fetch_interval_min</td>
<td>Maximum time in minutes to go back to for retrieving data. Example value: 180</td>
</tr>
</tbody>
</table>
### Offset Min

**Name:** offset_min  
**Value:** Number of minutes to shift the time interval back by.  
**Description:** Used to offset a delay in the availability of data on external systems. For example, data for 12PM is available only at 12:00:30 which is a 30 seconds delay. `offset_min` ensures reading that data, which otherwise might have been missed.  
**Example value:** 5

### Period Sec

**Name:** period_sec  
**Value:** The granularity in seconds of the returned data points.  
**Example value:** 60

### Regions

**Name:** regions  
**Value:** Regions (as they are defined in the AWS account), to get data from.

---

7. Click **Test connector** to verify that the MID Server can communicate with the external server host.  
   If the test fails, follow the instructions on the page to correct the problem and then run another test. The description of the reason for failure is shown in the MID Server log, according to the type of error, such as Events, Metrics, or Bi-Directional.  
8. After a successful test, select the **Active** check box and then click **Update**.

---

### Configure a Zabbix metric connector instance

Event Management provides the Zabbix connector definition which you can use to configure or create a connector instance to pull metric data from a Zabbix server. Operational Intelligence then analyses metric data to provide statistical scores and detect anomalies.

Event Management and Operational Intelligence share a single connector definition and a single connector instance to pull events and metric data from a Zabbix server. You can configure this shared connector to pull from the data source only events, only metric data, or both. Therefore, it is important to search all connector instances for an existing Zabbix connector instance that is already configured for pulling events. If such connector exists, update that connector instance to also pull metric data.

To start:

1. Decide if you want to create a Zabbix connector instance for pulling only events, only metric data, or both.  
2. Navigate to **Event Management > Event Connectors (Pull) > Connector Instances** and search for an existing Zabbix connector instance that is already configured for pulling events.  
3. If you want to create a Zabbix connector instance for pulling both events and metric data and a Zabbix connector does not exist:
   1. **Configure event collection from Zabbix server.**  
   2. **Configure** that same connector to pull metric data as described in the following procedure.

The Zabbix connector instance requires a credential that lets the instance access Zabbix monitoring system accounts. You can use an existing credential or **create a new one**.
Role required: evt_mgmt_admin

After you configure the Zabbix connector, you can run a test to ensure that the MID Server can authenticate itself to the Zabbix server account and read data from the account.

**Note:** Depending on whether you are creating a new connector instance or updating an existing one, some of the following steps might not be necessary. Do not skip the *Optional* steps if you are creating a new connector instance for pulling metric data only.

1. Navigate to **Event Management > Event Connectors (Pull) > Connector Instances**.
2. Select an existing Zabbix connector instance that is already configured to pull events, or click **New**.
3. Fill out the Connector Instance form.
   - If you are updating a connector instance that is already configured for Event Management, then some of the following fields are already set.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name for the connector instance record, such as the name of event source host.</td>
</tr>
<tr>
<td>Description</td>
<td>Any optional information that the administrator wants to use to identify this record.</td>
</tr>
<tr>
<td>Connector definition</td>
<td>Vendor and protocol used to gather metric data from the external source. Select Zabbix.</td>
</tr>
<tr>
<td>Host IP</td>
<td>Not used for this connector. Therefore any value such as 1.1.1.1, is valid.</td>
</tr>
<tr>
<td>Metrics collection</td>
<td>Designates collection of metric data for Operational Intelligence.</td>
</tr>
<tr>
<td>Metrics collection last run time</td>
<td>The date and time of the most recent metric data collection. The value of this field is automatically populated.</td>
</tr>
<tr>
<td>Last metrics collection status</td>
<td>Status of the metric data collection activity. The value of this field is automatically populated. This option appears only if the connector definition that is selected supports metric collection (such as SCOM) and if the <strong>Metrics collection</strong> option is selected.</td>
</tr>
<tr>
<td>Metrics collection schedule (seconds)</td>
<td>The time, in seconds, to repeat the metric data collection scheduled job. This option appears only if the connector definition that is selected supports metric collection (such as SCOM) and when the <strong>Metrics collection</strong> option is selected.</td>
</tr>
<tr>
<td>Credential</td>
<td>A valid credential of the Basic Auth Credentials type, to the Zabbix metric data source host. Click the <strong>Lookup using list</strong> icon to select a credential, or to create a new one.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Last error message</td>
<td>Last error message received by the connector. If the test connector fails, an error message appears in this field.</td>
</tr>
</tbody>
</table>

4. Optional: In the MID Servers for Connectors related list, click **Insert a new row** and then select an Operational Intelligence MID Server to send metric data to.

5. Optional: Right-click the form header and select **Save**. The Connector Instance Values related list appears.

6. In the Connector Instance Values related list, review the following parameters, each affecting event collection, or metric data collection, or both. These parameters are preconfigured and it is not necessary to modify the default values. However, it is possible to modify a value by double-clicking the **Value** column and entering a new value.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>groupids</td>
<td>One or more host group IDs from which to collect metrics. To specify multiple host IDs, enter a comma-separated list of host group IDs such as 1, 2, 7. To identify a host group ID 1. On Zabbix server, navigate to <strong>Configuration &gt; Host Groups</strong>. 2. Select a group and note the group’s ID.</td>
</tr>
<tr>
<td>max_fetch_interval_min</td>
<td>Maximum time in minutes to go back to for retrieving data. Optional value: 180</td>
</tr>
<tr>
<td>offset_min</td>
<td>Number of minutes to shift the time interval back by. Used to offset a delay in the availability of data on external systems. For example, data for 12PM is available only at 12:00:30 which is a 30 seconds delay. <strong>offset_min</strong> ensures reading that data, which otherwise might have been missed. Optional value: 5</td>
</tr>
<tr>
<td>port</td>
<td>The port number to use with the specified <strong>protocol</strong>. For example, <strong>protocol</strong> is set to <strong>http</strong> and <strong>port</strong> is set to 80.</td>
</tr>
<tr>
<td>protocol</td>
<td>Protocol that is used with Zabbix server, such as <strong>http</strong> or <strong>https</strong>.</td>
</tr>
<tr>
<td>with_triggers</td>
<td>If <strong>true</strong>, then the connector collects only metrics that have triggers. With any other value, the connector collects data for all metrics.</td>
</tr>
</tbody>
</table>

7. Click **Test connector** to verify that the MID Server can authenticate itself to the Zabbix server account to enable communication. If the test fails, follow the instructions on the page to correct the problem and then run another test. The description of the reason for failure is
shown in the MID Server log, according to the type of error, such as Events, Metrics, or Bi-
Directional.

8. After a successful test, select the **Active** check box and then click **Update**.

9. Optional: **Disable event collection**.

1. **Create or configure data source registration** to register new metric types incoming from the Zabbix server.

2. **Enable or disable metrics** to limit metric collection from the Zabbix server to only specific data that is needed.

3. To ensure that metric data is pulled:
   - Verify that **Collect metrics** in the connector definition is selected.
   - Verify that **Metrics collection** in the connector instance is selected.
   - Verify that **Registration mode** in the metric type registration is set to **Active**.

**Configure a SolarWinds metric connector instance**

Event Management provides the SolarWinds connector definition which you can use to configure or create a connector instance to pull metric data from the SolarWinds monitoring system. Operational Intelligence then analyses metric data to provide statistical scores and detect anomalies.

Event Management and Operational Intelligence share a single connector definition and a single connector instance to pull events and metric data from the SolarWinds data source. You can configure this shared connector to pull from the data source only events, only metric data, or both.

Therefore, it is important to search all connector instances for an existing SolarWinds connector instance that is already configured for pulling events. If such connector exists, update that connector instance to also pull metric data.

To start:

1. Decide if you want to create a SolarWinds connector instance for pulling only events, only metric data, or both.

2. Navigate to **Event Management > Event Connectors (Pull) > Connector Instances** and search for an existing SolarWinds connector instance that is already configured for pulling events.

3. If you want to create a SolarWinds connector instance for pulling both events and metric data and a SolarWinds connector does not exist:
   a. **Create a SolarWinds connector instance for pulling events**.
   b. Configure that same connector to pull metric data as described in the following procedure.

The SolarWinds connector instance requires a credential that lets the instance access SolarWinds monitoring system accounts. You can use an existing credential or create a new one.

Role required: evt_mgmt_admin

The SolarWinds connector does not pull all the metric data that the SolarWinds monitoring system collects, only the following metrics from the following tables:

- CPU and memory metrics from table: (Orion.CPULoad)
  - MinLoad, MaxLoad, AvgLoad, MinMemoryUsed, MaxMemoryUsed, AvgMemoryUsed, AvgPercentMemoryUsed
Default event rules bind CPU metrics at the Host level CIs.

- Interface traffic metrics from table: (Orion.NPM.InterfaceTraffic):

Default event rules bind interface metrics at the Interface level CIs.

- Response time metrics from table: (Orion.ResponseTime):
  - AvgResponseTime, MinResponseTime, MaxResponseTime, PercentLoss, PercentDown, Availability

Default event rules bind response time metrics at the Host level CIs.

- Volume usage metrics from table: (Orion.VolumeUsageHistory):
  - DiskSize, AvgDiskUsed, MinDiskUsed, MaxDiskUsed, PercentDiskUsed, AllocationFailures

Default event rules bind volume performance metrics at the Volume level CIs.

- Volume performance metrics from table: (Orion.VolumePerformanceHistory):
  - AvgDiskQueueLength, MinDiskQueueLength, MaxDiskQueueLength, AvgDiskTransfer, MinDiskTransfer, MaxDiskTransfer, AvgDiskReads, MinDiskReads, MaxDiskReads, AvgDiskWrites, MinDiskWrites, MaxDiskWrites

Default event rules bind volume usage metrics at the Volume level CIs.

---

**Note:** Depending on whether you are creating a new connector instance or updating an existing one, some of the following steps might not be necessary. Do not skip the **Optional** steps if you are creating a new connector instance for pulling metric data only.

1. Navigate to **Event Management > Event Connectors (Pull) > Connector Instances**.
2. Select an existing SolarWinds connector instance that is already configured to pull events, or click **New**.
3. Fill out the connector instance form.

   If you are updating a connector instance that is already configured for Event Management, then some of the following fields are already set.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name for the connector instance record, such as the name of event source host.</td>
</tr>
<tr>
<td>Description</td>
<td>Any optional information that the administrator wants to use to identify this record.</td>
</tr>
<tr>
<td>Connector definition</td>
<td>Vendor and protocol used to gather metric data from the external source. Select SolarWinds.</td>
</tr>
<tr>
<td>Host IP</td>
<td>Host IP of the SolarWinds server.</td>
</tr>
<tr>
<td>Credential</td>
<td>A valid credential to the SolarWinds host. Click the <strong>Lookup using list</strong> icon to select a credential, or to create a new one.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Metrics collection</td>
<td>Designates collection of metric data for Operational Intelligence.</td>
</tr>
<tr>
<td>Metrics collection last run time</td>
<td>The date and time of the most recent metric data collection. The value of this field is automatically populated.</td>
</tr>
<tr>
<td>Last metrics collection status</td>
<td>Status of the metric data collection activity. The value of this field is automatically populated.</td>
</tr>
<tr>
<td>Metrics collection schedule (seconds)</td>
<td>The time, in seconds, to repeat the metric data collection scheduled job.</td>
</tr>
<tr>
<td>Last error message</td>
<td>Last error message received by the connector. If the test connector fails, an error message appears in this field.</td>
</tr>
</tbody>
</table>

4. Optional: In the MID Servers for Connectors related list, click **Insert a new row** and then select an Operational Intelligence MID Server to send metric data to.

5. Optional: Right-click the form header and select **Save**. The Connector Instance Values related list appears.

6. In the Connector Instance Values related list, review the following parameters, each affecting event collection, or metric data collection, or both. These parameters are preconfigured and it is not necessary to modify the default values. However, it is possible to modify a value by double-clicking the **Value** column and entering a new value.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>initial_sync_in_days</td>
<td>Number of days of data that the initial pull must contain. Default value is 7 days.</td>
</tr>
<tr>
<td>max_fetch_interval_min</td>
<td>Maximum time in minutes to go back to for retrieving data. Optional value: 180</td>
</tr>
<tr>
<td>nodes_custom_properties</td>
<td>SolarWind property names that are associated with the relevant node. This information is added to the Additional Information field of the event in JSON format. SolarWinds monitoring system custom properties are user-defined fields, such as country, that you can associate with monitored network objects. Separate multiple entries with a comma.</td>
</tr>
<tr>
<td>offset_min</td>
<td>Number of minutes to shift the time interval back by. Used to offset a delay in the availability of data on external systems. For example, data for 12PM is available only at 12:00:30 which is a 30 seconds delay. offset_min ensures reading that data, which otherwise might have been missed. Optional min value: greater than 1</td>
</tr>
</tbody>
</table>
7. Click **Test connector** to verify that the MID Server can authenticate itself to the SolarWinds server account to enable communication. If the test fails, follow the instructions on the page to correct the problem and then run another test. The description of the reason for failure is shown in the MID Server log, according to the type of error, such as Events, Metrics, or Bi-Directional.

8. After a successful test, select the **Active** check box and then click **Update**.

9. Optional: **Disable event collection**.

1. **Create or configure data source registration** to register new metric types incoming from the SolarWinds monitoring system.

2. **Enable or disable metrics** to limit metric collection from the SolarWinds monitoring system to only specific data that is needed.

3. To ensure that metric data is pulled:
   - Verify that **Collect metrics** in the connector definition is selected.
   - Verify that **Metrics collection** in the connector instance is selected.
   - Verify that **Registration mode** in the metric type registration is set to **Active**.

**Add optional parameters to the connector definition**
You can add optional parameters to the SolarWinds connector definition, which then appear as optional values for the instance.

Role required: admin

You can add the following connector parameters:

<table>
<thead>
<tr>
<th>Connector parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>debug</td>
<td>A basic level of logging for the queries and responses between the MID Server and the SolarWinds system.</td>
</tr>
<tr>
<td>debug_response</td>
<td>A more detailed level of logging for the queries and responses between the MID Server and the SolarWinds system. Add this parameter temporarily to help with troubleshooting.</td>
</tr>
</tbody>
</table>

1. Navigate to **Event Management > Connector Instances** and edit each SolarWinds connector instance:
   a) Clear **Active**.
   b) Click **Update**.

3. At the bottom of the Connector Parameters list, click **Insert a new row** and add a parameter.

4. Click **Update**.

5. Navigate back to **Event Management > Connector Instances** and edit each SolarWinds connector instance:
a) In the Connector Instance Values section on the Connector Instance form, set values for the new parameters.

b) Select Active.

c) Click Update.

Configure Nagios metric connector instance

Event Management provides the Nagios connector definition which you can use to configure or create a connector instance to pull metric data from the Nagios XI server. Operational Intelligence then analyses metric data to provide statistical scores and detect anomalies.

Event Management and Operational Intelligence share a single connector definition and a single connector instance to pull events and metric data from the Nagios XI data source. You can configure this shared connector to pull from the data source only events, or events and metric data.

Therefore, it is important to search all connector instances for an existing Nagios connector instance that is already configured for pulling events. If such connector exists, you will update that connector instance to also pull metric data.

To start:

1. Decide if you want to create a Nagios connector instance for pulling only events, event and metric data.

2. Navigate to Event Management > Event Connectors (Pull) > Connector Instances and search for an existing Nagios connector instance that is already configured for pulling events.

3. If you want to create a Nagios connector instance for pulling both events and metric data and a Nagios connector does not exist:
   a. Configure event collection from Nagios XI.
   b. Configure that same connector to pull metric data as described in the following procedure.

The Nagios connector instance requires a credential that lets the instance access Nagios XI server accounts. You can use an existing credential or create a new one.

Role required: evt_mgmt_admin

![Note: Depending on whether you are creating a new connector instance or updating an existing one, some of the following steps might not be necessary. Do not skip the Optional steps if you are creating a new connector instance for pulling metric data only.]

1. Navigate to Event Management > Event Connectors (Pull) > Connector Instances.

2. Select an existing Nagios connector instance that is already configured to pull events, or click New.

3. Fill out the connector instance form.
   If you are updating a connector instance that is already configured for Event Management, then some of the following fields are already set.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name for the connector instance record, such as the name of event source host.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Description</td>
<td>Any optional information that the administrator wants to use to identify this record.</td>
</tr>
<tr>
<td>Connector definition</td>
<td>Vendor and protocol used to gather metric data from the external source. Select NagiosXI.</td>
</tr>
<tr>
<td>Host IP</td>
<td>Host IP of the Nagios server.</td>
</tr>
<tr>
<td>Credential</td>
<td>A valid credential to the Nagios data source host. Click the Lookup using list icon to select a credential, or to create a new one.</td>
</tr>
<tr>
<td>Metrics collection</td>
<td>Designates collection of metric data for Operational Intelligence.</td>
</tr>
<tr>
<td>Metrics collection last run time</td>
<td>The date and time of the most recent metric data collection. The value of this field is automatically populated.</td>
</tr>
<tr>
<td>Last metrics collection status</td>
<td>Status of the metric data collection activity. The value of this field is automatically populated. This option appears only if the connector definition that is selected supports metric collection (such as SCOM) and if the Metrics collection option is selected.</td>
</tr>
<tr>
<td>Metrics collection schedule (seconds)</td>
<td>The time, in seconds, to repeat the metric data collection scheduled job. This option appears only if the connector definition that is selected supports metric collection (such as SCOM) and when the Metrics collection option is selected.</td>
</tr>
<tr>
<td>Metrics database host</td>
<td>IP address or the host name of the database used by the Nagios system.</td>
</tr>
<tr>
<td>Metrics database port</td>
<td>Port for the database used by the Nagios system.</td>
</tr>
<tr>
<td>Metrics database credential</td>
<td>Credentials for the database that is used by the Nagios system.</td>
</tr>
<tr>
<td>Last error message</td>
<td>Last error message received by the connector. If the test connector fails, an error message appears in this field.</td>
</tr>
</tbody>
</table>

4. Optional: In the MID Servers for Connectors related list, click **Insert a new row** and then select an Operational Intelligence MID Server to send metric data to.

5. Optional: Right-click the form header and select **Save**. The Connector Instance Values related list appears.

6. In the Connector Instance Values related list, review the following parameters, each affecting event collection, or metric data collection, or both. These parameters are preconfigured and it is not necessary to modify the default values. However, if need to, it is possible to modify a value by double-clicking the **Value** column and entering a new value.
<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>max_fetch_interval_min</td>
<td>Maximum time in minutes to go back to for retrieving data.</td>
</tr>
<tr>
<td></td>
<td>Optional value: 180</td>
</tr>
<tr>
<td>Note:</td>
<td>Required for pulling metric data.</td>
</tr>
<tr>
<td>port</td>
<td>The port of the Nagios server.</td>
</tr>
<tr>
<td></td>
<td>Default value is 17778</td>
</tr>
<tr>
<td>Note:</td>
<td>Required for pulling metric data.</td>
</tr>
<tr>
<td>debug</td>
<td>A basic level of logging for the queries and responses between the MID Server and the Nagios system.</td>
</tr>
</tbody>
</table>

7. Click **Test connector** to verify that the MID Server can authenticate itself to the Nagios XI server account to enable communication. If the test fails, follow the instructions on the page to correct the problem and then run another test. The description of the reason for failure is shown in the MID Server log, according to the type of error, such as Events, Metrics, or Bi-Directional.

8. After a successful test, select the **Active** check box and then click **Update**.

9. Optional: **Disable event collection**.

10. The Nagios metrics connector uses the servicechecks and hostchecks tables in the Nagios XI system to pull metrics data. If data is not flowing into the servicechecks and hostchecks tables in the Nagios XI system, complete the following steps. For more information about configuring the Nagios XI server to use individual options instead of data_processing_options, see [ND Москвы - Data Processing Options in ndomod.cfg](#) in the Nagios Support Knowledgebase.

   a) On the Nagios server, edit the file `/usr/local/nagios/etc/ndomod.cfg`.

   b) Comment out the data_processing_options line by adding `#` at the beginning of the line:
   ```
   #data_processing_options=67108669
   ```

   c) Paste the following snippet after the line you just commented out:
   ```
   acknowledgement_data=1
   adaptive_contact_data=1
   adaptive_host_data=1
   adaptive_program_data=1
   adaptive_service_data=1
   aggregated_status_data=1
   comment_data=1
   contact_status_data=1
   downtime_data=1
   event_handler_data=1
   external_command_data=1
   flapping_data=1
   host_check_data=0
   host_status_data=1
   log_data=1
   main_config_data=1
   notification_data=1
   object_config_data=1
   process_data=1
   ```
program_status_data=1
retention_data=1
service_check_data=0
service_status_data=1
statechange_data=1
system_command_data=1
timed_event_data=0

d)  Save the file.
e)  Restart the Nagios service:
    service nagios restart

1. **Create or configure data source registration** to register new metric types incoming from the Nagios system.

2. **Enable or disable metrics** to limit metric collection from the Nagios system to only specific data that is needed.

3. To ensure that metric data is pulled:
   - Verify that **Collect metrics** in the connector definition is selected.
   - Verify that **Metrics collection** in the connector instance is selected.
   - Verify that **Registration mode** in the metric type registration is set to **Active**.

### Create configuration settings rule

Configuration settings affect how metric data is processed. Configuration settings rules override the default values of these configuration settings, letting you build efficient statistical models for different CI classes.

Role required: evt_mgmt_admin

A number of configuration settings determine the behavior of Operational Intelligence MID Servers. In the base system, these configuration settings are configured with default values, data types, and range of valid values. You cannot directly modify these configuration settings or add new ones. However, you can create a metric configuration rule with new configuration settings that override the default values on the MID Servers.

Then, manually apply these rules to all Operational Intelligence MID Servers in a single synchronization operation, or rely on an hourly system job to perform the synchronization.

To take effect, Operational Intelligence MID Servers must be synchronized with the updates to the configuration settings rules.

It is valid to have multiple rules for a setting that affect the same CIs, in which case:

- **Rules in which a filter is defined take precedence over a global rule in which no filter has been defined.**
- **If multiple rules that affect the same set of CIs have the same priority, then only the latest rule to be defined is applied.**
- **If multiple rules with different priorities affect the same set of CIs, then rules with the highest priority are applied.**

1. **Navigate to Operational Intelligence > Configure > Metric Config Rules.**
2. On the Metric Configuration Rules pane, click **New**, and fill out the form.
Metric Configuration Rules form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Rule name.</td>
</tr>
<tr>
<td>Order</td>
<td>Rule priority within all other rules. Higher numbers represent higher priorities.</td>
</tr>
<tr>
<td>Filter by</td>
<td>Check box for displaying the <strong>Rule</strong> field, where you can specify conditions that CIs must meet for the rule to apply. For example, in the <strong>choose field</strong> list, select <strong>Add Related Fields</strong> and then add the filter (<code>class(is)('Linux Server')</code>). If clear, the rule applies globally to all CIs in the Metric To CI Mapping (sa_metric_map) table.</td>
</tr>
</tbody>
</table>

3. Right-click the form title, and click **Save**.

4. In the Metric overridden configurations form section click **New**, fill out the form, and then click **Submit**.

**Synchronize configuration settings rules**

Operational Intelligence configuration settings rules contain user specified values that override default values that currently exist on Operational Intelligence MID Servers. To take effect, the Operational Intelligence MID Servers must be synchronized with the updated set of configuration settings rules.

Role required: evt_mgmt_admin

You can manually initiate a synchronization to immediately apply the updates on all Operational Intelligence MID Servers. Or, you can rely on a system job, that runs on an hourly recurring schedule, checking for updates to the metric configuration rules. If it is determined that there are updates, the system job sends these updates to the Operational Intelligence MID Servers.

1. Navigate to **Operational Intelligence > Configure > Metric Config Rules**.
2. On the Metric Configuration Rules pane, click **Sync to MID**.
   - Verify that all Operational Intelligence MID Servers have been synchronized with the updated set of configuration settings rules:
     1. Navigate to **Output and Artifacts > ECC Queue**.
     2. In the **Queues** pane, search the **Topics** column for **MetricConfigProbe**.
     3. Check the **Agent** column and verify that all MID Servers are updated.
Configure the action level of anomaly detection

Create a configuration setting rule that refines the level of anomaly detection processing and analysis that is applied to specific CIs and metrics. Set a processing level that reflects the importance of metrics at different stages of implementation, to reduce data load if needed.

Anomaly detection consists of multiple levels of processing. At the lowest level, metric data is gathered from data sources. At the highest level, statistical models are created, anomaly scores are calculated, and anomaly alerts and IT alerts are created. You can apply the full anomaly detection process or a reduced level of processing, for specific data series.

Use the `anomaly_detection_action_level` configuration setting in a configuration setting rule to set the level of processing for specific CIs and metrics. For example, you can initially set only a small percentage of CIs and metrics to generate anomaly alerts, and later increase that percentage.

Action levels

The `anomaly_detection_action_level` configuration setting provides action levels starting at ‘Metrics only’ for basic anomaly processing, and ending at ‘IT Alerts’ for full processing and analysis.

Action levels from lowest to highest:

- **Metrics Only**
  Only gather metrics from the data source without any further processing.

- **Bounds**
  ‘Metrics Only’ processing level and in addition creates statistical model and show bounds in Insights Explorer.

- **Anomaly Scores**
  ‘Bounds’ processing level and in addition calculates and display anomaly scores.

- **Anomaly Alerts**
  ‘Anomaly Scores’ processing level and in addition creates anomaly alerts as applicable.

- **IT Alerts**
  ‘Anomaly Alerts’ processing level and in addition creates IT alerts which are based on anomaly alerts, as applicable. Creating IT alerts which are based on anomaly alerts, is equivalent to having an alert promotion rules.

Specify custom upper and lower metric bounds

Use the Bounds Settings wizard to override learned control bounds by specifying custom upper and lower bounds for an Operational Intelligence metric.

Role required: evt_mgmt_admin

Operational Intelligence calculates upper and lower control bounds for metrics using statistical models learned from historical metric data. Upper and lower bounds are then used in the analysis for detecting anomalous CIs or resources, affecting anomaly scores. Based on historical data, some CIs, resources, or metrics might have values that you specifically want or do not want to be notified about, despite the calculated ranges. For example, trying to meet an SLA without allowing a metric to exceed or be below a certain value for too long without being notified. When concrete upper or lower bound values are known for a metric, you can configure that
metric with custom bounds to override the calculated bounds. For example, a CPU metric which does not exceed 85%.

Use the Bounds Settings wizard to specify custom static bounds or ranges of bounds, and to preview anomaly analysis of actual data based on the custom settings. The metric class and the configuration setting rule that custom bounds must be associated with, are both automatically generated by the Bounds Settings wizard.

In the Bounds Settings wizard, you can choose one of the following options for custom control bounds:

**Static upper and lower bounds**

Custom static upper and lower bound values are used as the control bounds in effect, completely overriding the learned values for upper and lower bounds for the metric. The median of the metric data must be within the specified static bounds range, otherwise the static bounds are not applied.

**Ranges for upper and lower bounds**

Custom upper and lower bounds, each expressed as a range of values. The bounds in effect are a combination of the custom minimum and maximum values that define the bound range, and the learned upper and lower bounds:

- If a learned bound value for a point in time is within the custom range of upper or lower bound, then the learned bound value is in effect.
- If a learned bound value for a point in time is outside the custom range, then the Max or the Min values of the custom range are in effect respectively. If the learned value exceeds the custom range, then the custom Max value is in effect, and if below then the Min custom value is in effect.

When a metric value is outside a control bound, the deviation from the control bound is normalized by a width value that the system calculates from data. Lower and upper width values determine how much a metric value needs to exceed the control bounds to be anomalous. Changing a width for the control bounds affects the speed of reaching a high anomaly score and being notified about the anomaly. In addition to setting custom control bounds, you can override width values by specifying custom deviation and time values that the system uses to calculate custom widths values.

The system stores custom control bounds and custom widths for a metric in a metric class. Custom values in a metric class override the learned bounds and widths for the metric, and are then used in subsequent anomaly analysis.

1. Navigate to **Operational Intelligence > Configure > Bounds Settings**.
2. In the Bounds Settings list view, click **Add** to open the Bounds Settings wizard.
3. On the **Select Scope** tab, configure the following settings and then click **Next**.

<table>

</thead>
<tbody>
<tr>
<td>Upper Bound Range</td>
<td>Min and Max of the custom upper bound range Applies to the Set ranges for upper and lower bounds setting.</td>
</tr>
</tbody>
</table>

5. On the Preview and Confirm tab:
   a) Select a Source Metric Type and optionally a Metric Type for the preview.
   b) Optionally, enter a CI Name and a Resource Name that you want to include in the preview. If you specify a CI or a resource, it must be within the scope that was previously specified.
   c) Click Preview to perform anomaly detection for the specified metric and CI, using the newly specified custom bounds.
   d) Examine the preview results and if the results are as expected, click Finish. Otherwise, go back to the previous Apply Bounds Settings tab, adjust settings, and then preview again. The preview results are a stripped-down version of anomaly model testing. For more details about the results, and changing chart settings, see Anomaly model testing.

CIs in maintenance mode

Configure anomaly detection to exclude metrics for CIs that are in maintenance mode from model learning.

You can change the settings of system properties to include or exclude metric data for CIs while they are in maintenance mode.

When the system property sa.model_learner.maint_event_record_history_enabled is set to true (default), Operational Intelligence stores historical information about the times CIs enter and exit maintenance mode. When the system property sa_metric.maint_exclusion is set to true (default), metrics from CIs that are in maintenance mode are excluded from model learning.

View metric to CI and resource binding

View the metric to CI and resource binding results, including details for failed bindings which you can use to mitigate the failure. If Operational Intelligence cannot map and bind a metric to a CI or to a resource, then that CI or resource is not included in anomaly detection until it is properly mapped.

Role required: evt_mgmt_admin

If resource binding is not enabled, then no resource binding results appear.

Operational Intelligence uses event rules to map metric data with the specific CI or resource that is associated with the metric event. The results of these mappings are stored in the Metric to CI Mappings (sa_metric_map) table. If mapping fails, then the binding status for the metric indicates the general reason for the failure and further details about the failure are provided. Examine the details for a mapping failure and mitigate the problem to improve accurate and effective metric data processing.

- If mapping to a CI is successful, then the mapped CI appears in the Configuration Item column. If resource binding was attempted but failed, then the mapped CI does not appear, even if the mapping to a CI was successful. Missing or duplicate CIs can cause CI mapping to fail.
If mapping to a resource is successful, then the mapped resource appears in the Resource column. Missing a resource table that is mapped to the CI type to which the event is bound, or a missing resource_path attribute in the event, cause resource binding to fail.

Records in the CI Mappings (sa_metric_map) table remain in effect for 24 hours (by default, if mapping to the CI is not successful), or for 5 days (by default, if mapping to the CI is successful). Later, if within that time period raw data arrives for a metric/CI pair that already has a record, the existing mapping is used to match the data to an existing CI. After Metric to CI Mappings records expire, incoming new raw data requires remapping. These records expire when:

- The 24-hour or 5-day cycle ends.
- An event rule has changed — Triggering an immediate expiration of the respective mapping record.

Adjusting mappings to reflect the addition or removal of CIs by Discovery, takes effect only upon the beginning of the next cycle.

1. Navigate to Operational Intelligence > Configure > Metric to CI.

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source</td>
<td>Data source for the metric.</td>
</tr>
<tr>
<td>Metric Type Id</td>
<td>Metric that is measured for the CI, such as disk% and cpu%.</td>
</tr>
<tr>
<td>Metric Identifier</td>
<td>A string in the form of CI/resource/metric that uniquely identifies a CI and a metric.</td>
</tr>
<tr>
<td>Configuration Item</td>
<td>The CI in the CMDB that is mapped to a metric. A missing value indicates that:</td>
</tr>
<tr>
<td></td>
<td>• The mapping of the metric to a CI was unsuccessful.</td>
</tr>
<tr>
<td></td>
<td>• Resource binding is enabled, but has failed. Configuration Item is missing even though binding to a CI was successful.</td>
</tr>
<tr>
<td>Resource</td>
<td>The resource that is mapped to a metric. If resource binding is enabled, then a missing value indicates that the mapping of the metric to a resource was unsuccessful.</td>
</tr>
<tr>
<td>Expiration Date</td>
<td>Record expiration date.</td>
</tr>
<tr>
<td>Binding Status</td>
<td>Status of the mapping of the metric to a CI or resource.</td>
</tr>
<tr>
<td></td>
<td>A CI Found status indicates that the mapping was successful, in which case the mapped CI appears in the Configuration Item column. Any other status indicates that the mapping failed, and a general reason for the failure is provided. Further details about the failure are provided in the Binding Failure Reason column.</td>
</tr>
<tr>
<td>Binding Failure Reason</td>
<td>Specific details about the mapping that failed, such as class and host names, and the queries that were used. Click the respective Event link to see further details in the Processing Notes field.</td>
</tr>
</tbody>
</table>
2. Examine the **Binding Status** and **Binding Failure Reason** as appropriate. Use the details provided to remediate the problem:

<table>
<thead>
<tr>
<th>Binding Status</th>
<th>Remediation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host CI Missing</td>
<td>Run Discovery or use any other method to populate the CMDB with the missing host CI.</td>
</tr>
<tr>
<td>Non-Host CI Missing</td>
<td>Run Discovery or use any other method to populate the CMDB with the missing non-host CI.</td>
</tr>
<tr>
<td>Non-Host CI Duplicate</td>
<td>Use the <a href="#">Duplicate CI Remediator</a> to remediate the duplication.</td>
</tr>
<tr>
<td>Dependent CI Duplicate</td>
<td>Use the <a href="#">Duplicate CI Remediator</a> to remediate the duplication.</td>
</tr>
<tr>
<td>Dependent CI Missing</td>
<td>Run Discovery or use any other method to populate the CMDB with the missing dependent CI.</td>
</tr>
<tr>
<td>Duplicate Metric Map Entry Exists</td>
<td>Check <strong>Binding Failure Reason</strong> and compare the metric identifiers associated with the duplicate metric map entries. If metric identifiers have changed (for example, an identifier was added), set the entry for this series in the CI Mappings (sa_metric_map) table to expire or delete the entry. Also check the associated event rule and ensure that it extracts the attributes correctly and that it does not extract the same CI for two different metric identifiers. This error might appear when 2 different metric identifiers map to the same CI/metric.</td>
</tr>
<tr>
<td>Resource ID Not Found</td>
<td>Verify that the CI Type To Resource Class (sa_ci_type_to_resource_class) table contains a mapping record for the respective CI type, or for one of its parents. Then ensure that a table with the name of resource class for this record, exists.</td>
</tr>
</tbody>
</table>

Group **Binding Failure Reason** by **Binding Status** to create a summary report with the number of records per failure category. Use this report to efficiently remediate the problems.

**Anomaly model testing**

Use anomaly model testing to apply and evaluate anomaly detection for a small set of CIs and metrics, using actual metric data. Compare test results to expected results, then fine-tune the anomaly detection model before enabling anomaly detection for the tested CIs and metrics in the production environment.

For example, before enabling anomaly detection for Linux Servers, you can use anomaly model testing with actual metric data collected for those Linux Servers. Existing alerts might indicate an anomaly for a specific metric and CI. You can create an anomaly test rule to test anomaly detection for those CIs and metrics, and then check if the expected anomaly is detected. You can also examine the bounds calculated by the anomaly model to see if they match expected bounds. After you fine-tune the test model, you can enable anomaly detection for Linux Servers.
Anomaly model testing supports up to 20 time series, which can include 20 metric types for the same CI, the same metric type for 20 different CIs, or any combination of those options.

**View test results in the Insights Explorer**

Upon completion of a test run, a URL to an Insights Explorer becomes available. The anomaly model testing results appear in this trimmed-down version of the Insights Explorer. This Insights Explorer is pre-loaded with the charts and scores for the metric series specified in the anomaly test rule. You cannot add any CMDB groups or application services to this Insights Explorer.

Each chart in the Insights Explorer, contains the Anomaly Test Statistics section in its **Chart Settings**. This section is specific to anomaly model testing and provides the following options:

- **Show Bounds**: Displays a computed upper and lower bound for the metric in an anomaly model testing, based on learning of past metric values. The upper and lower bounds always appear together.
- **Show Anomaly Scores**: Displays anomaly scores on a virtual axis of 0-10, for an anomaly model test. Color code is based on the score thresholds that are defined in the Anomaly Score to Event Severity Map (sa_metric_anomaly_score_to_event_severity_map) table.

**Use test results to fine-tune anomaly detection**

Anomaly model testing uses the **upper and lower bounds** configured for selected series in the anomaly test rule. The anomaly model test results show how many anomaly alerts would have been generated based on the specified settings, if anomaly detection was enabled for the tested CIs and metrics. You can then decide if this result is acceptable. Fine-tune the bounds so that the number of anomaly alerts that are generated is not excessive, but sufficient to accurately indicate an out of bounds score.

**Create an anomaly test rule**

To use the anomaly model testing, create an anomaly test rule in which you specify up to 20 metric series to test anomaly detection for. Run the anomaly test, and after it completes, use the provided URL to open the Insights Explorer which is pre-loaded with the model testing results.

Role required: evt_mgmt_user

1. Navigate to **Operational Intelligence > View Metric & Anomalies > Anomaly Model Testing**.
2. Select an existing anomaly test rule to edit and run again, or click **New** and fill out the Anomaly Test Rules form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name for the model test rule.</td>
</tr>
<tr>
<td>Applies to</td>
<td>The table from which to select CI/metric pairs for the model test rule. The table used is Metric To CI Mapping (sa_metic_map).</td>
</tr>
<tr>
<td>Rule</td>
<td>Filter conditions to specify pairs of CIs/metrics for the anomaly model testing. If the rule yields more than 20 pairs of CIs/metrics, then the list is truncated to 20.</td>
</tr>
<tr>
<td>Start date/End data</td>
<td>The time period for which to apply the anomaly detection testing. The time period must be within the past 7 days.</td>
</tr>
</tbody>
</table>
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Status</td>
<td>Status of the test, automatically updated by the system during a test run. Status is initially Scheduled and eventually changes to Complete.</td>
</tr>
<tr>
<td>URL</td>
<td>URL to the Insights Explorer in which the anomaly model test results are pre-loaded.</td>
</tr>
<tr>
<td>Notes</td>
<td>Logging summary, automatically updated by the system with details of each test run of the anomaly test rule.</td>
</tr>
</tbody>
</table>

3. **Click Run Anomaly Test.**

   During the test run, the **Status**, **URL**, and **Notes** fields are automatically updated to reflect the progression of the job.

4. **After Status changes to Complete, click the URL link to open the Insights Explorer to see the results of the test.**

The bounds and the chart for the anomaly model test, appear in faint colors in Insights Explorer. Also, the upper and lower bounds that are calculated by the test, use a line pattern that is different than line pattern used for actual anomaly detection results. These differences let you distinguish between actual anomaly detection and anomaly model test results, if both are selected in the chart settings.

- Modify the date range for the test or choose different time series, and click **Run Anomaly Test** again to continue and fine-tune the model.
- Click the **Chart Settings** icon for a chart to toggle the display of statistics and aggregations on the chart. Select **Show Bounds** and **Show Anomaly Scores** in the Anomaly Test Statistics and in the Anomaly Statistics sections, to display test results next to actual anomaly detection results.

**Note:** Anomaly Model Testing results might be very similar to actual anomaly detection results. If you configure the chart to display both at the same time, as you move the mouse over the chart, it might be difficult to identify points of differences.
When you are satisfied with the anomaly test results, enable anomaly detection in the production environment, for the metrics and CIs specified in the test. See Choose and configure metrics to monitor for more details.

View metric values in the Insights Explorer

Operational Intelligence calculates statistics for CI metric data. Insights Explorer displays these metric values as metric charts for the CIs in the CMDB. Insights Explorer lets you overlap any metrics for any CIs in a single chart to create a multi-layered view of metric values across a time range.

Role required: evt_mgmt_user

The Insights Explorer provides a canvas to which you can drag various metrics for CIs and create charts. You can place a single metric on the canvas, for an individual metric for a CI. For a more comprehensive chart, you can layer several metrics for a single CI or for different CIs to create a multi-metric chart. In such layered chart, each metric is distinguished by a unique color, which lets you compare metric values across CIs within a specific time range.

You can also access the Insights Explorer from the following maps:

- View metrics in a Dependency Views map
- View metrics from a business service map
Insights Explorer

If the host name of the CI is available, it appears underneath the CI name. Host name is populated by retrieving the node information from the generated binding event as part of metric binding.

To navigate to a CI for which to display metrics:

- Use Hottest Configuration Items ( ) to quickly access the 10 most anomalous CIs.
Use Configuration Items ( ) to create a separate custom list of any CIs from the CMDB and then add the metrics for these CIs to the canvas.

Use Application Services ( ) to create a custom list of application services that let you drill into the CIs of these services. You can then add metrics for these CIs to the canvas.

Use CMDB Groups ( ) to create a custom list of CMDB Groups that let you drill into the CIs of these groups. You can then add metrics for these CIs to the canvas.

The following colors, which are based on color settings for alert severities, indicate anomaly severities:

- **Red**
  Critical severity (highest severity).

- **Orange**
  Major severity.

- **Yellow**
  Minor severity.

- **Blue**
  Warning severity (lowest severity).

- **Green**
  Informational. No severity.

The dots at the upper left on the CI icons indicate general anomaly tracking status:

- Grey: Metrics are being tracked for the CI, but none of those metrics have ever had an anomaly.
- Green: Metric for CI had at least one anomaly in the past, but anomaly score is currently 0.
- Colored: Corresponds to the last recorded severity level according to the configuration of the color band ranges.
- No dot: There are no metrics for the CI and there is no data to drill into.

*Note: Configuration Items and Application Services are likely to include CIs for which there is no metric data.*

Operational Intelligence does not track changes to an anomaly score if it is within the green band range.

As you create charts, a legend for each series chart automatically appears underneath the chart. For a single-metric chart, the legend has entries for the aggregations in the chart. For a multi-metric chart, the legend has entries for the metrics in the chart.

Modifications in the Insights Explorer remain during the session, and once the Insights Explorer is refreshed it returns to its initial state.

1. Navigate to **Operational Intelligence > View Metric & Anomalies > Insights Explorer**.
2. Click a CI to drill down to its associated list of metrics, ordered by their most recent anomaly scores.
For each metric, a sparkline displays metric values for the CI for the last hour. Point to the sparkline to display the metric value at each point of time.

If resource binding is enabled, then the list of series being monitored for a CI also contains series that belong to a resource and metric. The naming convention for such series is `<resource name>/<metric name>`. For a series that is only bound to a CI, the naming convention is `<metric name>`.

3. Drag a metric to the Drop Metric To Create Chart area on the canvas. Point to the chart to display the exact metric value at each point of time. The metric chart displays data for the specified time period, according to the chart settings. By default, raw data is displayed. If the time period is longer than a week or earlier than the last week, then average data is displayed.

Drag subsequent metric to the canvas as follows:

- In the Drop Metric To Create Chart area, so it is displayed individually in a new chart.
- Onto an existing chart, in the Replace Chart highlighted block to overwrite the existing chart.
- Onto an existing chart, in the Add Metric highlighted block to overlap it with the existing metrics in the chart.

When you display multiple metrics in a single chart, the same aggregation selection applies to all the metrics, and statistics settings are not available. For example, if Average is selected in the Chart Settings, then averaged values are displayed for all the metrics in the chart.

4. Use the Search box to search and filter for specific configuration items, application services, or CMDB groups that are not listed by default. In the SEARCH RESULTS section, click the + icon next to an item that you want to add to the ADDED ITEMS section. Or, use advanced search:

- Select and then click Add Configuration Item to add any specific CIs. In the Add Configuration Items dialog box, select a CI Class Type such as Linux Server. Then specify a filter condition such as (Operating System) is (Linux Red Hat) to narrow down the search.

- Select and then click Add Application Service to add all CIs included in a specified application service. In the Add Application Services dialog box, select Discovered Service or Manual Service as the CI Class Type and then specify filter conditions to narrow down the search.

  Note: You can add an application service only if its Operational Status is "operational".

- Select and then click Add CMDB Group to add all CIs included in a specified CMDB group. In the CMDB Groups dialog box specify filter conditions such as (GroupName) starts with (d), to narrow down the search.

After selecting the items that you want to add, click Add.

5. Add related CIs:

a) Click the Add related CIs icon next to a CI.

The Add Related Configuration Items dialog box appears, displaying all relationships in which the selected CI is a parent or a child.
b) To further filter the list, you can define specific conditions that must be met.

c) Select the relationships from which you want to add the parent or the child CI, whichever is not the selected CI.

d) Click **Add**.

The CIs from the selected relationships, which are not the selected CI, are added to the list of CIs in the Insights Explorer.

6. Point to a legend item and click its 'X' icon to remove the corresponding metric from the chart, or to disable the corresponding series from the Chart Settings.

7. Click the cog **Settings** icon to open application settings:
   - Enable, disable, or set the frequency for refreshing anomaly data on the Insights Explorer.
   - Activate or deactivate the display of related lists such as All Alerts, Incidents, and Problems. For more information, see [Create or modify map indicators](#).

8. Click the **Chart Settings** icon to toggle the display of statistics and aggregations on the chart. Enabling or disabling an item to add or to remove metrics from a chart, also updates the legend of the chart to reflect the change.

<table>
<thead>
<tr>
<th>Chart Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Show Bounds</td>
<td>Displays a computed upper and lower bound for the metric, based on learning of past values. The upper and lower bounds always display together.</td>
</tr>
<tr>
<td>Show Anomaly Scores</td>
<td>Displays anomaly scores on a virtual axis of 0-10. Color code is based on the score thresholds that are defined in the Anomaly Score to Event Severity Map (sa_metric_anomaly_score_to_event_severity_map) table.</td>
</tr>
<tr>
<td>Average</td>
<td>Displays aggregated average metric values calculated in one hour intervals. Aggregated averages are displayed as follows:</td>
</tr>
<tr>
<td></td>
<td>• For data that is up to 8 days old: Displays 10-minute aggregation windows.</td>
</tr>
<tr>
<td></td>
<td>• For data that is up to 94 days old: Displays 10-minutes aggregation windows.</td>
</tr>
<tr>
<td></td>
<td>• For older data: Displays 1-hour aggregation windows.</td>
</tr>
<tr>
<td>Minimum</td>
<td>Displays aggregated minimum metric values calculated per one hour time periods. Aggregated minimum values are displayed as follows:</td>
</tr>
<tr>
<td></td>
<td>• For data that is up to 8 days old: Displays 10-minute aggregation windows.</td>
</tr>
</tbody>
</table>
### Chart Setting

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
</table>
| Maximum | Displays aggregated maximum metric values calculated for one hour time periods. Aggregated maximum values are displayed as follows:  
  - For data that is up to 8 days old: Displays 10-minute aggregation windows. |
| Raw | Displays the raw, unaggregated metric values. These values are kept only for the last 8 days. |

- Point to the icon of a CI in the right-hand side bar to display the CI type.
- Zoom in or out by changing the default **Last Hour** time range selection. Select one of the preset time periods to display anomaly scores for the last **6 Hours** for example, or specify a custom time period for up to 90 days back.

To zoom in, highlight a section of a chart by pointing to the upper left corner of the section and dragging the mouse device to the lower right corner of the section. The time range of the chart changes accordingly. If there are other charts on the canvas, they are all automatically synchronized to display data for the same time range. The time range in the title bar automatically updates to reflect the new time range.

- Right-click on a CI in the right-hand side bar and select **View Form** to open its CI form.
- Click the map icon next to an application service listed in the **Application Services** tab, to open its application service map.
- Click Remove (_remove_) next to a CI to remove it from the Insights Explorer.
- Click the Export icon in a chart to download it as a .png or .svg image, or as a .pdf document.

### Insights Explorer Settings

You can configure Insights Explorer settings to control for example, the refresh frequency or the display of related records.

Click the cog **Settings** icon to open the Application settings dialog box.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Refresh interval</td>
<td>Enable and set the frequency for refreshing metrics data on the Insights Explorer.</td>
</tr>
</tbody>
</table>
| Indicators  | Enable any indicator to display related records such as incidents or problems for CIs. The respective icon displays on the timeline in the metric chart, indicating the number of records for the CI.  
  A toggle is available only if the **Active in Metrics** field is selected on the Map Indicator form for the respective table. For example, the **Incident** toggle is available only if **Active in Metrics** is selected on the Map Indicator form for the incident (Incident) table. |
Create an Insights Explorer view

You can create a custom view in the Insights Explorer that saves any metric charts that were added to the canvas, and any added configuration items. After you create a view, you can share a link to the view.

1. Navigate to **Operational Intelligence > View Metric & Anomalies > Insights Explorer.**
2. Click **Create View** ( ), and enter a **Name** in the Create New View dialog box. If you are already creating a view, then you can choose **Create With Existing** to load an existing view to work with rather than starting with a blank canvas.
3. Click **Create**.
4. Add items to be included in the view:
   a) Drag metrics and create charts on the canvas.
   b) Add configuration items.

While modifying a view, it is automatically saved every time you update it. The time settings are not saved in views, and when a saved view is loaded, its time period is always set to **Last hour** displaying current information.

- Share a view: Click **Share View** ( ), and then in the Share dialog box, click **Copy Link**. Send or paste the link to make it accessible to whoever you want to share the view with. A shared link captures the time range of the view, the charts that were added to the canvas, and any added configuration items.
- Display a saved view: Open the **Select a Saved View** drop down list, and select a previously saved view that you want to display.

**Anomaly alerts**

Anomaly alerts indicate deviation from projected metric values for monitored CIs. Anomaly alerts are separate from the regular IT alerts, and are not displayed in the Alert Console. You can define an anomaly alert promotion rule to generate an IT alert that is based on anomaly alerts.

Role required: **evt_mgmt_user**

The statistical model is used to calculate standard deviations, upper and lower bounds, and statistical outliers which are then used to detect anomalies. An anomaly is when metric values are out of the projected values according to the statistical model. The system monitors the frequency and persistence of statistical outliers across time to compute a score between 0-10 that indicates how abnormal a deviation is.

Operational Intelligence constantly generates anomaly alerts whenever the anomaly score is above zero. If there is a score that is above four and which has changed from the previous score, then it is sent to the instance. On the instance, the entire sequence of anomaly scores over time can then be displayed in the Insights Explorer.

You can view a list of anomaly alerts as described below. For summaries and reports, you can view the **Anomaly Map** and the **Anomaly Alert Dashboard**.

1. Navigate to **Operational Intelligence > View Metric & Anomalies > Anomaly Alerts.**
2. In the **Alerts Anomalies** list view, double-click an alert that you want to view.

Information about an anomaly alert includes details such as the metric value, promotion parameter, and upper and lower bounds. Description includes details about why the
anomaly alert was generated, and other details such as the metric name and the anomaly score.

- You can [create an alert promotion rule](#) to generate regular IT alerts that are based on anomaly alerts.
- Right-click an alert, and then click **View Metrics** to open the integrated Insights Explorer and Dependency Views map for the CI associated with the alert.

**View Anomaly Map**

Anomaly Map displays the 10 CIs with the highest metric anomaly scores across a time period. The map lets you drill down into each CI to display anomaly scores for each of the CI’s metrics. Anomaly scores are color coded to help you isolate problem areas at a glance.

Role required: evt_mgmt_user

Operational Intelligence monitors metric data for CIs and detects anomalies when values are out of bounds, according to the statistical model. Anomalies are scored on a scale of 0-10 and mapped into color codes based on score thresholds defined in the Anomaly Score to Event Severity Map (sa_metric_anomaly_score_to_event_severity_map) table.
If the CIs host name is available, it appears underneath the CI name. Host name is populated by retrieving the node information from the generated binding event as part of metric binding.
To navigate to the CI for which to display metrics:

- Use Hottest Configuration Items ( ) to quickly access the 10 most anomalous CIs.
- Use Configuration Items ( ) to create a separate custom list of any CIs from the CMDB that have metric data.
- Use Application Services ( ) to display all the CIs included in a specified application service.

**Note:** Some CIs in an application service might not have metric data. In this case, the respective icon does not have a dot on the upper left side, and no metric data is displayed.

- Use CMDB Groups ( ) to display all the CIs included in a specified CMDB group.

1. Navigate to **Operational Intelligence > View Metric & Anomalies > Anomaly Map**. In the Anomaly Map, point to a colored anomaly box to display the details of the CI and the time period for the anomaly scores.
   The color of each anomaly box represents the highest anomaly score of all metrics for the CI for the time period.
2. Click a CI in the left-hand side bar to display a breakdown of its metrics with the respective anomaly scores across the time period.
   If resource binding is enabled, then the list of series being monitored for a CI also contains series that belong to a resource and metric. The naming convention for such series is `<resource name>/<metric name>`. For a series that is only bound to a CI, the naming convention is `<metric name>`.
3. Point to an anomaly box to display its precise anomaly score.
   The color coded anomaly score next to the metric represents the latest anomaly score for the CI.
4. Use the Search box to search and filter for specific configuration items, application services, or CMDB groups that are not listed by default. In the SEARCH RESULTS section, click the + icon next to an item that you want to add to the ADDED ITEMS section. Or, use advanced search:
   - Select and then click **Add Configuration Item** to add any specific CIs. In the Add Configuration Items dialog box, select a CI Class Type such as Linux Server. Then specify a filter condition such as (Operating System) (is) (Linux Red Hat) to narrow down the search.
   - Select and then click **Add Application Service** to add all CIs included in a specified application service. In the Add Application Services dialog box, select Discovered Service Or Manual Service as the CI Class Type and then specify filter conditions to narrow down the search.

**Note:** You can add an application service only if its Operational Status is 'operational'.
Select and then click Add CMDB Group to add all CIs included in a specified CMDB group. In the CMDB Groups dialog box specify filter conditions such as (GroupName) (starts with) (d), to narrow down the search.

After selecting the items that you want to add, click Add.

- Point to a CI's icon in the left-hand side bar to display the CI type.
- Click for a CI to drill to the CI's metrics. Click next to a metric to view the metric in the Advanced Insights Explorer.
- Click the cog Settings icon to open application settings and to configure the Refresh interval. Enable and set the frequency for refreshing anomaly data on the Anomaly Map.
- Zoom in or out by changing the default Last Hour time range selection. Select one of the preset time periods to display anomaly scores for the last 6 Hours for example, or specify a custom time period for up to 90 days back. Click the timestamp at a column heading to drill into the time period between the current column and the column to the right.
- Right-click a CI in the left-hand side bar and select View Form to open its CI form.
- Click a tile in the Anomaly Map to switch to the Insights Explorer, which displays the metric chart for the CI that was clicked.

Anomaly Alert Dashboard

View important anomaly alert reports in a single dashboard. Anomaly Alert Dashboard provides summaries about anomaly alerts and promoted alerts, in relation to Event Management alerts.

The reports in the Anomaly Alert Dashboard use Performance Analytics indicators and Reporting, and require that Performance Analytics (com.snc.pa) is activated.

To access the Anomaly Alert Dashboard, navigate to Operational Intelligence > Reports > Anomaly Alert Dashboard.

Role required to view reports: evt_mgmt_user

% Daily Alerts are Promoted Anomalies

Shows the percentage of newly promoted alerts, in relation to the overall new IT alerts, for the time period. The change in minutes from the previous report is also available. Click the tile to drill down for more details.

Avg Resolve Time of Promoted Alerts

Shows the average number of hours it took to resolve anomaly alerts that were promoted to IT alerts within the time range. The percentage point change from the previous report is also available. Click the tile to drill down for more details.

Number of Anomaly Alerts

Shows the number of anomaly alerts that were created per day in the time range, broken down by promotion to Event Management alerts.
Bars in the chart are broken down into sections which are color coded by the associated alert type:

- Anomaly alerts that were promoted to Event Management alerts.
- Anomaly alerts that were not promoted to Event Management alerts.

To view further details:

- Click Promoted or Not Promoted in the report legend, to show or hide details for an alert type.
- Point to a section on a bar to show the date and the number of promoted or not promoted anomaly alerts for the specified day.
- Click a bar to view a detailed scorecard for the bar.

Create anomaly alert promotion rule

Anomaly alerts are generated by Operational Intelligence to indicate deviation from projected metric values for monitored CIs. You can create an anomaly alert promotion rule to generate a regular IT alert that is based on an anomaly alert.

Role required: evt_mgmt_admin

Anomaly alerts are separate from regular IT alerts and they do not appear in the Alert Console. However, anomaly alerts that were promoted to IT alerts do appear in the Alert Console.

You can create an [anomaly alert promotion rule blacklist](#) to exclude the promotion of alerts for specific CIs that would otherwise be promoted by an anomaly alert promotion rule.

1. Navigate to Operational Intelligence > View Metric & Anomalies > Anomaly Alerts.
2. Right-click an alert in the Alert Anomalies list and select Promote Anomaly Alert.
3. Fill in the fields on the Alert promotion rule form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Descriptive name for the anomaly alert promotion rule.</td>
</tr>
<tr>
<td>Promotion type</td>
<td>A filter that defines the scope of anomaly alerts for which the rule applies to. Filtering anomaly alerts can be based on:</td>
</tr>
<tr>
<td></td>
<td>• Metric name: The value of Source_metric_type in the Additional_info field in the anomaly alert.</td>
</tr>
<tr>
<td></td>
<td>• CI type: Type of the configuration item in the alert.</td>
</tr>
<tr>
<td></td>
<td>• Configuration item: Configuration item in the alert.</td>
</tr>
<tr>
<td></td>
<td>• Promotion parameter: In Additional Info of the anomaly alert, use the field specified in Field name for anomaly promotion in the Metric Registration table.</td>
</tr>
<tr>
<td>Source</td>
<td>Data source that is monitoring the metric type.</td>
</tr>
<tr>
<td>Metric name</td>
<td>The raw metric to filter anomaly alerts by. This field appears only when Promotion type is set to Metric name.</td>
</tr>
<tr>
<td>CI type</td>
<td>The CI type to filter anomaly alerts by. This field appears only when Promotion type is set to CI type.</td>
</tr>
<tr>
<td>Configuration item</td>
<td>The configuration item to filter anomaly alerts by. This field appears only when Promotion type is set to Configuration item.</td>
</tr>
<tr>
<td>Regular expression for the promotion parameter field</td>
<td>The regex applicable for the specified source, to filter anomaly alerts by. This field appears only when Promotion type is set to Promotion parameter.</td>
</tr>
<tr>
<td>Alert</td>
<td>The anomaly alert which was used to initiate the creation of this rule.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Active</td>
<td>Select to enable the rule.</td>
</tr>
<tr>
<td>Minimal score</td>
<td>A threshold value between 0-10 that the anomaly score of an anomaly alert</td>
</tr>
<tr>
<td></td>
<td>must be equal to or greater than, for the anomaly alert to be promoted.</td>
</tr>
<tr>
<td></td>
<td>The <strong>Additional information</strong> field in an anomaly alert form contains the</td>
</tr>
<tr>
<td></td>
<td>alert's anomaly_score value.</td>
</tr>
</tbody>
</table>

4. Click **Submit**.

After the anomaly alert promotion rule runs for an event that matches the rule criteria, a new Event Management alert is created that appears in the Event Management dashboard. Also, the anomaly alert that the new Event Management alert is based on, is updated with details about the promotion. To examine these details:

1. Navigate to **Operational Intelligence > View Metric & Anomalies > Anomaly Alerts**.
2. Double-click an alert that has been promoted.
   - Click **Processing Notes** to display processing details.
   - Click **History** to display details about the alert promotion.

Add a blacklist item to prevent the creation of a new Event Management alert that would otherwise be created by an anomaly alert promotion rule. Right-click an anomaly alert and select **Blacklist CI**.

**Create anomaly alert promotion rule blacklist**

You can create a blacklist of CIs to be excluded from promotion to regular alerts. Alerts related to the CIs in the blacklist would otherwise be promoted to regular alerts by an anomaly alert promotion rule.

*Anomaly alert promotion rules* must exist, otherwise, blacklist CIs have no effect.

Role required: evt_mgmt_admin

Anomaly alert promotion rules promote anomaly alerts to regular alerts. Alerts generated by CIs that are included in the blacklist, are not promoted even if they satisfy the anomaly alert promotion rule filter.

1. Navigate to **Operational Intelligence**.
2. Open the **Alert Promotion Rules Blacklist** by doing either of the following:
   - Navigate to **Settings > Anomaly Alert Promotion CIs Blacklist**, and then click **New** or open an existing rule.
   - Navigate to **View Metric & Anomalies > Anomaly Alerts**, right-click an alert in the **Alert Anomalies** list, and then select **Blacklist CI**.
3. Fill in the fields, as appropriate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configuration item</td>
<td>The CI from the alert, that is to be added to the CIs blacklist.</td>
</tr>
<tr>
<td>Source</td>
<td>Data source of the alert.</td>
</tr>
</tbody>
</table>

4. Click **Submit**.
Use Advanced Insights Explorer to query CI metric data

Advanced Insights Explorer lets you query metric data for CIs for which metric data is collected. CIs for the query can be from different sources such as application services, relationships, or a list of anomalous CIs. Query results are displayed in charts for further understanding of system behavior.

Role required: evt_mgmt_user

Use Advanced Insights Explorer to create queries such as:

- Server CPU metric value that is higher than a given value.
- Metrics for all Apache Servers in which CPU utilization is greater than 90% and anomaly score is greater than 8 for a given time period.
- Metrics for the top 10 Apache Servers with CPU utilization of 80%.

A query in the Advanced Insights Explorer consists of a query title, a time range, a combination of one or more guided expressions or script expressions, and the resulting chart of the query. Each guided expression or script expression defines a set of CIs and a metric type whose values are retrieved for the set of CIs. The Advanced Insights Explorer utilizes the platform scripting capability to run the queries.

**Guided Expression**

A query expression that you create by using a wizard. After you complete the wizard, the query is converted into a JavaScript code snippet that can run using the platform scripting capability.

**Script Expression**

A query expression that is based on a direct entry of JavaScript. You can create a custom script, which, for example, queries for data that is not supported by default. You can create a custom function to use in a script expression.

Some of the data that the Advanced Insights Explorer queries, is stored as time series. The Advanced Insights Explorer uses metric data time series, anomaly scores time series, and upper and lower bounds time series. The result of a query then is a single time series or a set of time series that satisfy the criteria specified in the query expressions.

Open the Advanced Insights Explorer, by navigating to Operational Intelligence > View Metric & Anomalies > Advanced Insights Explorer. Then do any of the following steps.

- In the Queries sidebar, select a query to edit or click New Query and then select the new query to edit.
- Add a guided expression to a query:
  a) If the Guided Expression tile is not visible, click Add Expression.
  b) Click Create Expression on the Guided Expression tile to open the Create An Expression dialog box.
  c) Configure the settings on the Select Data Source tab to define the data set and to select the metric type for the query, and then click Next.

Your selection of CI Source determines which other fields appear.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CI Source</td>
<td>Source from which to select CIs for the query. Most options are tables such as Metric table and Service table. Another option is Existing Guided Expression.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CIs</td>
<td>Filters the CIs from a table selected in CI Source to a specific class. You can add other conditions that CIs must satisfy.</td>
</tr>
<tr>
<td>Resource</td>
<td>Toggle to query for series belonging to resources for a CI class. Click the Resource filter icon to filter on resources.</td>
</tr>
<tr>
<td>Parent or Child</td>
<td>Filters the set of CIs for the query to those CIs that are parent or child CIs in the relationships in the CI Relationship (cmdb_rel_ci) table.</td>
</tr>
<tr>
<td></td>
<td>Applies when CI Source is set to Relationships table.</td>
</tr>
<tr>
<td>Guided Expression</td>
<td>Limits the CIs for the query to the results of an existing guided expression.</td>
</tr>
<tr>
<td></td>
<td>When CI Source is set to Relationships table, the specified guided expression further filters the set of CIs by joining the resulting CIs from the guided expression to the opposite of what is selected in Parent or Child.</td>
</tr>
<tr>
<td></td>
<td>For example: Parent or Child is set to Parent and a guided expression is specified. The list of records from which the parent CI is selected in the cmdb_rel_ci table, is further limited to only those records whose child CI is included in the results of the specified guided expression.</td>
</tr>
<tr>
<td></td>
<td>Also applies when CI Source is set to Relationships table.</td>
</tr>
<tr>
<td>Anomaly Score</td>
<td>Filters the set of CIs for the query to those CIs whose anomaly score satisfies the Anomaly Score criteria. Anomaly score values range from 0—10.</td>
</tr>
<tr>
<td></td>
<td>Applies when CI Source is set to Anomaly score table.</td>
</tr>
<tr>
<td>Metric Type</td>
<td>Metric type for which to retrieve data for the set of CIs in the query.</td>
</tr>
</tbody>
</table>

d) Configure the settings on the Filter Data Series tab to filter and sort anomaly score and data time series for the query. Then click Next.

You can independently set the Data Filter and the Anomaly Score Filter. Both filters can be enabled or disabled, or one of them can be enabled and the other disabled.

Each time series from the Select Data Source tab is filtered through the data filter and the anomaly score filter, if enabled. Only time series that satisfy the enabled filters, are included in the data set for the query. If both filters are disabled, then the entire data set from the Select Data Source tab, is included in the query without filtering.
### Data Filter/Anomaly Score Filter

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aggregation</td>
<td>Aggregation type (such as average, minimum, or maximum) to use for aggregating each time series.</td>
</tr>
<tr>
<td>Start date</td>
<td>Time range of the time series to which the specified Aggregation is applied.</td>
</tr>
<tr>
<td>End date</td>
<td></td>
</tr>
<tr>
<td>Condition</td>
<td>Condition that the aggregated time series needs to satisfy to be included in the query.</td>
</tr>
<tr>
<td>Value</td>
<td></td>
</tr>
</tbody>
</table>

### Limit and Sort

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limit Data Series</td>
<td>The number of data series to use for the query, counting from the top of the set of filtered and sorted data series.</td>
</tr>
<tr>
<td>Sort</td>
<td>The sort order for the resulting CIs. If both, the data filter and the anomaly score filter are enabled, then choose which of those filters to use for sorting the results.</td>
</tr>
</tbody>
</table>

### Transform Options

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group by</td>
<td>A CI column (attribute) by which to group the query results. For example, the datacenter attribute of the CI.</td>
</tr>
<tr>
<td>Transform Output</td>
<td>Aggregation type to apply when aggregating all the time series in each group (as specified in Group by) into a single time series. Click the '+' or '-' to add or remove transforms to apply to the query results.</td>
</tr>
</tbody>
</table>

### Output Types

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Metric</td>
<td>Include charts of metric time series in the query results.</td>
</tr>
<tr>
<td>Bounds</td>
<td>Include charts of upper and lower bounds time series in the query results.</td>
</tr>
</tbody>
</table>
Add a script expression to a query:
   a) If the Script tile is not visible, click Add Expression.
   b) Click Create Expression in the Script tile.
   c) Type in a custom Java script.

Query actions:
   - Click Run to run a query.
   - Click Save to save a query.
   - Point to specific areas on the report graph to show details specific to that time.
   - Use Search in the Queries sidebar, to search for a query.
   - Click a query title in the header of the query pane to rename a query.
   - Set a time range for a query by overwriting the default start and end times in the header of the query pane.
   - Click to export the report in a PNG, SVG, or PDF format.

   Click (expression options) next to an expression and then click any of the actions such as Edit (available only for guided expressions) or Duplicate.

   Click to modify chart configuration settings and then click Apply.

   Set the display_monitored_object_type system property to ‘true’ to configure Advanced Insights Explorer to show the specific monitored object type that is associated with a referenced source metric type.

   A single source metric type can be associated with multiple monitored object types, therefore it is useful when the specific monitored object type appears next to the source metric type that is referenced. For example, ‘% Idle Time’ is associated with ‘Microsoft.Linux.RHEL.5.OperatingSystem’ and ‘Microsoft.Windows.Server.2003.LogicalDisk’.

   - To open the System Property (sys_properties) table, enter sys_properties.list in the navigation filter.
   - To see the Monitored Object Type and Source Metric Type combinations in the Monitoring System Metric Types list view, navigate to Operational Intelligence > Configure > Metric Types.

Create a custom function

Create a custom function, which is a JavaScript that you can then use in a script expression in Advanced Insights Explorer.

Role required: evt_mgmt_user

1. Navigate to Operational Intelligence > Settings > Metric Expression Functions.
2. Click **New** and then fill out the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The function that the argument is associated with.</td>
</tr>
<tr>
<td>Eval</td>
<td>JavaScript associated with the function.</td>
</tr>
<tr>
<td>Order</td>
<td>The order in which the function is added to the environment. For example, if one function is calling another function, then the order of the first function is higher than the order of the second function.</td>
</tr>
<tr>
<td>Active</td>
<td>Select to denote that the function is active.</td>
</tr>
<tr>
<td>Return Type</td>
<td>Type of what the function returns: NUMBER, SERIES, or STRING.</td>
</tr>
</tbody>
</table>

For example, the script for a function named ‘foo’, would be similar to:

```javascript
var foo = function(bar) {
    //Your JS code here
}
```

3. Click **Submit**.

4. Navigate to **Operational Intelligence > Settings > Metric Expression Function Arguments** and create a record for each argument in the function:
   a) Click **New**.
   b) Fill out the form for the argument.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Function Name</td>
<td>The function that the argument is associated with.</td>
</tr>
<tr>
<td>Order</td>
<td>Denotes the order of arguments in the function. For example, for a function <code>foo(arg1, arg2)</code>, two records for the two arguments are needed. In one record, <code>Order = 1</code>, and in the other <code>Order = 2</code>.</td>
</tr>
<tr>
<td>Type</td>
<td>Type of the argument: NUMBER, SERIES, or STRING.</td>
</tr>
<tr>
<td>Domain</td>
<td>Domain associated with the argument.</td>
</tr>
</tbody>
</table>

c) Click **Submit**.

In Advanced Insights Explorer, you can now use this function in a script expression.

For example: `foo('testArg');`
Agent Workspace for Operational Intelligence

Agent Workspace for Operational Intelligence provides an easy-to-navigate interface where service agents can view the health of a CI associated with an alert. Health details for a CI include various metric charts with control bounds, and aggregations for a time period.

In Agent Workspace, when viewing an IT alert with a CI associated with it, click the Metrics button on the alert form to access the following Operational Intelligence details:

- Charts, control bounds, and aggregations for key metrics for CIs, in a single location.
- Aggregation of metrics for CIs with resources, in a single consolidated time series.
- Ability for administrators to configure which metric types appear for each CI class.

The set of metric charts that appear for a CI class in Agent Workspace, is determined by metric chart configurations in the Metric Dashboard Metadata (sa_metric_dashboard_metadata) table. The Metric Dashboard Metadata table is initially populated with configurations for common classes and important metrics for those classes. A user with the admin or evt_mgmt_admin role can update the default metric chart configurations in the Metric Dashboard Metadata table.

There can be only up to 10 active metric charts configured for a class at any point.

Plugins

All plugins related to Event Management, Operational Intelligence, and Agent Workspace, are required.

Roles

- To access Operational Intelligence metrics in Agent Workspace, the workspace_agent and itil roles are required.
- To configure the set of metrics that appears in Agent Workspace for a class, the admin or evt_mgmt_admin role is required.

Chart types

A metric chart that appears in the metric charts form in Agent Workspace can be a time-series chart or a single-score chart.

Time-series chart
The time-series chart type is a graph of all data points in the specified time range, for the metrics of the CI associated with the chart. Time-series charts are similar to charts in Insights Explorer, and depending on settings, show lower and upper bounds.

**Single-score chart**
The single-score chart type shows a single number which is an aggregation of the data points in the time series for the metric and CI of the chart. The aggregation is an average of the data points, or the maximum, minimum, or last data point in the time series.

View metric charts in Agent Workspace

Agent Workspace for Operational Intelligence provides easy access to metric charts for a CI. On an alert form, you can drill down to important metric charts for the CI that is associated with the alert.

- The CI that you want to view metric charts for, must be associated with an alert.
- The Metric Dashboard Metadata (sa_metric_dashboard_metadata) table must contain active chart configurations for the CI class for which you want to view metric charts.

Role required: workspace_agent and itil

The set of metric charts, chart types, and other chart characteristics, is determined by the chart configurations in the Metric Dashboard Metadata (sa_metric_dashboard_metadata) table, for the CI class.

1. Navigate to Agent Workspace and click Agent Workspace Home.
2. In Agent Workspace, click List and in the Lists panel, select one of the Alerts categorized lists such as All Alerts or Top Priority.
3. In the alerts list view, open an alert.
   The alert must have a Configuration item associated with it.
4. In the Details tab of the alert form, click Metrics.

All metric charts that are configured for the CI associated with the alert, and that are active, appear on the metric charts form in the Metrics tab. The calculation of the default time range for the charts is based on the times that the first and last events that generated the alert, occurred.
• Modify the time range for the charts by changing **Start Time** and **End Time**. When you modify the time range, all charts are updated to reflect the new time range.
• Click the cog wheel **Open settings** icon and change the settings for all charts:
  - **Show bounds**: Show the bounds in the chart. Even if enabled, there are no bounds in a chart for aggregated resources.
  - **Show legend**: Show chart legend.
• Click **Insights Explorer** to open the Insights Explorer in a new browser tab. That Insights Explorer opens with the current CI pre-selected and with the current time range settings in Agent Workspace.

**Configure metric charts for Agent Workspace**

Configure the set of Operational Intelligence metric charts, chart types, and other chart characteristics, that appear in Agent Workspace.

Role required: admin or evt_mgmt_admin

Up to 10 metric charts for a class can be configured to appear in the Operational Intelligence metric charts form in Agent Workspace. Metric chart configurations are stored in the Metric Dashboard Metadata (sa_metric_dashboard_metadata) table, determining which metric charts appear for a CI that is associated with an alert. By default, the Metric Dashboard Metadata contains pre-configured metric charts for several classes.

If **resource binding** is enabled and you specify a **Resource Type** in the metric chart configuration, then all the resources for the CI are included in the chart. The class table for the resource class (such as **ci_resource_metric_extension**) that you specify is used for retrieving all the resources for the CI. Then, for each point in time in the data series, the values of resources are aggregated into a single data point which is the average of the metric values of all resources for that point of time.

**Chart aggregation**

Aggregation is applied differently, depending on the setting of **Chart Type**, and on whether resources are included in the chart as indicated by the setting of **Resource Type**:

<table>
<thead>
<tr>
<th>Chart type</th>
<th>Resources</th>
<th>Aggregation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time_Series</td>
<td>No</td>
<td>No aggregation</td>
</tr>
<tr>
<td>Time_Series</td>
<td>Yes</td>
<td>Resources are averaged per data point.</td>
</tr>
<tr>
<td>Single_Score</td>
<td>No</td>
<td>Data points are aggregated according to the <strong>Chart Aggregate</strong> setting.</td>
</tr>
<tr>
<td>Single_Score</td>
<td>Yes</td>
<td>Resources are averaged per data point and then data points are aggregated according to the <strong>Chart Aggregate</strong> setting.</td>
</tr>
</tbody>
</table>

1. **Navigate to Operational Intelligence > Settings > Dashboard Metadata.**
2. In the Metric Dashboard Metadatas (Dashboard Metadata) list view, select an existing configuration or click **New**.
3. **Fill out the Metric Dashboard Metadata form.**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active</td>
<td>Include the chart on the Operational Intelligence charts form in Agent Workspace.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Resource Type</td>
<td>Resource class associated with the CI and for which to retrieve and aggregate all resources.</td>
</tr>
<tr>
<td>Configuration Item Type</td>
<td>CI class that the chart applies to such as cmdb_ci_metric_extension.</td>
</tr>
<tr>
<td>Chart Aggregate</td>
<td>Type of aggregation that is applied for single-score charts. Aggregation can be the average of the data points in the time series. Or, the minimum, maximum, or the last data point in the time series.</td>
</tr>
<tr>
<td>Source Metric Type</td>
<td>Metric such as “% Free Space” that is being monitored for the CI type.</td>
</tr>
<tr>
<td>Order</td>
<td>Order in which the metric chart appears within all metric charts specified for the class. For proper appearance and alignment, all single-score charts always appear after any time-series charts, regardless of order settings.</td>
</tr>
<tr>
<td>Chart Type</td>
<td>• Time_Series: Charts all the data points in the time series for the metric and CI of the chart.</td>
</tr>
<tr>
<td></td>
<td>• Single_Score: A single number which is the aggregation of all data points in the time series for the metric and CI of the chart. Aggregation is determined by the setting of Chart Aggregate.</td>
</tr>
</tbody>
</table>

**Self-health monitoring for Operational Intelligence**

Use Event Management self-health monitors to monitor the health of Operational Intelligence infrastructure components and processes, and to alert about potential issues. Self-health monitoring allows you to proactively remediate issues and minimize data loss.

Operational Intelligence is pre-configured to use Event Management self-health monitors to ensure that essential components and processes are functioning properly. If a monitor detects a failure, then the Event Management self-health monitoring system creates an event for the issue. These events are then converted into an Event Management alert or get appended to a previous alert. Operational Intelligence self-health monitors run every 60 seconds.

For example, if an Operational Intelligence MID Server distributed cluster experiences an issue, an event is generated with the status of **Major**. Then, this event is converted into an alert. Later, when the issue is resolved, a new event is generated with the status of **Info** and the original alert is closed.
Monitored components and processes

<table>
<thead>
<tr>
<th>Component/Process Check</th>
<th>Error Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operational Intelligence extension is running properly</td>
<td>Monitor checks the status field of the ecc_agent_ext_context_metric table to detect a state of Error or Warning.</td>
</tr>
<tr>
<td>Operational Intelligence MID Server distributed cluster is running properly</td>
<td>Monitor checks the status field of the ecc_agent_cluster table to detect a state of Error, Segmented, or Stopped.</td>
</tr>
<tr>
<td>Note: For a state of Stopped, an event is created only if the error_message field is not empty.</td>
<td></td>
</tr>
</tbody>
</table>
| Metrics are collected by active connectors that are configured for metrics collection | For each connector with the Metrics collection flag set to true:  
  Monitor checks the status of the last_kpi_status field in the em_connector_instance table to detect a status of Error. |
| Essential Operational Intelligence scheduled jobs are active  | Monitor checks the following essential scheduled jobs, to detect if any is inactive:  
  • Operational Intelligence — Metric configuration job  
  • Operational Intelligence — Sync tables with mid  
  • Operational Intelligence — Validate MID Distributed cluster |

For more information about enabling or disabling an Operational Intelligence self-health monitor, see Configure a self-health monitor.

View self-health monitoring statistics for Operational Intelligence

Monitor the status of components and processes of Operational Intelligence. Use the XMLStats page to view statistics and diagnostic details that can help with troubleshooting issues with Operational Intelligence.

1. Open a browser and enter the URL to the instance.  
   Type in: http://<instance name>.service-now.com
2. Append the following text to the instance URL: xmlstats.do?include=XMLStatsOI.  
   The complete URL format is: http://<instance name>.service-now.com/xmlstats.do?include=XMLStatsOI
3. Hit Enter.

Details are separated between two sections, instance level statistics and node level statistics. Details in the node section are specific to the node in the URL.

Node section

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>batches_recieved</td>
<td>Number of batches of metrics that the node received from the MID Server.</td>
</tr>
</tbody>
</table>
Details in the instance section are for the entire instance, showing the status of the self-health monitors.

**Instance section**

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>batches_processed</td>
<td>Number of batches of metrics processed on the node.</td>
</tr>
<tr>
<td>scheduled_jobs_monitor</td>
<td>Status of the self-health monitor that checks if the essential Operational Intelligence scheduled jobs are active.</td>
</tr>
<tr>
<td>distributed_cluster_monitor</td>
<td>Status of the self-health monitor that checks if the Operational Intelligence MID Server distributed cluster is running properly.</td>
</tr>
<tr>
<td>oi_extension_monitor</td>
<td>Status of the self-health monitor that checks if the Operational Intelligence extension is running properly.</td>
</tr>
<tr>
<td>metrics_collection_monitor</td>
<td>Status of the self-health monitor that checks if metrics are being collected by active connectors that are configured for metrics collection.</td>
</tr>
</tbody>
</table>

**Domain separation and Operational Intelligence**

This is an overview of domain separation and Operational Intelligence. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can then control several aspects of this separation, including which users can see and access data.

**Overview**

**Support: Level 1**

Domain separation is supported in this application. Not all ServiceNow applications support domain separation; some include limitations on the data and administrative settings that can be domain separated. To learn more, see [Application support for domain separation](#).

**How domain separation works in Operational Intelligence**

When domains are separated in Operational Intelligence, users can view and manage alerts and events only in their own (tenant) domain. After the binding process has finished, the domain of the configuration item (CI) is used so that users within that domain can explore metric data. A domain column is present for Operational Intelligence tables that are provided in the base system. The domain column shows the name of the domain to which the CI belongs.

**Note:** If the domain column does not appear in the list, click (Personalize List) and add the required column. In addition, you can add a column that displays the domain path.
The following Operational Intelligence features have limited domain separation support.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Metric types</td>
<td>Supported at global level. The instance owner can control the metric types for all domains.</td>
</tr>
<tr>
<td>Metric type registration</td>
<td>Supported at global level. The instance owner can control the metric type registration for all domains.</td>
</tr>
<tr>
<td>Metric class</td>
<td>Supported at global level. The instance owner can control the metric classes that are used for all domains.</td>
</tr>
<tr>
<td>Configuration settings rules</td>
<td>Supported at global level. The instance owner can control the configuration settings rules for all domains.</td>
</tr>
</tbody>
</table>

Configure domain separation

You can configure Operational Intelligence for domain separation to create logically defined domains that limit unauthorized access to data.

**Before you begin**

Role required: evt_mgmt_admin and evt_mgmt_integration

**Procedure**

2. Configure the MID Server for Operational Intelligence as a user that belongs to the desired domain with the role `mid_server` assigned to it.
3. Configure a MID Server distributed cluster in the domain you desire and add Operational Intelligence MID Servers that belong to the same domain. For more information about setting up MID Servers for Operational Intelligence, see [MID Server and MID Server distributed cluster for Operational Intelligence](#).

**Note:** The Event Management’s binding events are configured using the domain of the logged-in MID Server user. Once the process has finished, the record’s domain is updated to use the domain from the CI so that any user within that domain can see the metric data.

**ITOM Optimization**

The ServiceNow® ITOM Optimization product includes two features: *Cloud Management* and *Cloud Insights*. 
Features of ITOM Optimization

Deployed together, the features provide an integrated, service-centric approach that maximizes business service quality, drives efficient processes, and ensures robust governance.

Cloud Management

The Cloud Management feature gives you tools to provision private and public cloud infrastructure and services and to achieve consistent management and cost visibility.

Cloud Insights

The Cloud Insights feature, available in the ServiceNow Store, helps you to analyze the full range of costs associated with cloud assets so you can identify and take action on opportunities to save money and optimize operations.

Using guided setup to implement IT Operations Management applications

IT Operations Management Guided Setup provides a sequence of tasks that help you configure IT Operations Management applications on your ServiceNow instance. To open IT Operations Management guided setup, navigate to Guided Setup > ITOM Guided Setup. For more information about using the guided setup interface, see .

Cloud Management

With the ServiceNow® Cloud Management application, you can use a single interface to access cloud resources, publish cloud offerings to a catalog, and manage the usage of those resources. You can also manage the life cycles of those resources. Cloud Management is integrated with both private and public cloud providers, including Amazon Web Services, Microsoft Azure, and VMware offerings.

Cloud Management is available as a separate subscription from the rest of the platform. You must also request activation from ServiceNow personnel.

Note:

This Cloud Management application is new starting with the Jakarta release. The new Cloud Management application is incompatible with the legacy Cloud Management application. The legacy and the new Cloud Management applications cannot be used simultaneously.

Using guided setup to implement Cloud Management

Cloud Management guided setup provides a sequence of tasks that help you configure Cloud Management on your instance. To open Cloud Management guided setup, navigate to Guided Setup > ITOM Guided Setup.

For more information about using the guided setup interface, see Using guided setup.

Request the Cloud Management application

The Cloud Management application is available as a separate subscription and requires the Cloud Management plugin (com.snc.cloud.mgmt).

Role required: admin

To purchase a subscription, contact your ServiceNow account manager. The account manager can arrange to have the plugin activated on your organization's production and sub-production instances, generally within a few days.

If you do not have an account manager, decide to delay activation after purchase, or want to evaluate the product on a sub-production instance without charge, follow these steps.

1. From your instance, navigate to System Definition > Plugins.
2. On the All Applications page, click Request Plugin to open the request form on HI.
3. On HI, select to be redirected to the HI Service Portal Service Catalog.
4. On the Activate Plugin request form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target Instance</td>
<td>Instance on which to activate the plugin.</td>
</tr>
<tr>
<td>Plugin Name</td>
<td>Name of the plugin to activate.</td>
</tr>
<tr>
<td>Specify the date and time you would like this plugin to be enabled</td>
<td>Date and time must be at least two business days from the current time.</td>
</tr>
<tr>
<td>Reason/Comments</td>
<td>Information that would be helpful for the ServiceNow personnel who are activating the plugin. For example, if you need the plugin activated at a specific time instead of during one of the default activation windows, specify it in the comments.</td>
</tr>
</tbody>
</table>

5. Click Submit.

Day 1 setup guide for Amazon Web Services on Cloud Management

To set up Cloud Management for the very first time, you perform the procedures in this "Day 1" setup guide. Be sure to perform the procedures in order. After you have performed Day 1 setup, you can perform optional Day 2 setup and configuration procedures as needed and in any order. Detailed instructions for each procedure follow this overview.

Request the Cloud Management application

The Cloud Management application is available as a separate subscription and requires the Cloud Management plugin (com.snc.cloud.mgmt). See Request the Cloud Management application.

Roles required to set up Cloud Management

- Operations in the AWS Management Console require the administrator role.
- Operations in Cloud Management require the sn_cmp.cloud_admin role.
About terms that Cloud Management uses

Cloud providers often use proprietary names for account and credential settings. Because the Cloud Management application supports several cloud providers, Cloud Management uses general-purpose names for the settings. In AWS, the region-specific containers for virtual resources are called regions. In Cloud Management, regions are called datacenters or logical datacenters (LDCs). The term “logical” is used to reinforce the idea that Cloud Management is provider-agnostic. All infrastructure or applications that are deployed using Cloud Management are associated with a datacenter.

Quick overview of the setup process

Your setup process includes these tasks:

- If needed: Request the Cloud Management application.
- Assign appropriate roles to cloud users.
- Set up the MID Servers that will handle secure communications with the provider API endpoints.
- On the provider portal, collect your account settings and the credentials that the Discovery process will use (through a MID Server) to programmatically access your provider accounts. Securely associate the account settings and credentials with a service account in Cloud Management.
- Set up a cloud account to represent your entire managed cloud infrastructure and set up a service account that works with one of your provider accounts. You specify which datacenters in the service account should be included in the cloud account. (Later, on “Day 2”, you can set up additional cloud accounts and service accounts from the same or other providers.)
- Cloud Management uses CMDB data to help users request and manage cloud resources and to help you manage your cloud infrastructure. To populate the CMDB with resource data for all datacenters, you manually run the Discovery process on each datacenter in the service account. Then, to ensure that the data continues to be updated, you configure Discovery to run on a regular schedule. Your cloud account might look like this:

![Cloud Account Diagram]

- Providers offer services that can auto-update the CMDB whenever a create/modify/terminate life-cycle change or configuration update occurs to a resource. You can configure the service to integrate directly with Cloud Management.
What you will do to integrate Cloud Management with your AWS accounts

Detailed instructions for each procedure follow this overview.

1. Assign roles to AWS users of Cloud Management

You assign Cloud Management roles to user groups and to individual users based on user activities and responsibilities.

2. Set up MID Servers to connect Cloud Management to an AWS account

To ensure secure and reliable communications, the Discovery process communicates with your cloud provider accounts and cloud resources through one or more MID Servers. You can set up the MID Servers on your network or in one of your cloud networks. You can configure the MID Server for Cloud Management to use a proxy server. Using a proxy server supports all cloud-based activities such as running Discovery, billing downloads, provisioning virtual machines, and running life-cycle operations on virtual machines.

**Note:** Data is encrypted to the MID Server and between the MID Server and the API endpoint. To ensure high performance and security, you should configure one or more MID Servers for each datacenter under management. Configure the MID Servers even if you have already configured other MID Servers while setting up Cloud Management for another cloud provider.

3. Create the credentials that enable Cloud Management to access your AWS data

To securely access data on your provider account, the Discovery process must present appropriate credentials. To make the credentials available to Discovery, you first create a programmatic user in the AWS Management Console. You then securely store the credentials in a service account in your instance.

4. Create AWS GovCloud (US) credentials for Cloud Management

**Note:** Skip this procedure if your organization does not use AWS GovCloud (US).

To securely access data on your provider account, the Discovery process must present appropriate credentials. An AWS GovCloud (US) region is an isolated AWS region that meets stringent US government security and compliance requirements to host sensitive workloads. Cloud Management supports all AWS GovCloud (US) services.

5. Create a service account for AWS GovCloud (US)

**Note:** Skip this procedure if your organization does not use AWS GovCloud (US).

If your organization uses AWS GovCloud (US) regions, you create a service account for each region.

6. Set up a cloud account and service account for AWS

A service account is a secure record on your instance that stores the credential and access information for your provider account. Discovery uses the information to access your provider account to get data on each resource in each specified datacenter. A cloud account is the logical representation in Cloud Management of all or part of your managed cloud infrastructure. A cloud account can include multiple service accounts — even service accounts from different providers. For each service account, you specify which datacenters to include in the cloud account.

7. Set up AWS event processing for Discovery and Service Mapping
To integrate AWS events, configure a topic and enable event tracking in AWS.

8. Define the schedule for downloading AWS billing data

Define the scheduled job that regularly uses a MID Server to download billing data from the provider. Cloud Management saves the data in a cost table and uses the information to generate reports.

Next steps

When you have finished all Day-1 and Day-2 procedures in this setup guide, see the Cloud Management administration guide for information on using the Cloud Management application in your organization.

Assign roles to AWS users of Cloud Management

You assign Cloud Management roles to user groups and to individual users based on user activities and responsibilities.

Role required: user_admin or admin

Assign the following roles to groups and users as appropriate:

<table>
<thead>
<tr>
<th>Descriptive name and role name</th>
<th>Description and tasks</th>
<th>Access rights in Cloud Management</th>
</tr>
</thead>
<tbody>
<tr>
<td>Root administrator [sn_cmp.cmp_root_admin]</td>
<td>Highest level of application access for Cloud Management.</td>
<td>All</td>
</tr>
<tr>
<td>Cloud administrator [sn_cmp.cloud_admin]</td>
<td>Configures the Cloud Management application and sets up the cloud infrastructure.</td>
<td>Cloud infrastructure: Service accounts and cloud account</td>
</tr>
<tr>

### Set up MID Servers to connect Cloud Management to an AWS account

To ensure secure and reliable communications, the Discovery process communicates with your cloud provider accounts and cloud resources through one or more MID Servers. You can set up the MID Servers on your network or in one of your cloud networks.

Role required: admin or sn_cmp.cloud_admin

- Data is encrypted to the MID Server and between the MID Server and the API endpoint. To ensure high performance and security, you should configure one or more MID Servers for each datacenter under management. Configure the MID Servers even if you have already configured other MID Servers while setting up Cloud Management for another cloud provider.
- Internal network connection between the MID Servers and the AWS Cloud API endpoints: *.amazonaws.com
- You can configure the MID Server for Cloud Management to use a proxy server. See Using a proxy server for your MID Server.

1. You configure the connection to a MID Server in the same way as for any other applications that use MID Servers, like Discovery and Service Mapping. See MID Server for instructions on setting up and configuring MID Servers.
Note: Do not configure the MID Server Application related list.

2. Add the **Cloud Management** and **AWS** capabilities to the MID Server. See [Configure MID Server capabilities](#) for instructions. Alternatively, you can add the **ALL** capability, which includes the **Cloud Management** and the **AWS** capabilities.

Assuming member roles with an AWS API
The MID Server can call an AWS API and use the permanent credentials of an AWS master account (organization) to assume the role of one or more member accounts. By assuming the role, the MID Server receives temporary credentials for the member accounts generated by AWS for that role.

Assuming member account roles in a large AWS organization is more convenient and offers better security than using large numbers of permanent credentials for all member accounts. Temporary credentials are only acquired on behalf of a member account when there is no permanent credential specified for that member account in the Service Accounts (cmdb_ci_cloud_service_account) table.

AWS temporary credentials are used by Cloud Discovery to eliminate the need to manage AWS account credentials on your instance. For information on how to configure the MID Server to use these credentials, see [Assume an AWS role for temporary cloud Discovery credentials](#).

The MID Server uses the **AssumeRole** action in the **AWS Security Token Service API** to assume a member account role. Parameters passed to this API determine what additional security restrictions are applied to the role when it accesses AWS resources.

**Default member role configuration**
By default, the MID Server is configured to assume the **OrganizationAccountAccessRole**, which grants temporary credentials to all the members of a master account. This action occurs automatically if no permanent credentials exist for the member accounts. This configuration does not apply any additional security or restrict access to any resources in member accounts.

**Advanced member role configuration**
You can improve security by defining additional roles that a MID Server can assume.

Create records in the Cloud Management **AWS Org Assume Role Parameters** module that specify the roles and restrictions that apply. Records in the Cloud Service Account AWS Org Assume Role Params (cloud_service_account_aws_org_assume_role_params) table pass their parameters to the AWS Security Token Service API, which then provides the appropriate credentials and permissions to the MID Server.

**Note:** By default, temporary credentials for member accounts are cached for 60 minutes. For the MID Server properties used to control credential caching, see [Caching of temporary credentials](#).

Configure a custom AWS member role
Customize the AWS roles that a MID Server can assume to receive temporary credentials for member accounts. You can configure additional parameters to improve security and customize the way that the member account’s role is assumed when discovering cloud resources.

Role required: admin
Values that you enter in the Cloud Service Account AWS Org Assume Role Params (cloud_service_account_aws_org_assume_role_params) table are passed as parameters to the AWS AssumeRole API for the named service account.

1. Navigate to **Cloud Management > Organization Access Parameters > AWS Org Assume Role Parameters**.

2. Click **New** and then complete the form using these parameters:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access role name</td>
<td>Name of the AWS role in the member account which is used by the master account to acquire temporary credentials. <strong>Default</strong>: OrganizationAccountAccessRole</td>
</tr>
<tr>
<td>Role session name</td>
<td>Name for the session using the temporary security credentials that may help in distinguishing use of a role by a principal or purpose. This session name is visible in the AWS Cloud Trail logs. See <a href="#">Cloud API Trail</a> and the <a href="#">AWS documentation</a> on AWS Cloud Trail for details. <strong>Default</strong>: master_account_id__&lt;master account ID number&gt; An example of this is: master_account_id__321003876149.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| Credential TTL in seconds | Time in seconds for the temporary security credentials to live. **Default**: Calculated as follows:  
1. Retrieve the value in the `mid.aws.sts.assume_role.credential_ttl_minutes` **MID Server property**.  
2. Constrain this value to be between 15 and 720 minutes. If the setting in the property is less than 15 minutes, the system enters 15 minutes. If the setting is greater than 720 minutes, the system enters 720 minutes.  
3. Convert the resulting value into seconds. |
| External ID | Unique identifier that might be required by the trust policy of the role being assumed. **Default**: `ServiceNow_MID_Server` |
| Session policy | IAM policy in JSON format that further restricts the permissions of the temporary security credentials beyond the role configured policy. (JSON in AWS policy language.) **Default**: Blank |
| MFA (multifactor authentication) | Serial number of the Multi-Factor Authentication (MFA) device (hardware or virtual) used to authenticate the master account. **Default**: Blank |
| MFA token code | Token code supplied by the MFA device (hardware or virtual) used to authenticate the master account. **Default**: Blank |
| Cloud service account | Required. Service account to associate with the access parameters that you pass to the AWS AssumeRole API. Enter an account ID, either a master account or a member account, from the Service Accounts (cmdb_ci_cloud_service_account) table. |

**Note:** For information on how the parameters are used and what they mean, see the [AWS documentation](https://aws.amazon.com) on the AWS Security Token Service API for the AssumeRole action.

**Using a proxy server for your MID Server**
You can configure the MID Server for Cloud Management to use a proxy server. Using a proxy server supports all cloud-based activities such as running Discovery, billing downloads, provisioning virtual machines, and running life-cycle operations on virtual machines.

**Proxy server limitations**
- Windows or Linux platforms only are supported.  
- The Google Cloud Console integration does not support downloading billing data.  
- VMware is not supported.  
- Remote PowerShell scripts cannot be executed.  
- Custom APIs may not work.
### Supported proxy server configurations for Cloud Management

Create AWS GovCloud (US) credentials for Cloud Management

Skip this procedure if your organization does not use AWS GovCloud (US). To securely access data on your provider account, the Discovery process must present appropriate credentials. An AWS GovCloud (US) region is an isolated AWS region that meets stringent US government security and compliance requirements to host sensitive workloads. Cloud Management supports all AWS GovCloud (US) services.

Note: Skip this procedure if your organization does not use AWS GovCloud (US).

- role required: sn_cmp.cloud_admin
- AWS GovCloud (US) access key ID and the secret access key that you generated on the AWS Management Console.

Cloud Management accesses GovCloud regions using a set of credentials for each region. To configure Cloud Management to support a GovCloud region, you create one standard AWS account for each region (required for billing), obtain the credentials for the account, and then create a service account for the region. For more information on billing, see the ‘AWS GovCloud (US) Billing and Payment’ page on AWS documentation.

1. On the AWS Management Console, enter IAM in the AWS services search box to open the Identity and Access Managements (IAM) service.
2. On the IAM Resources portal, click Users.
3. Create the Discovery user that will have programmatic access to your AWS GovCloud (US) resource and billing data. Click Add user. On the Details page, configure the user settings, and then click Next.

<table>
<thead>
<tr>
<th>User name</th>
<th>Name for the programmatic user, for example, servicenowcloud.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access type</td>
<td>Select Programmatic access.</td>
</tr>
</tbody>
</table>

4. On the Permissions page, you attach the user to a policy. Configure the following settings and then click Next.

| Set permissions for <username> | Select Attach existing policies directly. |
5. On the Review page, verify your selections and then click Create user.

6. On the Complete page, perform two steps:

   - **Note:** Do not leave the page until you have completed both steps. The Secret access key value will not appear again. You will paste the values that you generate in these steps into a Cloud Management form.

   1. Click **Show** to display the Secret access key. Copy the value.
   2. Click **Download .csv** to save the CSV-format file that contains the user name, Access key ID, and the Secret access key value. You create the file as a backup in the case that you lose the values. Verify that the file was created and then store the file securely.

7. On your instance, navigate to **Orchestration > Credentials & Connections > Credentials**.

8. Click **New**, select **AWS Credentials**, enter a unique and meaningful **Name** (for example, **AWS GovCloud Creds 01**), and then fill in the form.

<table>
<thead>
<tr>
<th>AWS Credentials form fields</th>
<th>Input value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td>Enter a unique and descriptive name for the AWS credentials.</td>
</tr>
<tr>
<td><strong>Active</strong></td>
<td>Select the check box to use the credential.</td>
</tr>
<tr>
<td><strong>Access Key ID</strong></td>
<td>Enter the <strong>Access key ID</strong> that you generated on the AWS Management Console, such as: <strong>APIAIOSFODNN7EXAMPLE</strong>.</td>
</tr>
<tr>
<td><strong>Secret Access Key</strong></td>
<td>Enter the <strong>Secret access key</strong> that you generated on the AWS Management Console, such as: <strong>wPalrXUtHFEH/K7MDENG/bPxRfICYEXAMPLEKEY</strong>.</td>
</tr>
</tbody>
</table>

9. Click **Submit**.

   The instance records the credentials. Next, you **Create a service account for AWS GovCloud (US)**.
Create a service account for AWS GovCloud (US)
If your organization uses AWS GovCloud (US) regions, you create a service account for each region. Skip this procedure if your organization does not use AWS GovCloud (US).

**Note:** Skip this procedure if your organization does not use AWS GovCloud (US).

- Role required: sn_cmp.cloud_admin
- AWS GovCloud (US) credentials for each GovCloud region.
- AWS GovCloud (US) account ID (from the AWS Management Console).

A service account holds the credential and account information that you created in your provider account. Discovery uses the information to access your provider account and then obtain information on each logical datacenter that is associated with the account.

1. Navigate to **Cloud Management > Service Accounts**.
2. Click **New**, enter a unique and descriptive name for the account (for example, **AWS GovCloud SA O1**) and then fill in the Cloud Service Account form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Account ID</td>
<td>Account ID to which this credential belongs.</td>
</tr>
<tr>
<td>Discovery credentials</td>
<td>Select the name of the credentials that you created in the Create AWS GovCloud (US) credentials for Cloud Management procedure. In the example, you used the name AWS GovCloud Creds O1.</td>
</tr>
<tr>
<td>Datacenter URL</td>
<td>URL of the datacenter.</td>
</tr>
<tr>
<td>Datacenter type</td>
<td>Select the CMDB table that represents the type of datacenter.</td>
</tr>
<tr>
<td>Datacenter discovery status</td>
<td>Auto-generated value; Status and timestamp of the last execution of Discovery on the datacenter.</td>
</tr>
</tbody>
</table>

3. Click **Update** or **Submit**.
   The system creates the service account and displays the list of all discovered datacenters.

Repeat the process to create additional cloud accounts as needed. Run Discovery and set capacity limits for each datacenter.

Create the credentials that enable Cloud Management to access your AWS data
To securely access data on your provider account, the Discovery process must present appropriate credentials. To make the credentials available to Discovery, you first create a programmatic user in the AWS Management Console. You then securely store the credentials in a service account in your instance.

Roles required:
- AWS Management Console administrator
- Cloud Management: admin or sn_cmp.cloud_admin

Cloud providers often use proprietary names for account and credential settings. Because the Cloud Management application supports several cloud providers, Cloud Management uses general-purpose names for the settings.

1. On the AWS Management Console, enter **IAM** in the **AWS services** search box to open the Identity and Access Managements (IAM) service.
2. On the IAM Resources portal, click **Users**.

3. Create the Discovery user that will have programmatic access to your AWS resource and billing data. Click **Add user**. On the Details page, configure the user settings, and then click **Next**.

<table>
<thead>
<tr>
<th>User name</th>
<th>Name for the programmatic user, for example, servicenowcloud.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access type</td>
<td>Select <strong>Programmatic access</strong>.</td>
</tr>
</tbody>
</table>

4. On the Permissions page, you attach the user to a policy. Configure the following settings and then click **Next**.

<table>
<thead>
<tr>
<th>Set permissions for &lt;username&gt;</th>
<th>Select <strong>Attach existing policies directly</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attach one or more policies</td>
<td>Select the appropriate policy.</td>
</tr>
</tbody>
</table>

   **Note:** The **AdministratorAccess** policy has the most powerful permission level, including permission to provision cloud resources. The policy enables the same access that would be granted to the instance if you were not using IAM and used your AWS account Access Key ID and Secret Access Key. You might instead prefer to create a policy or combine multiple policies to grant the appropriate permission level. See [Create an IAM user policy for Cloud Management](#) for details.

5. On the Review page, verify your selections and then click **Create user**.

6. On the Complete page, perform two steps:

   **Note:** Do not leave the page until you have completed both steps. The **Secret access key** value will not appear again. You will paste the values that you generate in these steps into a Cloud Management form.

   1. Click **Show** to display the Secret access key. Copy the value.
   2. Click **Download .csv** to save the CSV-format file that contains the user name, Access key ID, and the Secret access key value. You create the file as a backup in the case that you lose the values. Verify that the file was created and then store the file securely.

7. On your instance, navigate to **Orchestration > Credentials & Connections > Credentials**.

8. Click **New**, select **AWS Credentials**, enter a unique and meaningful **Name** (for example, Cloud Management Account), and then fill in the form.

   **AWS Credentials form fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Input value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a unique and descriptive name for the AWS credentials.</td>
</tr>
<tr>
<td>Active</td>
<td>Select the check box to use the credential.</td>
</tr>
<tr>
<td>Field</td>
<td>Input value</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Access Key ID</td>
<td>Enter the <strong>Access key ID</strong> that you generated on the AWS Management Console, such as: APIAIOSFODNN7EXMPLE.</td>
</tr>
<tr>
<td>Secret Access Key</td>
<td>Enter the <strong>Secret access key</strong> that you generated on the AWS Management Console, such as: wPairXUtFEMI/K7MDENG/bPxRfICYEXMEMEKEY.</td>
</tr>
</tbody>
</table>

9. Click **Update** or **Submit**.

Create an IAM user policy for Cloud Management
If you are using IAM to manage users in AWS, you must create a user profile in IAM that Discovery uses to access AWS data.

Familiarize yourself with the [AWS documentation](#) on IAM. You must know how to create an IAM user and set up a user policy.

1. Log in to the AWS Management Console and create a new user in IAM.
   The access key must be auto-generated. You need the key when you configure AWS credentials in the instance.
2. Save the Access Key ID and Secret Access Key.
3. Open the user record in the instance for appropriate user.
4. Define a user policy in AWS using either of the following methods:
   - Grant Administrator Access to the instance, which is essentially the same access that would be granted to the instance if you were not using IAM and used your AWS account Access Key ID and Secret Access Key. Attach the **AdministratorAccess** policy to the user profile.
     
     **Note:** To create a user policy that supports only Discovery rather than the provisioning of cloud resources, attach the **ReadOnlyAccess** policy instead.
   - Create a custom policy with a descriptive name and the following code in the Policy Document field in the user policy:

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Action": "cloudfront:*",
    "Effect": "Allow",
    "Resource": "*"
  }, {
    "Action": "s3:*",
    "Effect": "Allow",
    "Resource": "arn:aws:s3:::*"
  }, {
    "Action": "elasticloadbalancing:*",
    "Effect": "Allow",
    "Resource": "*"
  }, {
    "Action": "sqs:*",
    "Effect": "Allow",
    "Resource": "*"
  }, {
    "Action": "rds:*",
    "Effect": "Allow",
    "Resource": "*"
  }]
```
},
{ "Action": "sns:*",
  "Effect": "Allow",
  "Resource": "*"
},
{ "Action": "ec2:*",
  "Effect": "Allow",
  "Resource": "*"
},
{ "Action": "cloudformation:*",
  "Effect": "Allow",
  "Resource": "*"
},
{ "Action": "directconnect:*",
  "Effect": "Allow",
  "Resource": "*"
},
{ "Action": "route53:*",
  "Effect": "Allow",
  "Resource": "arn:aws:route53:::*"
},
{ "Action": "dynamodb:*",
  "Effect": "Allow",
  "Resource": "*"
},
{ "Action": "apigateway:*",
  "Effect": "Allow",
  "Resource": "*"
},
{ "Action": "lambda:*",
  "Effect": "Allow",
  "Resource": "*"
},

{ "Action": [ "iam:DeleteServerCertificate",
              "iam:GetServerCertificate",
              "iam:ListServerCertificates",
              "iam:UpdateServerCertificate",
              "iam:UploadServerCertificate" ],
  "Effect": "Allow",
  "Resource": "arn:aws:iam::*:server-certificate/*"
},

{ "Action": [ "rds:DescribeDBInstances"
              ],
  "Effect": "Allow",
  "Resource": "*"
},

{ "Action": [ "elasticloadbalancing:DescribeLoadBalancers"
              ],
  "Effect": "Allow",
  "Resource": "*"
},

{ "Action": [ "dynamodb:ListTables"
              ],
  "Effect": "Allow",
  "Resource": "*"
},

{ "Action": [ "lambda:ListFunctions"
              ],
  "Effect": "Allow",
  "Resource": "*" }
Set up a cloud account and service account for AWS

A service account is a secure record on your instance that stores the credential and access information for your provider account. Discovery uses the information to access your provider account to get data on each resource in each specified datacenter. A cloud account is the logical representation in Cloud Management of all or part of your managed cloud infrastructure. A cloud account can include multiple service accounts — even service accounts from different providers. For each service account, you specify which datacenters to include in the cloud account.

- Operations in the AWS Management Console require the administrator role.
- Operations in Cloud Management require the sn_cmp.cloud_admin role.

When you finish the Day-1 setup process, your cloud account might look like this:

```json
{
    "Action": [ "apigateway:List*", "*" ],
    "Effect": "Allow",
    "Resource": "*"
}
{
    "Effect": "Allow",
    "Resource": "*"
}
}```

2. Select or create the cloud account:
   - Select an existing cloud account:
     1. On the Cloud Account page, click **Configure**.
     2. On the General Information page, click **Next** and then continue with the next step.
   - Create a cloud account:
     1. On the General Information page, click **New** and then enter a unique and meaningful **Name** and **Description** for the cloud account.
     2. Select the provider.
     3. Click **Next** and then continue with the next step.

3. On the Datacenters page, create a Service Account: Click the + next to the **Service Account** field, enter a unique and meaningful **Name** for the service account and then fill in the form.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Account ID</td>
<td>12-digit IAM user account number. Expand the list under the AWS account name on the AWS Management Console to view the number. <strong>Note:</strong> In the <strong>Account ID</strong> field, remove the dash characters from the number.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| Discovery credentials        | • Select the name of the credentials that you created in the Create the credentials that enable Cloud Management to access your AWS data procedure. In the example, you used the name AWS Main Account.  
  • Leave the field blank if the account is a member account of an AWS Organization and you have configured the associated master account with a credential.       |
| Datacenter URL               | Required only for AWS GovCloud (US) accounts: Full URL of the datacenter, for example: https://<IP-of-center>/sdk.                                                                                             |
| Datacenter type              | Select AWS datacenter.                                                                                                                                                                                      |
| Datacenter discovery status  | Auto-generated value: Status and timestamp of the last execution of Discovery on the datacenter.                                                                                                            |
| Parent account               | Appears when you select AWS datacenter.  
  • Select the AWS master account that represents the Organization in AWS that this member account belongs to.  
  • Leave the field empty if this account is not part of an AWS Organization.                                                                                                                                   |
| Is master account            | Appears when you select AWS datacenter.  
  • Clear the check box if the account is not the Organization account.  
  • Select the check box to associate the AWS service account with the master account. The master account corresponds to the Organization in AWS. You can identify any service account in your instance as a master account only if you already configured the account in AWS as an Organization and you already associated other accounts under the Organization. See the AWS documentation for information on Organizations. |
| Should pull events           | Enables Cloud Management to collect events from resource types in AWS LDCs in the `sn_cmp_cloud_event_list`.                                                                                               |

4. Click **Submit** to create the service account.  
5. Click **Discover Datacenters**.  
6. When the datacenters appear, select one or more datacenters to include in the cloud account and then click **Save**. The Cloud Account dashboard appears. The datacenters that you selected appear on the **Datacenters** tab.
7. Click a datacenter.
   The following lists appear:
   - **Resources**: Cloud resources for the current datacenter. Run Discovery to populate the
     CMDB for the datacenter and populate the tab. See [Discover all datacenters in a service
     account on-demand](#).
   - **Capacity Limits**: Limits on virtual CPUs, virtual networks, storage volume size, and other
     services. See [Set capacity limits on user requests for resources](#).
   - **Discovery Log**: The process creates a log record for each action associated with a
     discovery status.

After you complete all procedures in this initial ‘Day 1’ setup, you can create additional cloud
accounts and service accounts to organize and compartmentalize your cloud infrastructure.

**Configure the Amazon AWS Config service to auto-update the CMDB**

Integrate AWS Config with a Now Platform instance to receive near real-time Simple Notification
Service (SNS) notifications from AWS. To process AWS events, you must configure AWS Config and
SNS on the Amazon console. The AWS Config service can auto-update CI data in the CMDB
whenever Cloud Management or your AWS account makes a life-cycle state or configuration
change to an Amazon resource. As a result, the CI data in the CMDB is updated without having to
wait for Discovery to run.

- **Role required**: For Cloud Management: sn_cmp.cloud_event_integration. For Discovery:
  discovery_admin.
- You need an account with Amazon subscriptions (service accounts) and associated logical
datacenters.
- The AWS Config role should have access to the SNS and AWS Config Service, and the resource
types you are recording configuration changes for.
- If authentication to cloud event endpoint is required, assign a user with the
  sn_cmp.cloud_event_integration role. This role is required to set up an Alert Rule in the
  instance.

When AWS Config sends an update, the instance processes the event and creates or updates the
CI entry in the CMDB and the CI information in the Cloud User Portal. Each event is saved as a
record in the Cloud Event (sn_cmp_cloud_event) table.

Many of the steps in the topic are performed in the AWS portal. If you want to review the AWS
documentation, see the following:

- [Set Up Amazon SNS Notifications](#)
- [Viewing the AWS Config dashboard](#)

1. Log in to your AWS account.
2. On the **Services** page, navigate to **AWS Services > Find Services > Simple Notification Service**.
3. Create a topic (the communications channel used to send messages and subscribe to
   notifications). On the **SNS dashboard**, click **Topics**.
   1. Click **Create new topic**.
   2. Enter the **Name** and **Display name - optional** for the topic and then click **Create topic**.
4. Create one or more subscriptions to the topic. Subscriptions subscribe endpoints to the topic
to receive messages that AWS Config publishes to the topic.
   1. On the **Topic Details** page, click **Create subscription** and then specify the following
      values:
### Protocol

For the subscription that auto-update the CMDB, specify **HTTPS**.

**Note:** When you have created the HTTPS subscription, you can create a separate subscription that sends email to a specified person.

<table>
<thead>
<tr>
<th>Endpoint</th>
<th>URL of the instance plus additional information in the following format:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><code>https://&lt;username&gt;:&lt;user_password&gt;@&lt;instance_URL&gt;/api/now/cloud_event</code></td>
</tr>
</tbody>
</table>

**Example:**

```
https://abeltuter:123456@myinstance.service-now.com/api/now/cloud_event
```

2. Click **Create subscription**. Repeat the process to create as many subscriptions as needed.

5. On the **Services** page, navigate to **Config > Settings**.

6. On the **Settings** page, click **Turn on** to turn on recording.

This setting records the updates that happen to resources.

7. In the **Resource types to record** section: As needed, select **Record all resources supported in this region** or **Include global resources** (specify only the resource types for which CI classes exist in the system).

**Note:** Any configuration changes on the resources you have selected in the **Resource types to record** section, is considered an event and auto-updated to the CMDB.

8. Optional: To set a value other than the default data retention period, specify a period using the **Set a custom Data retention period for configuration items recorded by AWS Config** check box.

9. In the **Amazon S3 Bucket** section, **Create a bucket** or **Choose a bucket from your account** and choose the appropriate bucket from the **Bucket name** list.

10. In the **Amazon SNS topic** section, select **Stream configuration changes and notifications to an Amazon SNS topic** and then select **Choose a topic from your account**.

11. Select the **Topic name** from the list. AWS Config sends the updates to the topic.

12. In the **AWS Config role** section, select **Choose a role from your account**.

   a) Select a role, from the **Role name** list.

13. Click **Save**.

**Note:** If you have any trouble navigating the AWS interface, see Amazon documentation: [Selecting Which Resources AWS Config Records](#).

You have configured the AWS services to auto-update the CMDB.

After some events are generated, navigate to the **Cloud User Portal** to view the events.
Define the schedule for downloading AWS billing data

Define the scheduled job that regularly uses a MID Server to download billing data from the provider. Cloud Management saves the data in a cost table and uses the information to generate reports.

Role required: sn_cmp.cloud.governor

Prepare the following items before you begin:

- Set up a payer account that gets billing information for all linked accounts.
- Create the Amazon S3 bucket that is the data storage area for the daily detailed billing records on the AWS account. The credential that is used to access the report must have permissions to the S3 bucket. You must set the S3 bucket based on the Order location. The AssumeRole policies MUST include an S3 access policy. You might assume that the AWS account that you always use can create an S3 bucket in the region where the CFT is being provisioned. If you use STS-based authentication, however, the AWS account might not be able to create the bucket because authentication is tied to the AssumeRole policies. See the "Setting Up an Amazon S3 Bucket for AWS Cost and Usage Reports" page on the AWS documentation for details.
- Enable detailed billing reports on AWS. See the AWS documentation for details.

This procedure involves two tasks:

1. Fill in the AWS Billing Schedule form with information that you copy from the AWS portal. This action enables the instance to download AWS billing data.
2. Specify the schedule for downloading AWS billing information.

1. In the Cloud Admin Portal, navigate to Analyze > Billing.
2. On the Billing Schedules tab, click New, enter a unique and meaningful Name, and then fill in the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Provider</td>
<td>Select AWS.</td>
</tr>
<tr>
<td>Service Account</td>
<td>The AWS service account that you created during initial setup. (The AWS account to run the billing report on.)</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Bucket</td>
<td>Data storage area for the daily billing records on the AWS account. Follow this procedure to obtain the value:</td>
</tr>
<tr>
<td></td>
<td>1. Log in to the AWS Management Console and select My Billing Dashboard in the menu.</td>
</tr>
<tr>
<td></td>
<td>2. Select Reports.</td>
</tr>
<tr>
<td></td>
<td>3. Copy the value from the S3 bucket column into the Bucket field on the form.</td>
</tr>
<tr>
<td>Active</td>
<td>Select the check box to activate the download job.</td>
</tr>
<tr>
<td>Run</td>
<td>Frequency that the download job should run.</td>
</tr>
<tr>
<td>Time</td>
<td>Time of day that the download job should run.</td>
</tr>
</tbody>
</table>

3. Click **Save**. To run the schedule on demand, click **Execute Now**. On the Retrieve Billing Data window that appears, select a date range and then click **Download**.

*View cloud costs on the Billing dashboard*

Optional: Configure the download size of AWS billing data

A single set of cloud billing data can be large. The MID Server, therefore, sends the data to the ECC queue in manageable chunks. You can configure a system property to limit the size of each chunk to avoid performance issues caused by large data transfers.

Role required: admin

1. Open the System properties table by entering `sys_properties.list` in the application filter.
2. Filter the list to open the `sn_cmp.billing.page_size` property.
The default value is 3 MB.
3. Modify the value as needed. The maximum is 5 MB.
4. Save the property.

(Optional) Add an AWS service account to the cloud account

During Cloud Management Day 1 setup, you added one service account to the cloud account. To compartmentalize your infrastructure or to include different datacenters, you can add another service account. A particular datacenter, however, cannot be selected in more than one service account in a cloud account.

Role required: sn_cmp.cloud_admin

A service account is a secure record on your instance that stores the credential and access information for your provider account. Discovery uses the information to access your provider account to get data on each resource in each specified datacenter.

In this example, you added the service account named **ProviderB-ServiceAccount-1** and selected three datacenters to include in the cloud account:
**Note:** In a cloud account, you cannot select a particular datacenter in two different service accounts.

1. Navigate to **Cloud Management > Service Accounts**.
2. Click **New**, enter a unique and meaningful **Name**, and then fill in the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Account ID</strong></td>
<td>12-digit IAM user account number. Expand the list under the AWS account name on the AWS Management Console to view the number.</td>
</tr>
</tbody>
</table>

**Note:** In the **Account ID** field, remove the dash characters from the number.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| Discovery credentials | - Select the name of the credentials that you created in the [Create the credentials that enable Cloud Management to access your AWS data](https://servicecloud.com) procedure. In the example, you used the name **AWS Main Account**.  
  - Leave the field blank if the account is a member account of an AWS Organization and you have configured the associated master account with a credential. |
| Datacenter URL        | Required only for AWS GovCloud (US) accounts: Full URL of the datacenter, for example: `https://<IP-of-center>/sdk`.                                                                                       |
| Datacenter type       | Select **AWS datacenter**.                                                                                                                                                                                  |
| Datacenter discovery status | Auto-generated value: Status and timestamp of the last execution of Discovery on the datacenter.                                                                                                   |
| Parent account        | Appears when you select **AWS datacenter**.  
  - Select the AWS master account that represents the Organization in AWS that this member account belongs to.  
  - Leave the field empty if this account is not part of an AWS Organization. |
| Is master account     | Appears when you select **AWS datacenter**.  
  - Clear the check box if the account is not the Organization account.  
  - Select the check box to associate the AWS service account with the master account. The master account corresponds to the Organization in AWS.  
  You can identify any service account in your instance as a master account only if you already configured the account in AWS as an Organization and you already associated other accounts under the Organization. See the [AWS documentation](https://aws.amazon.com) for information on Organizations. |
| Should pull events    | Enables Cloud Management to collect events from resource types in AWS LDCs in the `sn_cmp_cloud_event_list`.                                                                                         |

3. **Click Update** or **Submit**.  
The system creates the service account and displays the list of all discovered datacenters.  
4. Repeat the process to add as many service accounts as needed.
Day 1 setup guide for Azure on Cloud Management

To set up Cloud Management for the very first time, you perform the procedures in this "Day 1" setup guide. Be sure to perform the procedures in order. After you have performed Day 1 setup, you can perform optional Day 2 setup and configuration procedures as needed and in any order. Detailed instructions for each procedure follow this overview.

Request the Cloud Management application

The Cloud Management application is available as a separate subscription and requires the Cloud Management plugin (com.snc.cloud.mgmt). See Request the Cloud Management application.

Roles required to set up Cloud Management

- Operations on the Azure portal require the Active Directory administrator or Azure administrator role.
- Operations in Cloud Management require the sn_cmp.cloud_admin role.

About terms that Cloud Management uses

Cloud providers often use proprietary names for account and credential settings. Because the Cloud Management application supports several cloud providers, Cloud Management uses general-purpose names for the settings. In Azure, the region-specific containers for virtual resources are called regions. In Cloud Management, regions are called datacenters or logical datacenters (LDCs). The term "logical" is used to reinforce the idea that Cloud Management is provider-agnostic. All infrastructure or applications that are deployed using Cloud Management are associated with a datacenter.

Quick overview of the setup process

Your setup process includes these tasks:

- If needed: Request the Cloud Management application.
- Assign appropriate roles to cloud users.
- Set up the MID Servers that will handle secure communications with the provider API endpoints.
- On the provider portal, collect your account settings and the credentials that the Discovery process will use (through a MID Server) to programatically access your provider accounts. Securely associate the account settings and credentials with a service account in Cloud Management.
- Set up a cloud account to represent your entire managed cloud infrastructure and set up a service account that works with one of your provider accounts. You specify which datacenters in the service account should be included in the cloud account. (Later, on "Day 2", you can set up additional cloud accounts and service accounts from the same or other providers.)
- Cloud Management uses CMDB data to help users request and manage cloud resources and to help you manage your cloud infrastructure. To populate the CMDB with resource data for all datacenters, you manually run the Discovery process on each datacenter in the service account. Then, to ensure that the data continues to be updated, you configure Discovery to run on a regular schedule. Your cloud account might look like this:
Providers offer services that can auto-update the CMDB whenever a create/modify/terminate life-cycle change or configuration update occurs to a resource. You can configure the service to integrate directly with Cloud Management.

What you will do to integrate Cloud Management with your Azure accounts

Detailed instructions for each procedure follow this overview.

1. Assign roles to Azure users of Cloud Management

You assign Cloud Management roles to user groups and to individual users based on user activities and responsibilities.

2. Set up MID Servers to connect Cloud Management to an Azure account

To ensure secure and reliable communications, the Discovery process communicates with your cloud provider accounts and cloud resources through one or more MID Servers. You can set up the MID Servers on your network or in one of your cloud networks.

Note: Data is encrypted to the MID Server and between the MID Server and the API endpoint. To ensure high performance and security, you should configure one or more MID Servers for each datacenter under management. Configure the MID Servers even if you have already configured other MID Servers while setting up Cloud Management for another cloud provider.

3. Create an Azure service principal

To securely access resource and billing data on your Azure account, the Discovery process must present appropriate Azure account credentials. You create a special programmatic account — an Azure service principal — to generate the required credentials.

4. Store the Azure service principal credentials in the instance

To securely access data on your provider account, the Discovery process must present appropriate credentials. To make the credentials available to Discovery, you first create Azure service principal credentials in the Azure Portal. You then securely store the credentials in a service account in your instance.

5. Add an Azure service account
A service account is a secure record on your instance that stores the credential and access information for your provider account. Discovery uses the information to access your provider account to get data on each resource in each specified data center.

6. Discover all datacenters in a service account on-demand

Discovery uses the information in the service account to identify all logical datacenters associated with the provider account.

7. Set up a cloud account for Azure

A cloud account is the logical representation in Cloud Management of all or part of your managed cloud infrastructure. A cloud account can include multiple service accounts — even service accounts from different providers. For each service account, you specify which datacenters to include in the cloud account.

8. Set capacity limits on user requests for resources

Capacity limits place restrictions on the attributes of cloud resources such as the number of virtual machines, virtual CPUs, or aggregate storage. You can set limits on resources separately for each logical datacenter in a cloud account.

9. Configure the Azure Alert service to auto-update the CMDB

The Azure Alert service can auto-update CI data in the CMDB whenever Cloud Management or your Azure account makes a life-cycle state or configuration change to an Azure resource. As a result, the CI data in the CMDB is updated without having to wait for Discovery to run.

10. Define the schedule for downloading Azure billing data

Define the scheduled job that regularly uses a MID Server to download billing data from the provider. Cloud Management saves the data in a cost table and uses the information to generate reports.

Next steps

When you have finished all Day-1 and Day-2 procedures in this setup guide, see the Cloud Management administration guide for information on using the Cloud Management application in your organization.

Assign roles to Azure users of Cloud Management

You assign Cloud Management roles to user groups and to individual users based on user activities and responsibilities.

Role required: user_admin or admin

Assign the following roles to groups and users as appropriate:

<table>
<thead>
<tr>
<th>Descriptive name and role name</th>
<th>Description and tasks</th>
<th>Access rights in Cloud Management</th>
</tr>
</thead>
<tbody>
<tr>
<td>Root administrator [sn_cmp.cmp_root_admin]</td>
<td>Highest level of application access for Cloud Management.</td>
<td>All</td>
</tr>
<tr>
<td>Descriptive name and role name</td>
<td>Description and tasks</td>
<td>Access rights in Cloud Management</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-----------------------</td>
<td>----------------------------------</td>
</tr>
<tr>
<td><strong>Cloud administrator</strong> [sn_cmp.cloud_admin]</td>
<td>Configures the Cloud Management application and sets up the cloud infrastructure.</td>
<td>Cloud infrastructure: Service accounts and cloud account, Networks and IPAM, Settings for provider services that auto-update the CMDB: - AWS Config - Azure Alert - Google Stackdriver Logging - IBM Cloud Update - VMware Events</td>
</tr>
<tr>
<td><strong>Governor</strong> [sn_cmp.cloud_governor]</td>
<td>Monitors overall cloud usage and enforces compliance of the organization’s rules, quotas, and policies. Also manages tags and permissions to various objects.</td>
<td>Governance: - Policies - Pools - Quotas - Permissions</td>
</tr>
<tr>
<td><strong>Service Designer</strong> [sn_cmp.cloud_service_designer]</td>
<td>Creates blueprints, ARM and CloudFormation templates, and catalog items.</td>
<td>Cloud Service Design: - Cloud templates - Blueprints - Blueprint catalog items - Resource blocks</td>
</tr>
<tr>
<td><strong>Cloud user</strong> [sn_cmp.cloud_service_user]</td>
<td>Requests and manages stacks and resources.</td>
<td>Cloud User Portal When you assign the role to a group, all members of the group share quota limitations and ownership of certain resources.</td>
</tr>
<tr>
<td><strong>Cloud operator</strong> [sn_cmp.cloud_operator]</td>
<td>Monitors and troubleshoots the Cloud Management application.</td>
<td>Dashboards and reports: - Cloud Operations Dashboard - Cloud Root Cause Analysis - Cloud Orchestration Trail - Cloud API Trail</td>
</tr>
</tbody>
</table>
### Set up MID Servers to connect Cloud Management to an Azure account

To ensure secure and reliable communications, the Discovery process communicates with your cloud provider accounts and cloud resources through one or more MID Servers. You can set up the MID Servers on your network or in one of your cloud networks.

Role required: admin or sn_cmp.cloud_admin

- Data is encrypted to the MID Server and between the MID Server and the API endpoint. To ensure high performance and security, you should configure one or more MID Servers for each datacenter under management. Configure the MID Servers even if you have already configured other MID Servers while setting up Cloud Management for another cloud provider.
- Internal network connection between the MID Servers and the Azure Cloud API endpoints: management.azure.com
- You can configure the MID Server for Cloud Management to use a proxy server. See *Using a proxy server for your MID Server*.

You configure the connection to a MID Server in the same way as for any other applications that use MID Servers, like Discovery and Service Mapping. See *MID Server* for instructions on setting up and configuring MID Servers.

**Note:** Do not configure the MID Server Application related list.

### Using a proxy server for your MID Server

You can configure the MID Server for Cloud Management to use a proxy server. Using a proxy server supports all cloud-based activities such as running Discovery, billing downloads, provisioning virtual machines, and running life-cycle operations on virtual machines.

**Proxy server limitations**

- Windows or Linux platforms only are supported.
- The Google Cloud Console integration does not support downloading billing data.
- VMware is not supported.
- Remote PowerShell scripts cannot be executed.
- Custom APIs may not work.

Supported proxy server configurations for Cloud Management

<table>
<thead>
<tr>

Create an Azure service principal

To securely access resource and billing data on your Azure account, the Discovery process must present appropriate Azure account credentials. You create a special programmatic account — an Azure service principal — to generate the required credentials.

On the Azure Portal, the Active Directory administrator or Azure administrator role is required.

A service principal for Azure cloud services is analogous to a Microsoft Windows service account that enables Windows processes to communicate with each other within an Active Directory domain.

You will enter the service principal credential values to create a service account in Cloud Management.

Note: Cloud providers often use proprietary names for account and credential settings. Because the Cloud Management application supports several cloud providers, Cloud Management uses general-purpose names for the settings. To ensure that you paste the correct Azure values into the Cloud Management forms, you will temporarily store the Azure values in a text file and then paste the values into the Cloud Management forms.

The text file that you generate during this procedure might look something like this example:
1. Open a text editor, paste the following text into the editor, and then save the file as Azure-Credentials.txt.

<table>
<thead>
<tr>
<th>Azure label</th>
<th>ServiceNow label</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Directory ID</td>
<td>Tenant ID</td>
<td>bdcdd120-9979-491e-8683-d9a4550bdd</td>
</tr>
<tr>
<td>Application ID</td>
<td>Client ID</td>
<td>e6821ea9-e5c5-428a-b50c-7ea62993b2d</td>
</tr>
<tr>
<td>Application key</td>
<td>Secret key</td>
<td>d348050-f893ccb1</td>
</tr>
<tr>
<td>Subscription ID</td>
<td>Account ID</td>
<td>4803be48c3ee89-96d2-4fed-bedb-22e49013c16</td>
</tr>
</tbody>
</table>

2. Log in to the Azure portal and click Azure Active Directory.
3. In the Azure Active Directory blade, select Properties.
4. On the Properties blade, navigate to the Directory ID and then click the Copy to Clipboard ( ) button.
5. Paste the **Directory ID** value (the UUID) into the text file.  
   To complete the next step, you must have permission to create and register an application. If not, ask your Active Directory admin for help.

6. On the **Azure Active Directory** blade, click **App registrations** blade, click **+ Add** or **+ New application registration**, enter the following values, and then click **Create**.
Create

* Name

ServiceNow Integration

Application type

Web app / API

* Sign-on URL

http://www.myinstance.com
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Unique name for the application and its integration credentials. For example, ServiceNow Integration.</td>
</tr>
<tr>
<td>Application type</td>
<td>Select Web app / API.</td>
</tr>
<tr>
<td>Sign-on URL</td>
<td>URL that will access Azure data — the URL of the ServiceNow instance.</td>
</tr>
</tbody>
</table>

7. In the list, click the **DISPLAY NAME** of the new application.

![Image of Application Table]

- a) Point to the **Display Name** and then click the **Copy to Clipboard** button. Paste the **Display Name** into the text file.

- b) Point to the **Application ID** and then click the **Copy to Clipboard** button. Paste the **Application ID** into the text file.
8. In the navigation pane, under **API ACCESS**, click **Keys**.

9. Specify the following values, and then click **Save**.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>Unique description of the key.</td>
</tr>
<tr>
<td>Expires</td>
<td>Your organization may apply policies to restrict key durability. Select the appropriate duration.</td>
</tr>
</tbody>
</table>
The key is saved and the key value appears in the **VALUE** column.
10. Copy the key **VALUE** and paste the value into the text file as the **Application key** value.

**Note:** Do not leave the page until you have copy/pasted the key value. The value will not appear again.

11. Enable the service principal to assign policy to a resource group.
By default, an Azure service principal has the Contributor role. The Contributor role cannot assign policy to a resource group. Create a custom role using the Azure command-line interface, as follows:

a) A user with the Owner role or the User access admin role should run the following command. In the example, you create the Policy Assignment Operator role:

```
az role definition create --role-definition ' {
  "Name": "Policy Assignment Operator",
  "Description": "Lets you assign policy",
  "Actions": ["Microsoft.Authorization/policyAssignments/write",
               "Microsoft.Authorization/policyAssignments/delete",
               "Microsoft.Authorization/policyAssignments/read"],
  "AssignableScopes": ["/subscriptions/<Your-subscription-ID-here>"]
}'
```

b) Assign the Policy Assignment Operator role to the service principal.

If you do not have access to the command-line interface or cannot create a custom role, then another option to enable the service principal to assign policy is to assign the User access administrator role to the service principal. This option, however, is risky because the role has other powerful access.

12. To enable the service principal to work with multiple Azure subscriptions, you must perform the following procedure for each subscription:

a) In the Azure portal, navigate to Subscriptions.

b) Copy the Subscription ID and paste it into the text file.

c) Open the subscription, select Access Control (IAM) from the menu, and then click + Add. Specify the following values:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value to set</th>
</tr>
</thead>
<tbody>
<tr>
<td>Role</td>
<td>Contributor</td>
</tr>
<tr>
<td>Assign access to</td>
<td>Azure AD user, group, or application</td>
</tr>
</tbody>
</table>
Create a record of the service principal credentials on the ServiceNow instance so that Cloud Management processes can access Azure data. See Store the Azure service principal credentials in the instance.

**Store the Azure service principal credentials in the instance**

To securely access data on your provider account, the Discovery process must present appropriate credentials. To make the credentials available to Discovery, you first create Azure service principal credentials in the Azure Portal. You then securely store the credentials in a service account in your instance.

Role required:
- Azure Portal administrator
- Cloud Management: admin or sn_cmp.cloud_admin

1. Create an Azure service principal and open the text file that you created during the procedure.
2. In the Cloud Admin Portal, navigate to Manage > Credentials.
3. Click New and then select Azure Service Principal.
4. Specify the following values on the Azure Service Principal form:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the service principal to register with the instance. For example, Azure service principal credentials.</td>
</tr>
<tr>
<td>Authentication Method</td>
<td>Select <strong>Client Secret</strong>. The <strong>Secret key</strong> field appears when you select Client Secret.</td>
</tr>
</tbody>
</table>

5. Copy/paste values from the Azure-Credentials.txt text file into the remaining fields.
6. Select the appropriate **EA credential** from the list, select the **Active** check box, and then click **Save** to create the record.

7. Click the **Discover Subscriptions** related link to find all subscriptions that are associated with the Azure service principal.

   The instance creates a service account for each discovered subscription.

8. The **Azure Subscriptions** related list displays all subscriptions that are associated with the Azure service principal. Click a subscription to view the service account that was created for the subscription.

9. Click a discovery status entry in the **Credential Discovery Status** list to view the associated discovery log. Each time that you click **Discover Subscriptions**, the instance generates a new discovery status and lists the status in the **Credential Discovery Status** list.

### Add an Azure service account

During Cloud Management Day 1 setup, you added one service account to the cloud account. To compartmentalize your infrastructure or to include different datacenters, you can add another service account. A particular datacenter, however, cannot be selected in more than one service account in a cloud account.

**Role required:** sn_cmp.cloud_admin

1. Open the **Azure-Credentials.txt** text file that you created during the **Create an Azure service principal** procedure.

2. Navigate to **Cloud Management > Service Accounts**.

3. Click **New**, enter a unique and meaningful **Name**, and then fill in the form.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Account ID</td>
<td>Paste the Azure Subscription ID value that you copied from the Azure Portal into the text file.</td>
</tr>
<tr>
<td>Discovery credentials</td>
<td>Select the name of the credentials that you created in the Store the Azure service principal credentials in the instance procedure. In the example, you used the name Azure service principal credentials.</td>
</tr>
<tr>
<td>Datacenter URL</td>
<td>Leave this field blank.</td>
</tr>
<tr>
<td>Datacenter type</td>
<td>Select Azure Datacenter.</td>
</tr>
<tr>
<td>Datacenter discovery status</td>
<td>Auto-generated value: Status and timestamp of the last execution of Discovery on the datacenter.</td>
</tr>
<tr>
<td>Should pull events</td>
<td>Enables Cloud Management to collect events from resource types in Azure LDCs in the sn_cmp_cloud_event_list.</td>
</tr>
</tbody>
</table>

4. Click **Update** or **Submit**.

The system creates the service account and displays the list of all discovered datacenters.

After you complete all procedures in this initial "Day 1" setup, you can create additional cloud accounts and service accounts to organize and compartmentalize your cloud infrastructure.
Set up a cloud account for Azure

A cloud account is the logical representation in Cloud Management of all or part of your managed cloud infrastructure. A cloud account can include multiple service accounts — even service accounts from different providers. For each service account, you specify which datacenters to include in the cloud account.

Role required: sn_cmp.cloud_admin

See Cloud accounts for more information about cloud accounts.

**Note:** Cloud providers often use proprietary names for account and credential settings. Because the Cloud Management application supports several cloud providers, Cloud Management uses general-purpose names for the settings. In Azure, the region-specific containers for virtual resources are called regions. In Cloud Management, regions are called datacenters or logical datacenters (LDCs). The term "logical" is used to reinforce the idea that Cloud Management is provider-agnostic. All infrastructure or applications that are deployed using Cloud Management are associated with a datacenter.

1. In the Cloud Admin Portal, navigate to Manage > Cloud Accounts.
2. Click New, enter a unique and meaningful Name and Description, and then select the cloud Provider for the account (Azure).
3. Click Next.

Based on the provider you select, the **Service Account** field is populated and a list of discovered datacenters appears. If no datacenters appear, click **Discover Datacenters** to find them. See Discover all datacenters in a service account on-demand for details.
4. When the datacenters appear, select one or more datacenters to include in the cloud account and then click Save. The Cloud Account dashboard appears. The datacenters that you selected appear on the Datacenters tab.

5. Click a datacenter. The following lists appear:
   - **Resources**: Cloud resources for the current datacenter. Run Discovery to populate the CMDB for the datacenter and populate the tab. See Discover all datacenters in a service account on-demand.
   - **Capacity Limits**: Limits on virtual CPUs, virtual networks, storage volume size, and other services. See Set capacity limits on user requests for resources.
   - **Discovery Log**: The process creates a log record for each action associated with a discovery status.

6. Repeat the process to add as many service accounts as needed.

**Configure the Azure Alert service to auto-update the CMDB**

The Azure Alert service can auto-update CI data in the CMDB whenever Cloud Management or your Azure account makes a life-cycle state or configuration change to an Azure resource. As a result, the CI data in the CMDB is updated without having to wait for Discovery to run.

- Role required: sn_cmp.cloud_event_integration
- The following Cloud Management plugins must be activated:
  - Cloud Management (com.snc.cloud.mgmt)
  - Cloud Management Core (com.snc.cloud.core)
  - Cloud API (com.snc.cloud.api)
  - Cloud Config Management (com.snc.config.mgmt)
- Discovery has successfully finished running with at least one resource group
- A valid MID Server with either ALL or 'Cloud Management' and 'Azure' capabilities must always be available.
- A cloud account with Azure subscriptions (service accounts) and associated logical datacenters are discovered.

**Note:** The alert configuration continues to ping alerts even when the MID Server is down. This causes a high number of errors in the ECC queue and you need to manually deactivate the Azure Alert configuration if there is no MID Server available.

When an alert sends an update, the instance processes the event and creates or updates the CI entry in the CMDB and the CI information in the User Portal. Each event is saved as a record in the Cloud Events sn_cmp_cloud_event table. Cloud Management supports all the alerts supported in a Resource Group if an alert/event has been generated to the resources in a Resource Group. You should configure only one rule for a service account. Alert rules are created for all resources within the service account.

2. On the Azure tab, click New and fill in the form:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service Account</td>
<td>Service account details which has the datacenters and Resource Groups discovered successfully.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Resource Group</td>
<td>Resource group which stores the alert rules. Select the service account that you created for an Azure account, as described in <a href="#">Add an Azure service account</a>. Cloud Management creates alert rules for all resources in the service account.</td>
</tr>
<tr>
<td>User/Password</td>
<td>Azure does not currently support authentication. To receive Azure Alert events, however, you must provide a user name for an account with the sn_cmp.cloud_event_integration role. In addition, you must disable Authentication for the Cloud Event Scripted REST API as follows:</td>
</tr>
<tr>
<td></td>
<td>1. As System Admin, open the Scripted REST API module.</td>
</tr>
<tr>
<td></td>
<td>2. Open the record for Cloud Events.</td>
</tr>
<tr>
<td></td>
<td>3. Under Resources, open <a href="#">Cloud Config Event Post</a>.</td>
</tr>
</tbody>
</table>
| Status (read only)    | - Updating  
- Activated  
- Deleting  
- Deleted                                                                                                                                                                                                   |

3. Click **Submit**.  
   On successfully configuring the Azure alert service, the status changes from **Started** to **Active**.  

4. Run discovery on the service account:  
   a) Navigate to **Cloud Management > Service Accounts**.  
   b) Click the name of a service account.  
   c) Click **Create Discovery Schedule**.  
      The **Create Discovery Schedule** related link does not appear unless you discover the associated datacenters. Click **Discover datacenters** first, and then click **Create Discovery Schedule**.  
   d) Configure the schedule. See [Schedule discovery of all resources in a service account](#) for details on all the fields.  
      Keep the **Discover** field **Cloud Resources**.  
   e) Click **Discover now** or wait for the scheduled discovery to run. 

After you complete these steps, events are saved in the Cloud Event (sn_cmp_cloud_event) table, and the corresponding CIs will be created, updated, or deleted. The horizontal discovery process does not run, unless the event is database-related or related to Azure web sites, so there are no Discovery Status or ECC Queue records.  
- All Azure events are populated with Source: **azure activity log**.
The **Event Name** field displays the actual event generated from the Azure console.

- Events are generated with the associated in the instance. Cloud Management identifies the VMs based on the **Resource ID**, not on the resource name.
- The **Resource Type** field indicates the resource type which generates the event.

Once an event has been generated, the Cloud Event Scheduler executes scheduled jobs in the background.

- By default, the Cloud Event Scheduler executes scheduled jobs every 10 seconds. You can modify the default repeat interval based on your requirements.
- The scheduled job passes the event payload to the Identification and Reconciliation Engine (IRE). The IRE then takes the necessary actions to modify the state of the resources based on the event.

For events on Azure databases and on Azure web servers, the horizontal discovery process triggers the Azure Database pattern and then a **Discovery Status record** and **ECC Queue records** are created. You can use these to track the status of the event processing just as you would track the progress of a standard CI discovery.

### Define the schedule for downloading Azure billing data

Define the scheduled job that regularly uses a MID Server to download billing data from the provider. Cloud Management saves the data in a cost table and uses the information to generate reports.

**Role required:** sn_cmp.cloud_governor

You must have an API Access Key credential for a Microsoft Enterprise Agreement EA for all Azure accounts that you want billing information for.

This task involves two procedures:

1. Fill in the Azure Enterprise Agreement Credentials form with information that you copy from the Azure Portal. This procedure enables the instance to use the EA credentials to download Azure billing data.

2. Specify the schedule for downloading Azure billing information.

   1. In the Cloud Admin Portal, navigate to **Manage > Credentials**.
   2. Click **New** and then select **Azure Enterprise Agreement Credentials**.
   3. Enter a unique and descriptive **Name** for the credential and then fill in the form.
<table>
<thead>
<tr>
<th>Enrollment number</th>
<th>Follow this procedure to obtain the <strong>Enrollment number</strong>:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>1.</strong> Log in to ea.azure.com</td>
</tr>
<tr>
<td></td>
<td><strong>2.</strong> The enrollment number appears under the Windows icon. In the example, the enrollment number is ABC01234.</td>
</tr>
<tr>
<td></td>
<td><strong>3.</strong> Copy/paste the value into the <strong>Enrollment number</strong> field on the form.</td>
</tr>
</tbody>
</table>
Follow this procedure to obtain the **Access key**:

1. Log in to ea.azure.com
2. In the **Reports** section, click the **Download Usage** tab and then click **API Access Key**.

   ![Image of API Access Key](image)

   **Note:** For a new account, you may need to generate a key.

3. This account has a primary key. Click **expand key** to display the key in the text box.

   ![Image of expanded key](image)
4. Click **Submit**.
   You created the Azure EA credential. Next, you specify the scheduled job that downloads Azure billing information.

5. In the Cloud Admin Portal, navigate to **Analyze > Billing**.

6. On the **Billing Schedules** tab, click **New**, enter a unique and meaningful **Name**, and then fill in the form.

<table>
<thead>
<tr>
<th>Provider</th>
<th>Cloud provider that the service account belongs to. Select <strong>Azure</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Credential</td>
<td>Select the Azure EA credential that you created earlier.</td>
</tr>
<tr>
<td>Active</td>
<td>Select the check box to activate the download job.</td>
</tr>
<tr>
<td>Run</td>
<td>Frequency that the download job should run.</td>
</tr>
<tr>
<td>Time</td>
<td>Time of day that the download job should run.</td>
</tr>
</tbody>
</table>

7. Click **Save**.
   Typically, you must wait to request data for about 48 hours after you set up the connection to a provider. To run the schedule on demand, click **Execute Now**. On the **Retrieve Billing Data** window that appears, select a date range and then click **Download**.

*View cloud costs on the Billing dashboard.*

*Optional: Configure the download size of Azure billing data*

A single set of cloud billing data can be large. The MID Server, therefore, sends the data to the ECC queue in manageable chunks. You can configure a system property to limit the size of each chunk to avoid performance issues caused by large data transfers.

**Role required: admin**

1. Open the System properties table by entering `sys_properties.list` in the application filter.
2. Filter the list to open the `sn_cmp.billing.page_size` property.
   The default value is 3 MB.
3. Modify the value as needed. The maximum is 5 MB.
4. Save the property.

---

**Day 1 setup guide for Cloud Optimization: Google Cloud Connector**

To set up the ServiceNow® Cloud Optimization: Google Cloud Connector application for the very first time, you perform the procedures in this “Day 1” setup guide. Be sure to perform the procedures in order. After you have performed Day 1 setup, you can perform optional Day 2 setup and configuration procedures as needed and in any order. Detailed instructions for each procedure follow this overview.

**Roles required to set up Google Cloud Connector**

- Operations in the Google Cloud Console require the Google administrator role.
- Operations in Cloud Management require the `sn_cmp.cloud_admin` role.
Domain Separation

The Google Cloud Connector app does not support domain separation.

About terms that Cloud Management uses

Cloud providers often use proprietary names for account and credential settings. Because the Cloud Management application supports several cloud providers, Cloud Management uses general-purpose names for the settings. In the Google Cloud Platform, the region-specific containers for virtual resources are called regions. In Cloud Management, regions are called datacenters or logical datacenters (LDCs). The term "logical" is used to reinforce the idea that Cloud Management is provider-agnostic. All infrastructure or applications that are deployed using Cloud Management are associated with a datacenter.

Quick overview of the setup process

Your Day 1 setup process includes these tasks:

- If needed: Request the Cloud Management application.
- Get the Connector app and supporting apps on the ServiceNow Store and set them up.
- Assign appropriate roles to cloud admins and end users.
- On the provider portal, collect your account settings and the credentials that the Discovery process will use (through a MID Server) to programatically access your provider accounts. Securely associate the account settings and credentials with a service account in Cloud Management.
- Set up the MID Servers that will handle secure communications with the provider API endpoints.
- Set up a cloud account to represent your entire managed cloud infrastructure and set up a service account that works with one of your provider accounts. You specify which datacenters in the service account should be included in the cloud account. (Later, on "Day 2", you can set up additional cloud accounts and service accounts from the same or other providers.)
- To populate the CMDB with resource data for all datacenters, you manually run the Discovery process on each datacenter in the service account. Then, to ensure that the data continues to be updated, you configure Discovery to run on a regular schedule. Your cloud account might look like this:
• Providers offer services that can auto-update the CMDB whenever a create/modify/terminate life-cycle change or configuration update occurs to a resource. You can configure the service to integrate directly with Cloud Management.

What you will do to integrate your Google Cloud Platform cloud accounts

Detailed instructions for each procedure follow this overview.

1. Get the Google Cloud Connector app on the ServiceNow Store

Google Cloud Connector works with Cloud Management. After you have set up Cloud Management, visit the ServiceNow Store website to get Google Cloud Connector and supporting plugins and apps.

2. Assign roles to Google Cloud Platform users

You assign Cloud Management roles to user groups and to individual users based on user activities and responsibilities.

3. Set up MID Servers to connect Google Cloud Connector to your Google Cloud Platform account

To ensure secure and reliable communications, the Discovery process communicates with your cloud provider accounts and cloud resources through one or more MID Servers. You can set up the MID Servers on your network or in one of your cloud networks.

Note: Data is encrypted to the MID Server and between the MID Server and the API endpoint. To ensure high performance and security, you should configure one or more MID Servers for each datacenter under management. Configure the MID Servers even if you have already configured other MID Servers while setting up Cloud Management for another cloud provider.

4. Specify the credentials that Google Cloud Connector uses to access Google Cloud Platform data

To securely access data on your provider account, the Discovery process must present appropriate credentials. To make the credentials available to Discovery, you open the Google Cloud Console to identify the Google Cloud Platform project that will have programmatic access to your Google Cloud Platform data. You then securely store the credentials in a service account in your instance.

5. Set up a cloud account and service account for Google Cloud Platform

A service account is a secure record on your instance that stores the credential and access information for your provider account. Discovery uses the information to access your provider account to get data on each resource in each specified datacenter.

6. Configure the Google Stackdriver Logging service to auto-update the CMDB

You can activate the Google Stackdriver Logging service to auto-update CMDB CI data whenever Google Cloud Connector or your Google account makes a life-cycle state or configuration change to a Google Cloud Platform resource. As a result, the CI data in the CMDB is updated without having to wait for Discovery to run.
Next steps

When you have finished all Day-1 and Day-2 procedures in this setup guide, see the *Cloud Management administration guide* for information on using the Cloud Management application in your organization.

Assign roles to Google Cloud Platform users

You assign Cloud Management roles to user groups and to individual users based on user activities and responsibilities.

Role required: user_admin or admin

Assign the following roles to groups and users as appropriate:

<table>
<thead>
<tr>
<th>Descriptive name and role name</th>
<th>Description and tasks</th>
<th>Access rights in Cloud Management</th>
</tr>
</thead>
<tbody>
<tr>
<td>Root administrator</td>
<td>Highest level of application access for Cloud Management.</td>
<td>All</td>
</tr>
<tr>
<td>[sn_cmp.cmp_root_admin]</td>
<td>Configures the Cloud Management application and sets up the cloud infrastructure.</td>
<td>Cloud infrastructure: Service accounts and cloud account Networks and IPAMp Settings for provider services that auto-update the CMDB: • AWS Config • Azure Alert • Google Stackdriver Logging • IBM Cloud Update • VMware Events</td>
</tr>
<tr>
<td>Cloud administrator</td>
<td>Monitors overall cloud usage and enforces compliance of the organization’s rules, quotas, and policies. Also manages tags and permissions to various objects.</td>
<td>Governance: • Policies • Pools • Quotas • Permissions</td>
</tr>
<tr>
<td>[sn_cmp.cloud_admin]</td>
<td>Creates blueprints, ARM and CloudFormation templates, and catalog items.</td>
<td>Cloud Service Design: • Cloud templates • Blueprints • Blueprint catalog items • Resource blocks</td>
</tr>
<tr>
<td>Governor</td>
<td>Requests and manages stacks and resources.</td>
<td>Cloud User Portal When you assign the role to a group, all members of the group share quota limitations and ownership of certain resources.</td>
</tr>
<tr>
<td>[sn_cmp.cloud_governor]</td>
<td></td>
<td></td>
</tr>
<tr>
<td>[sn_cmp.cloud_service_user]</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

---

**Set up MID Servers to connect Google Cloud Connector to your Google Cloud Platform account**

To ensure secure and reliable communications, the Discovery process communicates with your cloud provider accounts and cloud resources through one or more MID Servers. You can set up the MID Servers on your network or in one of your cloud networks.

Role required: admin or sn_cmp.cloud_admin

- Data is encrypted to the MID Server and between the MID Server and the API endpoint. To ensure high performance and security, you should configure one or more MID Servers for each datacenter under management. Configure the MID Servers even if you have already configured other MID Servers while setting up Cloud Management for another cloud provider.
- You can configure the MID Server for Cloud Management to use a proxy server. See **Using a proxy server for your MID Server**.

1. You configure the connection to a MID Server in the same way as for any other applications that use MID Servers, like Discovery and Service Mapping. See **MID Server** for instructions on setting up and configuring MID Servers.

   **Note:** Do not configure the MID Server Application related list.

2. Add the **Google** and **Terraform** capabilities to the MID Server. See **Configure MID Server capabilities** for instructions. Alternatively, you can add the **ALL** capability, which includes the **Google** and **Terraform** capabilities.
Using a proxy server for your MID Server

You can configure the MID Server for Cloud Management to use a proxy server. Using a proxy server supports all cloud-based activities such as running Discovery, billing downloads, provisioning virtual machines, and running life-cycle operations on virtual machines.

Proxy server limitations

- Windows or Linux platforms only are supported.
- The Google Cloud Console integration does not support downloading billing data.
- VMware is not supported.
- Remote PowerShell scripts cannot be executed.
- Custom APIs may not work.

Supported proxy server configurations for Cloud Management

<table>

Specify the credentials that Google Cloud Connector uses to access Google Cloud Platform data

To securely access data on your provider account, the Discovery process must present appropriate credentials. To make the credentials available to Discovery, you open the Google Cloud Console to identify the Google Cloud Platform project that will have programmatic access to your Google Cloud Platform data. You then securely store the credentials in a service account in your instance.

Roles required:
- Operations in the Google Cloud Console require the Google administrator role.
- Operations in Cloud Management require the sn_cmp.cloud_admin role.

Cloud providers often use proprietary names for account and credential settings. Because the Cloud Management application supports several cloud providers, Cloud Management uses general-purpose names for the settings.

1. If you have already generated the credentials that Google Cloud Connector should use, skip to the final step. Otherwise, continue with the next step.
2. On the Google Cloud Console dashboard, select the project.
3. Navigate to APIs & Services > Credentials.
4. On the Credentials tab, click Create credentials > Service account key and then create the key. Specify the JSON key type.
5. Identify the credentials that Google Cloud Connector and Discovery on your instance should use to access Google Cloud Platform data:
   a) Open the JSON key file in a text editor.
b) In the Cloud Admin Portal, navigate to Manage > Credentials, click New and then select Google Credentials.

c) Specify the Name of the credentials to register with the instance. For example, enter Google credentials-1 and then copy/paste values from the JSON key file into the form fields. Paste the private_key value into the Secret key field and the client_email value into the Email field.

d) Select the Active check box to use the credentials and then click Submit.

Set up a cloud account and service account for Google Cloud Platform

A service account is a secure record on your instance that stores the credential and access information for your provider account. Discovery uses the information to access your provider account to get data on each resource in each specified datacenter. A cloud account is the logical representation in Cloud Management of all or part of your managed cloud infrastructure. A cloud account can include multiple service accounts — even service accounts from different providers. For each service account, you specify which datacenters to include in the cloud account.

- Operations in the Google Cloud Console require the Google administrator role.
- Operations in Cloud Management require the sn_cmp.cloud_admin role.

When you finish the Day-1 setup process, your cloud account might look like this:

2. Select or create the cloud account:
   - Select an existing cloud account:
     1. On the Cloud Account page, click Configure.
     2. On the General Information page, click Next and then continue with the next step.
   - Create a cloud account:
     1. On the General Information page, click New and then enter a unique and meaningful Name and Description for the cloud account.
     2. Select the provider.
     3. Click Next and then continue with the next step.

3. On the Datacenters page, create a Service Account: Click the + next to the Service Account field, enter a unique and meaningful Name for the service account and then fill in the form.

4. From the JSON key file that is associated with the service account, copy/paste the project_id value into the Account ID field.
5. In the **Discovery credentials** field, select the appropriate credentials for the service account. These are the credentials that you generated in the Specify the credentials that Google Cloud Connector uses to access Google Cloud Platform data procedure.

6. Leave the **Datacenter URL** field blank.

7. Fill in the remaining fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Datacenter type</td>
<td>Select <strong>Google Cloud Platform Datacenter</strong>.</td>
</tr>
<tr>
<td>Datacenter discovery status</td>
<td>Select <strong>Google Cloud Platform Datacenter</strong>.</td>
</tr>
<tr>
<td>Should pull events</td>
<td>Enables Cloud Management to collect events from resource types in Google Project LDCs in the sn_cmp_cloud_event_list.</td>
</tr>
</tbody>
</table>

8. Click **Submit** to create the service account.

9. Click **Discover Datacenters**.

10. When the datacenters appear, select one or more datacenters to include in the cloud account and then click **Save**.

11. Click a datacenter.

The following lists appear:

- **Resources**: Cloud resources for the current datacenter. Run Discovery to populate the CMDB for the datacenter and populate the tab. See *Discover all datacenters in a service account on-demand*.
- **Capacity Limits**: Limits on virtual CPUs, virtual networks, storage volume size, and other services. See *Set capacity limits on user requests for resources*.
- **Discovery Log**: The process creates a log record for each action associated with a discovery status.

12. Repeat the process to add as many service accounts as needed.

After you complete all procedures in this initial “Day 1” setup, you can create additional cloud accounts and service accounts to organize and compartmentalize your cloud infrastructure.
Configure the Google Stackdriver Logging service to auto-update the CMDB

You can activate the Google Stackdriver Logging service to auto-update CMDB CI data whenever Google Cloud Connector or your Google account makes a life-cycle state or configuration change to a Google Cloud Platform resource. As a result, the CI data in the CMDB is updated without having to wait for Discovery to run.

- Google Cloud Platform administrator
- Role required: for Cloud Management: sn_cmp.cloud_event_integration
- The following Cloud Management plugins must be activated:
  - Cloud Management (com.snc.cloud.mgmt)
  - Cloud Management Core (com.snc.cloud.core)
  - Cloud API (com.snc.cloud.api)
  - Cloud Config Management (com.snc.config.mgmt)

- Activate Discovery and Service-mapping patterns.
- Discovery has successfully discovered logical datacenters of the Google project. For more information see, Set up a cloud account and service account for Google Cloud Platform

Note: Ensure that you select the Should pull events check box in the Google Service Account page, before you execute datacenter discovery.

Cloud Management supports StackDriver Monitoring API alerts from a given project in Google Cloud Platform. When an alert/event has been generated to the resources in a project, Cloud Management captures.

Create and manage alerting policies with the Stackdriver Monitoring console, the Stackdriver Monitoring API, and Cloud SDK. Each policy specifies the following:

- Conditions that identify that a resource or a group of resources are in an unhealthy state.
- Notifications sent through email, SMS, or other channels to inform that a resource state is unhealthy.
- Documentation or information that can be included in some types of notifications to help your support team resolve the issue.

When events trigger conditions in one of your alerting policies, Stackdriver Monitoring creates and displays an incident in the Stackdriver Monitoring console.

1. Log in to your Google Cloud Platform account. For your project, navigate to APIs & Services > Library.
2. Enable both the Stackdriver API and Stackdriver Logging API.
   a) In the library, search for Stackdriver.
   b) Click the Stackdriver API card.
   c) On the Stackdriver API page, click Enable.
d) Repeat for the Stackdriver Logging API.

3. By default, a scheduled job on your instance (Google Cloud Event Scheduler) polls the Google Stackdriver Logging service for updates every 5 minutes. To modify the schedule: On your instance, navigate to **System Scheduler > Scheduled Jobs** and then click **Google Cloud Event Scheduler** and then update the **Repeat** setting as needed.
4. **Click Update.**
   - Once the Google Cloud Platform generates an event and Cloud Management receives the event information, the ‘GCP-Events-job’ scheduled jobs execute in the background.
   - The scheduled job passes the event payload to the Identification and Reconciliation Engine (IRE). The IRE then takes the necessary actions to modify the state of the resources based on the event.

**(Optional) Add a Google Cloud Platform service account to the cloud account**

During Cloud Management Day 1 setup, you added one service account to the cloud account. To compartmentalize your infrastructure or to include different datacenters, you can add another service account. A particular datacenter, however, cannot be selected in more than one service account in a cloud account.

*Role required: sn_cmp.cloud_admin*

A service account is a secure record on your instance that stores the credential and access information for your provider account. Discovery uses the information to access your provider account to get data on each resource in each specified datacenter.

In this example, you added the service account named **ProviderB-ServiceAccount-1** and selected three datacenters to include in the cloud account:
1. Navigate to **Cloud Management > Service Accounts**.
2. Click **New**, enter a unique and meaningful **Name**, and then fill in the form.
3. Fill in the remaining fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Datacenter type</td>
<td>Select <strong>Google Cloud Platform Datacenter</strong>.</td>
</tr>
<tr>
<td>Datacenter discovery status</td>
<td>Auto-generated value: Status and timestamp of the last execution of Discovery on the datacenter.</td>
</tr>
</tbody>
</table>

4. Click **Update** or **Submit**.
   The system creates the service account and displays the list of all discovered datacenters.
5. Repeat the process to add as many service accounts as needed.

---

**Note:** In a cloud account, you cannot select a particular datacenter in two different service accounts.
Day 1 setup guide for Cloud Optimization: IBM Cloud Connector

To set up the ServiceNow® Cloud Optimization: IBM Cloud Connector application for the very first time, you perform the procedures in this “Day 1” setup guide. Be sure to perform the procedures in order. After you have performed Day 1 setup, you can perform optional Day 2 setup and configuration procedures as needed and in any order. Detailed instructions for each procedure follow this overview.

Roles required to set up IBM Cloud Connector

- Operations in the IBM Cloud Console require the IBM administrator role.
- Operations in Cloud Management require the sn_cmp.cloud_admin role.

Domain Separation

The IBM Cloud Connector app does not support domain separation.

Known issue

In some cases, Discovery for IBM Cloud is not able to change the state of some CIs that have been decommissioned in the cloud. In such a case, when an end user launches a cloud catalog item, the CI may still appear as a user-selectable value on the form (because the state hasn’t been updated) and may result in a failed request. Workaround: The cloud administrator can change the state of the affected CI to an appropriate value to remove the CI from the cloud catalog form.

About terms that Cloud Management uses

Cloud providers often use proprietary names for account and credential settings. Because the Cloud Management application supports several cloud providers, Cloud Management uses general-purpose names for the settings. In IBM Cloud, the region-specific containers for virtual resources are called locations. In Cloud Management, locations are called datacenters or logical datacenters (LDCs). The term "logical" is used to reinforce the idea that Cloud Management is provider-agnostic. All infrastructure or applications that are deployed using Cloud Management are associated with a datacenter.

What you will do to integrate your IBM Cloud Connector accounts

Detailed instructions for each procedure follow this overview.

1. Get the IBM Cloud Connector app on the ServiceNow Store

IBM Cloud Connector works with Cloud Management. After you have set up Cloud Management, visit the ServiceNow Store website to get IBM Cloud Connector and supporting plugins and apps. For details on system requirements, view the application listing on the ServiceNow Store website.

2. Assign roles to IBM Cloud Connector users

You assign Cloud Management roles to user groups and to individual users based on user activities and responsibilities.
3. Set up MID Servers to support IBM Cloud Connector

To ensure secure and reliable communications, the Discovery process communicates with your cloud provider accounts and cloud resources through one or more MID Servers. You can set up the MID Servers on your network or in one of your cloud networks.

**Note:** Data is encrypted to the MID Server and between the MID Server and the API endpoint. To ensure high performance and security, you should configure one or more MID Servers for each datacenter under management. Configure the MID Servers even if you have already configured other MID Servers while setting up Cloud Management for another cloud provider.

3. Create a Terraform config provider and run Discovery

A config provider is a secure record on your instance that stores the credential and access information for a particular configuration management server (for example, a host running Ansible, or Terraform). Discovery uses the information in the config provider record to access the server to get information on each resource template in the repository. You use the templates to generate catalog items that cloud users can order from the Cloud User Portal.

4. Create an IBM Cloud service account

A service account is a secure record on your instance that stores the credential and access information for your provider account. Discovery uses the information to access your provider account to get data on each resource in each specified datacenter.

5. Discover all datacenters in a service account on-demand

Discovery uses the information in the service account to identify all logical datacenters associated with the provider account.

6. Set capacity limits on user requests for resources

Capacity limits place restrictions on the attributes of cloud resources such as the number of virtual machines, virtual CPUs, or aggregate storage. You can set limits on resources separately for each logical datacenter in a cloud account.

**Next steps**

When you have finished all Day-1 and Day-2 procedures in this setup guide, see the Cloud Management administration guide for information on using the Cloud Management application in your organization.

**Assign roles to IBM Cloud Connector users**

You assign Cloud Management roles to user groups and to individual users based on user activities and responsibilities. Many of the roles might already be assigned for Cloud Management.

Role required: user_admin or admin

Assign the following roles to groups and users as appropriate:

<table>
<thead>
<tr>
<th>Descriptive name and role name</th>
<th>Description and tasks</th>
<th>Access rights in Cloud Management</th>
</tr>
</thead>
<tbody>
<tr>
<td>Root administrator [sn_cmp.cmp_root_admin]</td>

</tbody>
</table>

**Note:** Not supported by IBM Cloud Connector.

| Cloud Group administrator                  | Grants admin access to any group that you belong to.                                                                                                                                                                |                                                                                                              |
| [sn_cmp.cloud_group_admin]                |                                                                                                                                                                                                                      |                                                                                                              |

---

**Set up MID Servers to support IBM Cloud Connector**

To ensure secure and reliable communications, the Discovery process communicates with your cloud provider accounts and cloud resources through one or more MID Servers. You can set up the MID Servers on your network or in one of your cloud networks.

Role required: admin or sn_cmp.cloud_admin

- Data is encrypted to the MID Server and between the MID Server and the API endpoint. To ensure high performance and security, you should configure one or more MID Servers for each datacenter under management. Configure the MID Servers even if you have already configured other MID Servers while setting up Cloud Management for another cloud provider.
- You can configure the MID Server for IBM Cloud Connector to use a proxy server. See [Using a proxy server for your MID Server](#).

1. If you have already configured a MID Server to support Cloud Management, then skip this step. You configure the connection to a MID Server in the same way as for any other applications that use MID Servers, like Discovery and Service Mapping. See [MID Server](#) for instructions on setting up and configuring MID Servers.

   **Note:** Do not configure the MID Server Application related list.

2. Add the **IBM** and **Terraform** capabilities to the MID Server. See [Configure MID Server capabilities](#) for instructions. Alternatively, you can add the **ALL** capability, which includes the **IBM** and **Terraform** capabilities.

   **Using a proxy server for your MID Server**

   You can configure the MID Server for Cloud Management to use a proxy server. Using a proxy server supports all cloud-based activities such as running Discovery, billing downloads, provisioning virtual machines, and running life-cycle operations on virtual machines.

   **Proxy server limitations**

   - Windows or Linux platforms only are supported.
- The Google Cloud Console integration does not support downloading billing data.
- VMware is not supported.
- Remote PowerShell scripts cannot be executed.
- Custom APIs may not work.

**Supported proxy server configurations for Cloud Management**

<table>

Create an IBM Cloud service account

During Cloud Management Day 1 setup, you added one service account to the cloud account. To compartmentalize your infrastructure or to include different datacenters, you can add another service account. A particular datacenter, however, cannot be selected in more than one service account in a cloud account.

Role required: sn_cmp.cloud_admin

A service account is a secure record on your instance that stores the credential and access information for your provider account. Discovery uses the information to access your provider account to get data on each resource in each specified datacenter.

In this example, you added the service account named **ProviderB-ServiceAccount-1** and selected three datacenters to include in the cloud account:
Note: Cloud providers often use proprietary names for account and credential settings. Because the Cloud Management application supports several cloud providers, Cloud Management uses general-purpose names for the settings.

1. On your instance, navigate to **Orchestration > Credentials & Connections > Credentials**.
2. Click **New**, select **IBM Credentials**, and then enter a unique and meaningful **Name** for the credential set (in this example, **IBM Van Credentials**). If you use more than one set of IBM credentials, set the **Order** value (credential sets with lower values are checked first).
   In the following steps, you paste the IBM credential values into the Credentials form on your instance.
3. Log in to your Softlayer account at control.softlayer.com.
4. Navigate to **Account > Users > User List**.
5. On the Users page, click **View** for the appropriate **API KEY** (or generate an API key if needed).
6. From the API Key popup:
   a) Paste the full API User value into the Softlayer API User field on your instance.
   b) Paste the API Key value into the Softlayer API Key field.

7. Log in to your Bluemix account at console.bluemix.net.
9. Click Platform API Keys, click the Create button, and then enter a Name and Description for the key.
10. On the success page, click **Download** to download the key to a local JSON file.

11. Open the file (typically named `apiKey-n.json`), paste the **apiKey** value into the **Bluemix API Key** field on your instance, and then click **Update**.
You have created a record of the IBM credentials on your instance. Next, you create the service account that is associated with the credentials.

12. Navigate to **Cloud Management > Service Accounts**.
13. Click **New**, enter a unique and meaningful **Name**, and then fill in the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Account ID</td>
<td>Enter the IBM software user number that the instance should use to access the IBM Cloud Console.</td>
</tr>
<tr>
<td>Discovery credentials</td>
<td>Select the credentials record that you created earlier.</td>
</tr>
<tr>
<td>Datacenter URL</td>
<td>Leave the <strong>Datacenter URL</strong> field blank.</td>
</tr>
<tr>
<td>Datacenter type</td>
<td>Select <strong>IBM Datacenter (cmdb_ci_ibm_datacenter)</strong>.</td>
</tr>
<tr>
<td>Datacenter discovery status</td>
<td>Auto-generated value: Status and timestamp of the last execution of Discovery on the datacenter.</td>
</tr>
<tr>
<td>Should pull events</td>
<td></td>
</tr>
</tbody>
</table>

14. Click **Update** or **Submit**.

The system creates the service account and displays the list of all discovered datacenters.

15. Repeat the process to add as many service accounts as needed.

**Day 1 setup guide for VMware on Cloud Management**

To set up Cloud Management for the very first time, you perform the procedures in this "Day 1" setup guide. Be sure to perform the procedures in order. After you have performed Day 1 setup, you can perform optional Day 2 setup and configuration procedures as needed and in any order. Detailed instructions for each procedure follow this overview.

**Request the Cloud Management application**

The Cloud Management application is available as a separate subscription and requires the Cloud Management plugin (com.snc.cloud.mgmt). See [Request the Cloud Management application](#).

**Roles required to set up Cloud Management**

- Operations in the VMware Console require the VMware administrator role.
- Operations in Cloud Management require the sn_cmp.cloud_admin role.

**About terms that Cloud Management uses**

Cloud providers often use proprietary names for account and credential settings. Because the Cloud Management application supports several cloud providers, Cloud Management uses general-purpose names for the settings.

**Quick overview of the setup process**

Your setup process includes these tasks:

- If needed: Request the Cloud Management application.
• Assign appropriate roles to cloud users.
• Set up the MID Servers that will handle secure communications with the provider API endpoints.
• On the provider portal, collect your account settings and the credentials that the Discovery process will use (through a MID Server) to programatically access your provider accounts. Securely associate the account settings and credentials with a service account in Cloud Management.
• Set up a cloud account to represent your entire managed cloud infrastructure and set up a service account that works with one of your provider accounts. You specify which datacenters in the service account should be included in the cloud account. (Later, on ‘Day 2’, you can set up additional cloud accounts and service accounts from the same or other providers.)
• Cloud Management uses CMDB data to help users request and manage cloud resources and to help you manage your cloud infrastructure. To populate the CMDB with resource data for all datacenters, you manually run the Discovery process on each datacenter in the service account. Then, to ensure that the data continues to be updated, you configure Discovery to run on a regular schedule. Your cloud account might look like this:

![MyFirst-CloudAccount Diagram]

• Providers offer services that can auto-update the CMDB whenever a create/modify/terminate life-cycle change or configuration update occurs to a resource. You can configure the service to integrate directly with Cloud Management.

---

**What you will do to integrate Cloud Management with your VMware cloud accounts**

Detailed instructions for each procedure follow this overview.

1. **Assign roles to VMware users of Cloud Management**
   You assign Cloud Management roles to user groups and to individual users based on user activities and responsibilities.

2. **Set up MID Servers to connect Cloud Management to a VMware service account**
   To ensure secure and reliable communications, the Discovery process communicates with your cloud provider accounts and cloud resources through one or more MID Servers. You can set up the MID Servers on your network or in one of your cloud networks.

   **Note:** Data is encrypted to the MID Server and between the MID Server and the API endpoint. To ensure high performance and security, you should configure one or more MID Servers for each datacenter under management. Configure the MID Servers even if...
3. Create the credential and service account that will access your VMware data

To securely access data on your provider account, the Discovery process must present appropriate credentials. To make the credentials available to Discovery, you first create an account in the VMware Console. You then securely store the credentials in a service account in your instance. A service account is a secure record on your instance that stores the credential and access information for your provider account. Discovery uses the information to access your provider account to get data on each resource in each specified datacenter.

4. Discover all datacenters in a service account on-demand

Discovery uses the information in the service account to identify all logical datacenters associated with the provider account.

5. Set up cloud accounts for VMware

A cloud account is the logical representation in Cloud Management of all or part of your managed cloud infrastructure. A cloud account can include multiple service accounts—even service accounts from different providers. For each service account, you specify which datacenters to include in the cloud account.

6. Set capacity limits on user requests for resources

Capacity limits place restrictions on the attributes of cloud resources such as the number of virtual machines, virtual CPUs, or aggregate storage. You can set limits on resources separately for each logical datacenter in a cloud account.

7. Configure the VMware Events service to auto-update the CMDB

The VMware Events service can auto-update CI data in the CMDB whenever Cloud Management makes a life-cycle state or configuration change to a VMware resource. As a result, the CI data in the CMDB is updated without having to wait for Discovery to run.

VMware prerequisites

**vSphere**
- Enterprise or Enterprise Plus Edition 5.5 or newer.
- Enable the vSphere environment for Distributed Resource Scheduling (DRS).
- Place datastores under Storage DRS.

When provisioning Windows virtual machines, read and modify the named customization specifications.

**ESXi hosts**

If the IP address of a virtual machine is set manually using a script or post-init scripts run on the VM, then you must allow HTTPS traffic between the MID Server and the ESXi host for the VM. Enable NTP time sync. Enable the NTP client for the hypervisor on the vSphere web client. See the [vSphere documentation](#) for more information.

**vCenter server requirements**

vCenter 5.5 or 6.0 Standard or Foundation edition.

**vCenter access requirements**

Minimum permissions for the user that connects to vSphere through the instance:
- Datastore: All
- Datastore Cluster: All
- Folder: Create, Delete
- Global: Cancel task, License
- Host > Local operations: Create/Delete/Reconfigure virtual machines
- Profile-driven storage: All
- Network: Assign network
- Resource: Apply recommendation; Create/Modify/Assign/Remove virtual machines.
- Virtual machines: All

vCenter credentials

- Username
- Password
- URL or IP address of the vCenter server that the instance access through the MID Server.
- vCenter instance UUID. See Create the credential and service account that will access your VMware data for instructions on how to obtain the UUID.

Next steps

When you have finished all Day-1 and Day-2 procedures in this setup guide, see the Cloud Management administration guide for information on using the Cloud Management application in your organization.

Assign roles to VMware users of Cloud Management

You assign Cloud Management roles to user groups and to individual users based on user activities and responsibilities.

Role required: user_admin or admin

Assign the following roles to groups and users as appropriate:

<table>
<thead>
<tr>
<th>Descriptive name and role name</th>
<th>Description and tasks</th>
<th>Access rights in Cloud Management</th>
</tr>
</thead>
<tbody>
<tr>
<td>Root administrator</td>
<td>Highest level of application access for Cloud Management.</td>

| Governor                     | Monitors overall cloud usage and enforces compliance of the organization's rules, quotas, and policies. Also manages tags and permissions to various objects. | Governance:  
  - Policies  
  - Pools  
  - Quotas  
  - Permissions |
| Service Designer             | Creates blueprints, ARM and CloudFormation templates, and catalog items. | Cloud Service Design:  
  - Cloud templates  
  - Blueprints  
  - Blueprint catalog items  
  - Resource blocks |
| Cloud user                   | Requests and manages stacks and resources. | Cloud User Portal  
  When you assign the role to a group, all members of the group share quota limitations and ownership of certain resources. |
| Cloud operator               | Monitors and troubleshoots the Cloud Management application. | Dashboards and reports:  
  - Cloud Operations Dashboard  
  - Cloud Root Cause Analysis  
  - Cloud Orchestration Trail  
  - Cloud API Trail |
| Cloud Event Integration      | Authorizes access to the instance for external services that auto-update the CMDB when cloud events occur. This role gives the access to the cloud event REST endpoint. | Cloud infrastructure:  
  - Service accounts and cloud account  
  - Networks and IPAM  
  Settings for provider services that auto-update the CMDB:  
    - AWS Config  
    - Azure Alert  
    - Google Stackdriver Logging  
    - VMware Events |
| Cloud Group administrator    | Grants admin access to any group that you belong to. | |

Set up MID Servers to connect Cloud Management to a VMware service account

To ensure secure and reliable communications, the Discovery process communicates with your cloud provider accounts and cloud resources through one or more MID Servers. You can set up the MID Servers on your network or in one of your cloud networks.
Role required: admin or sn_cmp.cloud_admin

- Data is encrypted to the MID Server and between the MID Server and the API endpoint. To ensure high performance and security, you should configure one or more MID Servers for each datacenter under management. Configure the MID Servers even if you have already configured other MID Servers while setting up Cloud Management for another cloud provider.
- You can configure the MID Server for Cloud Management to use a proxy server. See Using a proxy server for your MID Server.

1. You configure the connection to a MID Server in the same way as for any other applications that use MID Servers, like Discovery and Service Mapping. See MID Server for instructions on setting up and configuring MID Servers.

   **Note:** Do not configure the MID Server Application related list.

2. Using a proxy server for your MID Server
   You can configure the MID Server for Cloud Management to use a proxy server. Using a proxy server supports all cloud-based activities such as running Discovery, billing downloads, provisioning virtual machines, and running life-cycle operations on virtual machines.

Proxy server limitations

- Windows or Linux platforms only are supported.
- The Google Cloud Console integration does not support downloading billing data.
- VMware is not supported.
- Remote PowerShell scripts cannot be executed.
- Custom APIs may not work.

### Create the credential and service account that will access your VMware data

To securely access data on your provider account, the Discovery process must present appropriate credentials. To make the credentials available to Discovery, you first create an account in the VMware Console. You then securely store the credentials in a service account in your instance.

Roles required:
- VMware Console administrator
- Cloud Management: admin or sn_cmp.cloud_admin
Cloud providers often use proprietary names for account and credential settings. Because the Cloud Management application supports several cloud providers, Cloud Management uses general-purpose names for the settings.

1. In the Cloud Admin Portal, navigate to Manage > Credentials.
2. On the Credentials tab, click New, select VMware Credentials, fill in the form, and then click Submit.

### VMware Credentials form fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Input value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Unique and meaningful name for the credentials (for example, Cloud Management VMware Credentials).</td>
</tr>
<tr>
<td>Active</td>
<td>Select the check box to enable the credential for use.</td>
</tr>
<tr>
<td>User name</td>
<td>User name for access to your vSphere account.</td>
</tr>
<tr>
<td>Password</td>
<td>Password for access to your vSphere account.</td>
</tr>
</tbody>
</table>

3. Navigate to Cloud Management > Service Accounts, click New, enter a unique and meaningful Name (for example, Cloud Management Service Account), and then fill in the form.

### New service account for VMware

<table>
<thead>
<tr>
<th>Account ID</th>
<th>There are two methods for determining the value:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• If you have access to the managed object browser for the vCenter (MOB): The Account ID is the instance UID. Open the MOB and then click Content &gt; About. Paste the value of the instanceUuid property in the Account ID field.</td>
</tr>
<tr>
<td></td>
<td>• If you do not have access to the MOB, enter the temporary text &quot;vmware-temp-1&quot; in the Account ID field. In a step that follows this table, you create the actual value and then return to this form to replace the temporary text with the actual value.</td>
</tr>
<tr>
<td>Discovery credentials</td>
<td>Name of the credentials that you created in the preceding step. Cloud Management VMware Credentials in the example.</td>
</tr>
<tr>
<td>Datacenter URL</td>
<td>Full URL of the vCenter, for example: https://&lt;IP address&gt;/sdk.</td>
</tr>
<tr>
<td>Datacenter Type</td>
<td>Select VMware vCenter datacenter (cmdb_ci_vcenter_datacenter).</td>
</tr>
<tr>
<td>Datacenter discovery status</td>
<td>Auto-generated value: Status and timestamp of the last execution of Discovery on the datacenter.</td>
</tr>
<tr>
<td>Should pull events</td>
<td>Enables Cloud Management to collect events from resource types in VMware vCenter datacenter in the sn_cmp_cloud_event_list.</td>
</tr>
</tbody>
</table>

4. Click the Discover Datacenters related link. Using the credential, Discovery accesses the vCenter at the specified URL to discover VMware datacenters.

5. If you used the instance UUID value in the Account ID field, click Submit and skip the remaining steps in this procedure.

6. On the Cloud Admin Portal, navigate to Operate > Trails.

7. On the Cloud API Trail tab, find the entry with the Method name value of ListDatacenters and Provider name value of vmware-compute (typically the most-recent entry). Open the entry.

8. On the CAPI Trail Logs related list, open the route_result entry.

9. In the Log value text box, copy the locationId value. This value is the Account ID that you will paste into the form in the next step.

10. On the instance, navigate to Cloud Management > Service Accounts and then click the service account that you created earlier (Cloud Management Service Account in the example).

11. Paste the locationId value (that you copied from the CAPI Trail Log form) in the Account ID field on the form and then click Update.
12. Click **Submit**.
   The system creates the service account and displays the list of all discovered datacenters.

**Discover all datacenters in a service account on-demand**

After you set up a service account, run Discovery to populate the datacenters in the account.

- Role required: sn_cmp.cloud_admin
- A cloud account must exist with service accounts and associated datacenters. You must run on-demand Discovery to discover datacenters before you can schedule Discovery.
- Download the Discovery and Service Mapping pattern from the ServiceNow Store.

Cloud providers often use proprietary names for account and credential settings. Because the Cloud Management application supports several cloud providers, Cloud Management uses general-purpose names for the settings. In the Google Cloud Platform, the region-specific containers for virtual resources are called **regions**. In Cloud Management, regions are called datacenters or logical datacenters (LDCs). The term "logical" is used to reinforce the idea that Cloud Management is provider-agnostic. All infrastructure or applications that are deployed using Cloud Management are associated with a datacenter.
You can run Discovery on demand without waiting for the next scheduled run. See Schedule Discovery of all resources in a datacenter.

1. Navigate to **Cloud Management > Service Accounts**.
2. Click the name of a service account and then click the **Discover Datacenters** related link.
3. Wait for the **Datacenter discovery status** field to show a status of **Complete**.
   - If Discovery is successful, you see the following message in the **Datacenter discovery status** field: `YYYY-MM-DD HH:MM:SS: Completed ...`. **Reload this form to see an updated datacenter list.**
4. **Reload the form.**

The discovered datacenters appear in the Logical Datacenters related list.

**Note:** Check the **Cloud API Trail** and the **Orchestration Trail** if Discovery encounters issues.

### Set up cloud accounts for VMware

A cloud account is the logical representation in Cloud Management of all or part of your managed cloud infrastructure. A cloud account can include multiple service accounts — even service accounts from different providers. For each service account, you specify which datacenters to include in the cloud account.

**Role required:** `sn_cmp.cloud_admin`

See **Cloud accounts** for detailed information.

1. In the Cloud Admin Portal, navigate to **Manage > Cloud Accounts**.
2. Click **New**, enter a unique and meaningful **Name** and **Description**, and then select the cloud **Provider** for the account (VMware vCenter).
3. Click **Next**.
Based on the provider you select, the **Service Account** field is populated and a list of discovered datacenters appears. If no datacenters appear, click **Discover Datacenters** to find them. See *Discover all datacenters in a service account on-demand* for details.

4. Select one or more datacenters to associate with the cloud account, click **Save**, and then close the popup.
   The Cloud Account dashboard appears. The datacenters that you selected appear on the **Datacenters** tab.

5. Click a datacenter.
   The following lists appear:
   • **Resources**: Cloud resources for the current datacenter. Run Discovery to populate the CMDB for the datacenter and populate the tab. See *Discover all datacenters in a service account on-demand*.
   • **Capacity Limits**: Limits on virtual CPUs, virtual networks, storage volume size, and other services. See *Set capacity limits on user requests for resources*.
   • **Discovery Log**: The process creates a log record for each action in an datacenter.

Repeat the process to create additional cloud accounts as needed. Run Discovery and set capacity limits for each datacenter.

*Add a datacenter to a cloud account*
At any time, you can add a logical datacenter to the cloud infrastructure that is represented by a cloud account.
Role required: sn_cmp.cloud_admin

1. In the Cloud Admin Portal, navigate to Manage > Cloud Accounts.
2. Open a cloud account, set the state to Draft, and then click Configure in the form header.
3. Click the Datacenters tab and then select the Service Account that holds the credentials that enable access to the provider account that includes the datacenter to add.

When you select the service account, the list of discovered datacenters for the service account appears.

<i>Note: </i>If the expected datacenters do not appear, click Discover Datacenters to update the list. Discovery runs and displays all datacenters associated with the service account.

4. Select the datacenters to add and then click Save.

In the example, you select <i>ap-northeast-2</i>.
The datacenters are added to the cloud account and appear on the **Datacenters** tab. When Discovery runs, the resources in the datacenter appear on the **Resources** tab.

![Datacenters Image]

**Configure the VMware Events service to auto-update the CMDB**

The VMware Events service can auto-update CI data in the CMDB whenever Cloud Management makes a life-cycle state or configuration change to a VMware resource. As a result, the CI data in the CMDB is updated without having to wait for Discovery to run.

- **Role required:** sn_cmp.cloud_event_integration
- **You must have** a cloud account with VMware service accounts and associated logical datacenters.
- **The following Cloud Management plugins must be activated:**
  - Cloud Management (com.snc.cloud.mgmt)
  - Cloud Management Core (com.snc.cloud.core)
  - Cloud API (com.snc.cloud.api)
  - Cloud Config Management (com.snc.config.mgmt)
- **A MID server needs to be available with VMware capabilities.**
- **The Vcenter datacenters are successfully discovery and associated data is populated.**

When VMware Events sends an update, the instance processes the event and creates or updates the CI entry in the CMDB and the CI information in the Cloud User Portal. Each event is saved as a record in the Events table on your instance. Configure all event/alert rules from the vCenter.

**Note:** To connect to a different MID Server or vCenter: Update the settings and then click the **Start** related link. The **Status** value changes to **Updating** and then to **Started**.

1. On the **Cloud Admin Portal**, navigate to **Manage > Alert Configurations**.
2. On the **VMware** tab, click **New**, enter a unique and meaningful **Name** and **Short description**, and then fill in the form:

<table>
<thead>
<tr>
<th>Execute on</th>
<th>Select <strong>Specific MID Server</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>MID Server</td>
<td>Select a MID Server.</td>
</tr>
</tbody>
</table>
3. Right-click in the header and select **Save**.

4. Test the connection between the vCenter and the MID Server: Click **Test parameters**. A pop-up displays **Parameters verified** for success. The **Status** field does not change. To update a parameter (for example, to change the MID Server or vCenter), change the setting and then click **Update parameters**.

5. Click the **Start** related link to start collecting events for vCenter.  
   - To confirm that the instance is receiving events, verify that the **Status** field displays **Started**.  
   - Click **Stop** to stop collecting events for a particular vCenter.  
   - Click **Restart** to restart event collection.

vCenter events are being populated in **sn_cmp_cloud_event** table.  
- If the vCenter has events in the Event Manager and the same events are configured, Cloud Management gathers the events and take action on the CIs accordingly.  
- Identification and Reconciliation Engine (IRE) changes the CI state based on event payload received and the IRE cannot be customized.

### Additional Cloud Management setup on day 2

After you have performed Day 1 setup, you can perform optional setup and configuration procedures as needed and in any order. Detailed instructions for each procedure follow this overview.

#### Optional setup and configuration operations

Detailed instructions for each procedure follow this overview.

#### Set up an additional cloud account

A cloud account is the logical representation in Cloud Management of all or part of your managed cloud infrastructure. A cloud account can include multiple service accounts — even service accounts from different providers. For each service account, you specify which datacenters to include in the cloud account.

#### Add a datacenter to a cloud account

At any time, you can add a logical datacenter to the cloud infrastructure that is represented by a cloud account.

#### Schedule discovery of all resources in a service account

You can add a custom schedule for Discovery to discover all resources each datacenter in a service account and then update the CMDB with the new information.

#### Schedule Discovery of all resources in a datacenter

<table>
<thead>
<tr>
<th>vCenter</th>
<th>Select the vCenter to monitor.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Extension (read only)</td>
<td>The MID Server extension of this context. Updated when data collection starts.</td>
</tr>
<tr>
<td>Status (read only)</td>
<td>The status of the data collection process, for example, Starting, Started, and so on.</td>
</tr>
<tr>
<td>Executing on (read only)</td>
<td>The MID Server that is executing the event collector</td>
</tr>
</tbody>
</table>
To update a particular datacenter more frequently than is scheduled for the cloud account, you can add a custom schedule for discovering all resources in the datacenter. To view information about a discovered resource, select a datacenter on the Logical Datacenters related list and then click the resource.

**Discover all resources in a datacenter on-demand**

At any time, you can run Discovery on a datacenter to update the CMDB.

**Discover all datacenters in a service account on-demand**

After you set up a service account, run Discovery to populate the datacenters in the account. Discovery uses the information in the service account to identify all logical datacenters associated with the provider account.

**Set capacity limits on user requests for resources**

Capacity limits place restrictions on the attributes of cloud resources such as the number of virtual machines, virtual CPUs, or aggregate storage. You can set limits on resources separately for each logical datacenter in a cloud account.

**Next steps**

When you have finished all Day-1 and Day-2 procedures in this setup guide, see the Cloud Management administration guide for information on using the Cloud Management application in your organization.

**Set up an additional cloud account**

During initial installation, you set up one cloud account. To organize and compartmentalize your infrastructure, you can set up additional cloud accounts to include different providers or service accounts or datacenters.

Role required: sn_cmp.cloud_admin

A cloud account is the logical representation in Cloud Management of all or part of your managed cloud infrastructure. A cloud account can include multiple service accounts— even service accounts from different providers. For each service account, you specify which datacenters to include in the cloud account. See Cloud accounts for detailed information.

1. In the Cloud Admin Portal, navigate to Manage > Cloud Accounts.
2. Click New, enter a unique and meaningful Name and Description, select the cloud Provider for the account (MyProvider in the example), and then click Next.
Based on the provider you select, the **Service Account** field is populated.

3. Select the appropriate **Service Account**.
   A list of discovered datacenters appears. If no datacenters appear, click **Discover Datacenters**. See *Discover all datacenters in a service account on-demand* for details.

4. Select each of the datacenters that you want to associate with the cloud account, click **Save**, and then close the popup.

   The datacenters appear on the **Datacenters** tab for the cloud account.
5. When the datacenters appear, select one or more datacenters to include in the cloud account and then click Save. The Cloud Account dashboard appears. The datacenters that you selected appear on the Datacenters tab.

6. Click a datacenter. The following lists appear:
   - Resources: Cloud resources for the current datacenter. Run Discovery to populate the CMDB for the datacenter and populate the tab. See Discover all datacenters in a service account on-demand.
   - Capacity Limits: Limits on virtual CPUs, virtual networks, storage volume size, and other services. See Set capacity limits on user requests for resources.
   - Discovery Log: The process creates a log record for each action associated with a discovery status.

7. Repeat the process to add as many service accounts as needed.

Repeat the process to create additional cloud accounts as needed. Run Discovery and set capacity limits for each datacenter.

Add a datacenter to a cloud account

At any time, you can add a logical datacenter to the cloud infrastructure that is represented by a cloud account.

Role required: sn_cmp.cloud_admin

1. In the Cloud Admin Portal, navigate to Manage > Cloud Accounts.
2. Open a cloud account, set the state to Draft, and then click Configure in the form header.
3. Click the Datacenters tab and then select the Service Account that holds the credentials that enable access to the provider account that includes the datacenter to add.
When you select the service account, the list of discovered datacenters for the service account appears.

**Note:** If the expected datacenters do not appear, click Discover Datacenters to update the list. Discovery runs and displays all datacenters associated with the service account.

4. Select the datacenters to add and then click **Save**.
   
   In the example, you select **ap-northeast-2**.

   The datacenters are added to the cloud account and appear on the **Datacenters** tab. When Discovery runs, the resources in the datacenter appear on the **Resources** tab.
Schedule discovery of all resources in a service account

You can add a custom schedule for Discovery to discover all resources each datacenter in a service account and then update the CMDB with the new information.

- Role required: sn_cmp.cloud_admin
- A cloud account must exist with service accounts and associated datacenters. You must run on-demand Discovery to discover datacenters before you can schedule Discovery.
- Download the Discovery and Service Mapping pattern from the ServiceNow Store.

- Scheduled Cloud Discovery discovers only datacenters that are part of the service account when the schedule is created. If datacenters have been added since the time you created the schedule, Discovery does not discover those datacenters. Delete the old schedule and create a new schedule every time the datacenters in a service account change.
- Discovery populates the CMDB with the discovered resources and updates the resource information on the Resources tab. You can view Discovery results on the Discovery Log tab.

1. In the Cloud Admin Portal, navigate to Manage > Discovery Schedules.
2. Click Add Cloud Schedule.
3. On the Add Account page, select the cloud Provider and enter a unique, descriptive Name for the schedule.
4. In the Service Account section, select Select Account, specify the service account, and then click Next.
   
   **Note:** To create a service account, select Add Account and then fill in the form. For details, see the process of setting up a service account in the Day 1 setup guide.

5. On the Select Datacenters page, you specify which of the datacenters in the service account to discover. Move the datacenters to discover into the Selected list or select Discover all datacenters listed below to move all datacenters to the Selected list. Click Next.

6. On the Create Schedule page, you specify the time and frequency of discovery.
Note: Run time setting uses the system time zone.

<table>
<thead>
<tr>
<th>Frequency</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>On Demand</td>
<td>Does not run on a schedule. Click Discover now to run Discovery. This is the default option.</td>
</tr>
<tr>
<td>Daily</td>
<td>Runs every day. Use the Start time field to specify the time of day.</td>
</tr>
<tr>
<td>Weekly</td>
<td>Runs on one designated day of each week. Use the Start time field to specify the time of day.</td>
</tr>
<tr>
<td>Monthly</td>
<td>Runs on one designated day of each month. Use the Day field to select the day, specify the time of day, if the designated day does not occur in the month, for example, if you designate day 30, the schedule does not run in February.</td>
</tr>
<tr>
<td>Periodically</td>
<td>Runs every designated period of time. Use the Repeat Interval field to define how often the schedule runs. The first Discovery runs at the point in time defined in the Starting field. The subsequent discoveries run after each Repeat Interval period passes.</td>
</tr>
<tr>
<td>Once</td>
<td>Run one time as designated by the date and time defined in the Starting field.</td>
</tr>
<tr>
<td>Weekdays</td>
<td>Runs every Monday, Tuesday, Wednesday, Thursday, and Friday. Use the Start time field to select the time of day.</td>
</tr>
<tr>
<td>Weekends</td>
<td>Runs every Saturday and Sunday. Use the Start time field to select the time of day.</td>
</tr>
<tr>
<td>Month Last Day</td>
<td>Run the last day of every month. Use the Start time field to select the time of day.</td>
</tr>
<tr>
<td>Calendar Quarter End</td>
<td>Runs on March 31, June 30, September 30, and December 31. Use the Start time field to select the time of day. To change the dates, modify the DiscoveryScheduleRunType script include.</td>
</tr>
<tr>
<td>After Discovery</td>
<td>Allows you to sequentially stagger the schedule. Use this option to run this schedule after the Discovery designated in the Run after field finishes. Select the Even if canceled check box to designate that this discovery should run even if the Discovery is canceled before it finishes.</td>
</tr>
<tr>
<td></td>
<td>• This option is not valid when the Discovery is started via DiscoverNow, or when you cannot designate an inactive Discovery schedule.</td>
</tr>
<tr>
<td></td>
<td>• You cannot create a loop by designating the run after Discovery to be the same Discovery.</td>
</tr>
<tr>
<td></td>
<td>• This Discovery does not run if the Run after Discovery does not finish, with the exception that the Even if canceled check box is selected and the Discovery is canceled.</td>
</tr>
<tr>
<td>Cancel Discovery if longer than Time limit for running the discovery. When the specified time elapses, the remaining tasks for the discovery are canceled even if the discovery is not finished. If the check box is not selected, the discovery runs until finished. This setting constrains system load to a desirable time window.</td>
<td></td>
</tr>
</tbody>
</table>

7. Click Finish and Run Now.

Discovery runs immediately. Discovery runs at the specified times and then adds discovered datacenters to the Logical Datacenters related list.

If you configured a Discovery schedule, it appears in the Discovery Config - Logical Datacenters related list. To run Discovery on a single datacenter, add the datacenter to the Discovery schedule in the related list, then run Discovery again.

Open a datacenter record to see the relationships between the datacenter and the resources in the datacenter.
To view discovery status, discovery logs, discovered devices, and the ECC queue, click **Advanced View**.

If Discovery fails, check the Cloud Discovery results on the [home page](#).
Schedule Discovery of all resources in a datacenter

To update a particular datacenter more frequently than is scheduled for the cloud account, you can add a custom schedule for discovering all resources in the datacenter. To view information about a discovered resource, select a datacenter on the Logical Datacenters related list and then click the resource.

- Role required: sn_cmp.cloud_admin
- A cloud account must exist with service accounts and associated datacenters. You must run on-demand Discovery to discover datacenters before you can schedule Discovery.
- Download the Discovery and Service Mapping pattern from the ServiceNow Store.

- Scheduled Discovery discovers only datacenters that are part of the service account when the schedule is created. If datacenters have been added since the time you created the schedule, Discovery does not discover those datacenters. Delete the old schedule and create a new schedule every time the datacenters in a service account change.
- You can run Discovery on-demand without waiting for the next scheduled Discovery. See Discover all resources in a datacenter on-demand.

To view the list of defined schedules:

1. In the Cloud Admin Portal, navigate to Manage > Cloud Accounts.
2. Open the cloud account that includes the service account with the datacenter and then click the Schedules tab.
3. Select a schedule to view details.

1. Navigate to Cloud Management > Service Accounts.
2. Click a service account and, on the Discovery Config - Logical Datacenters related list, click New.
3. On the Discovery Jobs tab, click Schedule Discovery and then fill in the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discovery schedule</td>
<td>Select the schedule for Discovery.</td>
</tr>
<tr>
<td>Logical datacenter</td>
<td>Select the datacenter to discover on the schedule.</td>
</tr>
<tr>
<td>Service account</td>
<td>The service account that you selected appears in the field. You can select a different service account.</td>
</tr>
</tbody>
</table>

4. Select the Active check box to activate the schedule and then click Submit.

Discover all datacenters in a service account on-demand

After you set up a service account, run Discovery to populate the datacenters in the account.

- Role required: sn_cmp.cloud_admin
- A cloud account must exist with service accounts and associated datacenters. You must run on-demand Discovery to discover datacenters before you can schedule Discovery.
- Download the Discovery and Service Mapping pattern from the ServiceNow Store.

Cloud providers often use proprietary names for account and credential settings. Because the Cloud Management application supports several cloud providers, Cloud Management uses general-purpose names for the settings. In the Google Cloud Platform, the region-specific...
containers for virtual resources are called regions. In Cloud Management, regions are called datacenters or logical datacenters (LDCs). The term “logical” is used to reinforce the idea that Cloud Management is provider-agnostic. All infrastructure or applications that are deployed using Cloud Management are associated with a datacenter.

- You can run Discovery on demand without waiting for the next scheduled run. See Schedule Discovery of all resources in a datacenter.

1. Navigate to Cloud Management > Service Accounts.
2. Click the name of a service account and then click the Discover Datacenters related link.
3. Wait for the Datacenter discovery status field to show a status of Complete. If Discovery is successful, you see the following message in the Datacenter discovery status field: YYYY-MM-DD HH:MM:SS: Completed …. Reload this form to see an updated datacenter list.
4. Reload the form.

The discovered datacenters appear in the Logical Datacenters related list.

**Note:** Check the Cloud API Trail and the Orchestration Trail if Discovery encounters issues.

**Discover all resources in a datacenter on-demand**

At any time, you can run Discovery on a datacenter to update the CMDB.

- Role required: sn_cmp.cloud_admin
- A cloud account must exist with service accounts and associated datacenters. You must run on-demand Discovery to discover datacenters before you can schedule Discovery.
- Download the Discovery and Service Mapping pattern from the ServiceNow Store.

1. In the Cloud Admin Portal, navigate to Manage > Cloud Accounts.
2. Click a cloud account and, on the Datacenters tab, select a datacenter.
   The Resources tab lists the resources in the CMDB.

3. Change the state to **Draft** and then click Discover Now. Wait for Discovery to finish.
4. Change the state of the cloud account to Published.

Discovery populates the CMDB with the discovered resources and updates the information on the Resources tab. You can view Discovery results in the Discovery Log tab.

**Set capacity limits on user requests for resources**

Capacity limits place restrictions on the attributes of cloud resources such as the number of virtual machines, virtual CPUs, or aggregate storage. You can set limits on resources separately for each logical datacenter in a cloud account.

- Role required: sn_cmp.cloud_admin
- A cloud account must exist with service accounts and associated datacenters. You must run on-demand Discovery to discover datacenters before you can schedule Discovery.
- Download the Discovery and Service Mapping pattern from the ServiceNow Store.

**Note:** You can also use quotas to set per-user and total capacity limitations on resources. See [Quota governance for Cloud Management](#).

1. Navigate to **Cloud Management > Cloud Admin Portal > Manage > Cloud Accounts**.
2. Click a cloud account, and then, on the **Datacenters** tab, select a datacenter.
3. Set the state to **Draft**.
4. On the **Capacity Limits** tab, set the **Capacity Limit** values as needed.
<table>
<thead>
<tr>
<th>Name</th>
<th>Discovered</th>
<th>Provisioned</th>
<th>Capacity Limit</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Network Count</td>
<td>11</td>
<td>1</td>
<td>100</td>
<td>Single</td>
</tr>
<tr>
<td>Storage Size</td>
<td>57</td>
<td>0</td>
<td>3000</td>
<td>GB</td>
</tr>
<tr>
<td>VM Count</td>
<td>4</td>
<td>2</td>
<td>1000</td>
<td>Single</td>
</tr>
<tr>
<td>vCPUs Count</td>
<td>4</td>
<td>2</td>
<td>2000</td>
<td>Single</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discovered</td>
<td>Total value discovered by the Discovery process for all resources in the selected service account.</td>
</tr>
<tr>
<td>Provisioned</td>
<td>Total value provisioned for the selected service account.</td>
</tr>
<tr>
<td>Capacity Limit</td>
<td>Maximum allowed value calculated as the sum for all resources in the selected service account.</td>
</tr>
<tr>
<td>Unit</td>
<td>Unit of measure for the specified value. For example, storage is measured in units of GB.</td>
</tr>
</tbody>
</table>

5. Click **Update**.
6. Set the state to **Published**.

Click **Discover Now** to run Discovery on the logical datacenters.
Cloud Management administration guide

After you set up the Cloud Management application on your instance, there are many items that you must configure before your users can request and manage any cloud resources.

Requirements

Role required: cloud_admin

About Cloud Management

Before you begin

Set up Cloud Management

See the appropriate setup guide for your cloud provider:

- Cloud Management setup guide for AWS
- Cloud Management setup guide for Azure
- Cloud Management setup guide for VMware

What to do after setup

Create resource profiles

Resource profiles contain the attributes that a resource can have. Users select values for these attributes when they order a cloud resource. Configure these types of resource profiles: Compute (such as the size of a VM), Operating System (such as the type and version), Storage (such backup) and Security Groups (such as whether or not to use HTTPS). See Resource profiles for more information.

Configure governance

Governance tools that you can use to restrict the provisioning of cloud resources include quotas and policies. Examples of things you can configure include the approval workflow that is used after a user requests a cloud resource, whether or not an email is sent after a cloud resource is stopped, and which datacenter should be automatically selected when a user selects a resource from a specific cloud provider. See Cloud Management governance for more information.

Populate the Cloud Service Catalog

After you apply governance quotas and policies, create Service Catalog items. You can create a catalog item in the following ways:

- Import a template from AWS or Azure
- Use or modify a base-system catalog item
• Generate a catalog item from a blueprint. A blueprint is a configurable template for a catalog item.

See [Blueprints](#) for more information.

**Domain separation in Cloud Management**

This is an overview of domain separation in Cloud Management. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can then control several aspects of this separation, including which users can see and access data.

**Overview**

Domain separation is not supported in this application. For more information, see [Application support for domain separation](#).

**Cloud Management Recipes**

Multi-cloud recipes provide ready content for typical cloud deployment and common operations scenarios across cloud platforms.

**Recipes for Enterprise Workloads and Day-2 Operations**

Cloud Management recipes are ready-to-use catalog items built from sample CFT and ARM templates to support real-world cloud deployment use-cases. These recipes are ready for use in Proof of Concept as well as non-production environments. For production environments, ensure that the recipes are well tested and internally evaluated. You can avail the recipes, as update sets, to be downloaded from the SHARE in the developer portal under the ‘Cloud Management Recipes’ category.

</tr>
</tbody>
</table>

### Day 2 Operations for AWS VM

An update set is provided for some of the important Day 2 operations on AWS cloud provider. Broadly, Day 2 operations are the type of operations that are executed on workloads after they are provisioned. Day 2 operations can include complex life-cycle processes or simple utilities. In this update set, you have access to the following set of operations:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AttachVolume</td>
<td>Attaches and exposes an Amazon (Elastic Block Store) EBS volume to the instance with the specified device name.</td>
</tr>
<tr>
<td>CreateSnapshot (AWS datacenter level discovery operation)</td>
<td>Creates a snapshot of your Amazon (Elastic Block Store) EBS volume.</td>
</tr>
<tr>
<td>DescribeSnapshots</td>
<td>Describes the specified Amazon (Elastic Block Store) EBS snapshots available to you or all EBS snapshots available to you.</td>
</tr>
<tr>
<td>DetachVolume</td>
<td>Detaches an EBS volume from an instance.</td>
</tr>
<tr>
<td>ModifyInstanceAttribute (Only InstanceType)</td>
<td>Modify the specified attribute of the specified instance.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ModifyVolume (Only Size)</td>
<td>Modify parameters of an existing Amazon (Elastic Block Store) EBS volume.</td>
</tr>
<tr>
<td>Day 2 Operations for AWS VM – Set 1</td>
<td>Catalog Item for Day 2 operations for an AWS VM, Set 1.</td>
</tr>
</tbody>
</table>

**Cloud accounts**

A cloud account is the logical representation in Cloud Management of all or part of your managed cloud infrastructure. A cloud account can include multiple service accounts — even service accounts from different providers. For each service account, you specify which datacenters to include in the cloud account.

From a cloud account, you can:

- Add LDCs. A logical datacenter (LDC) is a region-specific virtual cloud that is associated with a service account. The datacenter hosts your cloud resources.
- Run Discovery on LDCs to update the CMDB with configuration changes or life cycle changes (create/modify/terminate) for each resource in each logical datacenter (LDC) that is associated with the cloud account.
- Set capacity limits on cloud services like virtual machines, virtual CPUs, virtual networks, aggregate storage volume size, and others. Set limits to help ensure that cloud resources are provisioned at appropriate scales. Limits are especially important for capacity-constrained environments like private clouds.
- Publish a cloud account to enable business teams to deploy stacks.

**Structure of a cloud account**

An advantage of cloud accounts is that you can group specified service accounts with only the regions (datacenters) that you want to allow cloud resources in. For example, your AWS account could have more than a dozen datacenters globally. However, you might use only one or two regions. To conform with your security and compliance rules, you might not want any resources provisioned to additional regions around the world.
A cloud account can contain as many service accounts as necessary in the following scenarios:

**Possible cloud account structures**

<table>
<thead>
<tr>
<th>Structure</th>
<th>Supported</th>
<th>Not supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add the same service account as many times as necessary, provided each entry is associated with a different LDC.</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>Add the same LDC from different service accounts in one cloud account.</td>
<td></td>
<td>X</td>
</tr>
<tr>
<td>Add different LDCs from different service accounts to a particular cloud account, provided the regions are not the same. Example: You have us-west-1 in serviceaccount1 and us-west-2 in serviceaccount2. Both can be added to cloudaccount1. However, both us-west-1 in serviceaccount1 and us-west-1 in serviceaccount2 cannot be added to cloudaccount1.</td>
<td>X</td>
<td></td>
</tr>
</tbody>
</table>
Update a cloud account

You keep a cloud account in the **Draft** state until you are ready to make the datacenters and capacity limits available for use — in blueprints and the Cloud User Portal, for example. You can change the state to **Published** after you run Discovery.

Set up an additional cloud account

See [Set up an additional cloud account](#).

Add a datacenter to a cloud account

At any time, you can add a logical datacenter to the cloud infrastructure that is represented by a cloud account. See [Add a datacenter to a cloud account](#).

Set capacity limits on user requests for resources

Capacity limits place restrictions on the attributes of cloud resources such as the number of virtual machines, virtual CPUs, or aggregate storage. You can set limits on resources separately for each logical datacenter in a cloud account.

**Set capacity limits on user requests for resources**

**Service categories discovered in AWS**

The Discovery process discovers AWS services.

**Services categories discovered in AWS**

**Cloud Admin Portal**

The Cloud Admin Portal is a role-based portal. You can manage, design, govern, operate, and analyze all your cloud resources from a unified base.

Depending on the role you are logged in with, the Cloud Admin Portal displays different metrics. As an example, if you are logged in to the Cloud Management application as a Cloud Service Designer, the Cloud Admin Portal displays only the **Design** metrics.
Log in to the portal with the following Cloud Management roles to view or manage the associated metrics:

<table>
<thead>
<tr>
<th>Descriptive name and role name</th>
<th>Access to the metrics in Cloud Admin Portal</th>
</tr>
</thead>
<tbody>
<tr>
<td>Root administrator</td>
<td>All the metrics.</td>
</tr>
<tr>
<td>[sn_cmp.cmp_root_admin]</td>
<td>• Manage</td>
</tr>
<tr>
<td></td>
<td>• Design</td>
</tr>
<tr>
<td></td>
<td>• Govern</td>
</tr>
<tr>
<td></td>
<td>• Operate</td>
</tr>
<tr>
<td></td>
<td>• Analyze</td>
</tr>
<tr>
<td>Cloud administrator</td>
<td>All the metrics.</td>
</tr>
<tr>
<td>[sn_cmp.cloud_admin]</td>
<td>• Manage</td>
</tr>
<tr>
<td></td>
<td>• Design</td>
</tr>
<tr>
<td></td>
<td>• Govern</td>
</tr>
<tr>
<td></td>
<td>• Operate</td>
</tr>
<tr>
<td></td>
<td>• Analyze</td>
</tr>
<tr>
<td>System administrator</td>
<td>All the metrics.</td>
</tr>
<tr>
<td>[admin]</td>
<td>• Manage</td>
</tr>
<tr>
<td></td>
<td>• Design</td>
</tr>
<tr>
<td></td>
<td>• Govern</td>
</tr>
<tr>
<td></td>
<td>• Operate</td>
</tr>
<tr>
<td></td>
<td>• Analyze</td>
</tr>
<tr>
<td>Governor</td>
<td>• Govern</td>
</tr>
<tr>
<td>[sn_cmp.cloud_governor]</td>
<td>• Analyze</td>
</tr>
<tr>
<td>Service Designer</td>
<td>• Design</td>
</tr>
<tr>
<td>[sn_cmp.cloud_service_designer]</td>
<td></td>
</tr>
<tr>
<td>Operator</td>
<td>• Operate</td>
</tr>
</tbody>
</table>

Only the Root administrator, the Cloud administrator, and the System administrator roles can view and manage all the metrics in the Cloud Admin Portal.

Click **Guided Setup** to configure the Cloud Management application on your ServiceNow instance. You are guided through completing various configuration tasks. The percentage of the tasks that you have completed is displayed for you to monitor your progress.

Click **Get Help** to ask a question, open an incident, go to the product documentation or the Knowledge base website.

**Resource profiles**

Resource profiles are cloud provider-agnostic definitions that specify the allowed attribute values for a resource. Resource profiles enable you to control the choices that the user sees when requesting a cloud resource. As a result, you do not need to define a unique blueprint for each variation of the resource.
Note: In addition to the cloud-agnostic profiles, you can add provider public images to the Cloud Management catalog. See Add an AWS public image to Cloud Management and Add an Azure public image to Cloud Management.

Example: Compute profile

You might create a compute profile named Micro and map it to a "micro" hardware type, with specified values for memory and CPU. Later, when a user selects a compute resource while requesting a virtual server, Micro appears as an option in the list of available compute resources. The user does not need to specify values for memory and CPU — the values come from the profile.

Resource profile mappings

Resource profiles create mapping associations between the following items:

- A cloud account.
- A logical datacenter in the cloud account.
- A specific resource type in the CMDB that provides the attributes.
- Optional: A pricing value that appears to users when they request a resource that uses the resource profile.

By default for AWS and Azure, Cloud Management maps profiles to templates after Discovery runs. For other providers, such as Google cloud, you must manually associate the profile with the correct template and datacenter.
## Resource types

Each resource profile has associated attributes. The attributes depend on the resource types that are populated after you run Discovery on a cloud account.

<table>
<thead>
<tr>
<th>Resource profile type</th>
<th>Description and attributes</th>
<th>Resource type and template</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application profile</td>
<td>An application profile specifies application software to install on newly-provisioned resources. Users can select applications when they request a stack. Use application profiles when you integrate with configuration management (continuous delivery) providers such as Ansible playbooks. Attributes: Applications running on virtual machines.</td>
<td>Application Template (sn_cmp_application_template)</td>
</tr>
<tr>
<td>Compute profile</td>
<td>A compute profile specifies the hardware to use for newly-provisioned virtual machines. Attributes: The size of computing resources, including the virtual CPUs, memory, and local storage.</td>
<td>Hardware Type (cmdb_ci_compute_template)</td>
</tr>
<tr>
<td>Compute Security Group profile</td>
<td>A compute security group profile applies specified security rules to newly-provisioned resources. You map a compute security group profile to the following items: a cloud account, a datacenter, a Compute Security Group template, and security rules for the template. Attributes: Firewall rules, such as enabling HTTP and HTTPS.</td>
<td>Compute Security Group Template (cmdb_ci_security_grp_template)</td>
</tr>
<tr>
<td>OS profile</td>
<td>An OS profile installs a specified image on a newly-provisioned virtual machine. You map an OS profile to a cloud account, a location (datacenter), an image template, and a cloud script. Attributes: Operating system images, including the OS type and version, the root device type, and the image source.</td>
<td>Image (cmdb_ci_os_template)</td>
</tr>
<tr>
<td>Schedule profile</td>
<td>You map a schedule profile to an instance schedule. The schedule profile applies to all newly-provisioned resources that use the profile. For example, a schedule profile can specify the days of the week and times of day when a stack should start and stop. Attributes: Schedule attributes such as when a stack should be started, stopped, or deprovisioned.</td>
<td>N/A</td>
</tr>
</tbody>
</table>
Create an application profile

An application profile specifies application software to install on newly-provisioned resources. Users can select applications when they request a stack. Use application profiles when you integrate with configuration management (continuous delivery) providers such as Ansible playbooks.

- Role required: sn_cmp.cloud_admin
- You must have a cloud account with datacenters. You must run Discovery on the service accounts to populate the datacenters.

This example shows an application profile mapping for a Tomcat server on Ansible.
1. In the Cloud Admin Portal, navigate to Manage > Resource Profiles.
2. In the Profiles list, select Application Profile and then click New.
3. Enter a unique and descriptive Name and Description for the profile and then click Submit. The profile is created.

4. Map the profile to a template.
   a) In the list, click the profile that you created.
   b) In the Application Profile Mappings related list, click New, fill in the form, and then click Submit.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Workload Config Provider</td>
<td>Select a configuration management provider to associate with the profile.</td>
</tr>
</tbody>
</table>
| Application Template          | Select a template that the profile should be mapped to. If you ran Discovery on the Configuration Provider, the templates are already populated. The resource type associated with an application profile is sn_cmp_application_template. Click the reference icon (i) to view the details of the template. To create a new template:
   1. Click the reference icon (i) to open the Application Templates list.
   2. Click New and then fill in the Application Template form:
      - Name: Enter a descriptive name for the template.
      - Template ID: Enter an ID to use for the template.
      - Config runlist provider: Click the list, select a table from the Table name list, and then select records for the table from the Document list.
      - Config runlist: Specify a configuration runlist.
      - Provider instance: Select a provider instance. |

5. Create as many mappings as needed.

Create a compute profile

A compute profile specifies the hardware to use for newly-provisioned virtual machines. A compute profile maps to a cloud account, a datacenter, and a hardware template.

   - Role required: sn_cmp.cloud_admin
   - You must have a cloud account with datacenters. You must run Discovery on the service accounts to populate the datacenters.

1. In the Cloud Admin Portal, navigate to Manage > Resource Profiles.
2. In the Profiles list, select Compute Profile and then click New.
3. Enter a unique and descriptive **Name** and **Description** for the profile and then click **Submit**. The profile is created.

4. Click the resource profile that you created.

5. Map the profile to a template.
   a) In the list, click the profile that you created.
   b) In the **Profile Mappings** related list, click **New**, fill in the form, and then click **Submit**.

Example compute profile

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud Account</td>
<td>Select a cloud account that the profile is valid for.</td>
</tr>
<tr>
<td>Location</td>
<td>Select the datacenter that the profile is valid for.</td>
</tr>
<tr>
<td>Hardware Template (cmdb_ci_compute_template)</td>
<td>Select the hardware type that the profile should be mapped to.</td>
</tr>
<tr>
<td></td>
<td>Click the reference icon (i) to view the details of the template.</td>
</tr>
</tbody>
</table>

Create a compute security group profile

A compute security group profile applies specified security rules to newly-provisioned resources. You map a compute security group profile to the following items: a cloud account, a datacenter, a Compute Security Group template, and security rules for the template.
Role required: sn_cmp.cloud_admin
You must have a cloud account with datacenters. You must run Discovery on the service accounts to populate the datacenters.

1. In the Cloud Admin Portal, navigate to Manage > Resource Profiles.
2. In the Profiles list, select Compute Security Group Profile and then click New.
3. Enter a unique and descriptive Name and Description for the profile and then click Submit. The profile is created.
4. Map the profile to a template,
   a) In the list, click the profile that you created.
   b) In the Compute Security Group Profile Mappings related list, click New, fill in the form, and then click Submit.

```
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud Account</td>
<td>Select a cloud account for the profile.</td>
</tr>
<tr>
<td>Location</td>
<td>Select the datacenter that belongs to the cloud account.</td>
</tr>
<tr>
<td>Compute Security Group Template</td>
<td>Select or create a template that the profile should be mapped to.</td>
</tr>
<tr>
<td></td>
<td>To create a new template, click the list icon and then click New. Enter a name and a template ID and click Submit.</td>
</tr>
<tr>
<td></td>
<td>Click the reference icon (i) to view the details of the template.</td>
</tr>
</tbody>
</table>
```

5. Add rules to the template. You can create more than one rule per template.
Create an OS profile

An OS profile installs a specified image on a newly-provisioned virtual machine. You map an OS profile to a cloud account, a location (datacenter), an image template, and a cloud script. OS profiles are provider-agnostic and you can use the same profile for multiple cloud accounts.

- Role required: sn_cmp.cloud_admin
- You must have a cloud account with datacenters. You must run Discovery on the service accounts to populate the datacenters.

Create an OS profile

An OS profile installs a specified image on a newly-provisioned virtual machine. You map an OS profile to a cloud account, a location (datacenter), an image template, and a cloud script. OS profiles are provider-agnostic and you can use the same profile for multiple cloud accounts.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CIDR Range</td>
<td>Specify a CIDR range. For example, 10.0.0.0/24.</td>
</tr>
<tr>
<td>IP Protocol</td>
<td>Select an IP protocol. In Azure, the protocols supported are TDP and UDP. ICMP is not supported.</td>
</tr>
<tr>
<td>From Port</td>
<td>Specify the source port number.</td>
</tr>
<tr>
<td>Is Outbound</td>
<td>Enter 0 for inbound and 1 for outbound.</td>
</tr>
<tr>
<td>Name</td>
<td>Specify a name for the rule.</td>
</tr>
<tr>
<td>Network Type</td>
<td>Select the type of network.</td>
</tr>
<tr>
<td>To Port</td>
<td>Specify the destination port number.</td>
</tr>
</tbody>
</table>

Note: Profile mappings that specify more details run first. For example, a mapping that specifies a blueprint, OS profile, and resource alias takes precedence over a mapping that specifies only an OS profile.

1. In the Cloud Admin Portal, navigate to Manage > Resource Profiles.
2. In the Profiles list, select OS Profile and then click New.
3. Enter a unique and descriptive Name and Description for the profile and then click Submit. The profile is created.
4. Map the profile to a template.
   a) In the list, click the profile that you created.
   b) In the OS Profile Mappings related list, click New, fill in the form, and then click Submit.
5. Map the profile to a cloud script. In this procedure, you specify an existing script. See [Create cloud initialization script templates and a script](#).
a) On the Cloud Script OS Profile Mappings related list, click **New** and then fill in the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blueprint</td>
<td>(Optional) Select a blueprint to limit the script to a specific resource block used in the blueprint.</td>
</tr>
<tr>
<td>Cloud script</td>
<td>Select a cloud script to map the OS profile to.</td>
</tr>
<tr>
<td>Active</td>
<td>Select the check box if the cloud script should be run after the virtual machine is provisioned.</td>
</tr>
<tr>
<td>OS profile</td>
<td>If you specify a blueprint, the cloud script is run when the blueprint is provisioned.</td>
</tr>
<tr>
<td>Resource Alias</td>
<td>(Optional) If you specify a resource alias for the blueprint, then the cloud script is executed when the blueprint with the specified resource alias is provisioned.</td>
</tr>
</tbody>
</table>

b) Right-click the form header and select **Save**. The **Name** attribute `[scriptName]` appears in the OS Profile Mapping Overrides list.

Optional: In the OS Profile Mapping Overrides list, enter an attribute name and value to use when the resource is provisioned.

Create a schedule profile

You map a schedule profile to an instance schedule. The schedule profile applies to all newly-provisioned resources that use the profile. For example, a schedule profile can specify the days of the week and times of day when a stack should start and stop.

- **Role required:** `sn_cmp.cloud_admin`
- You must have a cloud account with datacenters. You must run Discovery on the service accounts to populate the datacenters.

1. In the Cloud Admin Portal, navigate to **Manage > Resource Profiles**.
2. In the **Profiles** list, select **Schedule Profile**.
3. Click **New**, enter a unique and descriptive **Name** and **Description**, fill in the form, and then click **Submit**.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schedule</td>
<td>Select an existing schedule or define a custom schedule. A schedule is a rule that includes or excludes specified time periods for actions.</td>
</tr>
<tr>
<td>Multiplier</td>
<td>Auto-populated value between 0 and 1: The fraction of time that a stack with this schedule is expected to be powered on.</td>
</tr>
</tbody>
</table>
Add credentials to an image template
When you add credentials to an image template, the credentials are inherited by all VMs that are provisioned using the template.

- Role required: cloud_admin
- A set of basic authentication credentials must exist.

1. Perform one of the following actions:
   - If an OS profile is mapped to the virtual machine template:
     1. Open the OS profile (Manage > Resource Profiles).
     2. In the OS Profile Mappings related list, click the Name of the template in the Image Template column.
   - For VMware templates, navigate to Configuration > VMware > Virtual Machine Templates.

2. On the Image form, select the basic authentication Credentials.
3. Click Update.

Add an AWS public image to Cloud Management
You can make any AWS image selectable in an OS profile.

Role required: sn_cmp.cloud_admin

1. In the AWS console, select the EC2 service and then click IMAGES > AMIs.

2. Filter the list of images and then take note of the AMI Name and AMI ID values for the image of interest.
3. On the instance, enter cmdb_ci_os_template.list in the Filter navigator text box to open the Images (cmdb_ci_os_template) table and then click New.
4. On the Image form, enter the following values:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object ID</td>
<td>AMI ID value from AWS.</td>
</tr>
<tr>
<td>Name</td>
<td>Meaningful name that is based on the AMI Name value from AWS.</td>
</tr>
</tbody>
</table>
5. On the **Credentials** field, click the magnifying glass and then click **New** on the Credentials page.

6. In the list, click **Basic Auth Credentials**.

7. On the Basic Auth Credentials form, enter a meaningful **Name** for the credential.

8. Enter a **User name** and **Password** to use for instances that are provisioned from this image.

   **Note:** If the name `ec2-user` or `root` does not work, check with your AMI provider.

### Username guidelines

<table>
<thead>
<tr>
<th>Type</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Linux</td>
<td>ec2-user</td>
</tr>
<tr>
<td>RHEL</td>
<td>ec2-user or root</td>
</tr>
<tr>
<td>Ubuntu</td>
<td>ubuntu or root</td>
</tr>
<tr>
<td>Centos</td>
<td>centos</td>
</tr>
<tr>
<td>Fedora</td>
<td>ec2-user</td>
</tr>
<tr>
<td>SUSE</td>
<td>ec2-user or root</td>
</tr>
</tbody>
</table>

9. Click **Submit** to close the Basic Auth Credentials form.

10. Right-click in the header and select **Save** to save the current configuration of the new image record.

   In the Related Items list, you can see that the image is associated with the specified datacenter.

11. Click **Update** to make the public image selectable in an OS profile.

   This step also creates a relationship between the public image and the logical datacenter (LDC) in the CMDB.

---

### Add an Azure public image to Cloud Management

You can make any Azure image selectable in an OS profile.

**Role required:** sn_cmp.cloud_admin

1. In the Azure command-line interface, make note of the values of the **Offer**, **Publisher**, **Sku**, and **Version**.

   On the command line, you can search by offer or by publisher or by both, as show in the example. Each line item is an image of a particular version of CentOS from OpenLogic.
2. On the instance, enter `cmdb_ci_os_template.list` in the Filter navigator text box to open the Images (cmdb_ci_os_template) table and then click New.
3. Configure the form layout to show Offer, Serial number, Version, and Vendor.
4. On the Image form, enter the following values:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object ID</td>
<td>Enter <code>/publisher/offer/sku/version</code>. You can get these values from the Azure CLI. As an example, <code>/OpenLogic/CentOS/6.5/6.5.201501</code>.</td>
</tr>
<tr>
<td>Name</td>
<td>Meaningful name that represents the version of the OS. CentOS 6.5 in the example.</td>
</tr>
<tr>
<td>Guest OS</td>
<td>Operating system.</td>
</tr>
<tr>
<td>Offer</td>
<td>Offer value from Azure.</td>
</tr>
<tr>
<td>Serial Number</td>
<td>Sku value from Azure.</td>
</tr>
<tr>
<td>Version</td>
<td>Version value from Azure.</td>
</tr>
<tr>
<td>Vendor</td>
<td>1. Click the magnifying glass and then click New.</td>
</tr>
<tr>
<td></td>
<td>2. In the Name field, enter the Publisher value from Azure.</td>
</tr>
<tr>
<td></td>
<td>3. Click Submit.</td>
</tr>
</tbody>
</table>

5. On the Credentials field, click the magnifying glass and then click New on the Credentials page.
6. In the list, click Basic Auth Credentials.
7. On the Basic Auth Credentials form, enter a meaningful Name for the credential.
8. Enter a User name and Password to use for instances that are provisioned from this image.
9. Click Submit to close the Basic Auth Credentials form.
10. Right-click in the header and select Save to save the current configuration of the new image record.
    In the Related Items list, you can see that the image is associated with the specified datacenter.
11. Click Update to make the public image selectable in an OS profile.
    This step also creates a relationship between the public image and the logical datacenter (LDC) in the CMDB.
**IPAM integration**
If you use an IP address management (IPAM) tool such as Infoblox, you can manage cloud IP addresses, networks, and subnets in your cloud catalog offerings.

**Infoblox integration**

By default, Cloud Management supports Infoblox integration. You can create Infoblox credentials and then set up an Infoblox instance record. See [Register an Infoblox server](#) for instructions.

**Subnets**

If you have subnets in your AWS and Azure clouds, Cloud Management finds them when Discovery runs on a service or cloud account.

**Note:** If you have networks and subnets in a VMware vSphere platform, Discovery does not create subnet records in the CMDB and cannot map the subnet to the appropriate network. You must create the records manually.

**Register an Infoblox server**

To integrate with Infoblox, you must create an Infoblox record and associate it with the appropriate credentials to register your Infoblox server with the instance.

- Role required: sn_cmp.cloud_admin
- Create [Infoblox credentials](#).

1. In the Cloud Admin Portal, navigate to Manage > Networks & IPAM > IPAM Providers > Infoblox.
2. Click **New**, enter a unique and descriptive **Name**, fill in the form, and then click **Submit**.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>URL</td>
<td>Enter the URL of the Infoblox server.</td>
</tr>
<tr>
<td>Credential</td>
<td>Select the Infoblox credential.</td>
</tr>
</tbody>
</table>

**Create an IP pool**

Create an IP pool to associate a cloud subnet with an IPAM provider instance.

- Role required: sn_cmp.cloud_admin
- Create [Infoblox credentials](#) and [register an Infoblox server](#).
- Run Discovery on the cloud account to find subnets or [manually create cloud subnets](#).

1. In the Cloud Admin Portal, navigate to Manage > Networks & IPAM.
2. On the **IP Pools** tab, click **New**, enter a unique and descriptive **Name**, and then fill in the form.
Field | Description
--- | ---
IPAM Provider | Select an IPAM provider.
Provider Instance | Select an instance for the provider.
Provider Version | Enter a version for the provider.
Subnet | Select a subnet. For AWS or Azure, select a discovered subnet that has been configured in AWS or Azure. For VMware, copy the CIDR range from the IPAM tool and paste the CIDR range in this field. See [Create a cloud subnet](#).
Mode | Select a mode based on the provider that you are creating this IP pool for. The model varies based on the provider.

3. Click **Submit**.

The related subnet appears in the **Subnet** related list at the bottom of the form.

Create a cloud subnet

If you have subnets in your VMware vSphere account, create a cloud subnet record in the instance.

Role required: sn_cmp.cloud_admin

1. In the Cloud Admin Portal, navigate to **Manage > Networks & IPAM**.
2. On the **IP Pools** tab, click **New** to create a new record.
3. In the **Subnet** field, click the lookup icon.
   The Cloud Subnets list appears.
4. Click **New**.
5. Fill out the form fields (see table).

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Provide a descriptive name.</td>
</tr>
<tr>
<td>Status</td>
<td>Leave the status value as <strong>Installed</strong>.</td>
</tr>
<tr>
<td>CIDR/Gateway/Subnet Mask</td>
<td>Enter the CIDR associated with the subnet, the IP address of the gateway, and the subnet mask. For VMware, the CIDR, Gateway, and Subnet Mask fields are mandatory.</td>
</tr>
<tr>
<td>Primary and Secondary DNS</td>
<td>Enter the DNS values. For VMware, the Primary DNS field is mandatory.</td>
</tr>
</tbody>
</table>

6. Click **Submit**.

Create a relationship between a VMware network and subnet  
If you discover VMware networks and subnets, you must manually create a relationship between the two.

Role required: sn_cmp.cloud_admin

If no relationship exists and a user must select a virtual network and subnet in the Cloud User Portal, the user can encounter an error.

1. In the Cloud Admin Portal, navigate to **Manage > Service Accounts**.
2. Open the datacenter that contains the VMware cloud network.

   ![Note: VMware cloud networks are saved in the VMware vCenter Network (cmdb_ci_vcenter_network) table. AWS and Azure cloud networks are saved in the Cloud Networks (cmdb_ci_network) table.](image)

   3. Under **Related Items**, click the plus icon to add a new relationship.
   4. Make sure the **Use suggested relationships** check box is selected, and then select the **Contains (Parent)** relationship.
   5. Under **Filter**, create the filter necessary to find the subnet.
   6. Under **Configuration Items**, select the check box next to the subnet.
   7. In the **Relationships** section, click the plus icon.

   The relationship is added to the list.

8. Click **Save and Exit**.

Reserve IP addresses for VMware vSphere virtual machines in InfoBlox

Create a policy to reserve IP addresses for VMware vSphere virtual machines in Infoblox, at the time of provisioning the virtual machines.

Role required: sn_cmp.cloud_admin.

You can create a policy that is invoked when a VMware virtual machine is provisioned to get an IP address from Infoblox. Before the virtual machine is provisioned, the instance makes a call to Infoblox that creates a host record with the IP address.

1. In the Cloud Admin Portal, navigate to **Govern > Policies**.
2. Click **New** and then fill in the form.
Register IP addresses for AWS and Azure virtual machines in Infoblox

Create a policy to register IP addresses for AWS and Azure virtual machines in Infoblox, once these virtual machines are provisioned.

Role required: sn_cmp.cloud_admin.

When AWS and Azure virtual machines are provisioned, IP addresses are automatically allocated to them. You can create a policy and the policy is invoked, once these virtual machines are provisioned, to get their IP addresses and register these IP addresses in Infoblox.

1. In the Cloud Admin Portal, navigate to Govern > Policies.
2. Click New and then fill in the form.
   
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policy Name</td>
<td>Enter a descriptive name.</td>
</tr>
<tr>
<td>Policy Trigger</td>
<td>Select on Resource operation.</td>
</tr>
<tr>
<td>Resource Block</td>
<td>Select ResourceBlock Virtual Server.</td>
</tr>
<tr>
<td>Operation</td>
<td>Select Virtual Server interface provision.</td>
</tr>
<tr>
<td>Moment</td>
<td>Select Pre Operation.</td>
</tr>
</tbody>
</table>

3. Click Submit to publish the policy.
4. Create a policy rule for the policy. Specify two conditions in the condition builder for locating the vSphere virtual machine. Select Request from > starts with and enter vSphere.
5. Click Update.
6. In the Policy Rules Action related list, click New to create a policy action.
7. Select IP Address Management in the Create Policy Rule Action dialog box. Enter a name in the Action Name field, select Infoblox in the Provider Type list, and select Reserve IP address in the IPAM Method Name list.
8. Click Submit.
9. In the Policy Rule Action Attributes section, enter the domain name of your network in the DNNSuffix field. As an example, corp.servicenow.com. Values for all the other properties are already populated.
10. Click Update and republish the policy.
8. Click Submit.
9. In the Policy Rule Action Attributes section, enter the domain name of your company’s network in the DNSSuffix field. As an example, corp.servicenow.com. Values for all the other properties are already populated.
10. Click Update and republish the policy.

Delete a host record in Infoblox
When a virtual machine is de-provisioned, delete the host record from Infoblox. Deleting the host record enables that IP address to be available and be reused for other virtual machines.

Role required: sn_cmp.cloud_admin.

1. In the Cloud Admin Portal, navigate to Govern > Policies.
2. Click New.
3. Fill out the fields on the Policy form (see table).

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policy Name</td>
<td>Enter a descriptive name.</td>
</tr>
<tr>
<td>Policy Trigger</td>
<td>Select on Resource operation.</td>
</tr>
<tr>
<td>Resource Block</td>
<td>Select ResourceBlock Virtual Server.</td>
</tr>
<tr>
<td>Operation</td>
<td>Select Virtual Server interface Deprovision.</td>
</tr>
<tr>
<td>Moment</td>
<td>Select Post Operation.</td>
</tr>
</tbody>
</table>

4. Click Submit to publish the policy.
5. Create a policy rule for the policy and click Update.
6. In the Policy Rules Action related list, click New to create a policy action.
7. Select IP Address Management in the Create Policy Rule Action dialog box. Enter a name in the Action Name field, select Infoblox in the Provider Type list, and select Release IP address in the IPAM Method Name list.
8. Click Submit.
9. In the Policy Rule Action Attributes section, enter the domain name of your company network in the DNSSuffix field. As an example, corp.servicenow.com. Values for all the other properties are already populated.
10. Click Update and republish the policy.

Support for continuous delivery (configuration management)
The Cloud Management application supports integration with continuous delivery solutions (also known as configuration management). Ansible is supported as the default config management provider.

The Cloud Management application supports configuration management providers in two ways:

- **Application profile based approach**: Create an application profile for an entity and in the order catalog form, select that profile to deploy that entity. Each profile has a config installable. You can create multiple application profiles- as an example, one for PostgreSQL and one for Apache. Each profile can be mapped to a configuration management provider. In the Cloud User Portal, based on the profile you select, a configuration grid appears populated with attributes and values for that specific configuration management provider. You can modify any values in the order form and provision the entity.
- **Resource block based approach**: Use a resource block, like Apache2, in a blueprint to represent an entity that a configuration management provider manages. The same resource block can be used to support more than one entity of the same kind. As an example, an Apache2 resource block can be used to support multiple Apache2 servers. In the order catalog form, select a provider type and then select a provider. Based on the specific provider,
configuration management attributes and values appear. Once you provision the entity, you can save the configuration of the resource block and store it in the CMDB for future use.

What to do

<table>
<thead>
<tr>
<th>Step</th>
<th>Goal</th>
<th>See these topics</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Create credentials for Ansible.</td>
<td>Enable Cloud Management to access the configuration provider with the necessary credentials.</td>
<td>- Configure Ansible Tower user name and password</td>
</tr>
<tr>
<td>2. Create the workload provider type, and then create the provider.</td>
<td>Configure Cloud Management to work with the configuration management provider of your choice. Then run discovery on the provider, using the credentials you provide, to find the resources that the provider already owns.</td>
<td>- Create workload provider type and Create a configuration management provider and run Discovery</td>
</tr>
<tr>
<td>3. Create an application profile with a mapping</td>
<td>Create the profile that defines the application that the configuration management provider manages. The profile is based on the discovered inventories in the provider.</td>
<td>- Create an application profile</td>
</tr>
<tr>
<td>4. Create a blueprint</td>
<td>Create a blueprint with BootstrapNode, Register Node, and ExecuteConfigPackages operations on the virtual resource that the configuration provider manages. You can also customize the input parameters on the form to allow the user to select important inputs, like the application profile template, organization, and credential ID.</td>
<td>- Create a blueprint for configuration management provider integration and Create a blueprint for Ansible Tower integration</td>
</tr>
<tr>
<td>5. Provision a resource from the Cloud User Portal</td>
<td>The resource should provision, with the stack status indicating the BootstrapNode, Register Node, and ExecuteConfigPackages steps.</td>
<td></td>
</tr>
</tbody>
</table>

Configure Ansible Tower user name and password

Configure Ansible Tower credentials to access the Ansible Automation Engine through your instance.

Role required: sn_cmp.cloud_service_designer

1. Navigate to Orchestration > Credentials, and then click New.
2. Click Ansible Tower Credentials.
3. Fill out the form fields (see table):

To integrate Cloud Management with the Ansible configuration management account, you need only to configure the user name and password for the administrator account in Ansible.
Form fields for Ansible Tower credentials

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Provide a descriptive name.</td>
</tr>
<tr>
<td>User name/Password</td>
<td>Enter the authentication credentials for the Ansible Tower user with administrator rights.</td>
</tr>
</tbody>
</table>

Note: You do not need to configure the other fields.

Create workload provider type
Create a workload provider type for each new configuration management provider. This information appears in the order catalog form as management attributes that your users can select when provisioning a virtual resource through a configuration management provider.

Role required: cloud_admin

1. In the Cloud Admin Portal, navigate to Manage > ConfigManagement.
2. Click Workload Config Provider Types, and then click New.
3. Fill in the form fields (as shown in the table).

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a name for the workload provider type.</td>
</tr>
<tr>
<td>Product Type</td>
<td>Select a product type from the list.</td>
</tr>
<tr>
<td>Config CI</td>
<td>Select the configuration table created for the provider that displays the discovered resources from the list.</td>
</tr>
<tr>
<td>Credential Resolver</td>
<td>Select a credential resolver from the list.</td>
</tr>
<tr>
<td>Server Type</td>
<td>Select the type of server for the provider like Opensourced, Enterprise, etc.</td>
</tr>
<tr>
<td>Version</td>
<td>Enter the version of the provider.</td>
</tr>
<tr>
<td>Credential Type</td>
<td>Select the table where the credentials are stored for this provider.</td>
</tr>
</tbody>
</table>
4. Add properties for the workload type in the **Workload Provider Properties** section. In addition to the existing properties, you can add more properties. Workload provider properties are displayed in the order catalog form (in the Cloud User Portal) as management attributes.

For example, for an Ansible provider type, **Inventory** and **Hostgroup** are required. The values for these properties come from Resource Pools.
5. Click **Submit**.

Create a configuration management provider and run Discovery

Create a configuration management provider such as Chef or Ansible, and then run Discovery on the provider to find its resources.

- Role required: cloud_admin
- For Chef, you need a Chef server and **Chef credentials**.
- For Ansible, you need an Ansible server and **Ansible credentials**.

1. In the Cloud Admin Portal, navigate to **Manage > Config Management**.
2. Click **New**.
3. Fill out the form fields (see table). Obtain most of this information from your Chef server setup.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a descriptive name.</td>
</tr>
<tr>
<td>Organization</td>
<td>Enter the Chef or Ansible Tower organization for access control. You can obtain this information from the configuration management provider console.</td>
</tr>
<tr>
<td>URL</td>
<td>Enter the full URL of your Chef server or Ansible Tower, including the https protocol (for Ansible) and the port number (for Chef).</td>
</tr>
<tr>
<td>Provider</td>
<td>Select <strong>Chef Server 12</strong> or <strong>Ansible Tower</strong>. If you are adding a configuration management provider, create provider type information for that provider. Once you create the provider type information, the provider type appears in the <strong>Provider</strong> list.</td>
</tr>
<tr>
<td>Server Type</td>
<td>Select a server type: For Chef Server 12, select one of these types: Hosted, Private, Enterprise. For Ansible Tower, select one of these types: Opensourced, Licensed.</td>
</tr>
<tr>
<td>Credential</td>
<td>Select Chef credentials.</td>
</tr>
</tbody>
</table>

4. Click **Submit**.
5. On the Config Providers page, click the provider tile.
6. To find the resources in the config provider, click **Discover Now**.

   **Note:** If you provision or otherwise change resources through the configuration management provider interface, you must manually run Discovery again through this configuration management provider form. You cannot create a scheduled discovery for configuration management providers.

The discovered resources appear under **Entities**.

The discovered resources for Chef are:

- Chef Server Cookbook
- Chef Server Node

The discovered resources for Ansible Tower are:

- **Ansible Inventory** categorizes the applications and virtual resources.
- **Cfg Installable** holds the actual components that run when the applications install. For Ansible, the items in this list are *playbooks*, which are also referred to as *runlists* in this form.
Example Ansible Inventory
Ansible config installables (playbooks)

7. Click **Chef Server Cookbook** or **Ansible Inventory** to explore the contents.

© 2020 ServiceNow, Inc. All rights reserved.

After a user provisions a resource from the blueprint, the Stack Status indicates how the system runs through the Create node, Bootstrap, and ExecuteConfigPackage steps. You can obtain the IP address of a virtual machine in the User Portal by going to Stacks > {category} and selecting the new virtual machine. Open the configuration management provider server to see the newly provisioned resource on the node the user specified.

Create a blueprint for configuration management provider integration

After you set up your configuration management provider and run Discovery on it, configure resource blocks.

Role required: sn_cmp.cloud_service_designer

For an example of a virtual machine configured to work with Ansible, see Create a blueprint for Ansible Tower integration.

1. In the Cloud Admin Portal, navigate to Design > Blueprints.
2. Click New.
3. Create a deployment model with a container, virtual machine, and a datacenter.
4. Click the **Operations** tab, select an operation, and then click **Add**. The Add Resource Operation dialog box appears.

5. Add the following resource operations for the Virtual Server one at a time:
   - **Bootstrap Node**: prepares the virtual server to communicate with Ansible Tower.
   - **Register Node**: registers the configuration management provider.
   - **ExecuteConfigPackages**: runs the applications or playbooks.

6. Click **Submit** once you have added the resource operations. The operations are added to the graph.
7. Make the following changes to these operations, and then click **Save** after each change:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Make this change</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blueprint Container Resource.Provision</td>
<td>Enable the <strong>WorkloadConfigProvider</strong> and <strong>WorkloadConfigProvider Type</strong> parameters. On the Cloud User Portal, users can see these fields to select the configuration management provider.</td>
</tr>
</tbody>
</table>

| Management Attributes | Every operation has management attributes. |

The form parameters, **Virtual_Server_ApplicationProfile**, **Virtual_Server_ConfigurationOverrides**, and **Virtual_Server_ManagementAttributes**, are displayed in the Cloud User Portal while launching a catalog.

8. Go to the Cloud User Portal. Select the workload provider type in the order catalog form. Based on the workload provider type you select, the **Workload Config Provider** field gets loaded.

9. Select an application profile. Based on the profile, the configuration overrides appear. These overrides are the discovered config installable parameters.

10. Publish the catalog item.

Create a blueprint for Ansible Tower integration

For resources that a configuration management provider manages, you must add operations beyond the standard **Provision** operation. This example shows you how to create a blueprint for a virtual server in Ansible.

Role required: **sn_cmp.cloud_service_designer**

1. In the Cloud Admin Portal, navigate to **DesignBlueprints**, and then click **New**.
2. Enter a unique and meaningful **Name** and **Description**
3. Specify the service **Category** for the blueprint.
4. Click **Save**.
5. Add a **Virtual Server** resource block and a datacenter.
6. Complete the following steps to create the containment connections.
7. Modify the operations as follows:
   a) Click the **Provision** operation in the **Operations** tab under the deployment model.
b) Next to Provision, click Add.
c) Add these operations to the virtual server resource in the blueprint:

<table>
<thead>
<tr>
<th>Interface</th>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Virtual Server Interface</td>
<td>Bootstrap Node</td>
<td>Prepares the virtual resources to communicate with Ansible Tower.</td>
</tr>
<tr>
<td>Virtual Server Interface</td>
<td>Register Node</td>
<td>Registers with the Ansible Tower server that is configured.</td>
</tr>
<tr>
<td>Virtual Server Interface</td>
<td>ExecuteConfigPackages</td>
<td>Runs the playbooks.</td>
</tr>
</tbody>
</table>

**Add Resource Operation**

- **Resource**: Virtual Server
- **Interface**: Virtual Server Interface
- **Operation**: Bootstrap Node

**Bootstrap Node operation**

This graphic illustrates the operations:
d) Click **Provision** in the Blueprint Container Resource row.

```
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>WorkloadConfigProvider</td>
<td>${parameter.WorkloadConfigProvider}</td>
</tr>
<tr>
<td>WorkloadConfigProviderType</td>
<td>${parameter.WorkloadConfigProviderType}</td>
</tr>
</tbody>
</table>
```

If these parameters do not exist, you can create them by clicking the plus (**Add Attributes**) icon.

f) Click **Save**.
g) Click **Provision** in the Virtual Server row.

h) Make sure that the check box next to the **ComputeFirewallName** parameter is selected.

![ComputeFirewallName](image)

i) Click **Save**.

j) Also on the **Provision** operation for the virtual server, change the value for the **DiscoverAndAttachIP** input attribute to **True**. You do not need to select the check box for this parameter because the user does not need to see it.

k) Click **Save**.

l) Click the **Bootstrap** operation for the virtual server and make sure that the check box next to **ManagementAttributes** is selected. On the Cloud User Portal, users select the inventory and the actual application they want to install from the **Virtual Server Management Attributes** field.

m) Click the **ExecuteConfigPackages** operation for the virtual server and make sure that the check box next to **ConfigurationOverrides** is selected.

On the Cloud User Portal, users can specify values for several attributes of the application, such as the username and password, from the **Virtual Server Configuration Overrides** field.

The settings that can be overridden come from the Ansible Tower template. Make sure that the values in the **EXTRA VARIABLES** field in the Ansible template are saved in JSON so that the MID Server can process the data.
8. Click **Generate Catalog**.
9. Click the **Draft/Published** slider to **Published**.

**Day 2 operations using workflows**

Take advantage of the workflows framework to automate your Day 2 operations. Quickly write a workflow that communicates with a Cloud API or a particular resource. Use SSH, PowerShell, or a similar tool, to access and then extend the workflow capabilities.

Day 1 operations provision resources in a cloud as part of ordering from the ServiceNow catalog or the cloud catalog. These operations result in a stack that contains a list of provisioned resources. Day 2 operations can be carried out on the resources that are part of the stack or the resources discovered by the system.

Previously, to execute Day 2 operations in Cloud Management, you had to interact directly with the Cloud API (CAPI), which frequently meant that you had to write new APIs to support a new operation. With the ability to map Day 2 operations to workflows, you can now more easily use base-system workflow capabilities.

Capabilities include:
- SSH/PowerShell to connect to a VM.
- Use REST end points to call various Cloud Providers.
Rules with workflows

Cloud Management supports using Now Platform rules with workflows. Rules are collections of conditions and actions. If all conditions of a rule evaluate to true, the system performs the actions. If any condition evaluates to false, the system does not perform the actions. Creating rules helps you track activities and more quickly respond to and resolve issues.

Learn more

To learn about workflows in general, see:

- Workflow
- Create a workflow from a table

To learn about how to work with variables in workflows, see:

- Workflow input variables
- Using variables in a workflow

Credential handling

Extend the workflow engine to manage processes and automate things outside of an instance with Orchestration. Use the appropriate credentials required by Orchestration: SSH requires SSH and PowerShell activity elements: SSH requires SSH and PowerShell requires Windows.

The Cloud Management application generates credentials (node credentials) after a VM is provisioned. Node credentials are used to connect to a VM. In addition to node credentials, the system generates SSH/Windows credentials. These credentials are required for Orchestration, which provides the automation for workflows.

Pre-existing VMs

Cloud Management now generates SSH private key credentials and Windows credentials for all active pre-existing VMs provisioned through Cloud Management.

Delete credentials

When you deprovision or delete a VM, all associated credentials are deleted, including the node credential and SSH private key credentials/Windows credentials, as well as the credentials alias tag.

Use the credentials

See Use credentials with SSH workflows for details.

Use credentials with SSH workflows

Add an SSH workflow with a credentials tag.

- Orchestration must be installed.
- Role required: Cloud designer or sn_cmp.cloud_admin

You can use an expression to get the Credential alias tag. See Create an SSH activity for instructions.
This example uses a VM provisioned on an AWS LDC datacenter.

1. In the Cloud User Portal, click **Launch a Stack** and then select the AWS VM.
2. On the General Info tab, enter a unique and meaningful **Stack Name**, select **AWS Datacenter** for the **Location**, and then click **Next**.
3. On the Provision tab, enter a **Virtual Server Node Name** (the name can be the same as the stack name) and then click **Submit**.
   The Cloud Activities page displays the VM that you requested and the status of your request. The Request Status section displays Deployment Successful when complete.
4. In your instance, view the workflow:
   a) Filter for workflow and then click **Workflow Editor**.
   b) At the right of the workflow list window, filter in the Workflows tab and select the workflow to work with. When the workflow appears in the canvas, you can see the Execute SSH Command activity pill in the workflow.
5. To edit the activities in the workflow, click the workflow properties icon (circle containing an i) and perform the following:
   a) On the **Custom** tab at the right, go to **Custom Activities > Global** and double-click the activity to modify.
      When the new activity opens in the Activity Designer, you can use the form to create a reusable orchestration activity.
   b) To change from the Cloud Management application to the Global application to edit the record, click ‘here’ in the menu bar. The Global application makes the activities available across the entire platform.
6. Edit the fields in each of the following activity tabs. Click **Continue** to move to the next tab.

<table>
<thead>
<tr>
<th>Activity tab</th>
<th>Field descriptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>General</td>
<td>Enter a unique name for the activity</td>
</tr>
<tr>
<td>Inputs</td>
<td>Enter values for the host, type, and whether the activity’s mandatory</td>
</tr>
</tbody>
</table>
| Execution Command  | To form the command to be executed, drag inputs from the list to the form. Available inputs:  
   - Host, which is the IP address of the VM to connect to.  
   - Command, which is any script or command single line to be run on the VM.  
   - Credential tag, which is the alias for the sys_id of the VM. You can either enter the credential tag manually or provide an expression in the resource script, which then auto-populates the Credential tag field.  
   Script: $(Script:CMPVMUtil.getCredentialAlias(arg= $(parameter.resourceID))) |
| Output             | Enter the name of each output, and the type of each output, for example, string     |
| Conditions         | Enter any required conditions. Conditions are optional                              |

Use SSH to shutdown a VM using workflow type operation

Use SSH to remotely shutdown a VM using a workflow type operation. Follow this use case to step through all of the tasks required to accomplish this type of shutdown.
Role required: workflow designer or sn_cmp.cloud_admin

1. To create the SSH custom activity, follow these steps:
   a) Navigate to Admin Portal > Workflows > Workflow Editor.
   b) Click the Custom tab, then click + (plus sign) to create a new custom activity.
   c) From the list of types of activities, choose SSH.
   d) The Activity Designer opens with the General tab displayed. Enter a unique name for the activity, then click Continue.
   e) In the Inputs tab, add the input variables with the following steps, then click Continue:
      f) In the Input table, click the + in a circle to create a new input variable.
      g) Click to the right of ABC in the Name column, and type the input name.
         Inputs vary according to the object to be impacted. Here, we’re creating an activity to stop a VM, so the inputs reflect the values needed to accomplish that action.
         The Type and Mandatory columns populate automatically according to input you enter.
      h) Create a new input object for each input in the following table, then click Continue:

<table>
<thead>
<tr>
<th>Input variable</th>
<th>Type</th>
<th>Mandatory</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>String</td>
<td>No</td>
</tr>
<tr>
<td>Command</td>
<td>String</td>
<td>No</td>
</tr>
<tr>
<td>CredentialTag</td>
<td>String</td>
<td>No</td>
</tr>
</tbody>
</table>

   i) On the Execution Command tab, perform the following:
   j) In the Output table, click the + in a circle to create a new output variable.
   k) Click to the right of ABC in the Name column, and type the output name.
      The output variables reflect the possible outcomes when the workflow attempts to SSH to the VM. The Type column populates automatically.

<table>
<thead>
<tr>
<th>Outputs</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>error</td>
<td>String</td>
</tr>
<tr>
<td>output</td>
<td>String</td>
</tr>
</tbody>
</table>
l) Click and drag the error variable to the Variable name field in the Parsing rules table.
m) In the Parsing rule for error dialog, in the Parsing source drop-down, select the appropriate source; in this case, executionResult.errorMessages.
n) Repeat for the output variable, selecting executionResult.output as the Parsing source, then click Submit.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>error</td>
<td>String</td>
</tr>
<tr>
<td>output</td>
<td>String</td>
</tr>
</tbody>
</table>

o) Click Continue.
Conditions are optional.
p) Click Save, then click Publish to make the activity available to use in the workflow.

2. To create the SSH workflow needed to power off the VM, follow these steps:
When you create a workflow, you associate it with a table and with an activity.
• You can create the workflow on a table at the global-level or a table on the application-level. Use the global table to make the workflow available to use with all ServiceNow applications. Here, we use a table for the Cloud Management, so this workflow will only be available to use with that application.
• You can create the workflow from the Workflow Editor or from the Activity Designer. Here, the Activity Designer is used.

a) From the Activity Designer, select the Workflows tab at the right, then click the + (plus sign) to add a new workflow.
b) In the New Workflow window, enter a unique name for the workflow.
c) From the Table drop-down, select the table to use. Here, we search for and use the Virtual Machine instance cmdb_ci_vm_instance because we intend to use the workflow to power off a VM.
d) Click Submit.
e) When the workflow displays in the canvas, delete the connection line between the start point and end point of the workflow.
f) Delete the connection line between the start point and end point of the workflow.
g) Right-click the more info canvas and select Edit Inputs.
h) Create the following inputs:

Note: Take the input names from the Column field, not from the Label field. If the workflow is associated with a global-level table, the input name in the Column field...
is prefixed with u_, for example, u_ipaddress. Here, the table is application-level, so it needs no prefix.

<table>
<thead>
<tr>
<th>Type</th>
<th>Label</th>
<th>Column (automatically added)</th>
<th>Max Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>IPAddress</td>
<td>ipaddress</td>
<td>100</td>
</tr>
<tr>
<td>String</td>
<td>CredentialTag</td>
<td>credentialtag</td>
<td>100</td>
</tr>
</tbody>
</table>

i) Click Submit.

j) Right-click the canvas and select Add Custom Activity.

k) In the Versions window, search for and select the activity you created initially in this use case.

l) In the New Activity window for that activity (Workflow Activity New record (Diagrammer view)), enter a name for the activity.

m) In the Host field, type the input mapping that the activity expects. Here, that is the IP address of the host: $(workflow.inputs.u_ipaddress)

   Use this expression to get the IP Address:
   $(Script: CMPVMUtils.getReachableIp(arg=$(Stack.items[Virtual Server].attributes[sys_id])))

n) In the Command field, type shutdown -h now

o) In the Credential tag field, type $(workflow.inputs.u_credentialtag)

   Use this expression to get the credential tag:
   $(Script: CMPVMUtils.getCredentialAlias(arg=${Stack.items[Virtual Server].attributes[sys_id]})

p) Click Submit.

   The activity displays in the workflow canvas.

q) Right-click the canvas, and select Add Core Activity to add a run script activity.

r) In the Workflow Activity Definitions window, search for and select Run Script.

s) In the New Activity: Run Script window, type a name for the activity.

t) Cut and paste a script (appropriate for your environment) in the Script field.

   Example script:
   ```java
   if ( gs.nil(data.get(3).error)) {
       current.state = 'off';
       current.setWorkflow(false);
       current.update();
   }
   ```

u) Click Submit.

v) In the canvas, connect the connectors between the Begin point, the activity, the Run Script, and the End point.

w) Validate the workflow by using the workflow validation.
3. To add the operation to a resource block, following these steps:
   You can select from the existing operations in a resource block to work with your workflow or you can create a custom operation.
   a) In the Cloud Admin Portal, navigate to Design > Resource Blocks.
   b) Select a resource block, for example Virtual Server.
   c) Move the state of the resource block from Published to Draft to make it editable.
   d) Select the Operations tab, then from the Interface drop-down field, select an interface that is available to the user. The default interface is Virtual Server Interface.
   e) Click + to the right of the Operation field, then in the Add Operation dialog, enter a meaningful and unique name.
   f) Select an operation from the Operation Type drop-down.
   g) Select Public from the Access Type field.
   h) Fill in the form, and then click Submit.

<table>
<thead>
<tr>
<th>Operation Type</th>
<th>Select the operation to perform.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access Type</td>
<td>For the user to see the operation at the Resources level during provisioning, select Public. Operations set to Private are not visible during provisioning.</td>
</tr>
</tbody>
</table>

The operation is available on the resource when you select the resource for your workflow.

i) To add a resource operation step to invoke the workflow, still in the Operations tab, click Steps > Add Step.
   To enable the workflow to be exported as part of the update sets, you must create an extension interface and add the new operation. See Extend Cloud Management resource blocks with an override operation for details.

j) In the Add Operation Steps popup, select Invoke Workflow for Operation Type.

k) Select the Workflow from the list of workflows that you created.
   The system can filter the list using tags. To add a tag:
   1. Navigate to System Properties.
   2. Locate and select the system property sn_cmp.workflow_tag_filter.
   3. Edit the property. Add a tag or comma-separated list of tags.
   4. Click Save.

l) To filter the workflows:
   1. On the workflow table, open the workflow.
   2. Click Add Tag.
   3. Enter the value that you provided earlier in the property sn_cmp.workflow_tag_filter.
   4. Click Enter to add the value as a tag to the workflow. The new step appears after the software generates the new Day 2 Operation Catalog.
m) Workflows can exist that are created on tables other than global. You can add a workflow created on such a table. To execute operations on this type of workflow, you need the sys_id of the record in which the workflow is executing to create the current record. So when the designer adds a workflow that is on table other than global, the system creates a `wf_current` parameter in the operation input parameter. You can then write an expression to map the sys_id of the resource in which the operation is executing. Once this is completed, the designer can use the ‘current’ key word in workflow scripts.

To add the workflow:

1. After you create the step, the system adds the workflow inputs to the operation input parameters. You can then provide the mapping for these parameters, if needed.
2. Click the Generate Catalog button to create the catalog item for the operation.
3. After the catalog generates, you can add from the load and field change rules to the catalog items.

n) Set the resource block to the Published state to make the workflow available in the Cloud User Portal.

4. To execute the operation from the User Portal, follow these steps:
   a) Provision a simple AWS VM from the portal.
   b) After the VM provisioning completes, navigate to the stack > VM Resource.
   c) In the Select Resource Operation option, select the custom stop activity you created earlier in this use case, then click OK.
      The operation executes after the RITM is created and the VM state changes in the AWS console.
   d) Navigate to Operate > Trails to view the trail logs and trace the operation steps.

5. To troubleshoot, if needed, follow these steps:
   a) Use the request item (RITM) and navigate to the RootCauseAnalysis Dashboard. The RITM has the link to the workflow context of the currently executed operation.
   b) Check for these common errors:

<table>
<thead>
<tr>
<th>Symptom</th>
<th>Error message</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM shuts down but there has been an issue with the SSH connection</td>
<td>Error: job finished with status ERROR: Problem in SSH session, job aborted: Connection unexpectedly closed by SSH server: \n',</td>
</tr>
<tr>
<td>VM is already shutdown / not able to reach the VM</td>
<td>'Cannot connect, status is TCP_CONNECTION_FAILURE. Timed out while waiting for TCP to connect to 10.198.252.224:22: \n',</td>
</tr>
</tbody>
</table>

**Note:** Confirm that the IP address of the VM in the wf_context is the appropriate address. The VM might have been already shutdown. Confirm the IP address is accessible.
### ServiceNow New York IT Operations Management

<table>
<thead>
<tr>
<th>Symptom</th>
<th>Error message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Root access unavailable</td>
<td>'Failed to issue method call: Access denied\nMust be root.\nExit status: 1\n'</td>
</tr>
</tbody>
</table>

**Note:** Confirm that the Must Sudo box is checked in the SSH activity at the beginning of this use case.

Create the SSH custom activity
Create an SSH custom activity so you can use it in your workflow.

Role required: cloud designer or admin

1. Navigate to **Admin Portal > Workflows > Workflow Editor**.
2. Click the **Custom** tab, then click + (plus sign) to create a new custom activity.
3. From the list of types of activities, choose **SSH**.
4. The Activity Designer opens with the General tab displayed. Enter a unique name for the activity, then click **Continue**.
5. In the Inputs tab, add the input variables with the following steps, then click **Continue**:
   a) In the Input table, click the + in a circle to create a new input variable.
   b) Click to the right of ABC in the Name column, and type the input name.
      - Inputs vary according to the object to be impacted. Here, we're creating an activity to stop a VM, so the inputs reflect the values needed to accomplish that action.
      - The Type and Mandatory columns populate automatically according to input you enter.
   c) Create a new input object for each input in the following table, then click **Continue**:

<table>
<thead>
<tr>
<th>Input variable</th>
<th>Type</th>
<th>Mandatory</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>String</td>
<td>No</td>
</tr>
<tr>
<td>Command</td>
<td>String</td>
<td>No</td>
</tr>
</tbody>
</table>
6. On the Execution Command tab, perform the following:
   a) Click and drag the input variables from the left to the template fields at the right. This step 
      creates the expressions that will be used.
   b) Check the Must Sudo box so that you can later log in to the virtual server.
   c) Click Continue.

7. On the Outputs tab, add the output variables with the following steps:
   a) In the Output table, click the + in a circle to create a new output variable.
   b) Click to the right of ABC in the Name column, and type the output name.
      The output variables reflect the possible outcomes when the workflow attempts to SSH to 
      the VM. The Type column populates automatically.

<table>
<thead>
<tr>
<th>Outputs</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>error</td>
<td>String</td>
</tr>
<tr>
<td>output</td>
<td>String</td>
</tr>
</tbody>
</table>

   c) Click and drag the error variable to the Variable name field in the Parsing rules table.
   d) In the Parsing rule for error dialog, in the Parsing source drop-down, select the appropriate 
      source; in this case, executionResult.errorMessages.
   e) Repeat for the output variable, selecting executionResult.output as the Parsing source, 
      then click Submit.
f) Click **Continue**.

   Conditions are optional.

g) Click **Save**, then click **Publish** to make the activity available to use in the workflow.

You have now created a custom activity that exists as a container until you add in the input mappings to it. The mappings tell the activity where the information it needs is coming from. You enter the input mappings during the workflow creation procedure. See [*Create an SSH workflow*](#).

### Create an SSH workflow

Create the SSH workflow needed to power off the VM. Use the SSH custom activity that you already created.

- **Role required:** workflow designer or admin
- **Have an SSH custom activity already created**

When you create a workflow, you associate it with a table and with an activity.

- You can create the workflow on a table at the global-level or a table on the application-level.
  - Use the global table to make the workflow available to use with all ServiceNow applications.
  - Here, we use a table for the Cloud Management, so this workflow will only be available to use with that application.
- You can create the workflow from the Workflow Editor or from the Activity Designer. Here, the Activity Designer is used.

1. From the Activity Designer, select the **Workflows** tab at the right, then click the + (plus sign) to add a new workflow.

2. In the New Workflow window, perform these steps:
   a) Enter a unique name for the workflow.
   b) From the **Table** drop-down, select the table to use. Here, we search for and use the **Virtual Machine instance cmdb_ci_vm_instance** because we intend to use the workflow to power off a VM.
   c) Click **Submit**.

3. When the workflow displays in the canvas, perform these steps:
   a) Delete the connection line between the start point and end point of the workflow.
   b) Right-click the more info canvas and select **Edit Inputs**.
   c) Create the following inputs:
Note: Take the input names from the Column field, not from the Label field. If the workflow is associated with a global-level table, the input name in the Column field is prefixed with **u_**, for example, **u_ipaddress**. Here, the table is application-level, so it needs no prefix.

<table>
<thead>
<tr>
<th>Type</th>
<th>Label</th>
<th>Column (automatically added)</th>
<th>Max Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>IPAddress</td>
<td>ipaddress</td>
<td>100</td>
</tr>
<tr>
<td>String</td>
<td>CredentialTag</td>
<td>credentialtag</td>
<td>100</td>
</tr>
</tbody>
</table>

d) Click Submit.

4. Right-click the canvas and select **Add Custom Activity**.

5. In the Versions window, search for and select the activity you created earlier in **Create the SSH custom activity**.

6. In the New Activity window for that activity (Workflow Activity New record (Diagrammer view)), perform these steps:
   a) Enter a name for the activity.
   b) In the Host field, type the input mapping that the activity expects. Here, that is the IP address of the host: **${workflow.inputs.u_ipaddress}**
      Use this expression to get the IP Address:
      ```javascript
      $(Script:CMPVMUtils.getReachableIp[arg=$(Stack.items[Virtual Server].attributes[sys_id])])
      ```
   c) In the Command field, type **shutdown -h now**
   d) In the Credential tag field, type **${workflow.inputs.u_credentialtag}**
      Use this expression to get the credential tag:
      ```javascript
      $(Script:CMPVMUtils.getCredentialAlias[arg=${Stack.items[Virtual Server].attributes[sys_id]}])
      ```
   e) Click Submit.
      The activity displays in the workflow canvas.

7. Right-click the canvas, and select **Add Core Activity** to add a run script activity.

8. In the Workflow Activity Definitions window, search for and select **Run Script**.

9. In the New Activity: Run Script window, perform these steps:
   a) Type a name for the activity.
   b) Cut and paste a script (appropriate for your environment) in the Script field.
      This script updates the state of the VM after it is shut down.
      Example script:
      ```javascript
      if ( gs.nil(data.get(3).error) ) {
        current.state = 'off';
        current.setWorkflow(false);
        current.update();
      }
      ```
© 2020 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
c) Click **Submit**.

10. In the canvas, connect the connectors between the Begin point, the activity, the Run Script, and the End point.
11. Click **Publish** to make the workflow available.
12. Validate the workflow by using the workflow validation.

**Note:** The system does not recommend the use of current.update(). This can be ignored.

Map credentials between Cloud Management and Terraform
You can map credential and service account fields between Cloud Management and Terraform using the IaC Provider Settings. This enables you to store and manage credentials in an external credential repository rather than directly in a ServiceNow credentials record.

Role required: sn_cmp.cloud_admin; Cloud Management: Terraform Cloud Connector (v1.06) must be installed.

You can use the (Infrastructure as Code) IaC Provider Settings user interface to perform credential and service account mappings for DataCenter Credentials used by the Terraform provider to provision datacenter resources and Cloud Management for discovery.

1. Navigate to **IaC Provider Settings > Terraform**, and click **New**. The **Terraform Datacenter Mapping** form appears.
2. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Terraform Provider</td>
<td>Name of the Terraform Provider.</td>
</tr>
<tr>
<td>Datacenter Block</td>
<td>Select the Resource Block whose credentials you are mapping from the lookup table.</td>
</tr>
<tr>
<td>Credential Type</td>
<td>Select the appropriate credential type from the lookup table. For example, Azure Service Principal (azure_service_principal).</td>
</tr>
<tr>
<td>Credential Resolver</td>
<td>Select an appropriate MID Server script from the lookup table. For example, Search and select the TerraformProviderCredentialResolver script.</td>
</tr>
</tbody>
</table>

3. Click **Submit**. The Terraform provider credentials record is created and displayed in the Terraform Datacenter Mappings list.

4. On the record you just created, select the **Credentials Mappings** tab, and then click **New**.  
   a) Complete the **Credential Mapping** form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Provider Authentication Key</td>
<td>Authentication key (variable) field name as used by the provider. For example, Terraform provider block for AWS uses the field secret_key.</td>
</tr>
</tbody>
</table>
5. Select the Service Account Mappings tab, and click New.
   a) Complete the Service Account Mapping form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discovery Credential Key</td>
<td>The corresponding field in the Discovery credentials from the lookup table. For example, access_key field in Terraform corresponds to Secret key field in ServiceNow.</td>
</tr>
<tr>
<td>Terraform Datacenter Mapping</td>
<td>Datacenter for which you are mapping the credentials.</td>
</tr>
</tbody>
</table>

   b) Click Submit.

The field values you added under the Credential Mapping and Service Account Mapping tabs are mapped.

Create a cloud catalog item
Create a cloud catalog item for provisioning, based on a template or a blueprint, and publish the catalog item to provide a service.

Role required: sn_cmp.cloud_service_designer.

While creating a catalog item, you can associate the catalog item with either a template or an existing blueprint. After you generate a catalog item, the system automatically generates components such as variable sets, lifecycle operations, rules, and pre- and post-provision operations. You can manage all these components from the Create Catalog Item page.

Note: You can create blueprints first and then generate a catalog item from the blueprint.

1. In the Cloud Admin Portal, navigate to Design > Cloud Catalog items.
   All the catalog items that you’ve created are listed in a card layout view. You can click an inactive catalog item to provision it.
2. Click New.
   The Cloud Catalog Items screen appears.
3. On the form, fill in the fields.
Cloud Catalog Item form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name for the catalog item.</td>
</tr>
<tr>
<td>Active</td>
<td>Option for making the catalog item available. This check box can be selected only after you've selected a blueprint.</td>
</tr>
<tr>
<td>Icon</td>
<td>Image to appear as an icon beside the item name in the catalog. You can upload a 16x16 pixel image. If no image is uploaded, the default icon appears beside this item. The uploaded image overwrites the default image. The image you upload appears in the service catalog, not in the ServiceNow Cloud Management application.</td>
</tr>
<tr>
<td>Picture</td>
<td>Image for the catalog item. The image that you select is displayed for the catalog item in the Cloud User Portal (after you click Launch a Stack).</td>
</tr>
<tr>
<td>Catalogs</td>
<td>Names of catalogs.</td>
</tr>
<tr>
<td>Category</td>
<td>Category for the item appears by default. You can change the category. Catalog searches find only items that are assigned to a category. The categories appear in the service catalog. The catalog item can appear in multiple categories. To add categories, click the Categories tab and then click New or Edit.</td>
</tr>
<tr>
<td>Source</td>
<td>Source type (Cloud Template or Custom) to associate the catalog item with.</td>
</tr>
<tr>
<td>Template type</td>
<td>If you selected Cloud Template as your source, then select the type of template (ARM Template or CloudFormation Template).</td>
</tr>
<tr>
<td>Blueprint</td>
<td>If you selected Custom in the Source field, then select a blueprint to associate with the catalog item.</td>
</tr>
<tr>
<td>Blueprint Operation</td>
<td>This field appears only when you select a blueprint. After you generate the catalog item, the value in this field is automatically populated.</td>
</tr>
<tr>
<td>Short description</td>
<td>Brief description of the catalog item. This description appears in the Cloud User Portal next to the catalog item.</td>
</tr>
<tr>
<td>Description</td>
<td>Full description of the catalog item. This description appears in the service catalog; not in the Cloud Management application. You can embed videos, images, links to internal knowledge base (KB) articles, and links to external sources of information and instruction documentation.</td>
</tr>
</tbody>
</table>

4. Click Submit.
The catalog item and all associated components such as variable sets, lifecycle operations, and rules are generated and appear as tabs in the Cloud Catalog Item page.

**Note:** If you selected Template from the Source type list, you must create a template and associate the template with the catalog item.

The related links are actions that you can perform on the catalog item.

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Export Catalog Item</td>
<td>Exports all the components (such as blueprints, resource blocks, rules) of the catalog item from one environment to the other. See <a href="#">Moving Cloud Management content across environments</a>.</td>
</tr>
<tr>
<td>Item Diagnostic</td>
<td>Identifies possible issues with the catalog item data and configuration. See <a href="#">Item diagnostic report</a>.</td>
</tr>
<tr>
<td>Manage Attributes</td>
<td>See <a href="#">Manage operation attributes</a>.</td>
</tr>
<tr>
<td>Reset Catalog Item</td>
<td>Resets (to the last change you made) any customizations that you've made to the catalog item.</td>
</tr>
</tbody>
</table>

**Create a cloud template.**

Publish a blueprint as a cloud catalog item

You can create and publish a catalog item directly from a blueprint.

Role required: sn_cmp.cloud_service_designer

1. In the Cloud Admin Portal, navigate to Design > Blueprints.
2. Open a blueprint (in draft mode), click the Catalog tab, and then click Create Catalog Item. The Create Blueprint Catalog dialog box appears.
3. Enter a name for the catalog item in the Name field and click Save. The catalog item is generated and appears in the Catalog tab.
4. Click the catalog item to make any updates to the catalog item. The Cloud Catalog Item screen appears.
5. Click Update to save the changes you made.

**Create a cloud template**

Create a cloud template and associate the template with a catalog item. Once you’ve created a template, you can reuse the template to quickly create additional catalog items for the services you want to provision.

Role required: sn_cmp.cloud_service_designer.

You can create a template by uploading a generic template file, importing a template from a public URL, or by copying and pasting the contents of an existing template. AWS CloudFormation templates support JSON and YAML. ARM supports JSON.

**Note:** Catalog items that were based on templates in earlier releases are now treated as if they are based on blueprints.

You can update a template as often as needed. With each update a new version of the template is created. A template can be in one of three states: draft, active, or history. When you
create a template and do not activate it, the template is in a draft state. Once you activate the template, the state changes to active. If you create another template and activate it, the state of the previous active template turns into history. At any given time, only one template is in active state. Each time you activate a template, the previous active template becomes history.

1. In the Cloud Admin Portal, navigate to **Design** > **Cloud Catalog Items** and open the catalog item.

2. Click **Cloud Templates** > **New** and then enter a meaningful short description in the **Short description** field.

3. Specify the **Ingestion method**.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Import from URL</td>
<td>Import a template by specifying a public URL where the template resides. Select this option and then click the lock icon (🔒) to unlock the Cloud template URL field. Enter the public URL in this field.</td>
</tr>
</tbody>
</table>

**Note:** For the public URL, only HTTP and HTTPS protocols are supported. FTP is not supported. Ensure that the size of the template should not exceed the default value of 3 MB. You can change the default value of the file size by changing the value in the `sn_cmp.template_content_size_supported_inbytes` property in the `sys_properties` table. Ensure that you enter the file size in bytes. There’s also a default time-out of 5 minutes for an HTTP request. You can change the time-out value in the `sn_cmp.template_url_import_http_timeout` property in the `sys_properties` table. Ensure that you enter the new value in milliseconds.

<table>
<thead>
<tr>
<th>Upload a file</th>
<th>Upload a template from your local workstation.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use template body</td>
<td>Paste the contents of the template file in the <strong>Body</strong> field.</td>
</tr>
</tbody>
</table>

After you specify the **Ingestion method**, the template is validated and the results appear in the **Validation status** and **Validation message** fields.

4. Click **Submit**.

The template is created and the Cloud Catalog Item page opens.

5. If this is the first version of template, skip this step. On the **Cloud Templates** tab, open the template (currently in Draft state) to view the template version parameters.

**Note:** The first version of a template that you create and publish has no conflict issues. If you update the template, a conflict can arise. If a parameter **Action Type** has the value **Update**, then specify a value for **Decision**.
6. Open each parameter with a **Decision** value of **Pending**, select a value, and then click the check mark.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Skip Update</td>
<td>Discards the updates to the template.</td>
</tr>
<tr>
<td>Use template</td>
<td>Applies the updates to the template.</td>
</tr>
</tbody>
</table>

7. After you update each **Pending** decision, click **Activate**. The state of the template changes from **Draft** to **Active** and the system generates the catalog item.

Create pre-provisioning operations

Pre-provisioning operations are invoked on catalog items after you submit a request and before the catalog item is provisioned. You can specify workflows, scripts, CAPI calls, or resource operations to run automatically before the catalog item is provisioned. For example, you might want to send out notifications that provisioning of the item is about to begin. Setting up an operation as a pre-provision operation means you don’t have to do any additional steps to invoke the operation, saving you time and effort.

Role required: sn_cmp.cloud_service_designer.
You can create pre-provisioning tasks only for catalog items that are based on templates.

1. In the Cloud Admin Portal, navigate to **Design > Cloud Catalog Items**.
2. Open a catalog item, click the **Pre Provisioning Operation** tab, click **New**, and then fill in the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step Type</td>
<td>Pre-provisioning operation. Based on the type of pre-provisioning operation you select, additional fields appear.</td>
</tr>
<tr>
<td></td>
<td>· CAPI:</td>
</tr>
<tr>
<td></td>
<td>· CAPI Provider</td>
</tr>
<tr>
<td></td>
<td>· CAPI Method</td>
</tr>
<tr>
<td></td>
<td>· CAPI Version</td>
</tr>
<tr>
<td></td>
<td>· InstanceScript:</td>
</tr>
<tr>
<td></td>
<td>· Script: Enter the name of the script.</td>
</tr>
<tr>
<td></td>
<td>· Resource:</td>
</tr>
<tr>
<td></td>
<td>· Resource Interface</td>
</tr>
<tr>
<td></td>
<td>· Interface Operation</td>
</tr>
<tr>
<td></td>
<td>· Workflow:</td>
</tr>
<tr>
<td></td>
<td>· Flow: Select a workflow.</td>
</tr>
<tr>
<td>Order</td>
<td>Order of pre-provisioning operation. Enter the order that pre-provisioning operation should be invoked. Lower numbers are invoked first. For example, if you enter 2 for CAPI and 3 for InstanceScript, then CAPI is invoked first and then the InstanceScript gets invoked. If you do not enter any value in this field, the system automatically enters a value in increments of 20.</td>
</tr>
<tr>
<td>Enabled</td>
<td>Option for enabling the pre-provision operation you want invoked.</td>
</tr>
</tbody>
</table>

3. Click **Submit**.
Parameters for the pre-provisioning operations are created as operation attributes in the Manage Attributes page.

4. To add values for the pre-provision operation attributes, click **Manage Attributes**. The Manage Attributes screen appears.

5. Click **Pre Provision**.
All attributes for the pre-provision operation are listed.
6. You can either create expression mappings for an attribute (in the Mapping field) or generate variables for an attribute. See Manage operation attributes for more information.

7. Click Apply Changes.
   All the configurations you made to the attributes are saved and you are returned to the Cloud Catalog Items screen.

Create or update a catalog item from a Google Cloud Deployment Manager (GDM) template
Instead of generating a catalog item based on a blueprint, you can generate a catalog item based on a template that is held in the GDM configuration management system. The system parses the attributes in both the template file and optional supporting files and then generates a blueprint and a catalog item.

Role required: sn_cmp.cloud_service_designer

Cloud Management supports Google Cloud Platform templates managed by Cloud Deployment Manager (GDM) that were created in YAML, Python, or Jinja2.

The procedure to create a catalog item from a template involves the following steps:

1. Create and save a catalog item record that references the template. The catalog item is in Draft state. In a later step, you activate the catalog item to make it available to cloud users.

2. Create a cloud template record. The cloud template specifies a configuration installable (a directory structure that includes the template file) to use as the source of the catalog item.

   Note: You can update the cloud template record later, by referencing an updated configuration installable. Instructions are included in this procedure.

3. Google Cloud Platform only: If the template file depends on supporting files (typically updates or template code that specifies attribute settings), you add the files to the Dependent Templates related list.

4. Activate the cloud template to generate a resource block and blueprint that are associated with the catalog item and to make the cloud template available for use by the catalog item.

5. Activate the catalog item so that cloud users in the Cloud User Portal can use it to provision resources.

1. In the Cloud Admin Portal, navigate to Design > Cloud Catalog Items.
2. Click New and then enter a unique and meaningful Name, Short description, and Description.
3. Specify the Source as Cloud Template and the Template Type as Google Cloud Deployment Manager.
4. Right-click in the header and select **Save**.
5. On the Cloud Templates related list, click **New** and enter a unique **Name** and **Short description**.
6. Specify the content of the template. You have three options:

- Paste the text of the template file into the form:
  1. Set **Ingestion method** to **Use Template Body**.
  2. You typically use either a custom template that you created or a template in a public GitHub or Bitbucket repository. Open the template file in a text editor and copy the full text of the file.
  3. On the Cloud Template Versions form, paste the text into the **Body** text box.
- Specify the URL of the template file:
1. Set **Ingestion method** to **Import from URL**.
2. In a browser, go to the template file. Copy/paste the full URL of the template into the **Cloud template URL** text box.

- **Upload the template file:**
  1. Set **Ingestion method** to **Upload a file**.
  2. Click the **Click to add** link for the **Upload file** field.
3. Click **Choose File**, select the file, and then click **OK**. The system adds the template and the filename appears in the **Upload file** field. The results of the import process appear in the **Validation status** and **Validation message** fields.

7. The template code appears in the **Body** text box. If the file does not include a path entry under `imports:`, then skip this step. If the file does include an entry, then the template file depends on at least one dependent file (typically updates or files that specify attribute settings). Perform the following procedure for each dependent file (`cloudsql.jinja` in the example):

   a) In a text editor, open the dependant template file (`cloudsql.jinja` in the example).
   b) Copy the full text of the file.
   c) On the **GDM Dependent Templates** related list, click **New**.
d) Paste the full text of the dependent template file into the **File content** text box.

e) Enter the exact name of the dependent template file into the **File name** text box.

![GDM Dependent Templates form]

f) Click **Submit**. The file appears in the **GDM Dependent Templates** related list.

g) Repeat the procedure for each dependent template file.

8. On the Cloud Template Versions form, click **Activate**.
   The system generates the catalog item and a blueprint with the name that you specified for
   the catalog item.

9. On the Cloud Catalog Item form, select the **Active** check box, and then click **Submit**.
   The system displays the catalog item on the Cloud Catalog Items page and publishes the
   catalog item to the Cloud Service Catalog for use by end users.
Verify that the catalog item appears in the Cloud User Portal.

Create or update a catalog item based on a Terraform template

Instead of generating a catalog item based on a blueprint, you can generate a catalog item based on a template that is held in the Terraform configuration management system. The system parses the attributes in the template files and then generates a record of the template data, blueprint, and resource block. You can then use the template record as the basis for a catalog item.

Role required: sn_cmp.cloud_service_designer

IBM Cloud Connector, VMware vSphere, and Microsoft Azure Cloud support Terraform template files in .tf and .tf.json formats.

The procedure to create a catalog item from a template involves the following steps:

1. Create and save a catalog item record that references the template. The catalog item is in Draft state. In a later step, you activate the catalog item to make it available to cloud users.

2. Create a cloud template record. The cloud template specifies a configuration installable (a directory structure that includes the template file) to use as the source of the catalog item.

   Note: You can update the cloud template record later, by referencing an updated configuration installable. Instructions are included in this procedure.

3. Google Cloud Platform only: If the template file depends on supporting files (typically updates or template code that specifies attribute settings), you add the files to the Dependent Templates related list.

4. Activate the cloud template to generate a resource block and blueprint that are associated with the catalog item and to make the cloud template available for use by the catalog item.
5. Activate the catalog item so that cloud users in the Cloud User Portal can use it to provision resources.

1. Create and save a catalog item record.
   a) In the Cloud Admin Portal, navigate to **Design > Cloud Catalog Items**.
   b) Click **New**, enter a unique and descriptive **Name**, fill in the form, and then right-click in the header and select **Save**.

<table>
<thead>
<tr>
<th>Source</th>
<th>Select Configuration Management Template.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Provider type</td>
<td>• Select Terraform Environment if Terraform is running on a Linux host.</td>
</tr>
<tr>
<td></td>
<td>• Select Terraform Windows Environment if Terraform is running on a Windows host.</td>
</tr>
<tr>
<td>Config provider</td>
<td>Select the appropriate config provider.</td>
</tr>
<tr>
<td></td>
<td>For instructions on creating a Terraform config provider record, see <strong>Create a Terraform config provider and run Discovery.</strong></td>
</tr>
</tbody>
</table>

   The catalog item record is created.

2. Create a cloud template that references a Terraform configuration installable.
   a) On the **Cloud Templates** related list, click **New**.
   b) Select the appropriate Terraform **Configuration installable** and then right-click in the header and select **Save**.

   The system creates the cloud template record, reports success, and displays the content of the configuration installable. Notice that the cloud template is in the **Draft** state. In the next step, you activate the cloud template to make it available for use by the catalog item.

   **Note:** A catalog item can include multiple versions of the cloud template but only one version can be active.
Note: Skip the next two substeps if you are defining a new cloud template record. Configuration conflicts can arise when you create a cloud template with an updated version of a Terraform configuration installable.
c) On the **Cloud Templates** tab, click the template to view the Template Version Parameters related list. If a parameter **Action Type** has the value **Update**, then you must specify a **Decision** to use the current parameter value in the cloud template or the value in the updated configuration installable.

<table>
<thead>
<tr>
<th>Template Version Parameters</th>
<th>Template Version Parameters</th>
<th>GDM Dependent Templates</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Template version = 3</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Name</strong></td>
<td><strong>Decision</strong></td>
<td><strong>Action type</strong></td>
</tr>
<tr>
<td><strong>adminUsername</strong></td>
<td><strong>Type</strong></td>
<td><strong>DataSource</strong></td>
</tr>
<tr>
<td><strong>Use Template</strong></td>
<td><strong>Use Template</strong></td>
<td><strong>DataSource Value</strong></td>
</tr>
<tr>
<td><strong>New</strong></td>
<td><strong>New</strong></td>
<td><strong>Default Value</strong></td>
</tr>
</tbody>
</table>

| **windowsOSVersion**        | **Use Template**            | **Update**              |
| **DataSource**              | **DataSource Value**        | **CSVList**             |
| **String**                  | **String**                  | **Datacenter,2012-R2,** |
| **2006-R2-SP1,**            | **Text**                    | **2012-R2,**            |
| **Datacenter,2012-R2,**     |                             | **Datacenter,2016,**    |
| **2016-Datacenter**         |                             |                         |

d) On the **Template Parameters** tab, specify the parameters that end users must specify when requesting a stack by selecting **Yes** in the **Create Param** field. Parameters with a value of **No** are not required when requesting a stack.

3. Click **Activate** to activate the cloud template.
   The system generates the resource block and blueprint/template that are associated with the catalog item and then makes the cloud template available for use by the catalog item. The Cloud Catalog Item form opens and displays a message that confirms that the version of the cloud template record is active.

4. On the Cloud Catalog Item form, select the **Active** check box and click **Submit**.
   The catalog item appears in the Cloud User Portal and cloud users can request the catalog item to provision resources.

**Note:** As with any catalog item, you can add or remove a user-viewable field. Click the card to open the catalog item form. On the **Variable Sets** tab, edit the variables.

Verify that the catalog item appears in the Cloud User Portal.

**Create a Terraform config provider and run Discovery**

A config provider is a secure record on your instance that stores the credential and access information for a particular configuration management server (for example, a host running Ansible, or Terraform). Discovery uses the information in the config provider record to access the server to get information on each resource template in the repository. You use the templates to generate catalog items that cloud users can order from the Cloud User Portal.

- Cloud Management role required: cloud_admin
• A host running the open-source version of the Terraform configuration management software must exist.
• On the host that runs Terraform, copy the following values for use in this procedure: Username, Password, SSH Passphrase, SSH private key.

The procedure involves the following steps:
1. Create a Credentials record to securely store Terraform credential information. You refer to the Credentials record when you create a config provider record.
2. Create a config provider.
3. Identify the resources on the Terraform configuration management server.

1. Create a Credentials record:
   a) On your instance, navigate to Orchestration > Credentials and then click New.
   b) Click SSH Private Key Credentials and then fill in the form.

<table>
<thead>
<tr>
<th>Name</th>
<th>Descriptive name for the set of credentials — often the name of the host that is running Terraform. Ensure that the name is unique because you might eventually use multiple Terraform repositories.</th>
</tr>
</thead>
<tbody>
<tr>
<td>User ID</td>
<td>User name for the host that is running Terraform.</td>
</tr>
<tr>
<td>Password</td>
<td>Password for the host that is running Terraform.</td>
</tr>
<tr>
<td>SSH Passphrase</td>
<td>Passphrase for the access credentials for the host that is running Terraform.</td>
</tr>
<tr>
<td>SSH private key</td>
<td></td>
</tr>
</tbody>
</table>
SSH private key | Key for the access credentials for the host that is running Terraform.
---|---
Active | Select the check box to make the credentials available for use.
Applies to | MID Server that uses these credentials for communications.
Order | Order of execution. Discovery tries credentials in sequence — credentials with lower Order values before credentials with higher Order values. Ordering credentials improves performance when there are many credentials, with credentials some used more frequently than others. For example, five credentials out of a total of 20 are used 90% of the time. Configure the five credentials with lower order numbers to try them first.

2. In the Cloud Admin Portal, navigate to Manage > Config Management.
3. Click New, fill in the form, and then click Submit.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Descriptive name for the Terraform host, for example, Terraform Config Provider-1.</td>
</tr>
</tbody>
</table>
| Provider | • Select Terraform Environment if Terraform is running on a Linux host.  
• Select Terraform Windows Environment if Terraform is running on a Windows host. |
| URL | Full URL or IP address of the Terraform host. |
| Server Type | Select Linux or Windows. |
| Credential | Login credential for the Terraform host. |

The config provider record is created and appears as a card on the Config Providers page.
4. Click the provider card. To identify the resources on the Terraform configuration management server, click **Discover Now**.

**Note:** You cannot schedule Discovery for configuration management providers. To get updated resource data from a provider, you must run **Discover Now** from this form.

The Terraform config installables contain the workspace and configuration templates.
The terr details appear after provisioning.
Table view of a configuration template:
Config Management

Table view of a workspace:

```json
provider "ibm" {
  region = "us-south"
  bluemix_api_key = "ODr3v7f5_
  softlayer_username = "SL_
  softlayer_api_key = "80a2_
}
resource "ibm_security_group" "sg1" {
  name = "sg1"
  description = "allow my app traffic"
}
```
You can create catalog items from the config installable.

Create post-provision operations

Create post-provision operations that are invoked on newly provisioned catalog items. You can specify workflows, scripts, CAPI calls, or resource operations. For example, you might want to specify a script that runs on the catalog item after the resource is provisioned. Setting up an operation as a post-provision operation means you don’t have to do any additional steps to invoke the operation, saving you time and effort.

Role required: sn_cmp.cloud_service_designer.

You can create post-provision operations only for catalog items that are based on templates.

1. In the Cloud Admin Portal, navigate to Design > Cloud Catalog Items.
2. Open the catalog item, click the Post Provisioning Operation tab, and then click New. The Operation Step form appears.
3. On the form, fill in the fields.
### Operation Setup form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| Step Type   | Post-provision operation. Based on the post-operation you select, additional fields appear.  
  - CAPI:  
    - CAPI Provider  
    - CAPI Interface  
    - CAPI Method  
    - CAPI Version  
  - InstanceScript:  
    - Script: Enter the name of the script.  
  - Resource:  
    - Resource Interface  
    - Interface Operation  
  - Workflow:  
    - Flow: Select a workflow. All workflows created in the instance are listed. |
| Order       | Order of post-provision operations. Enter the order (in numerals) in which you want the post-provision operation to be invoked. For example, if you enter the value 2 for CAPI and the value 3 for InstanceScript, then CAPI is invoked first and then the InstanceScript gets invoked. If you do not enter any value in this field, the system automatically enters a value in increments of 20. |
| Enabled     | Option for enabling the post-provision operation you want invoked. |

4. Click **Submit**.  
Parameters for the post-provision operation are automatically created as operation attributes on the Manage Attributes form.

5. To set attribute values for a post-provision operation:
   a) Click the **Manage Attributes** related link.  
      The Manage Attributes form opens.
   b) Select the post-provision operation to update.
      All attributes for the selected operation appear in the Operations list. You can either create expression mappings (shown in the **Mapping** column) for an attribute or can you generate variables for an attribute. See **Manage operation attributes** for more information.
c) On the Operation Attributes form, edit the values in the **Mapping** field as needed.

d) To set a value and not show the field to the cloud user, set **Generate Variable** to false. For VMware post-provision operations, you can set the following attribute values:
Post-provision operation attributes for VMware

<table>
<thead>
<tr>
<th>Attribute name</th>
<th>&lt;Value field&gt; to set in the Mapping expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>NodeCredential</td>
<td>$(capiResolver.NodeCredentialResolver#nodeCredentialId=sysID)</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> You must create the credentials manually to be able to specify the sys_id in the expression</td>
</tr>
<tr>
<td>NodeAddress</td>
<td>$(Script:CMPVMUtils.getReachableIp[arg=$(Stack.items&lt;VM Name&gt;.attributes[sys_id])])</td>
</tr>
<tr>
<td>ScriptExpression</td>
<td>${CloudScript.scripts.&lt;Script Name&gt;}</td>
</tr>
</tbody>
</table>

e) Click **Apply Changes**.
All configurations are saved and the Cloud Catalog Items page opens.

Add post-provisioning to a Cloud Formation Template-based catalog item
Create a workflow post-provisioning operation on a Cloud Formation Template (CFT)-based catalog item.

Role required: sn_cmp.cloud_service_designer.

In this example, create a key pair at the AWS console, then select the appropriate credentials, discover cloud accounts, create a CFT-based catalog item, add a workflow post provisioning operation to the catalog item, and lastly provision the catalog item.

Ensure that you’ve met the following prerequisites before you start working on this example:
- The Cloud Management plugin is activated.
- AWS Credentials and Service Account are set up.
- The Cloud Account for AWS Logical Data Center is created.
- The Key pair is configured on AWS and is available in CMP as “cmdb_ci_cloud_key_pair”.
- A workflow is available on an instance. This example uses the SSH_Workflow_New workflow.
- A script include to fetch the private and public IP is available.

1. At the AWS console, create a new key pair. Give the key pair a name, for example, ItappWOP. When you create a key pair, a PEM file is automatically downloaded onto your system.
2. Open the PEM file and copy all the contents of the file.
3. Navigate to the Credentials application using the filter navigator in your instance.
4. Click **New** and then select **SSH Private Key Credentials**.
5. In the **Name** field, enter a name (Itappwop).
6. In the **SSH Private Key** field, paste the contents of the PEM file.
7. In the **Credential alias** field, enter an alias name (Itappwop).
   The Alias name must be the same name that you entered in the **Name** field.
8. Click **Submit**.
9. To discover cloud accounts to sync data from AWS, run ServiceNow® Discovery.
10. Create a cloud catalog item based on AWS CFT to provision a stack.
   a) Navigate to **Cloud Admin Portal > Design > Cloud Catalog items**
b) Click **New**.
   The Cloud Catalog Item screen appears.

11. Enter a unique name for the catalog item in the **Name** field, select **Cloud Template** in the **Source** field and **Cloud Formation Template** in **Template type** field.

12. Click **Submit**.
   The catalog item is generated.

13. Create a cloud template and associate the template with the catalog item.
   a) Navigate to **Cloud Admin Portal > Design > Cloud Catalog Items**.
   b) Open the catalog item record that you want to create a cloud template for and click **Cloud Templates > New**.
      The Cloud Template Versions screen appears.
   c) In the Ingestion Method list, select **Use template body** and paste the contents of the AWS CFT in the **Body** field.
   d) Click **Save**.
      All variables extracted from the AWS CFT appear in the Template Version Parameters section.
e) Click **Activate**.
The catalog item is generated.
14. Go to the Cloud User Portal and open the catalog item that you just generated. On the Provision tab, you can see all variables extracted from the template. You can add a workflow post provision operation to the catalog item.

16. Open the catalog item record that you want to create the workflow post provisioning operation for.

17. Click the Post Provisioning Operation subtab and then click New. The Operation Step screen appears.

18. Select Workflow in the Setup Type list and select SSH_Workflow_New in the Flow list.

19. Click Submit. Parameters for the workflow operation are automatically created as operation attributes in the Manage Attributes screen.

20. Click Manage Attributes. The Manage Attributes screen appears.

22. Click the key_name attribute and enter either the Credential alias value (Itappwop), or enter an expression mapping in the Mapping field. Mappings specify where to pull the information in the system. See Using expressions in Cloud Management.

23. Click the Stack ID attribute and enter the expression mapping $(context.order.stack).

24. Click Apply Changes. Workflow is mapped as a post provision operation to the catalog item that you generated.

25. Provision the CFT-based catalog item in the Cloud User Portal.
   a) Navigate to Cloud User Portal and click Launch a Stack.
   b) Open the catalog item that you want to provision and enter values in all the mandatory fields on the General Info and Provision tabs.

26. To provision the catalog item, click Submit.

27. Validate the provisioned catalog item upon completion.

Create a variable set for Cloud Management

Variable sets allow you to create a collection of structured variables that can be reused across multiple catalog items and order guides.

Using variable sets saves time because you do not have to create the same variables individually for many catalog items. Also, when variables need to be modified, you can modify the variable set and the changes are reflected across all the catalog items that are associated with the variable set. Variable sets also allow you to define catalog client scripts and UI policies that are applicable to the variables in the set.

When you generate a catalog item, two variable sets, General Info and Provision, are automatically created. You can create as many variable sets as needed.

- Role required: sn_cmp.cloud_service_designer

1. Open a cloud catalog item and in the Variable Sets tab, click New. The Variable Set screen appears.

2. Fill in the form details (as shown in the table).

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Title</td>
<td>Enter a name for the variable set</td>
</tr>
</tbody>
</table>
### Field | Description
--- | ---
Internal Name | Enter a variable set name for internal use. 
**Note:** If this field is empty, its value is auto-populated based on the **Title** field for all variable types except **break**, **container split**, and **container end**.

Layout | Select a layout display: **1 Column Wide**, 2 **Columns Wide alternating sides**, or **2 Columns Wide, one side, then the other**.

Order | Enter an order number for the variable set.

Description | Enter a description for the variable set.

---

3. **Click Submit.**  
   The new variable set is created and appears in the **Variable Sets** tab. Open the new variable set and click **New** in the **Cloud Variables** tab to create variables for the set.

---

### Edit a variable for Cloud Management

Edit an existing cloud variable or create a new cloud variable to gather information for ordering a catalog item.

Role required: **sn_cmp.cloud_service_designer**

You can edit a variable to change its type, for example from **Masked** to **Lookup Select Box**. You can also change the variable set of a variable, its order, make it active in active, change its permission and availability options, and many more changes.

1. In the Cloud Admin Portal, navigate to **Design > Cloud Catalog Items**.
2. Open a catalog item, click the **Variable Sets** sub tab and click the variable set to which the variable to edit belongs to.  
   All the cloud variables for the selected variable set appear under the **Cloud Variables** sub tab.
3. Click the variable set that you want to edit.  
   The Cloud Variable form appears.
4. On the form, fill in the fields.

#### Cloud Variable form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| Type | Variable type to create.  
If you select **Lookup Select Box**, the **Type Specifications** subtab displays these fields:
  * **Use Pool Filter:** Select this check box to add a pool filter to the field.  
  * **Pool:** Select a pool to offer the cloud service user a list of values from an existing table in the catalog order form. For example, you can select **CloudAccountPool** to get a list of all the cloud accounts.  
  * **Pool Filter:** Select a filter to further narrow down the choices in the pool.

### Field
### Description

<table>
<thead>
<tr>
<th>Variable Set</th>
<th>The variable set that the variable belongs to.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mandatory</td>
<td>Option to make the variable mandatory as part of the ordering process.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to make the variable available for use.</td>
</tr>
<tr>
<td>Order</td>
<td>Order that the variable is placed on the page for the catalog item. The variables are organized from top to bottom, from the least to greatest order value. For example, a variable with an order value of 1 is placed above other variables with higher-order values.</td>
</tr>
</tbody>
</table>

### Questions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Question</td>
<td>Question to ask users ordering the catalog item. <strong>Note:</strong> If you select Select Box in the Type field, a Question Choices subtab appears at the end of the screen. You can enter a specific list of choices for the question.</td>
</tr>
<tr>
<td>Name</td>
<td>A name to identify the question. <strong>Note:</strong> If this field is empty, its value is auto-populated based on the Question field for all variable types except break, container split, and container end, HTML, container start, label, UI page, and duration.</td>
</tr>
<tr>
<td>Tooltip</td>
<td>Tooltip text to display when users point to the variable. Enter a brief note to describe the purpose of the question.</td>
</tr>
</tbody>
</table>
| Example text | Hint that's displayed in the question field before a user enters a value. Applicable for the following variables:  
  - IP address  
  - Email  
  - URL  
  - Single Line Text  
  - Multi Line text  
  - Date  
  - Date/Time |
### Annotation

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Show Help</td>
<td>If selected, displays the help text for the variable.</td>
</tr>
<tr>
<td>Always Expanded</td>
<td>This option appears only when the Show help check box is selected.</td>
</tr>
<tr>
<td></td>
<td>If selected, the Help text field value is expanded by default when the catalog item page loads.</td>
</tr>
<tr>
<td>Help tag</td>
<td>If the Always Expanded check box is cleared, click the value specified in this field to display the Help text field value.</td>
</tr>
<tr>
<td>Help text</td>
<td>Help information for a service catalog variable.</td>
</tr>
<tr>
<td>Instructions</td>
<td>Information that requires rich text formatting or adding images to support help information.</td>
</tr>
</tbody>
</table>

**Note:** For HTML tables, use sizes that are within the width of the variable.

### Type Specifications (The fields in this section vary for each variable type)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Width</td>
<td>Width for the variable on the catalog item page, to specify what percentage of the screen size that it can span. This field appears for all variable types except for break, container end, container start, container split, container layout, and label variables.</td>
</tr>
<tr>
<td>Validation (Regex)</td>
<td>Regular expression that validates the user input for the property.</td>
</tr>
<tr>
<td>Validation Error (Regex)</td>
<td>If the expression isn't valid, an error appears.</td>
</tr>
</tbody>
</table>

### Default Value

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>Default value for the variable.</td>
</tr>
<tr>
<td>Variable Attributes</td>
<td>Attributes for this variable.</td>
</tr>
</tbody>
</table>
### Permissions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Read Roles</td>
<td>Roles that can view the variable before or after requesting the catalog item or record producer. Only a user with the roles specified in this field can view the variable.</td>
</tr>
<tr>
<td>Write Roles</td>
<td>Roles that can edit the variable in the variable editor after requesting the catalog item or record producer. If a user doesn’t have the roles specified in this field, the variable is read-only in the variable editor.</td>
</tr>
<tr>
<td>Create Roles</td>
<td>Roles that can create values for the variable before requesting the catalog item or record producer. If a user doesn’t have the specified role, the variable is read-only before requesting the catalog item or record producer.</td>
</tr>
</tbody>
</table>

### Availability

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Visible</td>
<td>If selected, the variable is visible in the item form before ordering the item, in the Variable editor after ordering the item, and in the cart view of the item.</td>
</tr>
<tr>
<td>Read-only</td>
<td>If selected, the variable is read-only in the Cloud User Portal and cannot be edited.</td>
</tr>
</tbody>
</table>

5. **Click Update** once you’ve made all the changes to the variable.

### Manage operation attributes

You can specify attribute values for catalog items help cloud users to correctly provision catalog items. You can configure and manage attributes for provision, pre-provision, and post-provision operations.

Role required: `sn_cmp.cloud_service_designer`.

The attributes for provision, pre-provision, and post-provision operations are generated automatically. You can generate variables for these attributes and also create new attributes for the Blueprint Container Resource operation. You can also use the Manage Attributes screen to create variables for Orchestration attributes.

1. In the Cloud Admin Portal, navigate to **Design > Cloud Catalog Items**.
2. Open a catalog item and click the **Manage Attributes** related link.
   The Manage Attributes page lists the operations.
3. Click an operation to view its corresponding attributes.
4. Configure the attributes for each operation.
   - **Mapping**: View the auto-generated mapping values for each attribute. Mappings specify where to pull the information in the system. To modify the expression mappings, double-
click the mapping value and enter new values. Then click the check mark icon (✓).
Expressions can hold the values for information that's dynamically generated in the system, such as the values for the selections that users make in the Cloud User Portal. See Using expressions in Cloud Management.

- **Generate Variable**: Generates a variable for an attribute. Double-click the value (false), select True, and click the check mark icon (✓).

5. Click **Apply Changes** after you’ve made all the required changes. All the configurations you made to the attributes are saved and you’re returned to the Cloud Catalog Items screen.

**Blueprints**
A blueprint is a specialized catalog item template for offering cloud services, or stacks, to cloud users. Blueprints work with any cloud service provider, such as Amazon AWS Cloud or Microsoft Azure Cloud.

**Blueprint components**
The blueprint is the mechanism that is passed to the cloud provider to establish the cloud assets. Requesting a cloud catalog item is called launching a stack. After the cloud asset is obtained, it can then be discovered, managed, and maintained.
Resource blocks

The cloud resources included in the blueprint (catalog item). For example, a resource block can contain a virtual machine, an app that runs on the VM, and information about the datacenter that hosts the VM. Also referred to as resources.

Connections
The relationship between resources. For example, the VM has a host relationship with the app. There are two types of connections, containment and attached to.

- Containment: a connection where resource block contains another, visually depicted as a top-down relationship as shown in the image. For example, the blueprint container must contain at least one other resource block.
- Attached to: a connection between resources that require binding for direct communication to each other, visually depicted as a side-by-side relationship. For example, the binding between a virtual machine and storage forms an attached to relationship.

Operations

The actions that are performed on resource blocks or on the resource stack to manage the resources. For example, the cloud user can provision, start, and stop a resource.

Resource operations

The steps to perform the operation on the resource. For example, to provision the catalog item, the system must provision the VM and the app that runs on the VM. Click an operation to drill into the resource operations.

Attributes

The details of the resource. Attributes can appear on the catalog item form as catalog properties. For example, the blueprint can provide the version of the app to provision to the VM.

Constraints

An attribute option to constrain a cloud-agnostic resource block, such as a logical datacenter, to be used with a specific cloud provider. For example, a logical datacenter can be constrained to Amazon AWS Cloud. Later, if you switch or add Microsoft Azure Cloud or another cloud provider, you can change the constraint as needed.

Planning blueprints

Before creating blueprints, plan the stacks you want to offer in the service catalog. Prepare the following information before you begin development.

Resource blocks

Plan the resource blocks you want to use in blueprints. Ensure that the appropriate resource blocks are available to use in blueprints, and add them if necessary.

Service offerings (stacks)

To plan a service offering or stack, diagram the resource blocks that it needs, and how they are connected.

Cloud accounts and datacenters

Obtain a list of the cloud accounts and datacenters that the cloud administrator has configured. Determine whether any are constrained.

Service catalog variables and variable sets

Ensure that you have an understanding of how service catalog items use variables and variable sets. Understanding service catalog items and processes help with your understanding of blueprints.
Start here

*Build a Cloud Management blueprint*

Build a Cloud Management blueprint

Use the blueprint designer to create custom blueprints for the Cloud Management application.

Role required: sn_cmp.cloud_service_designer

1. In the Cloud Admin Portal, navigate to **Design > Blueprints**.
2. Click **New**, enter a unique and meaningful **Name** and **Description**, and then specify the service **Category**. Several categories are provided by default.
3. Click **Submit**.

The system creates the blueprint record and displays the Deployment Model tab of the blueprint designer. The Deployment Model tab is a visual canvas where you drop resource blocks. Each resource block represents a CI in a multi-tier application stack. The Deployment Model specifies the resources and connections between resources for the cloud items that you are defining.
4. To add a resource to the deployment model, click **Resources** and then select the resource from the list. The resources appear on the canvas. Move the resource to an appropriate location for the model that you have in mind. Add as many resources as needed.

5. Connect the container resource to the first resource to deploy. To create a connection between resources, select the parent resource, click the connection pad in the resource, and
then drop the connection in any resource with a dotted outline. The system does not allow certain connections (for example, an AWS datacenter cannot host an ARM resource).

6. Add and connect all resources that make up the blueprint. You must add and connect all resources before you configure operations and attributes in the Operations section.

As you update the resources in the Deployment Model tab, the system generates the Cloud Template: a complete representation of the blueprint in YAML script. You can export the Cloud Template representation of the deployment model and later import it into the Cloud Management application on another instance.

7. Configure the operations that the system performs on the resources and the attributes to use while performing the operations. By default, Provision, Stop, Start and Deprovision operations are provided. You can either select an existing operation or create a new blueprint operation.

- Select an existing operation: In the Operations section, select the Provision operation check box and click Provision to view a graph. You can rearrange the graph by deleting and adding operations. You can click Optimize All Plans for the Cloud Management application to suggest an optimized plan for you. The Cloud Management application looks at the blueprint you created and based on the attributes, the mappings, and the dependencies of each resource, suggests an optimized plan to execute. All the attributes for the Provision operation appear in the window. You can select or de-select any attribute. Once you configured the Provision operation, you can select the next operation and configure its attributes as needed.

- Create a new blueprint operation: Click New in the Operations section. The New Blueprint Operation dialog box appears. Enter a name, select an operation type, enter input parameters for the new operation, and click Save. The new blueprint operation appears in the Operations section.

8. If you have completed the design of the blueprint and you do not want to configure the blueprint any further, click the Draft toggle button to publish the blueprint. A message appears saying that your blueprint has been published. To continue configuring the blueprint, then skip this step.

9. To configure parameters such as variable sets, rules, life cycle operations for the blueprint catalog item, click the Catalog tab and then click the catalog. The Cloud Catalog Item screen appears.

10. Click Update if you made any changes to the form.

11. Click Publish to publish the blueprint. To view all published catalog items, click Published in the Blueprints landing page.

Execute blueprint operations in parallel
You can execute your blueprint resource operations to run in a linear or in a parallel way.

Role required: sn.cmp.cloud_service_designer.

By default, the blueprint resource operations are listed serially and follow an order. You can run operations in parallel by arranging them in branches. Identify the operations specified in a blueprint that have no dependencies and can run in parallel. Arrange such operations in a single branch. The Blueprint Designer runs these operations together. If an error occurs in a branch, the operations in the affected branch cease to execute. However, the operations in the other branches, that are unaffected by the error, continue to execute. The parallel way of executing operations hence cuts down time in provisioning stacks.

1. In the Cloud Admin Portal, navigate to Design > Blueprints.

2. Click a blueprint, click the Deployment Model tab and then click Operations. All the operations for the blueprint are listed.

3. Click an operation to view a graph. You can rearrange the graph by deleting and adding operations.
4. Click **Optimize Plan** for the Cloud Management application to suggest an optimized plan for you. The Cloud Management application looks at the blueprint you created and based on the attributes, the mappings, and the dependencies of each resource, the application suggests an optimized plan to execute.

Add a resource operation to the execution plan

The base system includes a large set of predefined resource operations. Rarely, you might add a custom operation for a resource.

**Role required:** sn_cmp.cloud_service_designer

1. While working in the blueprint designer, click the **Operations** tab and select the appropriate blueprint operation. As an example, you may select the **Provision** operation.

2. Click **Add**.

   The Add Resource Operation dialog box appears.

3. Fill in the form fields (as shown in the table).

<table>
<thead>
<tr>
<th>Resource</th>
<th>Select a resource to perform the operation on.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface</td>
<td>Select an interface for the resource.</td>
</tr>
<tr>
<td>Operation</td>
<td>Select an operation to perform for the step. By default, <strong>Provision</strong>, <strong>Stop</strong>, <strong>Start</strong> and <strong>Deprovision</strong> are provided. You at least need a provision operation for a user to order a cloud catalog item.</td>
</tr>
</tbody>
</table>

4. Click **Submit**.

   The new operation is added to the operation graph. The system adds the appropriate parameters for the operation.

5. Click the **Create Form Parameter** check box to select a parameter. Parameters differ for each operation. Enter a mapping expression for the selected parameter in the **Mapping** field. See [Using expressions in Cloud Management](#).

6. Click **Save**.

**Blueprint attributes**

When you add a blueprint operation to a resource, the system adds the appropriate attributes. You can choose whether or not to make the attributes available as catalog properties on the form when the system performs the operation.

**Common attributes for the provisioning operation for virtual machines**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VmFolderName</td>
<td>The name of the virtual machine folder.</td>
</tr>
<tr>
<td>ResourceGroupName</td>
<td>The name of the resource group to which the resource belongs.</td>
</tr>
<tr>
<td>StackName</td>
<td>The name of the stack that the user is provisioning.</td>
</tr>
<tr>
<td>CloudAccount</td>
<td>The cloud account to which the resource stack belongs.</td>
</tr>
<tr>
<td>OSProfile</td>
<td>The resource profile, in this case the Operating System profile, upon which the cloud resource is based.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DiscoverAndAttachIP</td>
<td>Finds a free elastic IP and assigns it to a virtual machine on AWS. By default, if a VM is deployed on a VPC in AWS, it will not get a public IP. If elastic IPs are not available, no IP can be assigned to the VM.</td>
</tr>
</tbody>
</table>

**Warning:** It is recommended that you do not use **KeyPreference**. If you use the attribute, do not set **KeyPreference** to **user**.

Configure a blueprint rule

Configure a rule that contains actions the system can take on blueprint attributes.

Role required: sn_cmp.cloud_service_designer

1. Open a blueprint that has the attribute for which you want to create a rule.
2. On the **Catalog** tab, click the operation, such as the provision operation, that contains the attribute.
3. In the Variable Sets related list on the Cloud Catalog Item form, click the name of the variable set that contains the variable.
4. In the Cloud Variables related list on the Variable Set form, click the name of the variable for which you want to create the rule.
5. In the Rules related list, click **New** and then fill in the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a name and description.</td>
</tr>
<tr>
<td>Description</td>
<td>Enter a number that tells the system which record to evaluate first in relation to others. The record with the lowest number runs first.</td>
</tr>
</tbody>
</table>

6. Right-click the form header and select **Save**.
This example rule is based on the **CloudAccount** property and contains an action that tells the system to update the list of locations when the user changes the cloud account.

**Example blueprint rule**

Configure an optional *condition* and a mandatory *action*.

Configure a blueprint rule condition
- Configure the condition on a blueprint form event rule that determines when the actions in the rule can run. Conditions are optional.

Role required: `sn_cmp.cloud_service_designer`

1. Open a *rule for a variable* on a blueprint.
2. On the Conditions related list, click **New**.
3. Fill out the form fields (see table).
## Field Description

**Operand**
Enter the property against which you can perform the conditional evaluation. For example, if your blueprint has a property which holds the value of a datacenter, enter the property name here.

**Operator**
Select an operator that evaluates the operand.

**Value**
Enter a value that the evaluated event rule must match.

**Condition Type**
If you configure multiple conditions, select the logical operator that determines how the system evaluates the condition in relation to the next condition (the next condition is determined by the **Order** field):

- **AND**: this condition must meet the criteria before the policy is eligible for execution.
- **OR**: this condition or the next condition that matches the criteria can allow the policy to be eligible for execution.

If you do not select an option, **AND** is used by default.

**Order**
Enter a number that tells the system which record to evaluate first in relation to others. The record with the lowest number runs first.

**Status**
Keep the status active to have the system process the condition. Change the status to inactive when you do not want the system to process the condition.

### 4. Click **Submit**.

This example condition applies when the user selects the AWS Datacenter for the Logical_Datacenter property, which is a field on the catalog item form:

![Example blueprint condition](image)

**Configure a blueprint action.**

Configure actions that the system runs when blueprint form attribute actions or event actions are triggered. You can configure actions like making a field mandatory, showing or hiding a field, or automatically populating a field.

Role required: sn_cmp.cloud_service_designer

1. Open a rule for a property or an event on a blueprint.
2. On the **Actions** related list, click **New** and then fill in the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Unique and descriptive name.</td>
</tr>
<tr>
<td>Action Type</td>
<td>Select an action type:</td>
</tr>
<tr>
<td></td>
<td>▪ Reload:</td>
</tr>
<tr>
<td></td>
<td>▪ Show:</td>
</tr>
<tr>
<td></td>
<td>▪ Hide:</td>
</tr>
<tr>
<td></td>
<td>▪ MakeMandatory:</td>
</tr>
<tr>
<td></td>
<td>▪ MakeNonMandatory:</td>
</tr>
<tr>
<td></td>
<td>▪ TriggerChangeEvent:</td>
</tr>
<tr>
<td></td>
<td>▪ SetValue:</td>
</tr>
<tr>
<td>Datasource</td>
<td>Select an action type:</td>
</tr>
<tr>
<td></td>
<td>▪ Reload Cloud Account:</td>
</tr>
<tr>
<td></td>
<td>▪ Reload Cloud Location:</td>
</tr>
<tr>
<td></td>
<td>▪ Check Quota:</td>
</tr>
<tr>
<td></td>
<td>▪ Reload Resource Profile:</td>
</tr>
<tr>
<td></td>
<td>▪ Reload From Profile:</td>
</tr>
<tr>
<td>Target Field</td>
<td>Enter the name of the field on the form that the action applies to. For example, if you selected <strong>TriggerChangeEvent</strong> for the action type, the value of the field changes when something changes on the form, as specified in the <a href="#">blueprint rule</a>.</td>
</tr>
<tr>
<td>Value</td>
<td>Enter an optional value that you want to assign to the target field. For example, if you selected <strong>SetValue</strong> for the <strong>Action Type</strong> field and you want to update the <strong>Resource Group Name</strong> field, you can use the value ${ResourceGroup}, which pulls the names of the resource groups from the blueprint.</td>
</tr>
<tr>
<td>Order</td>
<td>Enter a number that tells the system which record to evaluate first in relation to others. The record with the lowest number runs first.</td>
</tr>
</tbody>
</table>

3. Right-click the header and select **Save**.
4. Enter an optional **Key** and **Value** in the **KeyValues** related list. The value in the **Value** field is applied to the attribute in the **Key** field.
5. Create as many actions as necessary.

This example action applies to the [blueprint rule example](#), which is based on the CloudAccount attribute. The action tells the system to update the list of locations when the user changes the cloud account.
Example blueprint action

*Publish a blueprint as a cloud catalog item.*

Create a blueprint for configuration management provider integration

After you set up your configuration management provider and run Discovery on it, configure resource blocks.

Role required: sn_cmp.cloud_service_designer

For an example of a virtual machine configured to work with Ansible, see *Create a blueprint for Ansible Tower integration.*

1. In the Cloud Admin Portal, navigate to **Design > Blueprints.**
2. Click **New.**
3. Create a deployment model with a container, virtual machine, and a datacenter.
4. Click the **Operations** tab, select an operation, and then click **Add**.
   The Add Resource Operation dialog box appears.

![Add Resource Operation](image)

**Add Resource Operation**

- **Resource**: Virtual Server
- **Operation**: Bootstrap Node

5. Add the following resource operations for the Virtual Server one at a time:
   - **Bootstrap Node**: prepares the virtual server to communicate with Ansible Tower.
   - **Register Node**: registers the configuration management provider.
   - **ExecuteConfigPackages**: runs the applications or playbooks.

6. Click **Submit** once you have added the resource operations.
   The operations are added to the graph.
7. Make the following changes to these operations, and then click **Save** after each change:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Make this change</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blueprint Container Resource. Provision</td>
<td>Enable the <strong>WorkloadConfigProvider</strong> and <strong>WorkloadConfigProvider Type</strong> parameters. On the Cloud User Portal, users can see these fields to select the configuration management provider.</td>
</tr>
<tr>
<td>Management Attributes</td>
<td>Every operation has management attributes.</td>
</tr>
</tbody>
</table>

8. Go to the Cloud User Portal. Select the workload provider type in the order catalog form. Based on the workload provider type you select, the **Workload Config Provider** field gets loaded.

9. Select an application profile. Based on the profile, the configuration overrides appear. These overrides are the discovered config installable parameters.

10. Publish the catalog item.

---

**Form configuration with blueprints**

Blueprints control what the user sees on the catalog order form. You can configure the form to show or hide fields, populate fields with default values, and otherwise create a unique form for the user based on criteria.

You can also change the values in form fields using policies. See *Create a cloud policy* and *Create a policy action script* for examples.

---

**Components of blueprint form configuration**

Blueprints use these components to control how the system uses catalog form fields:

- **Catalog variables** define the basic structure of each field on catalog order forms.
- **Rules** specify an action that the system takes on a field when a condition is met.
- **Scripts** query the system for information that you need to show the catalog requester, populate form fields, and process the data that users submit.
UI groups to put related fields together in a tab. Users can progress through tabs to fill out all the form fields.

Start here

These tasks show you the basics of form configuration with blueprints:

- Add fields to a cloud catalog item order form
- Control visibility default values for Cloud catalog items
- Create a variable set for Cloud Management

Examples

These examples guide you through form configuration based on a specific goal: Cloud catalog form configuration examples.

Add fields to a cloud catalog item order form

Add fields to a cloud catalog form if you want the user to enter additional information beyond what a default blueprint provides.

- You need a blueprint that you published to the catalog. The blueprint should be in the draft state. See Build a Cloud Management blueprint if you did not complete this prerequisite.
- By default, cloud items appear in the Cloud Catalog, rather than the standard service catalog that comes with your instance. However, Blueprints utilize several features from the standard service catalog. It is suggested that you familiarize yourself with how the service catalog works. See Service Catalog to get started.
- Role required: sn_cmp.cloud_service_designer

Fields are represented as variables in blueprints. To add a field, you add a variable to an operation in the blueprint.

1. Open a blueprint that you already created.
2. Click the Catalog tab, and then click the operation, such as Provision, that you want to add the variable to.

The Cloud Catalog Item form opens.
3. In the Variable Sets related list at the bottom, click the set in which you want the variable to belong. For example, click General Info, which is a default variable set for all blueprints, to have the field appear in the first tab on the catalog order form. The Variable Set form opens.

4. In the Cloud Variables related list at the bottom, click **New**.

5. Fill in the important form fields, such as:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Select the type of variable, such as <strong>Single Line Text</strong> for a text field, <strong>CheckBox</strong>, or <strong>Date</strong>, for example.</td>
</tr>
<tr>
<td>Question tab</td>
<td>In <strong>Question</strong>, which is the value the user sees for the field on the catalog order form, enter a name. The <strong>Name</strong> field, which is the actual name of the variable, is automatically populated with the same value in lower case.</td>
</tr>
<tr>
<td>Other tabs</td>
<td>Fill in other fields on the remaining tabs to control the field’s visibility, form help text, default value, and access rights.</td>
</tr>
</tbody>
</table>

**Note:** This variable will not be available for orchestration. If you intend to use this variable for orchestration, please add it through Cloud Template or Blueprint instead.
6. Click **Submit**.

   The Variable Set form opens, showing the new variable in the Cloud Variables related list.

7. To control the position of the field on the form, change the value in the **Order** column. A lower order value moves the field higher up on the form, and vice versa.
In this example, the order is set to 1, which means the Email address field appears after the Logical Datacenter field and before the Cloud Account field.

8. On the form banner in the upper-left, click **Try It** to preview the order form as it would look to a user from the Cloud Catalog.

The form appears with the new field that you created.
9. Click the back arrow on the upper-left of the form.
10. Toggle the catalog item to Publish.

Control visibility default values for Cloud catalog items
Through blueprints, you can control how form fields appear to users in the cloud catalog. For example, you can control where the fields appear to users on the catalog item form, and whether they are read only or mandatory.

1. Open the blueprint to modify, and then toggle it from Published to Draft.
2. Click the Catalog tab.
   The Request Operation sub-tab opens and displays the published catalog items for the Provision operation.
3. Click the Provision tile for the catalog item.
   The settings in the Provision operation control the form that the user sees upon initial request of the item, before it is provisioned.

The Cloud Catalog Item form opens.
4. In the Variable Sets related list at the bottom, click the set in which you want the variable to belong. For example, click General Info, which is a default variable set for all blueprints, to have the field appear in the first tab on the catalog order form. The Variable Set form opens.

5. Click the variable you want to modify. The Cloud Variable form opens.

6. Complete any of the following actions.

<table>
<thead>
<tr>
<th>To</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Make the field mandatory</td>
<td>Select the Mandatory check box. Clear the check box to make the field optional.</td>
</tr>
<tr>
<td>Make the field read-only</td>
<td>Click the Availability tab, and then select the Read Only check box. Clear the check box to make the field editable. Use this option to automatically populate a value in the field that the user cannot change.</td>
</tr>
<tr>
<td>Show or hide the field</td>
<td>Click the Availability tab, and then select or clear the Visible check box.</td>
</tr>
<tr>
<td>Move the field to another tab</td>
<td>Select a different Variable set. General Info and Provision are provided in the base system, and you can configure additional form UI groups. To add a new tab for organizing fields in the catalog item, see Create a variable set for Cloud Management.</td>
</tr>
<tr>
<td>Set a default value</td>
<td>Click the Default Value tab and enter the value in Default value. If the field is not read-only, users can change the value on the cloud catalog form. Reference fields must use the Sys ID of the record that represents the default value.</td>
</tr>
</tbody>
</table>
| Add help for the user | Do any of the following:  
- Click the Question tab, and add a value in the Tooltip field to show a bubble with the text when the user hovers the cursor over the field.  
- Click the Annotation tab, select Show help, and then enter values in the Help text or Instructions fields to display additional text to the user above the field. |

7. Click Update.

8. Toggle the catalog item to Publish.

In this example, the Business Service field:

- Is populated with the Email business service record from the cmdb_ci_service table based on the Sys ID of the record.
- Is read-only so users cannot change it.
- Is mandatory because it is considered necessary before the system can provision the virtual resource.
- Contains help text to tell the user that the default selection is Email.
Cloud catalog form configuration examples

Several examples are provided to help you understand how to manipulate Cloud catalog order forms. These example cover blueprint rules, blueprint variables, and blueprint form UI groups.

<table>
<thead>
<tr>
<th>Example</th>
<th>Goal</th>
<th>Blueprint components used</th>
</tr>
</thead>
</table>
| **Populate the location based on the cloud account** | Use existing blueprint rules to illustrate how the Location field is populated based on the Cloud Account that the user selects. | This example illustrates:  
  • Rules |
| **Remove a field from a cloud catalog form** | Hide the Cost Center field on the catalog form when the catalog requester belongs to the Database group. | This example illustrates:  
  • Rules  
  • Resource pools |
<table>
<thead>
<tr>

</tbody>
</table>

Populate the location based on the cloud account

This example walks you through an existing set of blueprint rules that Cloud Management provides by default.

Before you can follow this example, you should be familiar with creating blueprints and blueprint rules. See these resources:

- **Blueprints**
- **Build a Cloud Management blueprint**
- **Configure a blueprint rule**

Role required: sn_cmp.cloud_service_designer

The goal of this example is to show you how a default set of blueprint rules accomplishes the task of populating the Location field based on the Cloud Account. Because this example walks you through default data, you do not need to create any records if you are following these steps.

This blueprint, which includes a virtual server that can be provisioned in an AWS datacenter, is used to illustrate the example:
1. Open a similar blueprint with a virtual server or similar.
2. On the blueprint form, click the Catalog tab, and then click the tile that represents the Provision operation.

3. Click the General Info variable set in the Variable Sets related list.
4. Click the CloudAccount variable to open the Cloud Variable form.

Notice these items:
- In the Rules related list at the bottom, two rules are provided:
  - ReloadLocation reloads the value in the relocation field. This rule runs first because it has a lower order number than the other rule.
  - TriggerChangeEvent Location tells the system to trigger the actions for the rules that are already configured for the Location variable.
- The Lookup Select Box field specifies that the Cloud Account field provides a selection for the user to make. The options that the user can select comes from the CloudAccountPool, which is on the Type Specifications field.
5. Click the **Reload Location** rule, and then click the **Reload Location** action from the Actions related list.

Notice these items:
- The **Action Type** is **Reload**, which tells the system to reload the catalog item form so that a new value for the field specified in the **Target Variable (the Location)** can be populated.

![Action Reload Location](image)

- The **DataSource** field tells the system to reload the location.
- The **KeyValues** list, which is only used when you specify a **Reload** action type, specifies that the user is passing in the cloud account via the form. The cloud account is necessary to reload the correct value for the location because the location is loaded from a pool. That pool has a filter that requires the input of the cloud account to return the correct location options.

6. Navigate back to the CloudAccount catalog property form and open the other rule: **TriggerChangeEvent Location**.

7. Click the **Actions** related list, open the **TriggerChangeEvent Location** action, and then click the **TriggerChangeEvent Location** action from the Actions related list.

Notice these items:
- The **Action Type** is **TriggerChangeEvent**, which tells the system to trigger the actions for the rules that are already configured for the Location property. By default, several rules are
already configured for the Location property. These include rules that reload other fields, like **OS Profile**, **Network**, and so on.

- No **KeyValues** are required because this action is not a reload action.

The result of these two rules on the CloudAccount attribute is illustrated in the following example:

8. Perform these steps to see why the system populated the value **AWS Datacenter - us-east-1** in the **Location** field and how the system determines which location is related to the **My Cloud Account** value:
a) In the same blueprint, open the **General Info** variable set, and then open the **Location** parameter.

b) Click the **Type Specifications** tab.

Notice the values that can be populated for the **Location** field from the **CloudLocationPool** resource pool.

c) Navigate to **Manage > Resource Pools**, open **CloudLocationPool**, and notice these items:

- The locations come from the records in the **Lookup Table**, which in this example is **Associated Datacenter (sn_cmp_ca_assc_datacenter)**.
- The actual value to display to users in the Location field on the catalog item form comes from the **Lookup Field**. In this example, the **Lookup Field** specifies the Alias column from the Associated Datacenter (sn_cmp_ca_assc_datacenter) table. The **Alias** column holds the actual, user-readable names for all locations.

d) Go to the standard interface of your instance, not the Admin Portal, and enter **sn_cmp_ca_assc_datacenter.list** in the navigation filter.

The list of datacenters that are already associated with cloud accounts appears.
Notice that the **My Cloud Account** cloud account is already associated with **AWS Datacenter - us-east-1**, which is the value that the user sees in the Location field. The system knew to display that value because of the association in this Associated Datacenter table. The system created this association when your Cloud Management administrator created the cloud account for AWS, and then ran discovery on the us-east-1 datacenter in that cloud account.

It is possible that multiple datacenters could be associated with **My Cloud Account**. In that case, the Location field reloads all the associated datacenters and in the Location field. Since the Location field is of type Select, the field allows the user to select which location to choose.

### Remove a field from a cloud catalog form

This example illustrates how to remove a field from the Cloud Management catalog form when the user belongs to a specific group.

Role required: sn_cmp.cloud_service_designer

Before you can follow this example, you should be familiar with creating blueprints and blueprint rules. See these resources:

- [Blueprints](#)
- [Build a Cloud Management blueprint](#)
- [Configure a blueprint rule](#)

The goal of this example is to hide the Cost Center field on the catalog form when the catalog requester belongs to the Database group. You can follow an example like this one when you want to show or hide catalog item fields based on values in other fields.

1. Create a blueprint with a virtual server. For this example, a blueprint with a virtual server on an AWS datacenter is used.

2. On the blueprint form, click the **Catalog** tab, and then click the tile that represents the **Provision** operation.
3. Click the General Info variable set in the Variable Sets related list.
4. Click the CostCenter variable to open the Cloud Variable form.
5. Configure the rule that removes the cost center based on the user group:
   a) In the Rules related list, click New.
   b) Fill out the Name and description Fields.
   c) Right-click the form header and select Save.

6. Configure the condition that requires the User Group to equal Database:
   a) In the Conditions related list, click New.
   b) Fill out the form fields as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value to enter or select</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operand</td>
<td>UserGroup</td>
<td>This value is the User Group field that the user selects.</td>
</tr>
<tr>
<td>Operator</td>
<td>--None--</td>
<td>Keep this value --None-- because this condition is the only condition you need to configure. If you add more conditions, you can select another operator to determine how the system evaluates this condition in relation to the others.</td>
</tr>
<tr>
<td>Value</td>
<td>287ee6fed9fe198100ada7952</td>
<td>This value is the Sys ID of the Database user group, which is provided as part of the demo data in your instance. See Sys ID for more information.</td>
</tr>
</tbody>
</table>

   c) Click Submit.

7. To understand why the Sys ID of the user group is required for the system, perform these steps:
   a) Open the blueprint again and click the Provision operation again.
   b) Click the General Info from the Variable Sets related list.
   c) Click the UserGroup variable.

   Notice that on the Type Specifications tab, the system populates user groups from UserGroupPool. The system runs the scripted pool filter named GroupsUserBelongsTo.
d) In the Cloud Admin Portal, navigate to Manage > Resource Pools.

e) Find and open UserGroupPool.

Notice that the values for the pool are derived from the table in the Lookup Table field, which in this case is the Group (sys_user_group) table.

Also notice that there are two queries in the Resource Pool Filters related list:

- **All** is a generic query that returns the list of all records from the Lookup Table. The value it returns from that table is from the Lookup Field, which in this case is the Sys ID. However, the system ignores the All query in this case because the scripted query is present.

- **GroupsUserBelongsTo** is a scripted query that returns the Sys ID of records in the Lookup Table.

**Important:** When a scripted query is present, the system uses it instead of the generic ALL query.

Both the generic query and the scripted query return the Sys ID of the record in the lookup table. But what is actually happening here is that the system ignores the All query and the value specified in the Lookup Field, and it uses the GroupsUserBelongsTo script.
A scripted query

Populate stack name with a script

This example illustrates how to populate the name of the stack that a user requests from the Cloud Management catalog by utilizing the user's ID. The example uses a script include that you can call from a blueprint rule action.

Role required: sn_cmp.cloud_service_designer

Before you can follow this example, you should be familiar with creating blueprints and blueprint rules. See these resources:
· **Blueprints**
· **Build a Cloud Management blueprint**
· **Configure a blueprint rule**

This example uses a script include. If you want to create similar script includes, familiarize yourself with the Glide System APIs that are part of your instance. See the [Developer site](#) for a comprehensive list of all APIs. See [Script Includes](#) for more information about how the system uses these scripts.

The goal of this example is to take the ID of the catalog requester and populate it in the Stack Name field. The field remains editable. Follow an example like this one when you want to loosely enforce a naming or labelling convention on certain values, but still allow the user to enter the text that they want.

1. Create a script include that returns the user ID of the person requesting the catalog item:
   a) In the standard interface for the instance (not in the Cloud Admin Portal), click the gear icon (⚙️) in the upper left, and then click **Developer**.
   b) In the **Application** field, select **Cloud Management Platform**.

The application scope of your instance changes to **Cloud Management Platform**. This selection means that the Cloud Management application can find the script include.

c) Close the System Settings window.

d) Navigate to **System Definition > Script Includes**.
e) Click **New**.

f) Fill in the form fields (see table):

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Provide a descriptive name without spaces.</td>
</tr>
<tr>
<td>Accessible from</td>
<td>Select <strong>All application scopes</strong>.</td>
</tr>
<tr>
<td>Script</td>
<td>Enter this script:</td>
</tr>
</tbody>
</table>

```javascript
var SetFields = Class.create();
SetFields.prototype = {
    initialize: function() {
    },
    setStackName: function(){
        return gs.getUserName();
    },
    type: 'HideFormAttributes'
};
```

The function `setStackName()` returns the user name of the catalog item requester. You can call this function from a blueprint rule action.
g) Click **Submit**.

h) Click the gear icon (🔧) in the upper left again, and then change the Application back to **Global**.

2. In the Cloud Admin portal, navigate to **Design > Blueprints** and open the relevant blueprint.

3. On the blueprint form, click the **Catalog** tab, and then click the tile that represents the **Provision** operation.
4. Click the **Stack Name** variable set in the Variable Sets related list. Notice that Stack Name is a single line text field that takes text input.

5. Create a rule to populate the stack name:
   a) Scroll down to the bottom of the form and click **New** in the **Rules** related list.
   b) Provide a name and description.
   c) Click **Submit**.

6. Configure the action as follows:
   a) From the Rule form, scroll down and click **New** in the **Action** related list.
   b) Configure the rule as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Provide a meaningful name and description, such as Set Stack Name to User ID.</td>
</tr>
<tr>
<td>Action Type</td>
<td>Select SetValueByScript to tell the system to call the script include that you specify in the Value field.</td>
</tr>
<tr>
<td>Target Variable</td>
<td>Select StackName to tell the system to set the value of the Stack Name field.</td>
</tr>
</tbody>
</table>
| Value           | Call the method in the script include that returns the user ID. The call must be in the following syntax:  
                  \$\{Script:ScriptIncludeName.methodName[]\}  
                  In this example, use  
                  \$\{Script:SetFields.setStackName[]\}  |
c) Click **Submit**.

In the Cloud User Portal, the catalog order form for the Provision operation shows the user ID of the logged-in user. This example uses the user Able Tutor, which comes in the base system as demo data. The value in the **Stack Name** field is the same value as in the User ID field on the User (sys_user) table. The profile icon for the same logged in user is also displayed in the upper right of the Cloud User Portal.
Set default values for a cloud catalog form fields
You can set default values for all users or you can populate fields with default values based on conditions. This example shows you how to set a default schedule profile and business service.

Role required: sn_cmp.cloud_service_designer

Before you can follow this example, you should be familiar with creating blueprints and blueprint rules. See these resources:

- [Blueprints](#)
- [Build a Cloud Management blueprint](#)
- [Configure a blueprint rule](#)

The goal of this example is to display a default value for both the schedule profile and the business service field. Each field derives its values differently:
- The schedule profile derives its values from a pool filter that returns a text value. Therefore, you must set the default value by applying the correct, matching text for one of the schedule profile options that appear to the user in a list.
- The business service derives its values from a reference to the Service (cmdb_ci_service) table. Therefore, you must set the value by specifying the Sys ID of the record that you want to display.

The example in this topic sets the values in different ways:
- The schedule profile default value is set directly on the Schedule Profile property and applies to all users without any conditions. You might want to do this to limit the use of virtual resources to specific schedule, such as during business hours only, for all users.
- The business service default value is set using an action on a blueprint rule. You might want to use a rule to set a default value when you want the value to be the default only when certain conditions are met. For example, if the user belongs to a user group that deals with only one business service, set the value for the user so they do not have to sort through a long list of all the business services in your organization.

1. Create a blueprint with a virtual server. For this example, a blueprint with a virtual server on an AWS datacenter is used.

2. On the blueprint form, click the Catalog tab, and then click the tile that represents the Provision operation.

3. Click the General Info variable set in the Variable Sets related list.
4. Click the ScheduleProfile variable.
Notice that the **Pool** field on the **Type Specifications** tab specifies the pool from which the values for the schedule profile are derived: ScheduleProfilePool.

The **ScheduleProfilePool** pool specifies the **All** filter, which returns the values in the Name field from the Schedule Profile (sn_cmp_schedule_profile) table. These values are static text values, which means that you can specify the exact text value for the name of the schedule profile that you want to make the default.

5. **On the Default Value** tab of the ScheduleProfile property form, enter the text that matches the value in the Name field from the Schedule Profile (sn_cmp_schedule_profile) table. In this example, that value is **8-5 weekdays**.
6. Click **Update**.
7. Click the **BusinessService** variable.

Notice that the **Reference** field on the **Type Specifications** tab specifies the Service (cmdb_ci_service) table, from which the values for the business service are derived.

By default, to refer to a specific record in a table, you must know the Sys ID of the record.

8. To obtain the Sys ID of a business service:
   a) In the main interface for the instance (not the Cloud Admin Portal interface), enter `cmdb_ci_service.list` in the application filter.
   b) Find the business service that you want to make the default.
   c) Right-click the record, and then select **Copy sys_id**.

   This example uses **Workday Enterprise Services**.
9. On the BusinessService variable form, create a rule, action, and condition with these values:
   a) In the Rule related list, click New.
   b) Provide a name and a description.
   c) Right-click the form header and select Save.
   d) In the Action related list for the rule, click New.
   e) Provide a name, and then configure these fields as specified:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action Type</td>
<td>SetValue</td>
</tr>
<tr>
<td>Value</td>
<td>The Sys ID of the business service that you copied.</td>
</tr>
</tbody>
</table>

In this example, the business service is set to Workday Enterprise Services by default, which is represented in the system with the Sys ID that you already copied.
<table>
<thead>
<tr>
<th>Name</th>
<th>Set Business Service Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display name</td>
<td>Set Business Service Action</td>
</tr>
<tr>
<td>Action Type</td>
<td>SetValue</td>
</tr>
<tr>
<td>Target Variable</td>
<td>BusinessService</td>
</tr>
<tr>
<td>Value</td>
<td>6a78f28f933a31003b4bb095e57ff8b8a</td>
</tr>
</tbody>
</table>

f) Click **Submit**.
You can create a condition or multiple conditions that must be met before the system sets the default value for the business service. For example, you might want to change the default value of business service to Workday Enterprise Services only when the group that the user belongs to is the Workday Admins group.

Resource blocks in Cloud Management

Resource blocks act as a type of middleware component between blueprints, the Cloud API (CAPI), and the CMDB.

The following graphic illustrates how resource blocks fit between other components in the system:
Blueprints

Each resource block becomes a building block within a blueprint. The blueprint eventually becomes a catalog item (also called a stack) that a user provisions from the Cloud Catalog.

Cloud API (CAPI)

Each resource block defines allowable operations, such as Provision and Deprovision. These operations call various components within CAPI to carry out the operation that is received from the stack.

The CMDB

Each resource block is based on a CI type from the CMDB. Resource blocks also have a response processor that handles responses from the cloud provider to take some type of action in the CMDB, such as creating or updating a CI.

How resource blocks are connected

Resource blocks are connected to each other in blueprints. For example, in this blueprint, a virtual server resource block is connected to storage. The virtual server and the storage are both connected to an AWS datacenter resource block.
For these connections to be successful, each resource block needs to specify a type of interface. This graphic illustrates these interfaces:
Types of interfaces for resource blocks

- The guest interface connects to the resource that is above it. The guest interface contains the operations (also called operation signatures), which allows users to take action on their resource.
- The host interface connects to the resource below the resource block in the blueprint. The host interface also contains operation signatures.
- The bindings connect adjacent resources.

Resource blocks can have as many guest interfaces, host interfaces, and bindings as necessary. Connections can be made in different directions:

- Vertical connections require the top resource block to have the same host interface as the bottom resource block guest interface.

  **Note:** In blueprints, this vertical connection is called a containment connection.

- Horizontal connections bind one resource to another, but both resources have to reside on top of the same resource block.

  **Note:** In blueprints, this horizontal connection is called an attached-to connection.

The same example blueprint with a virtual server with attached storage on an AWS datacenter, the resource blocks are configured as this graphic illustrates:
The binding between the virtual server and the storage is unidirectional. You configure the binding on the virtual storage resource block only by specifying the storage resource block. You do not need to configure another binding on the storage resource block.
Guest interfaces and operations

Each guest interface provides a default set of operations (also called operation signatures) that allow the user to choose what they want to do with a virtual resource. The most common operation is Provision, which means that a virtual resource is created. Many guest interfaces and corresponding operations are provided by default with the Cloud Management application. You can use these default guest interfaces for many of your resource blocks.

If you do need to create a new guest interface, these operations are provided by default:
- Start
- Stop
- Provision
- Deprovision
- Cleanup
- ModifySchedule
- ModifyLease

Resource block component details

Each resource block contains these components:

Layers

The logical layer in the stack that this resource block belongs to. The layers are provided by Cloud Management by default. When you configure resource blocks, you can choose the one that relates to you.

Operations for each guest interface

As mentioned, each guest interface provides operations. For example, the most common operations for a virtual server are Provision, Deprovision, Start, Stop.

Input parameters for each operation

The input parameters hold values that the cloud provider uses, via CAPI, when operations are run. These parameters hold the information that the user selects while performing an operation, such as provisioning, on a stack.

For example, a user typically must specify the location, which is a datacenter, that a stack belongs in. The value that the user selects in the Location field is held in the Location parameter. The system takes this parameter, which is available by default for the virtual server resource block, and passes it to the CreateNode CAPI interface operation. The CreateNode interface operation tells the cloud provider to create (or provision) the actual virtual server.

Steps for each operation

Each operation requires a step to do the actual work. Each step calls a specific interface and method in CAPI, and passes along the input parameters required by that method. For example, the Provision operation on a virtual server provides one step to first connect and create a virtual machine, and another step to create the node in the cloud provider. Each step provides different input parameters. To connect and create a virtual machine, the cloud account, among many other parameters, is required. To create the node, the cloud account is not required.

You can add as many steps as needed for each operation. You can also use output attributes to pass values in attributes from one step to another step, or from steps in one operation to
steps in a subsequent operation. For example, the **Provision** operation for a virtual server can provide an output attribute for the network interface ID and another for the node ID. When the cloud provider sends the response, the actual ID of the network and node are parsed out of the response and saved in the output attributes. Subsequent steps can then use the IDs to perform actions.

**Response processors**

Response processors tell the system what to do in the CMDB. When the cloud provider sends a response after an operation is run, the processor handles the response.

*i Note:* These processors are scripts that are system includes. They are not MID Server script includes like the CAPI scripts that you can create to integrate with the cloud provider.
How components work together

Users can see catalog items, also called stacks, in the Cloud Catalog. A catalog item is based on a blueprint, which in turn is composed of resource blocks that are connected together.

1. The user kicks off the process by requesting a stack. The request is the **Provision** operation in the system.
2. The system runs the steps in order for the **Provision** operation for the resource blocks that comprise the stack.
3. Each step calls CAPI to determine which method to run, while also passing in values for necessary parameters.
4. CAPI interfaces with the API of the cloud provider to provision the actual resource.
Process flow when a resource is created in the cloud provider

1. The cloud provider provisions the resource and responds with JSON.
2. The system parses the response inside the resource script in the resource block.
3. The system updates the CMDB. When provisioning a new resource, the system creates a CI in the correct table.
4. The new stack appears in the cloud user portal for the user to manage.

The Resource Blocks page

Manage resource blocks in the Resource Blocks page. Open the Cloud Admin portal, and then navigate to **Design > Resource Blocks**.
Create a custom resource block

If the blocks in the base system do not provide the cloud resources that you need to provision, you can create a custom resource block.

Role required: sn_cmp.cloud_service_designer

1. Navigate to **Cloud Management > Cloud Admin Portal > Design > Resource Blocks** and click **New**.
2. Enter a unique and meaningful **Name** and **Description** for the resource block, and then enter the following settings:
### Layer

Select the layer that represents the type of resource block:

- **Application**: Resources that are applications. For example, the 'PetStore' application might exist on a Tomcat or WebLogic platforms.
- **Platform**: Resources that are typically hosted on a virtual server like MySQL, Tomcat, or Apache.
- **Logical DataCenter**: Resources that are datacenters like AWS, Azure, or vSphere.
- **Virtual Infrastructure**: Resources that are virtual and still provide infrastructure for the virtual world like NetApp SVM, NetApp CDOT, CISCO ICF Cloud, or VMware NSX.
- **Virtual Workload**: Resources that are hosted on a datacenter. For example, Virtual Server, Storage Volume, Network, or Gateway.

**Note:**

- Applications are deployed on Platforms.
- Platforms are deployed on Logical Datacenters or Virtual Infrastructures.

### CI type

Select the type of CI in your CMDB that the resource block represents. When the user launches a stack, the cloud resources are provisioned and actual CIs that for the resources are created in the CMDB in this CI type. For example, if you select Storage Volume, the system creates a record in the Storage Volume (cmdb_ci_storage_volume) table when the user provisions a new volume.
| Default Guest Interface | Create interface | Select the guest interface that contains the *operations* you need for the resource. Later you can further define and select the operations to use for this default guest interface. The system gives you a set of default operations for each interface.

If another resource block specifies a *Host interface* (see the Host interface field description) that matches what you specify here in the *Guest interface* field, that resource block can be a potential host for this resource block.

If you select the *Create interface* check box, enter a name for the guest interface. The system creates the guest interface, opens the resource block that you are configuring in the resource block form, and lists the new interface in the *Resource Guest Interface* related list. See the description of the Resource Guest Interface in the following steps.

If you create a new guest interface, also keep in mind that other resource blocks can use the interface.

| Host interface | Select the interface that the potential host of this resource block must offer up. Any other resource block that offers up a default guest interface of the same type you specify here can become a host of this resource. Later on, you can select one or more actual host resources.

For example, by default the AWS Datacenter resource block specifies the *Compute* interface as a default guest interface. That means the AWS Datacenter is offering the *Compute* host interface to other resource blocks through which to connect to the AWS Datacenter.

Specify the *Compute* interface here as the host interface of the resource block so the resource block can look for any other resource block using the *Compute* interface as its guest interface. Since the AWS Datacenter does use the *Compute* interface as its guest interface, later you can select the AWS Datacenter as the actual host in the Host Resource related list.

Other resource blocks that offer the *Compute* interface by specifying *Compute* as the guest interface, are also potential hosts for this resource block.

You must know which interfaces the potential host resources offer as guest interfaces. And determine which operations are part of those guest interfaces. |
3. Click Submit. Continue updating settings on the related lists, as needed.

4. Optional: Complete the following steps to add another guest interface. You can specify an additional guest interface to offer to other resource blocks. For example, a datacenter resource block might offer a Compute interface, a Network Service Container interface, and a Firewall interface for other resource blocks to use.
   a) Under Guest Interface, click New.
   b) In the Guest interface field, select an interface.
   c) Click Submit or Update.

5. In Host Resource, specify the resource that can host this resource block, typically the one that offers the interface you specified in the Host Interface field.
   The selected host resource block handles the provisioning of this resource block. For example, the host resource is a virtual machine resource block that can host an Apache Web server. The host resource selection limits the options that are presented to users when they select a host.
   For example select vSphere Datacenter in the Host Resource field for this resource to be hosted in a VMWare cloud.
6. Optional: Complete the following steps to add bindings.

A binding is another resource block that this resource block can connect to. Select resource blocks that support the same **Guest interface** configured for this resource block.

When you create a blueprint, you can add an attach connection between two resource blocks that are connected with this binding. Understanding the direction of the binding is essential to configuring the resource block. You attach a virtual server to a network, or you attach storage to a virtual server. You cannot reverse these directions.

a) Under **Bindings**, click **New**.

b) In the **Host Resource** field, select a resource in the **Guest Resource** field.

   The guest resource is the resource block that you are attaching to the current resource block.

c) Click **Submit** or **Update**.

For example, a virtual server can connect to virtual storage. By default, the base system provides a Virtual Server resource block with a binding to the Storage Volume resource block to enable this connection.

---

**Note:** You can select only the host resources that support the **Host interface** previously specified for this resource block.
7. Complete the following steps to configure endpoint operations between the two resources to bind.

The endpoints call operations during binding. For example, a storage volume can specify an endpoint with required conditions and the operations to execute to make a connection to a virtual server. The virtual server must also support a binding interface to the storage volume.

Implement an endpoint type, such as **Block EP**, for the virtual server to consume the endpoint. Later, when you create blueprints, create the binding between the storage volume and the virtual server.

![Diagram of storage volume and virtual server binding](image)

**Example of binding in a blueprint**

a) Under **Endpoint Operations**, click **New**.

b) In **Binding Resource**, select the resource block that consumes the endpoint from this resource block.

c) Select the type of endpoint that the **Source Resource** presents.

d) In **Operation implementation**, select the implementation that performs the operation you are defining in this endpoint mapping.

e) Select the **Type** of operation to perform for the mapping.
   Only operations that are appropriate for the specified **Endpoint** appear in the list.
   Do not change the settings in **Source Resource**.

f) Click **Submit** or **Update**.

Specify a host resource for a resource block
Hosts that support the Host interface of a resource block are potential hosts for the resource block. You use the Host interface setting to further limit the options that are presented to the stack requester while selecting a host type.

Role required: admin

1. In the Cloud Admin Portal, navigate to Design > Resource Blocks.
2. Select the resource block and then select Draft on the Resource Blocks form:

3. In the Host Resource related list, click New.
4. On the Resource Host form, the Application and the Guest Resource (the resource block that you are currently configuring) are already specified. Specify the Host Resource. For example, for a virtual server, you might select AWS Datacenter or Azure Datacenter as potential host types.
5. Click Submit.

Specify bindings for resource blocks

Bindings represent endpoint relationships. For example, a storage volume might implement an endpoint type of Block EP (cmdb_ci_endpoint_block). A virtual server might consume an endpoint of that type. Bindings must support the Guest interface that is specified for the resource block.

Role required: admin

1. In the Cloud Admin Portal, navigate to Design > Resource Blocks.
2. Select the resource block and then select Draft on the Resource Blocks form:

3. In the Resource Bindings related list, click New.
4. On the Resource Binding form, the Application and the Guest Resource (the resource block that you are currently configuring) are already specified. Specify the Binding Resource.
5. Click Submit.

Configure endpoint operation mapping

You can configure endpoint mapping on a storage volume to make a connection to a resource.

Role required: admin

In the following example, the endpoint mapping that is configured for a storage volume specifies the conditions that must be met and the operation to execute to make a connection to a resource (a virtual server in the example) that supports a binding interface to a storage volume. The storage volume implements the endpoint (type Block EP in the example) and the virtual server consumes the endpoint:
The settings on the example **Resource Endpoint Mappings** related list specifies the conditions and an action:

- For a resource block that supports a binding interface to a **Storage Volume**
- For a **Source** resource with **CI type** of **Storage Volume**
- With an **Endpoint** type of **Block EP** (cmdb_ci_endpoint_block)

Use the **Attach** operation to implement the connection. Use the specified **Operation Implementation** to perform the **Attach** operation.

1. While configuring a resource block, open the **Resource Endpoint Mapping** related list, click **New**, and then specify the following settings:

   | Binding Resource | Resource block that consumes the **Endpoint** that the **Source Resource** presents. |
2. Repeat the process for as many mappings as are needed.

Configure resource block input parameters
You can configure operations for each interface of a resource block by specifying input parameters, steps, and output attributes. Input parameters hold values that the system requires to identify and manage a virtual resource, such as the datacenter and resource group that the resource is in.

Role required: sn_cmp.cloud_service_designer

The system automatically associates default operations from the Cloud API (CAPI) to the resource block when you add interfaces to it. It also provides default input parameters for each operation.

1. Open a resource block, and then click the **Operations** tab.

   ![Operations tab](image)

   The **Input Parameters** sub-tab appears by default.

2. Select the interface from the **Interface** choice list.

   ![Interface choice list](image)

   The interfaces in this choice list are derived from the **Resource Guest Interface** list on the **General Information** tab that you already configured when you created a resource block.

3. Select the operation on which you want to modify the input parameters. Optionally, you can create a new operation:
   a) Click the **Add Operation** icon.
b) Fill out the form (see table):

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a descriptive name.</td>
</tr>
<tr>
<td>Operation type</td>
<td>Select the type of operation from the choice list.</td>
</tr>
<tr>
<td>Access type</td>
<td>Select <strong>Public</strong> to make the resource block operation available from the catalog order form when a user manages a stack that they own. The actual operations appear in a list on the catalog order form: Select <strong>Private</strong> to prevent the operation from being used when a user launches a stack. This setting applies at the catalog-item level, not the whole-stack level. You can control the access type on the whole stack when you configure blueprints. As an example, you might want to mark the Deprovision operation as private for an individual VM, but not for the whole stack. This allows the user to deprovision everything at once and prevents the user from just deprovisioning the VM.</td>
</tr>
</tbody>
</table>

c) Click **Submit**.
4. Configure the input parameters to provide a way to input the items you need to run the selected operation.

For example, if you add a Provision operation for an AWS resource, you need, at minimum, the CloudAccount parameter and the Location parameter to perform the operation. You need to know the providers API to know what to pass to it. For example, if you want to add a provision operation for an S3 bucket on AWS, you need to know the allowable AWS operations on buckets and the Request Elements for things like creating a bucket (the PUT Bucket operation). You can typically find these resources in the AWS and Azure documentation.

a) Click the **Add Input Parameters** icon.

![Add Input Parameters icon](image)

b) Add the **Name** of the parameter that you obtained from the cloud provider API. In this example, you could add CreateBucketConfiguration for an AWS S3 bucket.

c) In the **Datasource** column, select the type of input parameter you are configuring. This value specifies the source or location where the parameter value comes from:

- **Text**: a text value that the user passes.
- **Pools**: the query that you want to run against a pool to get a value back from it. The pool **Datasource Value** should follow this convention: `ServiceNow::Pools::PoolName.Pool-Filter-Name`. See [Pool governance for Cloud Management](#) for more information on pools.
- **CSVList**: values from a comma-separated value list that you enter into the **Datasource Value**.
- **Array**: an array of values. You can programmatically send it an array in JavaScript. The format is as follows: `['abc','def']`.
- **FormData**: data submitted from the form configured in the blueprint.
- **ResourceScript**: an expression that passes a value. The expression should follow this convention in the **Mapping** field:

```javascript
$(Script:script-name.function[arg1=${value-to-pass},arg2=${value-to-pass}])
```
- **TLR**: the value inherited from the top-level resource container above this resource block in the blueprint.

d) Click **Save**.

e) In the **Mapping** column, you can view the auto-generated mapping values. Mappings specify where to pull the information in the system. You do not have to change the mapping values except for **ResourceScript** type parameters, where you must enter the expression.

f) In the **Default Value** column, specify a value that you want the system to use if the user does not pass any value or if you did not enter anything in the **Datasource Value**.

g) Select **Create Form** to make this attribute available in the order form that the user sees when trying to provision the stack item. You can also select **Mandatory** to force the user to enter a value.
In the Restricted To column, click the restricted icon (🔒), and then select a resource block to restrict the attribute to be passed to a specific host.

In this example, you are configuring a resource block for a virtual server on vSphere, which requires the name of the VM folder (represented by the `VmFolderName` attribute). Other datacenter types do not need the name of the VM folder. Therefore, you can restrict `VmFolderName` to the vSphere datacenter resource block.

This image illustrates how the `VmFolderName` attribute is restricted to the vSphere Datacenter.
Add operation steps to a resource block
After you configure operations and input parameters for your resource block, add steps for each operation to tell the system which Cloud API (CAPI) to call. Each step is a separate call to CAPI.

Role required: sn_cmp.cloud_service_designer

1. On the resource block, click the **Steps** sub-tab under **Operations**.
2. Click **Add Step**.
3. Fill in the form fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operation Type</td>
<td>Select the type of operation:</td>
</tr>
<tr>
<td></td>
<td>- <strong>Invoke Cloud API</strong>: Select this option to select a provider, interface, and method from CAPI.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Invoke Host Resource Operation</strong>: Select this option to use an operation (also called an operation signature) from the host interface that you already specified for this resource block.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Invoke Script</strong>: Select this option to invoke a method from an existing MID Server script include.</td>
</tr>
</tbody>
</table>

<p>| API Provider (Operation Type = Invoke Cloud API) | Select the API that provides the interfaces you need. The providers are part of the Cloud API (CAPI). |
|                                                 | For example, CAPI supplies the AWS provider, which has products, some of which have provider names. |
|                                                 | This value appears if you select the Invoke Cloud API operation type. |</p>
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API Interface</td>
<td>Select the interface that has the methods you want to use. For example, the Blob Storage Interface provides the CreateContainer interface, which the system uses during provisioning.</td>
</tr>
<tr>
<td>API Method</td>
<td>Select the method to perform the operation. In this example, CreateContainer is required to provision storage.</td>
</tr>
<tr>
<td>CAPI Version</td>
<td>Enter the version of the CAPI API.</td>
</tr>
<tr>
<td>Host Interface</td>
<td>Select the interface from which to call an operation. You can only select the same interface that you configured on the General Information tab of the resource block. To change the interface, navigate back to the General Information tab and select another value in the Host Interface field.</td>
</tr>
<tr>
<td>Interface Operation</td>
<td>Select the operation from the host interface. For example, if you select Storage Server Interface, you can call all the operations in that interface, such as CreateStorageVolume.</td>
</tr>
<tr>
<td>Scripts</td>
<td>Enter the script you want to invoke, along with a method in the script. Use this syntax: script-name.method.</td>
</tr>
<tr>
<td>Workflow</td>
<td>Do not use Workflow.</td>
</tr>
<tr>
<td>Condition</td>
<td>Enter an optional condition that must be met before the system uses this step.</td>
</tr>
</tbody>
</table>

If you look at the Azure API and the CreateNode method mapper, you can see that the endpoint operation is a script. It calls the MID Server script include, which shows you the createNode() function. This function uses AzureComputeVirtualMachine script include. Take time to review and understand this script include.

4. Click Submit.

The Input and Response Processor tabs appear for the step.

5. On the Input tab, configure the CAPI operation inputs.

On the CAPI interface, which in this case is Blob Storage Interface, open CreateContainer method. The inputs from CAPI are shown on the Input tab, where you create parameters.

Remember that the parameters on the Input Parameters tab is where users enter values. You can map those input parameters to the parameters on the Input tab. To do this, copy the Mapping value from the Input Parameters tab into the Value field on the Steps > Input tab.

If this step is invoking a script, and that script requires arguments to return values, you can add a new input parameter for each argument. Use this syntax in the Value field: $(parameter.arg1).

6. If any subsequent steps in this operation or subsequent operations require parameters values from this step to be passed to them, configure output attributes.
For example, the Provision operation for a virtual server can provide an output attribute for the network interface ID and another for the node ID. When the cloud provider sends the response, the actual ID of the network and node are parsed out of the response and saved in the output attributes. Subsequent steps use the IDs to perform actions.

a) Click the **Output Attributes** tab.

b) Enter code in the following notation:

```json
{
   "Attribute": "${Value}"
}
```

Where the value comes from a mapping to the interface and the operation.

For example, in the following output attribute:

```json
{
   "NodeId": "${Compute Interface.CreateNode.Output.resp.nodeId}"
}
```

- **NodeId** is the attribute.
- **Compute Interface** specifies the interface.
- **CreateNode** is the name of the method that creates the node.
- **Output.resp** is a mandatory part of the syntax.
- **nodeId**

Add an operation to a resource block to use with a workflow

You can select from the existing operations in a resource block to work with your workflow or you can create a custom operation.

**Role required:** Cloud designer or admin

1. In the Cloud Admin Portal, navigate to **Design > Resource Blocks**.
2. Select a resource block, for example **Virtual Server**.
3. Move the state of the resource block from **Published** to **Draft** to make it editable.
4. Select the **Operations** tab.
5. From the **Interface** drop-down field, select an interface that is available to the user. The default interface is **Virtual Server Interface**.
6. Click + to the right of the **Operation** field, and perform these steps in the Add Operation dialog:
   a) Enter a meaningful and unique name.
   b) Select an operation from the **Operation Type** drop-down.
   c) Select **Public** from the **Access Type** field.
7. Fill in the form, and then click **Submit**.

<table>
<thead>
<tr>
<th>Operation Type</th>
<th>Select the operation to perform.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access Type</td>
<td>For the user to see the operation at the Resources level during provisioning, select <strong>Public</strong>. Operations set to <strong>Private</strong> are not visible during provisioning.</td>
</tr>
</tbody>
</table>
The operation is available on the resource when you select the resource for your workflow.

**Add a resource operation step to invoke a workflow**

Add a resource operation step to invoke a workflow

You can invoke a workflow by adding an operations step to a resource and then associating the resource to a workflow.

- Role required: Cloud user, designer, or admin
- The Orchestration application is installed.

1. In the Cloud Admin Portal, navigate to **Design > Resource Blocks**.
2. Click the resource block to add an operations step to.
3. Set the resource block to **Draft** state and then click **Operations > Steps > Add Step**.
   
   To enable the workflow to be exported as part of the update sets, you must create an extension interface and add the new operation. See [Extend Cloud Management resource blocks with an override operation](...) for details.

4. On the Add Operation Steps popup, select **Invoke Workflow** for **Operation Type**.
5. Select the **Workflow** from the list of workflows that you created.

The system can filter the list using tags. To add a tag:

1. Navigate to **System Properties**.
2. Locate and select the system property **sn_cmp.workflow_tag_filter**.
3. Edit the property. Add a tag or comma-separated list of tags.
4. Click **Save**.

6. To filter the workflows:
   a) On the workflow table, open the workflow.
   b) Click **Add Tag**.
   c) Enter the value that you provided earlier in the property **sn_cmp.workflow_tag_filter**
   d) Click **Enter**.
   
   The value is added as a tag to the workflow.

The new step appears after the software generates the new Day 2 Operation Catalog.

7. Workflows can exist that are created on tables other than global. You can add a workflow created on such a table.

To execute operations on this type of workflow, you need the sys_id of the record in which the workflow is executing to create the current record. So when the designer adds a workflow that is on table other than global, the system creates a **wf_current** parameter in the operation input parameter. You can then write an expression to map the sys_id of the resource in which the operation is executing. Once this is completed, the designer can use the ‘current’ key word in workflow scripts.

To add the workflow:

a) After you create the step, the system adds the workflow inputs to the operation input parameters.

b) You can then provide the mapping for these parameters, if needed.

c) Click the **Generate Catalog** button to create the catalog item for the operation.

d) After the catalog generates, you can add from the load and field change rules to the catalog items.
8. Set the resource block to the **Published** state to make the workflow available in the Cloud User Portal.

Extend Cloud Management resource blocks with an override operation
You can extend your existing guest interface to create a new operation. You can also create a new guest interface with its own operations, parameters, and inputs.

- Role required: sn_cmp.cloud_admin
- Become familiar with resource block input parameters, operations, and steps. See [Configure resource block input parameters](#) and [Add operation steps to a resource block](#) for instructions.

The Cloud Management application is bundled with several useful resource blocks. Create extensions to the existing resource block interfaces to add more functionality to these resource blocks. After creating an interface extension, use it in a blueprint to execute a customized operation. For example, if you do not like the way a virtual server is provisioned, extend the virtual server resource block interface by adding operations or overriding existing operations.

![Note: Operations in resource blocks are also called operation signatures.](#)

1. Open a resource block.
2. Change the status of the resource block from **Published** to **Draft**.
3. Click the **Operations** tab.
4. Click the **Override Operation** icon.

5. Select an existing guest interface or select the **Create new** check box to create a new guest interface.
6. Optional: If you create an interface, enter a name in the **Interface** field.
7. Click **Submit** or **Update**.
   The new operation appears in the **Operation** list. If you create a new interface, it appears in the **Interface** list.
8. Configure the necessary input parameters, steps, and output attributes for your new guest interface.
9. To edit the operation or to change the access type:
   a) Click the **Edit Operation Signature** icon.
b) Change the **Operation Type** if necessary, and add, edit, or remove input parameters at the bottom.

c) If you want the blueprint designer to perform the operation directly on the resource only when it is instantiated, select **Private** for the **Access Type**.

d) Click **Update**.

10. After completing the customizations, toggle the switch to **Published**.

11. Navigate to **Cloud Management > Cloud Admin Portal > Design > Blueprints**.

12. Follow the steps in [Build a Cloud Management blueprint](#) to add a blueprint.

13. Click **Operations** and click the operation to modify in the resource block. The default resource block interface appears in the right column.

14. Click the **Edit Resource Operation** (pencil) icon to apply the interface extension you created.

15. Click **Submit**. The blueprint gets executed with the customized interface extension.

After you add this resource block to a blueprint, the parameters you added are available for you to customize.

**Add a resource script to a resource block**

A resource script operates on a resource during deployment or returns data to the CMDB after a resource is deployed.

Role required: sn_cmp.cloud_service_designer

1. In the Cloud Admin Portal, navigate to **Design > Resource Blocks**.

2. Open the resource block and then set it to **Draft** state.

3. On the **Resource Script** tab, specify a unique and meaningful **Name** and then define the script:

   ```
   Script code.
   ```
Configure a response processor

Configure a response processor to handle responses from datacenters.

- The CI class types for your resources must already exist in the CMDB. If you created custom products or providers in CAPI, you must also create custom CI types so the response processor knows how to identify CIs. See Create a CI class for a virtual cloud resource for information on creating CI types.
- Role required: sn_cmp.cloud_service_designer

After each step is completed, the datacenter sends a response to the ECC Queue of the MID Server. For example, if a user provisions a virtual server on an AWS datacenter, AWS sends information about the new virtual server to the ECC Queue. The system needs to create a CI in the CMDB for the virtual server. It does this using a response processor.

1. Open a resource block, and click the Resource Script tab.
2. Click New.
3. Enter a descriptive name and select Response Processor in the Type field.
4. In the Script field, enter a script.
5. Click Submit.
6. Click the Operations tab on the resource block.
7. Click the Steps sub tab.
8. Click a step.
9. Click the Response Processor tab for the step.
10. Click the add icon (➕).
11. In the Script Name field, select the processor you just created.
12. Click Submit.

The response processor script can process the response from the cloud provider for the CI type of the resource block.

Execute response processor for workflow

Execute a response processor for a workflow to get the workflow data back into a configuration item (CI). The response processor picks up the data, sends the data to the CMDB which in turn puts the data in a CI.
Role required: sn_cmp.cloud_service_designer.

Before you execute a response processor for a workflow, you need to create a workflow, attach the workflow to a resource block operation step, and then generate the catalog. To return the response from the workflow to the Cloud Management application, the workflow designer needs to add the Cloud Return Response activity to the workflow. A variable needs to be mentioned inside the Cloud Return Response activity for the response. See Workflow.

1. In the Cloud Admin Portal, navigate to Design > Resource Blocks.
2. Open a resource block that is in a draft state and navigate to OperationsSteps.
3. Click Add Step.
   The Add Operation Steps dialog box appears.
4. Add a workflow operation step. See Add operation steps to a resource block.
   The workflow operation step gets attached to the resource block and appears on the page. Any input parameters associated with the workflow appear on the Input tab.
5. Click Generate Catalog.
   The workflow appears in the Cloud User Portal as an operation. Select the workflow from the Select Operation picker to execute the operation. The status of the operation is visible in the Track operation sub tab.
6. Click the Response Processor tab and then click the plus icon.
   The Add Response Processor dialog box appears.

7. In the Script Name list, select a script for the response processor.
   For a script to appear in the Script Name list, the script should already have been created in the Resource Script tab.
8. Click Submit.
   The script appears in the Response Processor tab. You can open the script and make modifications to the script.

Virtual server response processor example
The Create_Virtual_Server_Response_Processor script, which is available by default in Cloud Management, is the response processor that handles the creation of AWS virtual machine CIs.

Create Virtual Server

The Create_Virtual_Server_Response_Processor resource processor script is available by default on the Virtual Server resource block. Its job is to create a virtual server record in the Virtual Machine Instance (cmdb_ci_vm_instance) table when a new virtual server is provisioned.
All response processors have this first line with these common parameters:

```javascript
function processResponse(response, cloudServiceAccountId, ldc, correlationId, step, requestorContext) {
    // This brings in the response from the cloud provider and the important information, such as the account ID, that is required for the new CI that the system can create. All of these parameters are required for all response processors.

    // Line 10 parses the response into JSON so that the system can process it. The information is held in the vmResponse variable:

    var vmResponse = global.JSON.parse(response);

    // Whenever you create or edit a response processor, you must know which inputs are required for the CI type. Line 11 handles one of the necessary inputs, the hardware ID, that the CMDB record requires:

    var hardwareId = vmResponse.hardwareId;

    // Line 39 shows the information that is required for the system to identify the new virtual server and related CIs, so the information can be put into the CMDB. In this case, the service account object ID identifies the account associated with the virtual server, the datacenter object ID identifies the datacenter in which the virtual server lives, and the virtual machine instance object ID identifies the virtual server itself. This identification code block prevents the creation of duplicate CIs.

    var vmInfo = {
        "cmdb_ci_vm_instance": {
            "validator": "virtual_machine_create_update_validator",
            "validator_overrides": {},
            "identification": {
                "cmdb_ci_cloud_service_account": {
                    "criterion": {
                        "object_id": cloudServiceAccountId
                    }
                },
                "cmdb_ci_aws_datacenter": {
                    "criterion": {
                        "object_id": ldc
                    }
                },
                "cmdb_ci_vm_instance": {
                    "criterion": {
                        "object_id": vmResponse.nodeId
                    }
                }
            }
        }
    }

    // Attributes are populated into the fields on in the cmdb_ci_vm_instance table. These attributes are defined in line 61:

    "attributes": {
        "name": vmResponse.nodeName,
        "object_id": vmResponse.nodeId,
        "state": status_map[vmResponse.state],
        "dns_suffix": vmResponse.dnsSuffix,
        "cpus": vmCPUs,
    }
```
References to other CIs can also be included in the response processor. In this case, the OS template that the virtual server is based on is identified by first identifying the object ID of the service account and the datacenter along with the actual OS template.

```
"references": {
  "cmdb_ci_os_template": {
    "identification": {
      "cmdb_ci_cloud_service_account": {
        "criterion": {
          "object_id": cloudServiceAccountId
        }
      },
      "cmdb_ci_aws_datacenter": {
        "criterion": {
          "object_id": ldc
        }
      },
      "cmdb_ci_os_template": {
        "criterion": {
          "object_id": imageIdTrim
        }
      }
    }
  }
},

The following code block adds the object ID of the OS image to the attributes list so that this information can be populated into the virtual server CMDB record.

```
"attributes": {
  "object_id": imageIdTrim
}
```

This code block performs additional identification on the Compute template (the hardware type) and then add it to the attributes:

```
"cmdb_ci_compute_template": {
  "identification": {
    "cmdb_ci_cloud_service_account": {
      "criterion": {
        "object_id": cloudServiceAccountId
      }
    },
    "cmdb_ci_aws_datacenter": {
      "criterion": {
        "object_id": ldc
      }
    },
    "cmdb_ci_compute_template": {
      "criterion": {
```
Additional code sections make the relationship with network interfaces and identify any storage attached to the virtual server.

This mandatory code block pushes the data to the CMDB and returns the JSON string:

```
cloudModelString.push(vmInfo);
return global.JSON.stringify(cloudModelString);
```

</tbody>
</table>

5. Click **Submit**.
6. Click the **Operations** sub tab and then click **Steps**.
7. Select **CreateStack** from the **Operations** list.
8. Click the **Add a Step** plus icon to open the Add Operation Steps dialog box and then fill in the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operation Type</td>
<td>Select the type of operation:</td>
</tr>
<tr>
<td></td>
<td>- <strong>Invoke Cloud API</strong>: Select this option to select a provider, interface, and method from CAPI.</td>
</tr>
</tbody>
</table>
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>API Provider</strong></td>
<td>Select the API that provides the interfaces you need. The providers are part of the Cloud API (CAPI). For example, CAPI supplies the Terraform OpenSource provider, which provides the Configuration Orchestration Interface. This value appears if you select the Invoke Cloud API operation type.</td>
</tr>
<tr>
<td><strong>API Interface</strong></td>
<td>Select the interface that has the methods you want to use. For this example, the Configuration Orchestration Interface provides multiple interfaces or methods, which the system uses during provisioning.</td>
</tr>
<tr>
<td><strong>API Method</strong></td>
<td>Select the method to perform the operation. In this example, <code>ExecuteCommand</code> is required to provision terraform templates.</td>
</tr>
<tr>
<td><strong>CAPI Version</strong></td>
<td>Enter the version of the CAPI API.</td>
</tr>
<tr>
<td><strong>Condition</strong></td>
<td>Enter an optional condition that must be met before the system uses this step.</td>
</tr>
</tbody>
</table>

9. Click **Submit**.
10. Click **Response Processor** and then click the plus icon. The Add Response Processor dialog box appears.
11. Select **Create_AzureTF_Stack_Response_Processor** from the **Script Name** list and click **Submit**.
12. Move the state of the resource block from **Draft** to **Published**. The Azure Datacenter resource block moves from the draft to the published state and no further changes can be made to the resource block. Changes to a resource block can be made only if the status is set to **Draft**.

### Add Terraform Orchestration interface on a resource block

After you have activated the Terraform store app for Cloud Management, to support cloud-based operations for cloud providers using Terraform Open Source Edition. Add the Terraform Orchestration interface on resource block, to execute cloud-based operations via terraform templates.

Role required: `sn_cmp.cmp_root_admin`, `sn_cmp.cloud_service_designer`

1. Navigate to On the Cloud Admin Portal, navigate to **Design > Resource Block**.
2. Click the resource block, for example **Azure Datacenter**.
3. Move the state of the resource block from **Published** to **Draft** to make it editable.
4. Navigate to **General Information > Guest Interface**, and then click **New**.
5. Search for and select the **Terraform Orchestration Interface** from the Guest Interface list, and click **Submit**.
6. Click the **Operations** tab.
7. In the **Input Parameters** tab, navigate to **Interface** and select **Terraform Orchestration Interface**
8. On the **Input Parameters** tab, configure the CAPI operation inputs.
On the CAPI interface, which in this case is Terraform Orchestration Interface, open CreateStack method. The inputs from CAPI are shown on the Input tab, where you create parameters.

Remember that the parameters on the Input Parameters tab is where users enter values. You can map those input parameters to the parameters on the Input tab. To do this, copy the Mapping value from the Input Parameters tab into the Value field on the Steps > Input tab.

If this step is invoking a script, and that script requires arguments to return values, you can add a new input parameter for each argument. Use this syntax in the Value field: ${parameter.arg1}.

9. Click the Steps sub-tab under Operations.
10. Click Add Step.
11. Fill in the form fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operation Type</td>
<td>Select the type of operation:</td>
</tr>
<tr>
<td></td>
<td>• Invoke Cloud API: Select this option to select a provider, interface, and method from CAPI.</td>
</tr>
<tr>
<td>API Provider</td>
<td>Select the API that provides the interfaces you need. The providers are part of the Cloud API (CAPI). For example, CAPI supplies the Terraform OpenSource provider, which provides the Configuration Orchestration Interface. This value appears if you select the Invoke Cloud API operation type.</td>
</tr>
<tr>
<td>API Interface</td>
<td>Select the interface that has the methods you want to use. For this example, the Configuration Orchestration Interface provides multiple interfaces or methods, which the system uses during provisioning.</td>
</tr>
<tr>
<td>API Method</td>
<td>Select the method to perform the operation. In this example, ExecuteCommand is required to provision terraform templates.</td>
</tr>
<tr>
<td>CAPI Version</td>
<td>Enter the version of the CAPI API.</td>
</tr>
<tr>
<td>Condition</td>
<td>Enter an optional condition that must be met before the system uses this step.</td>
</tr>
</tbody>
</table>

12. Click Submit.

The Input and Response Processor tabs appear for the step.

13. On the Input tab, configure the CAPI operation inputs.

On the CAPI interface, which in this case is Configuration Orchestration Interface, open ExecuteCommand method. The inputs from CAPI are shown on the Input tab, where you create parameters.

Remember that the parameters on the Input Parameters tab is where users enter values. You can map those input parameters to the parameters on the Input tab. To do this, copy the Mapping value from the Input Parameters tab into the Value field on the Steps > Input tab.
If this step is invoking a script, and that script requires arguments to return values, you can add a new input parameter for each argument. Use this syntax in the Value field: `${parameter.arg1}`.

**Note:** Please map the values as mentioned below for the following parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>AdditionalParameters</td>
<td>Enter the following script:</td>
</tr>
<tr>
<td></td>
<td>{&quot;ServerType&quot;:&quot;${Script:sn_cmp_terraform.TerraformCommandUtils.</td>
</tr>
<tr>
<td></td>
<td>getConfigProviderServerTypeByName[arg=${parameter.WorkloadConfigProvider}]&quot;}</td>
</tr>
<tr>
<td>ConfigMgmtProviderInfo</td>
<td>$(capiResolver.NodeCredentialResolver#nodeCredential[$ci.sn_cmp_wl_cfg_mgmt_provider[name=${parameter.WorkloadConfigProvider}].credential])</td>
</tr>
<tr>
<td>Node Address</td>
<td>$(ci.cmdb_ci_workload_config_provider[name=${parameter.WorkloadConfigProvider}].url)</td>
</tr>
<tr>
<td>Script</td>
<td>For CreateStack operation:</td>
</tr>
<tr>
<td></td>
<td>${CloudScript.scripts.TerraformDeploy}</td>
</tr>
<tr>
<td></td>
<td>For DeleteStack operation:</td>
</tr>
<tr>
<td></td>
<td>${CloudScript.scripts.DestroyTerraform}</td>
</tr>
</tbody>
</table>

14. On the **Response Processor** tab, configure the response processors by attaching resource scripts. You would have added Resource Scripts to the resource block, while creating the Resource Block.

15. From the Operation list, select the **CreateStack** or **DeleteStack** operation.

16. Click the add icon for **Add Response Processor**.

17. Click the **Resource Script** sub tab, and then click **New**.

18. Complete the form.

**New Record**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a name (For example, <strong>Create_AzureTF_Stack_Response_Processor</strong>)</td>
</tr>
<tr>
<td>Type</td>
<td>Select a type (<strong>Response Processor</strong>) for the script.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Script</td>
<td>Enter the following script:</td>
</tr>
<tr>
<td>Resource Script for Create</td>
<td>function processResponse (response, cloudServiceAccountId, ldc, correlationId, step, requestorContext, stackId) { var responseObject = global.JSON.parse(response); var tfState = global.JSON.parse(responseObject.terraform.state); var processor = new sn_cmp_terraform.TerraformResponseProcessor(); var processedResponses = processor.processResponse(tfState, cloudServiceAccountId, ldc, correlationId, step, requestorContext, stackId); return global.JSON.stringify(processedResponses); }</td>
</tr>
<tr>
<td>Script</td>
<td>Enter the following script:</td>
</tr>
<tr>
<td>Resource Script for Delete</td>
<td>function processResponse (response, cloudServiceAccountId, ldc, correlationId, step, requestorContext, stackId) { var responseObject = global.JSON.parse(response); var tfState = global.JSON.parse(responseObject.terraform.state); var processor = new sn_cmp_terraform.TerraformResponseProcessor(); var processedResponses = processor.processResponse(tfState, cloudServiceAccountId, ldc, correlationId, step, requestorContext, stackId); return global.JSON.stringify(processedResponses); }</td>
</tr>
</tbody>
</table>

19. From the **Script Name** list, select the script corresponding to the selected operation, and click **Submit**.

20. Move the state of the resource block from **Draft** to **Published**.

The datacenter resource block moves from the draft to the published state and no further changes can be made to the resource block. Changes to a resource block can be made only if the status is set to **Draft**.

**Cloud scripts and cloud script templates**

In the Cloud Management application, script execution is divided into cloud scripts and cloud script templates. Use scripts in blueprints, resource blocks, OS profiles, and use policy scripts to set request form attributes. Policy scripts cannot override user data.
Cloud scripts

Cloud scripts are simple java scripts that use platform features. An example of a sample cloud script:

```javascript
function evaluateTemplate() {
    // Template Resolver is a helper function which we will use to fetch a
    // template and replace its parameters,
    // var templateResolver=new TemplateResolver(); this comes inbuild
    // templateAttributes below will passed from the user.
    var listDir=templateResolver.getTemplate('Install',templateAttributes);
    return listDir;
}
```

Each cloud script contains certain parameters. Parameters are the attributes that you want to access. A parameter contains a name, a default value, and an override value. The default value can be a string literal, a resource block parameter or a complex script expression used in resource blocks.

A cloud script, by default, has access to the `templateResolver` object. The `templateResolver` object has, by default, a `getTemplate` method, whose first parameter is the cloud script template name. `templateAttributes` are the cloud script parameters created as part of a cloud script. If needed, customizations can be done in `templateAttributes`. As an example, see the following code snippet if the value of `DevName` parameter needs to be changed from John to Emily.

```javascript
function evaluateTemplate() {
    // Template Resolver is a helper function which we will use to fetch a
    // template and replace its parameters,
    // var templateResolver=new TemplateResolver(); this comes inbuild
    // templateAttributes below will passed from the user.
    templateAttributes['DevName'] = 'Emily';
    var customNodeName;
    var gr = new GlideRecord('some_custom_table_to_query');
    gr.addQuery('some_parameter','some_value');
    gr.query();
    if(gr.next())
        customNodeName=gr.getValue('some_custom_node_name');
    templateAttributes['NodeName'] = customNodeName;
    var listDir=templateResolver.getTemplate('Install',templateAttributes);
    return listDir;
}
```

Cloud script templates

Cloud script templates are actual executables which are passed to target a virtual machine for execution. Cloud templates can be of any type (Shell/PowerShell/Cloudinit) depending on the execution context. You need to create a cloud template first and then associate it with a cloud script.

Cloud scripts as CloudInit

Cloud providers provide a way to execute scripts at boottime for virtual machines. In the Cloud Management application, you can specify a cloudinit script at various levels:
• **Image level:** At the time of creating a cloud script, you can specify an image against which this script should be executed. Once an OS profile which contains this specific image gets selected, the default cloud script against this image is executed. In the example below, an Apache cloud script is associated with a particular image.

![Cloud Script Template](image)

• **OS profile level:** You can run a cloudinit against a specific cloud provider and against a specific AMI/image. You can also be generic and associate a cloudinit to an OS profile, irrespective of the underlying image. In the following example, multiple images are associated with the OS profile. You can map any cloud script to the OS profile in the Cloud Script OS Profile Mappings tab. The mapping of a cloud script with an OS profile takes precedence over the image-level cloud script association.
In this example, the Apache cloud script is mapped to the Centos OS profile. If needed, you can override the script parameters in the OS Profile Mapping Overrides section.

- Resource blocks: While mapping a cloud script to an OS profile, you can choose whether to execute the cloud script for a specific resource block used in a blueprint and against a particular resource alias. See Create an OS profile.

### Cloud scripts as Postinit

You can use cloud scripts as Postinit scripts in a resource block. Once you create a resource block with a virtual machine to be provisioned, you can add an ExecuteScript operation. The ExecuteScript operation takes a script parameter (a pool of cloud scripts) and you can select any script to execute. Use the `ScriptParameters` attribute in the ExecuteScript operation to override any script parameter. You can provide a JSON map of script parameter and its override value. All expressions that are supported by Cloud Management work in the `ScriptParameters` attribute.

Create cloud initialization script templates and a script

Create cloud initialization templates and a script to use during VM provisioning.

Role required: cloud_admin

1. In the Cloud Admin Portal, navigate to Design > Cloud Scripts > Cloud Script Templates.
2. Click New, enter the name and content of the script, and then click Submit.

Create as many script templates as needed.

3. In the Cloud Admin Portal, navigate to Design > Cloud Scripts.
4. Click New.
5. Enter a descriptive name and create script that uses the template name in the following line of code (`scriptName` is the name of the template):
   
   ```javascript
   templateResolver.getTemplate(scriptName);
   ```

   **Note:** For more information, see Cloud scripts and cloud script templates.

6. Click Submit.

To run a script at the time a virtual resource is provisioned, map the script to an OS profile. To run a post-provisioning script, create a blueprint and specify the script in the Execute Script operation. See Example: Post-provision cloud script for an example.

Map a script to an OS profile

To execute scripted actions during VM provisioning, you can map a script to an OS profile. The script runs on VMs that are created based on the image template in the OS profile.

- Role required: sn_cmp.cloud_admin
- You must have a cloud account with datacenters. You must run Discovery on the service accounts to populate the datacenters.

In this procedure, you specify an existing script. See Create cloud initialization script templates and a script.

**Note:** Profile mappings that specify more details run first. For example, a mapping that specifies a blueprint, OS profile, and resource alias takes precedence over a mapping that specifies only an OS profile.

1. In the Cloud Admin Portal, navigate to Manage > Resource Profiles.
2. In the Profiles list, select OS Profile and then open the profile.
3. On the Cloud Script OS Profile Mappings related list, click **New** and then fill in the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blueprint (Optional)</td>
<td>Select a blueprint to limit the script to a specific resource block used in the blueprint.</td>
</tr>
<tr>
<td>Cloud script</td>
<td>Select a cloud script to map the OS profile to.</td>
</tr>
<tr>
<td>Active</td>
<td>Select the check box if the cloud script should be run after the virtual machine is provisioned.</td>
</tr>
<tr>
<td>Application</td>
<td>Cloud Management is auto-selected.</td>
</tr>
<tr>
<td>OS profile</td>
<td>If you specify a blueprint, the cloud script is run when the blueprint is provisioned.</td>
</tr>
<tr>
<td>Resource Alias (Optional)</td>
<td>If you specify a resource alias for the blueprint, then the cloud script is executed when the blueprint with the specified resource alias is provisioned.</td>
</tr>
</tbody>
</table>

4. Right-click the form header and select **Save**. The **Name** attribute [scriptName] appears in the OS Profile Mapping Overrides list.

5. Optional: In the OS Profile Mapping Overrides list, enter an attribute name and value to use when the resource is provisioned.

Example: Post-provision cloud script
This example shows a cloud script that runs after a user provisions a virtual machine.

- Role required: cloud_admin
- OS resource profile that is mapped to an image template. The user provisions a resource using the profile. You must add basic authentication credentials to the image.
- Compute resource profile that is mapped to a hardware type.

In this example, you create a cloud init script, customize a resource block, and provision a VM from the Cloud User Portal.

1. Create a cloud script template and a cloud script that refers to the template.
2. Open the virtual server resource block, and then follow these steps:
   a) Set the Draft/Published switch to Draft.

   ![Virtual Server Interface](image.png)

   b) On the Operations tab, select **Virtual Server Interface** from the Interface list.
c) In the **Operation** field, verify that these operations exist:

- **Block Until Ready**
- **Execute Script**: This operation tells the blueprint to run a script.

![Operation field showing Block Until Ready and Execute Script options]

d) Click the **Input Parameters** tab to view the inputs for each operation.

e) On the **Steps** tab, add steps as needed.

f) For the **Script** parameter on each step, clear the **Script** check box and change the expression in the **Mapping** column to the following text:

```
$(CloudScript.scripts.scriptname)
```

where `scriptname` is the name of the script, not the script template, that you created earlier.
3. Publish the virtual server resource block, and use it in a blueprint that in turn is published to a catalog item.

4. Launch a new stack to provision a VM and specify the OS profile and Compute profile that you created as a prerequisite.

The Stack Status page runs through the **CreateNode**, **BlockUntilReady**, and **ExecuteShellScript** operations. The last operation kicked off the script you created. Validate a parameter value with the **AllowedPattern** property.

The **AllowedPattern** property in an Azure Resource Manager (ARM) and CloudFormation (CF) template performs input validation before sending a provisioning request.

Role required: sn.cmp.cloud_service_designer

You can provide rules to validate a parameter value before sending the provisioning request to the cloud. To be notified with an error message if the validation fails, specify the **ConstraintDescription** property in the template. You can customize the error message in the **ConstraintDescription** property to make the message clear and explicit. Usually, the CF templates already have the **AllowedPattern** and **ConstraintDescription** properties. If these properties are not present, you can add them as mentioned in the following procedure:

1. In the Cloud Admin Portal, navigate to **Design > Cloud Templates**.
2. Select a template or click **New** to create a new cloud template. If you select an existing template, rename the template.

3. In the **Body** text box, make the following changes in an ARM and a CF template.
   a) In an ARM template, make these changes:
      - In the parameters metadata section, enter `SNC::Parameter::Metadata`.
      - Add the **AllowedPattern** key and enter a valid value range.
      - Add the **ConstraintDescription** key and enter an error message.

        ```json
        "parameters": { 
            "newStorageAccountName": { 
                "type": "string", 
                "metadata": { 
                    "description": "Unique DNS Name for the Storage Account where the Virtual Machine's disks will be placed.", 
                    "SNC::Parameter::Metadata": { 
                        "allowedPattern": "[0-9a-z]{1,11}", 
                        "ConstraintDescription": "must be an alphanumeric " 
                    } 
                } 
            } 
        }
        ```

   b) In a CF template, make these changes:
      - Add the **AllowedPattern** key and enter a valid value range.
      - Add the **ConstraintDescription** key and enter an error message.

        ```json
        "Parameters" : { 
            "SSHLocation" : { 
                "Description" : "The IP address range that can be used to SSH to the EC2 instances", 
                "Type": "String", 
                "MinLength": "9", 
                "MaxLength": "18", 
                "Default": "0.0.0.0/0", 
                "AllowedPattern": "((\d{1,3})\.\d{1,3})\.(\d{1,3})/((\d{1,2}))", 
                "ConstraintDescription": "must be a valid IP CIDR range of the form x.x.x.x/x."
            } 
        }
        ```

4. Click **Submit**.

**Cloud Management governance**

Governance refers to the limitations that you can set on available cloud resources.

**Types of governance**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Quotas</strong></td>
<td>Quotas are limitations or requirements for groups and users on a resource block. Use quotas to prevent wasteful resource usage in your cloud environment.</td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Policies</td>
<td>A cloud policy can override a property value set by a user, create an approval task, reserve an IP address, pre-populate or hide form fields, execute custom scripts, call the Cloud API, or start or abort workflows. A cloud policy gives you system-wide control over approvals, resource operations, blueprint operations, or catalog item settings.</td>
</tr>
<tr>
<td>Pools</td>
<td>A resource pool is a query or script that filters a table. You configure a resource pool to limit the values that are available to users when they request a catalog item.</td>
</tr>
<tr>
<td>Permissions</td>
<td>Permissions are user group-level access rights to features in the Cloud Management application and to specific records in the instance, such as blueprints or cloud accounts.</td>
</tr>
</tbody>
</table>

*Permissions management for Cloud Management roles*

Permissions are user group-level access rights to features in the Cloud Management application and to specific records in the instance, such as blueprints or cloud accounts.

You can refine the actions that are allowed or prohibited for users based on user group. By default, each role includes access rights, but not all users with the same role can see or edit each others records. For example, by default users with the cloud_designer role have full read and write access to their own blueprints, but they do not have read or write access to blueprints created by other cloud designers. If you want them to have access, you must put the users into a group that has the cloud_designer role, then give that group read and write access to particular blueprints.

*Permission types*

**Access (Read)**

Users can see the record, but not edit or delete.

**Manage (Create & Update)**

Users can see the record and create and update new records in the same table, but cannot delete any records.

**Delete**

Users can delete specified records or all records in the table.

**Execute**

Users can execute an action on records in the table.

**All**

Users have permissions on all records in the table.

*Permissions suggestions*

Consider granting these permissions in your organization:
<table>
<thead>
<tr>
<th>Suggested group and role</th>
<th>Type of users in the group</th>
<th>Suggest permissions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Catalog user group</td>
<td>Users who order similar items from the catalog in the Cloud User Portal.</td>
<td>Access (read) or Execute</td>
<td>Catalog items, even after they are published, cannot be seen by users in the Cloud User Portal until you grant a user group to which that user belongs read access to the items. Grant Access and Execute permissions to cloud users on the Blueprint Catalog Item table and the Cloud Account table.</td>
</tr>
<tr>
<td>Cloud user</td>
<td>[sn_cmp.cloud_service_user]</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Blueprint designers</td>
<td>Users who design blueprints.</td>
<td>Manage (Create and update)</td>
<td>Blueprint designers cannot see or edit other blueprints or catalog items by default. To collaborate or reuse existing blueprints and catalog items, blueprint designers need access to each others’ blueprints through the Manage permission.</td>
</tr>
<tr>
<td>Service Designer</td>
<td>[sn_cmp.cloud_service_designer]</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Cloud admins</td>
<td>Users who create and manage cloud accounts.</td>
<td>Manage (Create and update)</td>
<td>Cloud admins must map templates to appropriate resource profiles. To collaborate or reuse existing resource profiles and templates.</td>
</tr>
<tr>
<td>Cloud administrator</td>
<td>[sn_cmp.cloud_admin]</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Assign a cloud permission

Assign a permission to refine the actions that are allowed or prohibited for users based on the user group they belong to.

- Role required: sn_cmp.cloud_governor
- The user group to which you want the permission applied.

1. Navigate to Cloud Management > Governance > Permission.
2. Fill out the form fields (see table).
Read permissions on cloud accounts

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target type</td>
<td>Select the cloud table in which the target record belongs.</td>
</tr>
<tr>
<td>All Entities</td>
<td>Select this option to apply the permission to all records in the table.</td>
</tr>
<tr>
<td>Permission</td>
<td>Select the permission type.</td>
</tr>
<tr>
<td>Target Entity</td>
<td>Select the record that the permission is based upon.</td>
</tr>
<tr>
<td>Group</td>
<td>Select the user group.</td>
</tr>
</tbody>
</table>

3. Click **Submit**.

**Policy governance in Cloud Management**

A cloud policy can override a property value set by a user, create an approval task, reserve an IP address, pre-populate or hide form fields, execute custom scripts, call the Cloud API, or start or abort workflows. A cloud policy gives you system-wide control over approvals, resource operations, blueprint operations, or catalog item settings.

A user requests a stack that triggers an approval policy.

1. On the Cloud User Portal, a user submits a request to provision a particular blueprint. The process of provisioning the blueprint is the trigger that causes the policy engine to apply an approval policy. A cloud approval policy specifies the users who must approve a specified cloud activity before the activity can proceed.

2. The policy engine determines that the request meets the condition specified in the rule for the policy. In this example, the condition evaluates to true whenever a particular blueprint is being provisioned.
3. Because the condition is met, the policy engine performs the action that is also specified in the rule. In this example, the action is to create an approval action for the manager.

4. While the approver (the manager) reviews the approval request, the user sees a 'waiting for approval' status message on the Cloud User Portal.

5. After the manager approves, the blueprint is provisioned.

About policy triggers

A trigger is an event — a user request or other activity — that triggers the policy engine. For example, the on Catalog item request end trigger fires after a user submits a request form. When you think about defining a policy, you might first consider how the policy will be triggered. Examples:

- A user requests a Stop operation on a virtual server (the on Stack resource operation trigger fires)
- A resource reaches the end of its lease (the on Lease End trigger fires)
- A user requests a particular stack (the on Blueprint provision trigger fires)

You typically refer to a policy by the name of the trigger for the policy. For example, you might refer to a policy that is triggered by the on Lease end trigger as a "Lease end policy." For more detail on the types of trigger that you can implement, see Triggers for cloud policies.

How policies work

For each policy, you typically configure a trigger that starts the policy engine. The policy engine enforces the policy by running all rules that are defined for the policy. A policy rule is a collection of conditions and actions. If all conditions evaluate to true, the policy engine performs the actions. If any condition evaluates to false, the policy engine does not perform the actions.
• Some policy types apply only to particular types of cloud operation, like start, stop, provision, or deprovision, or to a particular target, like ‘on blueprint123 provision operation’ or ‘on catalog item ABC launch’.

• You can configure a policy that does not specify a target, for example, ‘on any blueprint provision operation’ or ‘on any catalog item launch’. Errors on policies that apply to any object are ignored.

• If multiple policies apply, you can specify the order that the policies are applied (with an exception that is described in a following section).

• Policies can work with dynamic forms to allow you to show or hide form fields from end users. Users see only information that you decide they need for them to understand and complete their tasks.

Policy groups

A cloud policy group is a container for related policies. Consider grouping policies that are often used together or should be considered together. Grouping policies can help you to apply policies consistently across your organization.

Order of execution when multiple policies apply

Order of execution when multiple "approval" policies apply:

When multiple "approval" policies apply, the policies are applied in the following order. (The approval policies are on Blueprint provision (approval), on Stack operation (approval), on Stack resource operation (approval), and on Task remediation):

1. Only the first successful approval policy is applied and no other approval policies are applied.
2. If the applied approval policy has multiple rules, only the first successful rule is used.
3. If a rule has multiple actions, only the first successful action is performed.
4. If the applied approval policy includes both a custom approval and a Service Now approval, only the custom approval process is performed.

Order of execution for all other policy types:

• Policies are applied in the order that is specified by the Order of Execution property setting.
• If multiple policies have the same Order of Execution setting, then order is not guaranteed.

About operations in policies

Triggers are often based on user requests and the operations (start, stop, provision, or deprovision) that can run on a blueprint, a catalog item, a resource, or a stack. Some trigger types do not specify a cloud operation. For example, the on Lease End trigger fires independently of any operation.
About policy rules

A policy rule is a collection of conditions and actions. If all conditions evaluate to true, the policy engine performs the actions. If any condition evaluates to false, the policy engine does not perform the actions.

- Conditions: Conditions can consider request form data, resource activity, or user activity. Examples:
  - Is the size of the requested CPU greater than 32?
  - Is this a Stop operation?
  - Is the lease for this resource ending in the next 7 days?

- Actions: If all conditions evaluate to true, the policy engine runs the actions that the rule specifies. Expressions in policy actions can set or override values. Examples:
  - Override the value that the user specified by changing the CPU size to 16 and then start the approval process. (because the condition was met that the requested CPU is greater than 32).
  - Create an approval task for the manager. (because the condition was met that a Stop operation was requested).
  - Send notifications to every user in the ABC group. (because the condition was met that the lease ends in 7 days).

Policy action scripts

- Use policy action scripts to get, update, or set values in cloud requests.
- Your instance tracks tagged resources for billing and reporting. Policy action scripts can add and modify resource tags.

Cloud policy example

A base system cloud policy, Lease End ServiceNow, uses the on Lease end trigger that fires when a virtual resource is near the lease end date. If the conditions in the policy rule are met, the policy engine sends a notification to the owner of the resource and performs operations on the resource.

Role required: sn_cmp.cloud_governor or admin

In this example, you work with the Lease End ServiceNow policy. The policy performs the following actions when the conditions in the policy rule are met:

- Send a notification to the owner of a cloud resource when the resource lease is about to expire.
- Run a Stop operation on the resource.
- Run a Deprovision operation on the resource.

You can change any base-system policy by modifying settings or making the policy active or inactive.

1. In the Cloud Admin Portal, navigate to Govern > Policies.
2. Search for and open the Lease End ServiceNow policy.
3. Notice that the trigger is on Lease end, which means that the policy is triggered when the lease for the resource is near expiration.
4. Sort the Rules related list by **Order of Execution**. The rule with the lowest number runs first.
Notice that a notification rule runs first, followed by the Stop and Deprovision operations on the resource.

5. Click the Notify about upcoming lease end rule.
6. Notice that the rule specifies a condition: If it is one day before the end date, return true.

7. In the Policy Rule Actions related list, click the (empty) Name of the action.
8. On the Update Action popup, enter an Action Name (the value is required). Notice the value of the Notification (you will use it in the next step), and then close the popup.
9. Review the notification message other settings:
   a) On the instance (not the Cloud Admin Portal), navigate to **System Notification > Email > Notifications**.
   b) Search for and open the notification that is specified in the action by entering the filter text *Upcoming lease end* for **Name**:
   
   ![Notification Search](image)

   c) Click **Upcoming lease end** to open the notification form.
   
   Notice that the **Scheduled Operations (sn CMP scheduled_operation)** table is specified.

   **Note:** You base all notifications for Cloud Management on this table.
d) On the **When to send** tab, notice the conditions that apply:
<table>
<thead>
<tr>
<th>Condition</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operation Type is Notification</td>
<td>Specifies that the <strong>Operation Type</strong> field on the Scheduled Operations table must be <strong>Notification</strong>.</td>
</tr>
<tr>
<td>Status</td>
<td>Specifies that the system should trigger the notification when the status of the scheduled operation record is in progress, rather than waiting until it is complete.</td>
</tr>
<tr>
<td>Notification</td>
<td>Specifies that the <strong>Upcoming lease end</strong> notification must be specified.</td>
</tr>
</tbody>
</table>

**Fastpath:** When you create a custom notification, use the default conditions, but change the **Notification** condition to the name of your notification.

e) Click the **Who will receive** tab.

Notice that the **Users/Groups in fields** value is set to **Target.Assigned to, TargetOwned by**. You should use these settings to send the notification to the owner of the virtual resource.

10. In the Cloud Admin Portal, open the Lease End ServiceNow policy again, and then open the **Stop on lease end** rule.

![Image of Cloud Admin Portal with Lease End ServiceNow policy]

The rule has two actions — one action to send a notification and the other action to run the **Stop** operation on the virtual resource.

11. Click the (empty) **Action Name** of the action for the **Stop** operation.
12. On the Update Action popup, notice the settings:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policy and Rule Name</td>
<td>The policy and the rule to which this action belongs are specified in these fields by default.</td>
</tr>
<tr>
<td>Action Type</td>
<td>Run An Operation tells the policy engine to trigger a standard operation (Start, Stop, Deprovision, and so on) on the resource.</td>
</tr>
<tr>
<td>Blueprint Operation</td>
<td>The system runs the STOP operation on the resource.</td>
</tr>
</tbody>
</table>

The other rule, **Deprovision after lease end**, performs the Deprovision operation on the resource so that it does not stay active after the lease end date.

This example uses the settings available through the form configuration. To see example scripts that you could use in addition, see [Create a policy action script](#).

Triggers for cloud policies
A trigger is an event — a user request or other activity — that triggers the policy engine. For example, the on Catalog item request end trigger fires after a user submits a request form. When the trigger for a policy fires, the policy engine tests the conditions that are specified in the policy rule and, if the conditions are met, performs the actions that are specified in the rule.

### About triggers

- You typically refer to a policy by the name of the trigger for the policy. For example, you might refer to a policy that is triggered by the on Lease end trigger as a “Lease end policy.”
- Triggers are often based on user requests and the operations (start, stop, provision, or deprovision) that can run on a blueprint, a catalog item, a resource, or a stack. Some trigger types do not specify a cloud operation. For example, the on Lease End trigger fires independently of any operation.
- To optimize performance, limit the number of policies with general triggers like the on Catalog item triggers.
- A trigger that does not specify a target (a blueprint, catalog item, stack, or resource) is always executed. To optimize performance, therefore, minimize the use of such policies.
### Policy triggers

Types of policy trigger and the actions that are available for the associated policy rules

<table>
<thead>
<tr>
<th>Trigger name and actions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>on Blueprint provision</td>
<td>The <em>on Blueprint provision</em> trigger fires after execution of on Catalog item request start policies. A policy that is triggered by the <em>on Blueprint provision</em> trigger can run a script, override a user-requested attribute value, or abort and send a message about the provision operation. Use this trigger to override a value that the user enters. For example, when a user chooses a value for an attribute like the stack name, a policy with this trigger can change the stack name. In addition, another action can change the name again when the user finally provisions the resource. The user does not see the final value on the catalog item form because the change is made at provision time.</td>
</tr>
<tr>
<td>Actions:</td>
<td>- Execute a script&lt;br&gt;- Property override&lt;br&gt;- Abort process</td>
</tr>
</tbody>
</table>

*Create an action for an ‘on Blueprint provision’ policy*
<table>
<thead>
<tr>
<th>Trigger name and actions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Approval triggers</td>
<td>A cloud approval policy specifies the users who must approve a specified cloud activity before the activity can proceed. Approvers can include the manager of the user making a request, a specified user or group, or users with a specified role. You can specify multiple approvers. Approvals occur in the order that you specify. A policy that is triggered by one of the approval triggers can start approval workflows. The targeted approval policies complement the base-system approval operations.</td>
</tr>
<tr>
<td>- on Blueprint provision (approval): Triggered when the workflow begins to provision a blueprint. The trigger is invoked before the blueprint is provisioned. Because the provisioning process can alter request data (and possibly change costs), however, approval processes run after the blueprint is provisioned.</td>
<td>Note: The approval process is performed after properties are set because property values that were overridden could change costs.</td>
</tr>
<tr>
<td>- on Stack operation (approval): Triggered during any stack operation on the Cloud User Portal.</td>
<td>on Blueprint provision (approval) is applied before the blueprint is provisioned. Because the provisioning process can alter request data (and possibly change costs), approval processes run after the blueprint is provisioned.</td>
</tr>
<tr>
<td>- on Stack resource operation (approval): Triggered during any resource operation (start, stop, provision, and so on) on the Cloud User Portal.</td>
<td>Use on Stack operation (approval) to run an approval workflow when an operation is performed on a stack. By default, a change request is generated when an operation is performed on a stack, but it does not require an approval. This trigger can launch a mandatory approval.</td>
</tr>
<tr>
<td>- on Task remediation: Triggered when a user resubmits a failed request.</td>
<td>Use on Stack resource operation (approval) to run an approval workflow when an operation is performed on a single resource that is part of a stack. By default, a change request is generated when an operation is performed on a stack, but it does not require an approval. This trigger can launch a mandatory approval.</td>
</tr>
<tr>
<td>Actions:</td>
<td>A policy that is triggered by the on Task Remediation trigger can start approval workflows.</td>

</tbody>
</table>

Create a cloud policy

A cloud policy can override a property value set by a user, create an approval task, reserve an IP address, pre-populate or hide form fields, execute custom scripts, call the Cloud API, or start or abort workflows. A cloud policy gives you system-wide control over approvals, resource operations, blueprint operations, or catalog item settings.

- Role required: sn_cmp.cloud_governor or admin
- Optional: [Create one or more cloud policy groups](#)
This procedure describes every policy type except approval policies (on Blueprint provision (approval), on Stack operation (approval), on Stack resource operation (approval), and on Task remediation). See Create a cloud approval policy for instructions on creating a policy with an approval trigger.

1. In the Cloud Admin Portal, navigate to Govern > Policies.
2. Click New and then fill in the form.
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policy Trigger</td>
<td>Select a trigger that specifies when the policy should be applied. For example, the <strong>on Lease end</strong> trigger applies the policy when the lease for a stack ends. See <a href="#">Triggers for cloud policies</a>.</td>
</tr>
<tr>
<td>Resource Block</td>
<td>Select the resource block that the policy applies to.</td>
</tr>
</tbody>
</table>
| Blueprint | Select the blueprint that the policy applies to.  
  - If no blueprint is specified, then the policy applies for every blueprint. This condition can decrease performance.  
  - You can assign multiple policies to a blueprint. Multiple policies running simultaneously, however, might decrease performance. Publish a policy only when it should be enforced. |
| Operation | Select the operation that the policy applies to. For example, a policy can apply to the Deprovision operation only or to all operations on the blueprint or catalog item.  
  - **All**: Any operation executes.  
  - **Start**: The resource starts.  
  - **Stop**: The resource stops.  
  - **Provision**: The resource is provisioned.  
  - **Deprovision**: The resource is no longer available to users.  
  - **Execute Script**: A script runs on the resource. |
| Moment | Specify when the policy should be enforced:  
  - **Pre-operation**: Before the specified operation starts.  
  - **Post-operation**: After the specified operation finishes. |

Note: If you are integrating with Infoblox, use **Pre-operation** for a vSphere virtual machine. Use **Post-operation** for AWS and Azure clouds because AWS and Azure control the allocation of IP addresses. You can register the IP address that is provided with Infoblox.
### ServiceNow New York IT Operations Management

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Catalog item (appears when an on Catalog item launch, on Catalog item request start, or on Catalog item request end trigger is selected)</td>
<td>Select the catalog item that the policy applies to.</td>
</tr>
<tr>
<td>Start Date / End Date</td>
<td>Specify the start date when the policy should be considered and the end date when the policy should no longer be considered.</td>
</tr>
<tr>
<td>Order of Execution</td>
<td>Specify a number that represents the order in which the policy is applied. A policy with a lower number runs before a policy with a higher number.</td>
</tr>
</tbody>
</table>

For example, a policy with **Order** of **100** runs before a policy with an **Order** of **200**.

**Note:** The **Order of Execution** property does not apply for on Blueprint provision (approval), on Stack operation (approval), on Stack resource operation (approval), and on Task remediation policies. See [Create a cloud approval policy](#) for details.

<table>
<thead>
<tr>
<th>Status</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>· <strong>Published</strong> policies are enforced. You cannot edit a policy in the <strong>Published</strong> state. To edit a policy that is in the <strong>Published</strong> state, click <strong>Draft</strong> on the form header.</td>
<td></td>
</tr>
<tr>
<td>· <strong>Draft</strong> policies are not enforced. To enforce a policy, click <strong>Publish</strong> on the form header.</td>
<td></td>
</tr>
</tbody>
</table>

3. Right-click in the header and select **Save**.

**Configure a cloud policy rule** for the policy.

Configure a cloud policy rule

A policy rule is a collection of conditions and actions. If all conditions evaluate to true, the policy engine performs the actions. If any condition evaluates to false, the policy engine does not perform the actions.

- Role required: sn_cmp.cloud_governor or admin
- Optional: Create one or more cloud policy groups.

- A policy can include multiple rules. You can configure the order that rules are applied.
- Every rule is executed to completion.
- Any rule error stops execution. Exception: Policies that do not specify an operation.

1. In the Cloud Admin Portal, navigate to **Govern > Policies**.
2. Open a cloud policy. Set the policy to the **Draft** state if needed.
3. On the Rules related list, click **New** and then enter a descriptive **Name** for the rule.
- The rule name cannot be the same as the policy name.
- The rule name should not start with a number.

4. Using the base-system condition builder, specify the **Conditions** that must be met for the policy engine to perform the actions.

The following example rule is applied for a blueprint provision approval policy. The condition evaluates to true if the **OS profile** field on the request form has the value “Windows”.
### Field

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Criteria type)</td>
<td>Select one of the following options:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Request Form</strong>: Base the condition on a property (attribute) value in the request form in the Cloud User Portal. You specify which property to test. In the example, the condition tests whether the OS profile field on the request form has the value “Windows.”</td>
</tr>
<tr>
<td></td>
<td>• <strong>User</strong>: Base the condition on a user role or on the group that the user belongs to. For example, to create a condition that applies when the user belongs to the Marketing group, select:</td>
</tr>
</tbody>
</table>
|                                            |   • (Criteria Type): User  
|                                            |   • (User Entity): Group  
|                                            |   • (Relational Operator): Equals  
|                                            |   • (Group): Marketing |

**Note:** You use different criteria to build a condition for policies that are triggered by the **on Lease end** trigger. See the example that appears after the table.

<table>
<thead>
<tr>
<th>(Relational Operator)</th>
<th>Select an appropriate operator.</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Value)</td>
<td>Depending on the selected (Criteria type), enter or select a value.</td>
</tr>
<tr>
<td></td>
<td>• For <strong>Request Form</strong>, enter a value for the attribute.</td>
</tr>
<tr>
<td></td>
<td>• For <strong>User &gt; Group</strong>, select a group.</td>
</tr>
<tr>
<td></td>
<td>• For <strong>User &gt; Role</strong>, select a role.</td>
</tr>
</tbody>
</table>

| (Logical operator)                         | When defining multiple conditions, select a logical operator **OR** or **AND** that specifies the logical relationship with the next condition. |

5. **Click Submit.**

For policies that are triggered by the **on Lease end** trigger, use the base-system date condition builder to configure the condition to test. In addition to the condition, the following example shows the actions that the policy engine performs if the condition is met.
Create the policy actions that should run when all conditions of the rule evaluate to true.

Using expressions in Cloud Management

Expressions in policy actions can set or override values. Expressions in blueprints can access attributes of resources and can map values to request form fields. Expressions are available in resource blocks, blueprints, policies, and anywhere that Cloud Management allows scripts.
Using expressions

Expressions can hold the values for information that is dynamically generated in the system, such as the values for the selections users make on the Cloud User Portal. Expressions are available in resource blocks, blueprints, policies, and anywhere that Cloud Management allows scripts.

Using expressions in resource blocks

Each resource block operation uses an expression to hold a value for each parameter. The expression can use hard-coded values, data from the stack that the user provisions in the Cloud User Portal, data in the CMDB, and data that is derived from scripts. By default, Cloud Management generates a set of parameters and their expressions for each resource block operation.

For example, the parameter **Location**, which holds the datacenter that a resource belongs to, uses the expression `${parameter.Location}`
Blueprints can use expressions to map input parameters for each operation on a resource block. By default, the blueprint displays the same parameters and values that are specified in the resource block.

You can access blueprint attributes with expressions. The expression in the **Mapping** column defines blueprint attributes for each operation in a step. For example, the **Location** attribute, which appears on the stack request form, is accessible through the \(\{\text{parameter.Location}\}\) expression. The Location parameter with the \(\{\text{parameter.Location}\}\) value appears on the **Inputs** tab when you select a blueprint operation.

Using expressions in policy actions

Policy actions can use expressions to override parameter values that users submit in a request form on the Cloud User Portal. You can also access and override user data in stack operations. For example, use the following expression to rename a stack: \(\text{formData.Stackname} = \text{"your-naming-convention"};\).
You can access blueprint attributes with expressions. The expression in the **Mapping** column defines blueprint attributes for each operation in a step. For example, the **Location** attribute, which appears on the request form for a virtual machine, is accessed in the following expression: 

```
{$parameter.Location}
```

### Expression types

#### Definitional expressions

Definitional expressions are a form of early binding (or static binding). These bindings refer to compile-time binding and are evaluated when the user submits the stack request form (when stack or resource provisioning starts). Definitional expressions do not have access to the data that is generated during Orchestration. Definitional expressions are enclosed in curly braces. For example: 

```
${parameter.CloudAccount}
```

#### Runtime expressions

Runtime expressions are a form of late binding (or dynamic binding). These bindings refer to runtime binding and have access to the data that is created during Orchestration (for example, stack items). Runtime expressions are evaluated when called during an Orchestration run.
Runtime expressions are typically used for dot-walking to data in tables. Runtime expressions are enclosed in parentheses. For example: $(Stack.items[VM1].attributes[node_id])

**Definitional/Runtime expressions**

Some expressions include both definitional and runtime expressions.

**Complex expressions**

You can nest expressions of any type within other expressions.

### Definition expression syntax and examples

Allowable syntax uses a dollar sign and curly braces. These types are available:

- `${parameter.}`. Use this kind of expression to retrieve values from input attributes of processes like blueprint provisions. Data is not fetched from tables.
- `${Stack.items[]}`. Use this syntax to access attributes of specific items in a stack.
- `${randomNumber}`. Use this syntax to generate a random number. For example, you can provision a VM with a random node name or stack name.

#### Definition expression examples

<table>
<thead>
<tr>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>${parameter.BillingCode}</code></td>
<td>This expression shows how a billing code parameter appears in a blueprint.</td>
</tr>
<tr>
<td><code>${parameter.formData.CatalogAttributeType}</code></td>
<td>This expression takes a catalog attribute that is submitted by a user while the user fills out the form for a catalog item in the Cloud User Portal.</td>
</tr>
<tr>
<td><code>${parameter.userData.userId}</code></td>
<td>This expression takes the ID of a user while the user fills out the form for a catalog item in the Cloud User Portal.</td>
</tr>
<tr>
<td><code>${Stack.items[Virtual Server].attributes(sys_id)]</code></td>
<td>This expression gets the sys_id of a virtual server that is apart of a stack. Virtual Server is the alias of a resource block used in the stack.</td>
</tr>
</tbody>
</table>

### Runtime expression syntax and examples

Allowable syntax uses a dollar sign and parenthesis. These types are available:

- `$({tablename})` where tablename is a table in the system, usually a CI table in the CMDB. Use this syntax to access values of fields in the table.
- `$({Stack.items[]})`. Use this syntax to access attributes of specific items in a stack.

#### Runtime expression examples

<table>
<thead>
<tr>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>$({ci.cmdb_ci_cloud_subnet[ sys_id=12231231231231231231].cidr)</code></td>
<td>This expression dot walks to the Cloud Subnet table, finds the specific record with the given sys_id, and takes the value from the cidr column.</td>
</tr>
<tr>
<td>Example</td>
<td></td>
</tr>
<tr>
<td>---------</td>
<td></td>
</tr>
<tr>
<td>$(ci.sn_cmp_ip_pool[subnet=${parameter.formData.Subnet Id}])</td>
<td></td>
</tr>
<tr>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>This expression combines runtime and definition type expressions. The equal sign = is used to evaluate a value for a match. The expression dot-walks to the IP Pool table and looks for the subnet that has the subnet ID that the user submitted.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>$(ci.cmdb_ci_cloud_subnet[${parameter.formData.SubnetId}].cidr)</td>
</tr>
<tr>
<td>Description</td>
</tr>
<tr>
<td>This expression combines runtime and definition type expressions. The expression takes the value of the <em>cidr</em> field from a subnet that the user chose during provisioning. The square brackets [ ] indicate that the expression dot-walks to the Cloud Subnet table and then looks at the subnet value that the user submitted on a blueprint provision. The expression grabs the <em>cidr</em> field value and then walks to the value in the <em>cidr</em> field of the <em>sys_id</em> of the subnet.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>$(Stack.items[Virtual Server].attributes(sys_id))</td>
</tr>
<tr>
<td>Description</td>
</tr>
<tr>
<td>As in the definition expression example, this expression takes the <em>sys_id</em> of a virtual server that is apart of a stack.</td>
</tr>
</tbody>
</table>

**Example expression**

```$\{(ci.cmdb_ci_nic[$(Script:CMPVMNICs.getNICs[arg=$(Stack.items[Virtual Server].attributes[sys_id])])].private_ip)\}$
```

- **$ci:** Runtime expression to retrieve data from table.
- **cmdb_ci_nic:** CI for NIC (Network Interface Card).
- **$(Script):** Script-based expression.
- **CMPVMNICs:** Script include.
- **getNICs:** Function inside a script include.
- **arg:** Arguments to script include function. Arguments are separated by ",," when there are multiple attributes.
- **$(Stack.items):** Runtime stack expression to retrieve stack item from a stack. Argument is the alias specified in blueprint.
- **Virtual Server:** Alias of resource used in blueprint.
- **$(Stack.items(Virtual Server).attributes(sys_id))**: Retrieve *sys_id* of stack item ("Virtual Server") resource instance in a stack.
- **private_ip:** Attribute from cmdb_ci_nic. Replace with public IP if required.
Expressions

Simple parameter mapping expression
This type of expression retrieves values from input attributes of processes, such as blueprint operations, resource blocks, and policies. Data is not fetched from tables. Maps values from one layer to another, such as from a Blueprint to a Resource to the Cloud API.

- Type: definitional
- Syntax: \${parameter.}
- Examples:
  - \${parameter.BillingCode} returns the billing code.
  - \${parameter.formData.CatalogAttributeType} takes a catalog attribute that is submitted on the request form in the Cloud User Portal.
  - \${parameter.userData.userId} takes the ID of a user working on the request form in the Cloud User Portal.

Stack item expression
A CI instance in the CMDB represents each stack item. Use Stack Item expressions to look up first-level properties on the CI that back the stack item or on the stack item itself.

- Type: definitional/runtime
- Syntax: \${Stack.items[]} or $(Stack.items[])
- Examples:
  - \${Stack.items[VirtualServer1].attributes[sys_id]} is a definitional type expression that gets the sys_id of a virtual server in a stack. VirtualServer1 is the alias of a resource block that is used in the stack.
  - $(Stack.items[VirtualServer2].attributes[sys_id]) is a runtime type expression that takes the sys_id of a virtual server that is a part of a stack.
  - \${Stack.items[vm1].attributes[node_id]} reads the node_id attribute of the CI that was created for the VM. vm1 is the stack item name (or the alias of the resource in the blueprint).
  - $(Stack.items[vm1].status) reads the status of the stack item.
Property override expressions in policies

In policies, you can override properties by pulling a value from the system or by using a random number. You can use data from both the forms in the Cloud User Portal and from the user who performed the operation on the form.

- **Type:** definitional/runtime
- **Syntax:** `${parameter.formData.xyz}` or `${this.parameter.userData.xyz}`
- **Examples:**

  The following value can set the stack name to `Stack_Bob.Smith@company.com`:

  ```
  Stack_ ${parameter.userData.userId}
  ```

  Set stack or table values using runtime expressions by taking the subnet from the IP Pools table:

  ```
  $(ci.sn_cmp_ip_pool[subnet=${parameter.formData.Subnet Id}])
  ```

  In scripts, you can assign values as follows:

  ```
  formData.App_Server_NodeName = "MyNodeName";
  this.parameter.userData.userId == 'servicenowuserId';
  ```

- **See also** Create a policy action script.

Script expression

In the example, `VMProperties` is a script include with a function called `getIP`. A script expression is also an example of a complex expression (the expression is nested).

- **Type:** runtime
- **Syntax:** `$(Script:scriptName.function[])`
- **Examples:**

  ```
  $(Script:VMPropertiesUtil.getIP[ arg=
  $(Stack.items[VM1].attributes[object_id])])
  ```

  **Expression for Private IP:**

  ```
  $(ci.cmdb_ci_nic[$(Script:CMPVMNICs.getNICs[arg=
  $(Stack.items[Virtual Server].attributes[sys_id])])].private_ip)
  ```

  **Expression for Public IP:**

  ```
  $(ci.cmdb_ci_nic[$(Script:CMPVMNICs.getNICs[arg=
  $(Stack.items[Virtual Server].attributes[sys_id])])].public_ip)
  ```

  **Expression to get the credential alias:**

  ```
  $(Script:CMPVMUtils.getCredentialAlias[arg=
  $(Stack.items[Virtual Server].attributes[sys_id])])
  ```

  **Expression to get the IP address:**

  ```
  $(Script:CMPVMUtils.getReachableIp[arg=
  $(Stack.items[Virtual Server].attributes[sys_id])])
  ```
### CI lookup expression
Accesses values of fields in a table, usually a CI table in the CMDB.

- **Type:** definitional/runtime
- **Syntax:** $(ci.tableName)
- **Examples:**
  
  ```
  $(ci.sn_cmp _ip_pool[subnet=${parameter.formData.Subnet Id}])
  ```

  This combines runtime and definition type expressions. The = operator evaluates a value for a match. The expression dot-walks to the IP Pool table and looks for the subnet that has the subnet ID that the user submitted.

  ```
  $(ci.cmdb_ci_cloud_subnet[${parameter.formData.SubnetId}].cidr)
  ```

  The expression dot-walks to the Cloud Subnet table, looks at the subnet value that the user submitted on a blueprint provision, extracts the cidr field value, and then walks to the value in the cidr field of the sys_id of the subnet.

### Random number expression
Generates a random number. For example, you can provision a VM with a random node name or stack name.

- **Type:** runtime
- **Syntax and example:** `${randomNumber}

### Scratchpad expression/Resource operation output attribute expression
Reads output attributes from one operation into another operation.

- **Type:** runtime
- **Syntax:** varies
- **Example:** To set/expose outputs from one operation:
  ```
  $(Compute Interface.CreateNode.Output.resp.nodeId)
  ```

  To read the output attributes (where VM1.Provision is the operation whose output attributes are read):
  ```
  $(Outputs[VM1.Provision].NodeId)
  ```

### Conditions in expressions
You can use conditional expressions in blueprint steps and resource operation steps to conditionally execute or skip the step. The conditional expressions are Javascript expressions and they support expression substitutions.

- **Type:** definitional/runtime
- **Syntax:** varies
- **Examples:**
  ```
  '${{parameter.CloudAccount}}'=='Amazon Cloud Account'
  ```
  ```
  '${{Stack.items[vm1].attributes[node_id]}}'=='VM1'
  ```
Complex expression
You can nest expressions. In the example, ${parameter.ServerID} maps the sys_id of the CI and is replaced before the outer expression is consumed.

- Type: any
- Syntax: varies
- Example: ${ci.cmdb_ci_vm_instance[${parameter.ServerID}].name}

Order context
This expression is useful for life cycle operations and enables you to dot-walk on the order attributes as part of the sn_cmp_order table.

- Type: runtime
- Syntax: $(context.order.column_name)
- Examples:
  - Request Item: $(context.order.sc_req_item)
  - Dot-walk on request item object: $(context.order.sc_req_item.number)
  - Mixed Expression (Constant + Expression): "ram $(context.order.sc_req_item.number)"

Create an action for an 'on Blueprint provision' policy
The on Blueprint provision trigger fires after execution of on Catalog item request start policies. A policy that is triggered by the on Blueprint provision trigger can run a script, override a user-requested attribute value, or abort and send a message about the provision operation.

- Role required: sn_cmp.cloud_governor or admin
- Optional: Create one or more cloud policy groups. Configure a cloud policy rule and associated conditions.

1. In the Cloud Admin Portal, navigate to Govern > Policies.
2. Open a cloud policy. Set the policy to the Draft state if needed.
3. Open the rule that should perform the action and then click New on the Policy Rule Actions related list.
4. On the popup, click Create for the type of action to perform, enter a unique and meaningful Action Name, and then fill in the form for the action.
Create Policy Rule Action

**Execute a Script**

This action will execute a ServiceNow script on the instance. All the operation parameters are available as inputs to the script.

**Property Override**

This action will set the value of a given parameter of the operation.

**Abort Process**

This action will stop the workflow which drives the overall orchestration.

Settings for the 'Execute a Script' action

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action Script Category</td>
<td>Select a category.</td>
</tr>
<tr>
<td>Action Script Name</td>
<td>Specify a unique and meaningful name for the script.</td>
</tr>
<tr>
<td>Action Script</td>
<td>Create the script in the text box.</td>
</tr>
<tr>
<td></td>
<td>See <a href="#">Create a policy action script</a> for details.</td>
</tr>
</tbody>
</table>

Settings for the 'Property Override' action

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property</td>
<td>Specify the name of the property (attribute) on the user request form to override.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Value</td>
<td>Enter a value that overrides the value in the Property field. You can override text values only. You can specify a static value, an expression, or both. The example action, named SetTheCostCenter, specifies the value Marketing for the CostCenter property.</td>
</tr>
</tbody>
</table>

**Property Override**

- **Policy**: ProvisionActions
- **Rule Name**: FirstRuleProvision
- **Action Type**: Property Override
- **Action Name**: SetTheCostCenter
- **Property**: CostCenter
- **Value**: Marketing
- **Is Script Based**: [ ]

**Note:**
When a value is overwritten by both a policy rule and a form rule, the value in the form rule is used.

Expressions can perform the following actions (see Using expressions in Cloud Management for details):

- Set form data values using definition expressions. For example: ${parameter.formData.CatalogAttributeType}
- Assign user data values using definition expressions. For example: ${parameter.userData.userId}
- Set stack or table values using runtime expressions. For example: $(ci.sn_cmp_ip_pool[subnet=${parameter.formData.SubnetId}]) takes the subnet from the IP Pools table.
- Associate a random number with a field using static expressions. Use: ${randomNumber}
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is Script Based</td>
<td>Select the check box to display the <strong>Script</strong> text box and then specify the script. You can use the following example script snippet to override a stack name. The <strong>function( formData)</strong> section of the script modifies the values for fields on the form. MyStack is the stack name in this example.</td>
</tr>
</tbody>
</table>
|                       | ```javascript
customScript : function( formData){
  // Manipulation of form parameter is only supported here.
  // Change in any other attributes will be ignored
  // data available for manipulation are
  // Form Data
  // Ex. StackName can be accessed through formData.StackName
  formData.StackName = "MyStack";
  // User Data - Ex. User Id can be accessed through this.parameters.userData
  if(this.parameter.userData.userId == 'servicenowuserId')
  formData.StackName = "MyStack";
  return formData;
}
``` |

**Setting for the 'Abort Process' action**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Message</td>
<td>Enter the message to present to the requester when the process aborts.</td>
</tr>
</tbody>
</table>

Create an action for an 'approval' policy

A policy that is triggered by one of the approval triggers can start approval workflows. The approval triggers are (on Blueprint provision (approval), on Stack operation (approval), on Stack resource operation (approval), and on Task remediation.

- **Role required:** `sn_cmp.cloud_governor` or `admin`
- **Optional:** Create one or more cloud policy groups.
Configure a cloud policy rule and associated conditions.

When multiple "approval" policies apply, the policies are applied in the following order. (The approval policies are on Blueprint provision (approval), on Stack operation (approval), and on Stack resource operation (approval), and on Task remediation):

1. Only the first successful approval policy is applied and no other approval policies are applied.
2. If the applied approval policy has multiple rules, only the first successful rule is used.
3. If a rule has multiple actions, only the first successful action is performed.
4. If the applied approval policy includes both a custom approval and a Service Now approval, only the custom approval process is performed.

1. In the Cloud Admin Portal, navigate to Govern > Policies.
2. Open a cloud policy. Set the policy to the Draft state if needed.
3. Open the rule that should perform the action and then click New on the Policy Rule Actions related list.
4. On the popup, click Create for the type of action to perform.

- Custom Approval runs the workflow that you specify. The workflow should return a value of approved to complete the operation.
- Service Now Approval supports differing approvers based on the trigger for the policy:

<table>
<thead>
<tr>
<th>Trigger</th>
<th>Available approvers</th>
</tr>
</thead>
<tbody>
<tr>
<td>on Blueprint provision (approval)</td>
<td>• Manager Approval</td>
</tr>
<tr>
<td></td>
<td>• Assignment Group</td>
</tr>
<tr>
<td></td>
<td>• User (lock)</td>
</tr>
<tr>
<td>on Stack operation (approval)</td>
<td>Assignment Group</td>
</tr>
<tr>
<td>on Stack resource operation (approval)</td>
<td>Assignment Group</td>
</tr>
</tbody>
</table>
5. On the Approval form, specify a unique and meaningful **Action Name**.

Example: Action in the rule

6. If you selected **Custom Approval**, specify the workflow and then click **Submit**. If you selected **ServiceNow Approval**, specify who should approve the cloud activity.

**Approval fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Manager Approval</td>
<td>One or all of the following:</td>
</tr>
<tr>
<td></td>
<td>• Select the Manager Approval check box to require the manager of the approver to also approve the request. The default approval workflow goes to the manager first, then to the group, and finally to the user.</td>
</tr>
<tr>
<td></td>
<td>• Select a user group from the Assignment Group list.</td>
</tr>
<tr>
<td></td>
<td>• Unlock the User lock, select a user from the list, then close the lock.</td>
</tr>
</tbody>
</table>
Create an action for an ‘on Catalog item launch’ policy

The on Catalog item launch trigger fires when an order form (stack request form) is launched for a catalog item. A policy that is triggered by the on Catalog item launch trigger can run a script or override a user-requested value (text values only).

- Role required: sn_cmp.cloud_governor or admin
- Optional: Create one or more cloud policy groups.
- Configure a cloud policy rule and associated conditions.

1. In the Cloud Admin Portal, navigate to Govern > Policies.
2. Open a cloud policy. Set the policy to the Draft state if needed.
3. Open the rule that should perform the action and then click New on the Policy Rule Actions related list.
4. On the popup, click Create for the type of action to perform, enter a unique and meaningful Action Name, and then fill in the form for the action.
Create Policy Rule Action

Execute a Script

This action will execute a ServiceNow script on the instance. All the operation parameters are available as inputs to the script.

Property Override

This action will set the value of a given parameter of the operation.

Settings for the 'Execute a Script' action

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action Script Category</td>
<td>Select a category.</td>
</tr>
<tr>
<td>Action Script Name</td>
<td>Specify a unique and meaningful name for the script.</td>
</tr>
<tr>

<td>Select the check box to display the <strong>Script</strong> text box and then specify the script. You can use the following example script snippet to override a stack name. The function( formData) section of the script modifies the values for fields on the form. MyStack is the stack name in this example.</td>
</tr>
</tbody>
</table>

```javascript
customScript : function( formData){
  // Manipulation of form parameter is only supported here.
  // Change in any other attributes will be ignored
  // data available for manipulation are
  // Form Data - Ex. StackName can be accessed
  // through formData.StackName
  formData.StackName = formData.StackName = "MyStack";
  // User Data - Ex. User Id can be accessed
  // through this.parameters.userData
  // if(this.parameter.userAgentId == 'servicenowuserId')
  formData.StackName = "MyStack";
  return formData;
},
```

Create an action for an 'on Catalog item request start/end' policy

The **on Catalog item request start** trigger fires after a user opens a request form. The **on Catalog item request end** trigger fires after a user submits a request form. A policy that is triggered by the **on Catalog item request start** or **on Catalog item request end** trigger can run a script or execute a workflow.

- **Role required**: sn_cmp.cloud_governor or admin
- **Optional**: *Configure a cloud policy rule* and associated conditions.

1. In the Cloud Admin Portal, navigate to **Govern > Policies**.
2. Open a cloud policy. Set the policy to the **Draft** state if needed.
3. Open the rule that should perform the action and then click **New** on the Policy Rule Actions related list.
4. On the popup, click **Create** for the type of action to perform, enter a unique and meaningful **Action Name**, and then fill in the form for the action.

### Settings for the 'Execute a Script' action

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action Script Category</td>
<td>Select a category.</td>

---

Create an action for an 'on Resource operation launch' policy

The on Resource operation launch trigger fires before the catalog for a resource operation is loaded from the Cloud User Portal. A policy that is triggered by the on Resource operation launch trigger can run a script or can override a user-requested value (text values only).

- Role required: sn_cmp.cloud_governor or admin
- Optional: Create one or more cloud policy groups.
- Configure a cloud policy rule and associated conditions.

1. In the Cloud Admin Portal, navigate to **Govern > Policies**.
2. Open a cloud policy. Set the policy to the Draft state if needed.
3. Open the rule that should perform the action and then click New on the Policy Rule Actions related list.
4. On the popup, click Create for the type of action to perform, enter a unique and meaningful **Action Name**, and then fill in the form for the action.
Create Policy Rule Action

Execute a Script

This action will execute a ServiceNow script on the instance. All the operation parameters are available as inputs to the script.

Property Override

This action will set the value of a given parameter of the operation.

Settings for the ‘Execute a Script’ action

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action Script Category</td>
<td>Select a category.</td>
</tr>
<tr>
<td>Action Script Name</td>
<td>Specify a unique and meaningful name for the script.</td>
</tr>
<tr>
<td>Action Script</td>
<td>Create the script in the text box. See Create a policy action script for details.</td>
</tr>
</tbody>
</table>

Settings for the ‘Property Override’ action

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property</td>
<td>Specify the name of the property (attribute) on the user request form to override.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>

<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Value</td>
<td>Enter a value that overrides the value in the Property field. You can override text values only. You can specify a static value, an expression, or both. The example action, named SetTheCostCenter, specifies the value Marketing for the CostCenter property.</td>
</tr>
</tbody>
</table>

**Property Override**

- **Policy**: ProvisionActions
- **Rule Name**: FirstRuleProvision
- **Action Type**: Property Override
- **Action Name**: SetTheCostCenter
- **Property**: CostCenter
- **Value**: Marketing
- **Is Script Based**: no

![Property Override Form](image)

**Note:**
When a value is overwritten by both a policy rule and a form rule, the value in the form rule is used.

Expressions can perform the following actions (see [Using expressions in Cloud Management](#) for details):

- Set form data values using definition expressions. For example: `${parameter.formData.CatalogAttributeType}`
- Assign user data values using definition expressions. For example: `${parameter.userData.userId}`
- Set stack or table values using runtime expressions. For example: `$(ci.sn_cmp_ip_pool[subnet=${parameter.formData.SubnetId}])` takes the subnet from the IP Pools table.
- Associate a random number with a field using static expressions. Use: `${randomNumber}`
Create an action for an ‘on Resource operation request start/end’ policy

A policy that is triggered by the on Resource operation request start or on Resource operation request end trigger can run a script or override a user-requested attribute value.

- **Role required:** sn_cmp.cloud_governor or admin
- **Optional:** Create one or more cloud policy groups.
- **Configure a cloud policy rule** and associated conditions.

- The on Resource operation request start trigger fires after a user submits a resource operation request (Start, Stop, Deprovision).
- The on Resource operation request end trigger fires before completion of a life cycle operation on a resource (Start, Stop, Deprovision).

1. In the Cloud Admin Portal, navigate to Govern > Policies.
2. Open a cloud policy. Set the policy to the **Draft** state if needed.
3. Open the rule that should perform the action and then click **New** on the Policy Rule Actions related list.
4. On the popup, click **Create** for the type of action to perform, enter a unique and meaningful **Action Name**, and then fill in the form for the action.

---

### Create Policy Rule Action

**Execute a Script**

This action will execute a ServiceNow script on the instance. All the operation parameters are available as inputs to the script.

**Execute a Workflow**

This action will execute a ServiceNow workflow on the instance. The execution will not wait for the workflow to complete.

---

#### Settings for the 'Execute a Script' action

<table>
<thead>
<tr>

Configuring an ‘Execute a Workflow’ action to run the base-system ‘Change Request’ workflow

Create an action for an ‘on Task Remediation’ policy

The on Task Remediation trigger fires when a user resubmits a failed request. A policy that is triggered by the on Task Remediation trigger can start approval workflows.

- Role required: sn_cmp.cloud_governor or admin
- Optional: Create one or more cloud policy groups.
- Configure a cloud policy rule and associated conditions.

1. In the Cloud Admin Portal, navigate to Govern > Policies.
2. Open a cloud policy. Set the policy to the Draft state if needed.
3. Open the rule that should perform the action and then click New on the Policy Rule Actions related list.
4. On the popup, click Create for the type of action to perform.

- **Custom Approval** runs the workflow that you specify. The workflow should return a value of approved to complete the operation.
- **Service Now Approval** supports differing approvers based on the trigger for the policy:
  - Manager Approval
  - Assignment Group
  - User (lock)

5. On the Approval form, specify a unique and meaningful Action Name.
6. If you selected **Custom Approval**, specify the workflow and then click **Submit**. If you selected **ServiceNow Approval**, specify who should approve the cloud activity.

**Approval fields**

<table>
<thead>
<tr>
<th>Field</th>

</table>
Create a policy action script

Use policy action scripts to get, update, or set values in cloud requests.

Role required: sn_cmp.cloud_governor or admin.

For more information on using scripts, see [Cloud scripts and cloud script templates](#).

1. On the Cloud Admin Portal, navigate to **Govern > Policies**.
2. On the **Policy Action Scripts** tab, click **New**, enter a unique and descriptive **Name** and **Description**, fill in the form, and then click **Submit**. After you enter a name, a script appears with a variable that uses the name that you entered.

The following example script determines whether the user belongs to a user group and then overrides the user-specified application server node name value with the value **MyNodeName**.

```javascript
customScript : function(formData){
    var groups = this.parameters.userData.groups;
    if( groups.length > 0){
        formData.App_Server_NodeName = "MyNodeName";
    }
    return formData;
},
```

This example returns a random number:

---

© 2020 ServiceNow, Inc. All rights reserved. ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
This example script adds three hours to the lease date using the base-system `GlideDateTime` class.

```javascript
var SetLeaseShort = Class.create();
SetLeaseShort.prototype = Object.extendsObject(sn_cmp.PolicyExecutionBase, {
  customScript : function(formData){
    // Manipulation of form parameters are supported. Changes in
    // any other attributes
    // will be ignored.
    // The data available for manipulation is as follows:
    // Form Data - for example: StackName can be accessed through
    formData.StackName
    // formData.StackName = "MyStack";
    // User Data - for example: User Id can be accessed through
    this.parameters.userData
    // if(this.parameter.userData.userId == 'servicenowuserId')
    //   this.info("id = " + formData.StackName);

    var leaseValue = now();
    leaseValue = leaseValue.setHours(leaseValue.getHours()+4);
    formData.LeaseEndDate = leaseValue;

    if (formData.hasOwnProperty("LeaseEndDate")) {
      gdt = new GlideDateTime();
      // 10800 = 3 hours
      gdt.addSeconds(10800);
      formData.LeaseEndDate = gdt.getDisplayValue();
    }
    return formData;
  },
  execute: function() {
    if(this.parameters != null && this.parameters.formData != null){
      var inputData = JSON.parse(JSON.stringify(this.parameters.formData));
      var outputFormData = this.customScript(inputData);
      if( outputFormData != null){
        this.parameters.formData = outputFormData;
      }
    }
    var output = {};
    output.answer = this.parameters;
    return JSON.stringify(output);
  },
  type : 'SetLeaseShort'
});
var SetLeaseShortObj = new SetLeaseShort(inputAttributes);
var outputParams = SetLeaseShortObj.execute();
gs.info( "Output of script is = " + outputParams);
```
This example script sets the user-specified Azure Wordpress DNS name field from the form to the same name as the stack name:

```javascript
var WordpressFill = Class.create();
WordpressFill.prototype =
    Object.extendObject(sn_cmp.PolicyExecutionBase, {
        customScript : function(formData){
            // Manipulation of form parameters are supported. Changes in
            // any other attributes
            // will be ignored.
            // The data available for manipulation is as follows:
            // Form Data - for example: StackName can be accessed through
            formData.StackName
            // formData.StackName = "MyStack";
            // User Data - for example: User Id can be accessed through
            this.parameters.userData
            // if(this.parameter.userData.userId == 'servicenowuserId')
            //this.info("id = " + formData.StackName);
            formData.Azure_Wordpress_v6_vmDnsName = formData.StackName;
            return formData;
        }
    });
var WordpressFillObj = new WordpressFill(inputAttributes);
var outputParams = WordpressFillObj.execute();
```

Example policy action script that tags resources
Your instance tracks tagged resources for billing and reporting. Policy action scripts can add and modify resource tags. This example tags a storage volume resource.

Role required: sn_cmp.cloud_governor or admin

See Create a custom tag for cloud resources for information about how to create and use tags in Cloud Management.

2. On the Policy Action Scripts tab, click New and then enter a unique and descriptive Name.
3. Click the lookup icon for Action Script Category, click New to create a new category, and then click Submit.
4. On the Policy Rule Action Script page, enter the script, and then click Submit to save the script.

The script appears in the list.
5. On the Policies tab, click **New**, enter a unique and descriptive **Name** for the policy, fill in the form with the following example settings, and then click **Save**.

<table>
<thead>
<tr>
<th>Policy Trigger</th>
<th>on Resource operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resource Block</td>
<td>Storage Volume</td>
</tr>
<tr>
<td>Operation</td>
<td>Storage Volume Interface.Provision</td>
</tr>
<tr>
<td>Moment</td>
<td>Pre Operation</td>
</tr>
</tbody>
</table>

6. On the Rules related list, click **New**, enter **Add Custom Tags for Storage** for the **Name**, accept the default settings, and then click **Submit**.

7. On the Policy Rule Actions related list, click **New**.

8. At Execute a Script, click **Create**, fill in the form with the following example settings, and then click **Submit**.

<table>
<thead>
<tr>
<th>Action Name</th>
<th>CreateCustomTagsForStorage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action Script Category</td>
<td>ScriptsForCustomTags</td>
</tr>
<tr>
<td>Action Script</td>
<td>AddCustomTagsForStorage</td>
</tr>
</tbody>
</table>

9. Click **Update** on the Policy Rule page.

10. Return to the Policy page and then click **Publish**.

On the Cloud Admin Portal, launch the stack that is associated with the storage resource. You can then confirm that the tags are applied.

Create a cloud approval policy

A cloud approval policy specifies the users who must approve a specified cloud activity before the activity can proceed. Approvers can include the manager of the user making a request, a specified user or group, or users with a specified role. You can specify multiple approvers. Approvals occur in the order that you specify.

- **Role required**: sn_cmp.cloud_governor or admin
- **Optional**: *Create one or more cloud policy groups*.

In this example, a user requests a stack that triggers an approval policy.

1. On the Cloud User Portal, a user submits a request to provision a particular blueprint. The process of provisioning the blueprint is the trigger that causes the policy engine to apply an approval policy. A cloud approval policy specifies the users who must approve a specified cloud activity before the activity can proceed.

2. The policy engine determines that the request meets the condition specified in the rule for the policy. In this example, the condition evaluates to true whenever a particular blueprint is being provisioned.

3. Because the condition is met, the policy engine performs the action that is also specified in the rule. In this example, the action is to create an approval action for the manager.

4. While the approver (the manager) reviews the approval request, the user sees a "waiting for approval" status message on the Cloud User Portal.

5. After the manager approves, the blueprint is provisioned.
The targeted approval policies complement application-wide approval.

- **on Blueprint provision (approval)**: Triggered when the workflow begins to provision a blueprint. The trigger is invoked before the blueprint is provisioned. Because the provisioning process can alter request data (and possibly change costs), however, approval processes run after the blueprint is provisioned.
- **on Stack operation (approval)**: Triggered during any stack operation on the Cloud User Portal.
- **on Stack resource operation (approval)**: Triggered during any resource operation (start, stop, provision, and so on) on the Cloud User Portal.
- **on Task remediation**: Triggered when a user resubmits a failed request.

1. In the Cloud Admin Portal, navigate to **Govern > Policies**.
2. Click **New** and then fill in the form.
Example approval policy

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policy name</td>
<td>Enter a descriptive name that includes the word Policy. Do not start the name with a number.</td>
</tr>
<tr>
<td>Description</td>
<td>Enter a description of the intent of the policy.</td>
</tr>
<tr>
<td>Policy group</td>
<td>Optional: Select a policy group. Each policy in the group is enforced.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| Policy trigger | Select a trigger that specifies when the policy should be applied. The following triggers can start approval policies:  
- on Blueprint provision (approval)  
- on Stack operation (approval)  
- on Stack resource operation (approval)  
- on Task remediation |
| Blueprint | Select the blueprint that the policy applies to.  
- If no blueprint is specified, then the policy applies for every blueprint. This setting can decrease performance.  
- You can assign multiple policies to a blueprint. Multiple policies running simultaneously, however, might decrease performance. Publish a policy only when it should be enforced. |
| Operation | Select the operation that the policy applies to. For example, a policy can apply to the Deprovision operation only or to all operations on the blueprint or catalog item.  
**Note:** If no operation is specified, then the policy applies for every operation. This condition can decrease performance.  
- **All**: Any operation executes.  
- **Start**: The resource starts.  
- **Stop**: The resource stops.  
- **Provision**: The resource is provisioned.  
- **Deprovision**: The resource is no longer available to users.  
- **Execute Script**: A script runs on the resource. |
| Start Date / End Date | Specify the start date when the policy should be enforced and the end date when the policy should no longer be enforced. |
| Order of Execution | Specify a number that represents the order in which the policy is applied. A policy with a lower number runs before a policy with a higher number.  
For example, a policy with Order of 100 runs before a policy with an Order of 200. |
| Status | A new policy is in Draft state. Click Publish on the form header to enforce the policy. After a policy is published, you must set it to the Draft state to update it. |

3. Right-click in the header and select Save.
4. When you are ready to enforce the policy, click **Publish**.

**Configure one or more cloud policy rules.**

Create a cloud policy group

A cloud policy group is a container for related policies. Consider grouping policies that are often used together or should be considered together. Grouping policies can help you to apply policies consistently across your organization.

Role required: `sn_cmp.cloud_governor` or `admin`  
1. In the Cloud Admin Portal, navigate to **Govern > Policies**.  
2. Open a cloud policy and click the lookup icon for the **Policy Group**.  
3. Select the group to add the policy to.  
   - To add the policy to an existing group, select the group and then click **Submit**.  
   - To create a policy group to add the policy to, click **New** on the Policy Groups list, specify a unique and meaningful **Name**, and then click **Submit**. The policy is added to the new group.

Export or import a cloud policy

To back up, move, or restore a policy, you can export and import the policy as an update set. The update set includes rules, conditions, actions, scripts, and script categories.

Role required: `sn_cmp.cloud_admin` or `admin`.  
1. On the Cloud Admin Portal, navigate to **Govern > Policies**.  
2. Perform the following action to export a policy:  
   a) Click the export icon for the policy.

The instance generates an update set.

3. To import a policy, install the update set as follows:  
   a) On the instance to import to, navigate to **System Update Sets > Retrieved Update Sets**.
b) Click the **Import Update Set from XML** related link.

c) In the Import XML popup, click **Choose File**, select the file, and then click **Upload**.

If a policy that you exported from the source environment exists in the target environment and both policies have the same `sys_id`, then the policy in the target environment is updated.

**Note:** If the policy that you exported from the source environment exists in the target environment, and the policies have different `sys_ids`, then an error occurs during the import process. You must export a different policy from the source environment or delete the policy with the same name in the target environment.

---

**Pool governance for Cloud Management**

A resource pool is a query or script that filters a table. You configure a resource pool to limit the values that are available to users when they request a catalog item.

**Example use of a pool**

To limit a user to only the networks in a particular logical datacenter, use the resource pool called `NetworkPool` that runs against the Cloud Network (cmdb_ci_network) table. The resource pool uses a script to filter networks based on the LDC that the network belongs to.
How pools work

The naming convention for pools is:

get<thisItem>By<condition>
Where the condition is the top-level entity that forms the relationship between the return values. For example, `getObjectIdByServiceAccount` filters all ObjectIDs that are hosted on the specified service account.

Filters query tables using only the specified condition. Any record that matches the condition is therefore returned.

**Pools and blueprints**

When you configure blueprints, you specify variables for form behavior. You can specify resource pools as the data source for each variable and select which resource pools to use. The variable then uses the filtered values.

**Resource Pool in the base system**

<table>
<thead>
<tr>
<th>Pool</th>
<th>Based on this table</th>
<th>Filter type</th>
<th>Filter name and description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ApplicationPool</td>
<td>Application</td>

</tr>
</tbody>
</table>

Create a resource pool

Based on blueprint settings, resource pools control the values that a user sees in a catalog item when they request a resource. Only values that pass the pool filter or script appear as options on the catalog item request form.

Role required: `sn_cmp.cloud_governor`

1. In the Cloud Admin Portal, navigate to Manage > Resource Pools.
2. Click New, enter a unique and descriptive Resource Pool Name, and then fill in the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lookup Table</td>
<td>Select the table that contains the records that should appear as options in the catalog item for the resource.</td>
</tr>
<tr>
<td>Lookup Field (Not necessary if using a script. This field is ignored if you configure a script filter.)</td>
<td>Select the table field that contains the values to display to the user. The display value for the lookup field is not used on the Cloud User Portal. Instead, use the Lookup label field(s).</td>
</tr>
<tr>
<td>Lookup label fields (Not necessary if using a script. This field is ignored if you configure a script filter.)</td>
<td>Enter the lookup field label that should appear to the user.</td>
</tr>
</tbody>
</table>

3. Right-click in the header and select Save.
4. On the Resource Pool Filters related list, click New, enter a unique and descriptive Filter Name, and then fill in the form.
The resource pool filter is created.
5. Right-click the form header and select **Save**.

   **Note:** If you are returning filter values from a script in JSON, you do not need to configure filter values. Skip the following step.

6. If you must return a value to the pool and the value is mapped to another table, create a record in the Resource Pool Filter Values related list. On the Resource Pool Filter Values related list, click **New**, fill in the form, and then click **Update**.

   **Note:** If you are returning filter values from a script in JSON, you do not need to configure filter values. Skip this step.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resource Pool Filter</td>
<td>Enter the name of the filter that the filter value belongs to.</td>
</tr>
<tr>
<td>Type</td>
<td>Enter the type of filter value:</td>
</tr>
<tr>
<td></td>
<td>· Query:</td>
</tr>
<tr>
<td></td>
<td>· Metadata Rule:</td>
</tr>
<tr>
<td>Metadata Rule Name (Appears if you select the Metadata Rule type)</td>
<td>Enter the metadata rule name.</td>
</tr>
<tr>
<td>Operator</td>
<td>Select either:</td>
</tr>
<tr>
<td></td>
<td>· AND</td>
</tr>
<tr>
<td></td>
<td>· OR</td>
</tr>
<tr>
<td>Field</td>
<td>Enter the field that is in the <strong>Lookup Table</strong>. For example, <strong>CloudAccount</strong>.</td>
</tr>
<tr>
<td>Value</td>
<td>Enter the value that you are passing back to the resource pool in the format <strong>$(field)</strong>, where <strong>field</strong> is the value in the <strong>Field</strong> field. For example, <strong>$(CloudAccount)</strong>.</td>
</tr>
<tr>
<td>Order</td>
<td>Enter an order number that determines when the value is applied relative to other resource pool filter values. Lower values are applied first.</td>
</tr>
</tbody>
</table>
The resource pool filter is created.

You can use the resource pool in a blueprint. See Build a Cloud Management blueprint for more information.

**Bind a parameter to an SN pool**

To make catalog ordering less error-prone, you can bind a parameter to an SN pool (a pool provided in the base system). Parameters that are based on an SN pool list only specified values from existing tables on the catalog order form in the Cloud User Portal.

Role required: sn.cmp.cloud_service_designer.

The catalog order form lists only parameters values that have the datasource specified. For example, if you use the Resource Group Name parameter in your template, you can bind the Resource Group Name field to an existing SN pool (ResourceGroupPool) in the metadata section.

When you create a resource block using a cloud template, you can bind a parameter to an SN pool in the metadata section of the Azure Resource Manager (ARM) or CloudFormation (CF) template. All SN pools are listed in the procedure.

1. In the Cloud Admin Portal, navigate to Design > Cloud Templates .
2. Select an existing template or click New to create a new cloud template. If you select an existing template, rename the template.
In the next step, you modify the template definition for the appropriate template type (choose ARM or CloudFormation). You specify the SN pool filter as the **datasource** value.

### SN pools to use as the datasource value

<table>
<thead>
<tr>
<th>SN Pool</th>
<th>Filter</th>
</tr>
</thead>
<tbody>
<tr>
<td>AvailabilityZonePool</td>
<td>getAllObjects: Gets all availability zones.</td>
</tr>
<tr>
<td></td>
<td>getObjectsByLDC: Gets availability zone depending on LDC.</td>
</tr>
<tr>
<td>HardwareTypePool</td>
<td></td>
</tr>
<tr>
<td>ImagePool</td>
<td></td>
</tr>
<tr>
<td>LoadBalancerPool</td>
<td>All: Gets all load balancers.</td>
</tr>
<tr>
<td>NetworkPool</td>
<td>getAllObjects: Gets all networks.</td>
</tr>
<tr>
<td></td>
<td>getObjectsByLDC: Gets networks depending on LDC.</td>
</tr>
<tr>
<td>ResourceGroupPool</td>
<td>getObjectsByLDC: Gets resource groups depending on LDC.</td>
</tr>
<tr>
<td>SecurityGroupPool</td>
<td>getObjectsByNetwork: Gets all security groups.</td>
</tr>
<tr>
<td>SecurityGroupProfilePool</td>
<td>All: Gets all security group profiles.</td>
</tr>
<tr>
<td>SSHKeyPool</td>
<td>UserKeys: Gets all SSH keys.</td>
</tr>
<tr>
<td>StorageAccountPool</td>
<td>getObjectsByLDC: Gets storage accounts depending on LDC.</td>
</tr>
<tr>
<td>StorageVolumePool</td>
<td>All: Gets all storage volumes.</td>
</tr>
<tr>
<td>SubnetPool</td>
<td>getObjectsByNetwork: Gets all subnets.</td>
</tr>
<tr>
<td>VirtualMachinePool</td>
<td>getByAvailabilityZone: Gets all virtual machines.</td>
</tr>
</tbody>
</table>

3. Modify an ARM template definition:
   a) Add the attribute **SNC::Parameter::Metadata** in the **parameters** metadata section.
   b) For the **SNC::Parameter::Metadata** attribute, add **datasource** as the key. Enter an SN pool filter for the value. `StorageAccountPool.getObjectsByLDC` in this example.

```json
"parameters": {
  "newStorageAccountName": {
    "type": "string",
    "metadata": {
      "description": "Unique DNS Name for the Storage Account where the Virtual Machine's disks will be placed.",
      "SNC::Parameter::Metadata": {
        "allowedPattern": "[0-9a-z]{1,11}",
        "ConstraintDescription": "must be a alphanumeric",
        "datasource": "ServiceNow::Pools::StorageAccountPool.getObjectsByLDC"
      }
    }
  }
}
```
4. Modify a CloudFormation template definition:
   a) Add the attribute `SNC::Parameter::Metadata` and define the custom attribute name (`VpcId`) along with a `datasource`. For the `datasource` value, enter an SN pool filter. `NetworkPool.getObjectsByLDC` in this example.
   b) Define the `datasourceFilter` mapping attribute to bind the custom name (`VpcId`) to the actual attribute name (`Network`).

   ```json
   "Parameters": {
   "VpcId": {
   "Type": "AWS::EC2::VPC::Id",
   "Description": "VpcId of your existing Virtual Private Cloud (VPC)",
   "ConstraintDescription": "must be the VPC Id of an existing Virtual Private Cloud."
   },
   "SubnetId": {
   "Type": "AWS::EC2::Subnet::Id",
   "Description": "SubnetId of an existing subnet (for the primary network) in your Virtual Private Cloud (VPC)",
   "ConstraintDescription": "must be an existing subnet in the selected Virtual Private Cloud."
   },
   "Metadata": {
   "SNC::Parameter::Metadata": {
   "VpcId": {
   "datasource": "ServiceNow::Pools::NetworkPool.getObjectsByLDC",
   "datasourceFilter": {"Network": "VpcId"}
   },
   "SubnetId": {
   "datasource": "ServiceNow::Pools::SubnetPool.getObjectsByNetwork",
   "datasourceFilter": {"Network": "VpcId"}
   }
   }
   }
   }
   }
   ```

5. Click Submit.
6. After the resource block, blueprint, and catalog items are created, the cloud service user sees only the list of values of the pool data for the parameter in the catalog order form.

Example resource pool that limits choices to cost center
You can use resource pools with blueprints to limit the choices on the cloud catalog request form.

**Use case: Restrict cost center selection**

In this example, the cost of the cloud asset is charged against the budget of the cost center of the user. The base-system `UserCostCenter` resource pool ensures that a user can select only resources in their cost center.
Assumptions

- The Cost Management (con.snc.cost_management) plugin is active.
- Cost centers are defined and users are associated with the cost centers.
- At least one blueprint is defined. This example uses a blueprint named AWS Virtual Server.
- You are assigned the sn_cmp_cloud_admin role and know JavaScript and JSON scripting.

Components

Review resource pool filter

2. Open the CostCenterPool and review the related Resource Pool Filters.
   - All is a query filter that returns all cost centers in the table.
   - UserCostCenter is a script filter that looks up the cost center associated with the user who is ordering the item.

Here is the script for the UserCostCenter filter:

```javascript
getFilteredRecords();
//Do not remove function declaration
/**
 * @returns filtered records in the format
 * [{"value":"lookupValue",label:"displayValue"}]
 */
function getFilteredRecords() {
    var filteredRecords = [];
    var userId = gs.getUserID();
    var userGr = new GlideRecord('sys_user');
    if (userGr.get(userId)){
        var costCenterId = userGr.getValue('cost_center');
        if (costCenterId){
            var costCenterGr = new GlideRecord('cmn_cost_center');
            if (costCenterGr.get(costCenterId)){
                var costCenter = {};
                costCenter.value = costCenterGr.getUniqueValue();
                costCenter.label = costCenterGr.getValue('name');
                filteredRecords.push(costCenter);
            }
        }
    }
    //force to string
    return new global.JSON().encode(filteredRecords);
}
```

Blueprint catalog form parameters

1. Navigate to Design > Blueprints, and then click the tile for the blueprint you want to open.
2. With the blueprint in Draft state, click the Provision operation tile on the Catalog > Request Operation tab.
3. In the Variable sets related list, click the **General Info** variable set. By default, the CostCenter variable is in this variable set.

4. In the Cloud Variables related list on the Variable Set form, click the **CostCenter** variable.

5. On the Cloud Variable form, click the **Type Specifications** tab.

6. Look at the **Pool** and **Pool Filter** fields that refer to the resource pool and filter.
   - **CostCenterPool** is the name of the resource pool.
- **UserCostCenter** is the filter script that pulls in the cost center options for the user to select from.

7. Set the blueprint to **Published**.

**Cost center user**

Identify a user who is a member of a cost center and who has access to the Cloud User Portal.
Testing the resource pool filter

After reviewing the components that comprise this use case, test the cloud catalog item to verify that users can select only their cost center.

1. Impersonate the user, Alene Rabeck in this example.

2. On the Cloud User Portal, click Launch a Stack, and then select the cloud catalog item (AWS Virtual Server in this example).

3. Review the selections in the Cost Center list.
With the `CostCenterPool::UserCostCenter` datasource value for this catalog item, the only option for the Cost Center is the cost center the user is a member of.

**Changing the resource pool filter**

Test that the resource pool filter is controlling the behavior of the Cost Center field by changing it and viewing the results.

1. On the Cloud Admin Portal, navigate to Design > Blueprints and then click AWS Virtual Server.
2. Click the **Provision** operation tile.
3. In the Variable sets related list, click the **General Info** variable set. By default, the CostCenter variable is in this variable set.
4. In the Cloud Variables related list on the Variable Set form, click the **CostCenter** variable.
5. On the Cloud Variable form, click the **Type Specifications** tab.
6. Edit the **Pool filter** field to change the filter from **UserCostCenter** to **All**.

![Type Specifications tab](image)

7. Click **Update**, then click **Publish**.
8. Impersonate the user, **Alene Rabeck** in this example.
9. On the Cloud User Portal, launch a stack, and then select **AWS Virtual Server**.
10. Verify that all cost centers are listed.
Quota governance for Cloud Management
Quotas are limitations or requirements for groups and users on a resource block. Use quotas to prevent wasteful resource usage in your cloud environment.

You apply quotas to a resource, such as a virtual server, datacenter, or a generic cloud resource, and to users of a particular group. You can set a per-user limit, and a total limit for the group for the resource. For example, a quota might limit the number of virtual servers allowed for users in the Database group.

After this kind of quota is set, users who try to provision additional virtual servers will receive an error message and they will not be able to proceed with provisioning virtual servers until the resource count is under the quota limit. If a user belongs to more than one group, they receive the total quota limit from both groups combined.

Note: You can also set per-datacenter limitations on resources by using capacity limits in cloud accounts. See Set capacity limits on user requests for resources.
Resource block types, quota types, and attributes

You can assign quotas to users or groups for the following resource block types:

- Virtual Servers
- vCPUs
- Storage Volume Size
- Network

Quota types include:

**Sum**
The sum of all attributes for a resource, such as the sum of all virtual CPUs.

**Count**
The total number of attributes for a resource, such as the number of virtual machines.

Create a cloud quota definition
A cloud quota definition specifies the limitations on a resource block. You can use templates or manually create different types of configurations for each quota definition.

Role required: sn_cmp.cloud_governor

1. In the Cloud Admin Portal, navigate to **Govern > Quota**.
2. Click **New**, enter a unique and meaningful **Name** and **Description** and then fill in the form:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Quota Definition Type</td>
<td>Enter a unique identifier for the quota. Typically it is the resource name_count or resource name_size. For example: Network_Count, VM_Count, or StorageVolume_Size.</td>
</tr>
<tr>
<td>Quota Type</td>
<td>Type of quota restriction to set:</td>
</tr>
<tr>
<td></td>
<td>- Count</td>
</tr>
<tr>
<td></td>
<td>- Size</td>
</tr>
<tr>
<td>Attribute</td>
<td>Enter the column name from the underlying CI type on the resource block that holds the value to restrict with the quota. For example, if your quota limits the CPU count on a virtual server, the table of the underlying CI type is cmdb_ci_vm_instance. The cpus column holds that CPU data. So you would enter cpus. You can also enter instance.</td>
</tr>
<tr>
<td>Resource Name</td>
<td>Select the resource block to apply the quota to. See Resource blocks in Cloud Management for more information.</td>
</tr>
<tr>
<td>Template (optional)</td>
<td>Enter the table name of a resource type, for example Hardware Type [cmdb_ci_compute_template] or Image [cmdb_ci_os_template].</td>
</tr>
</tbody>
</table>
3. **Right-click the header and select** **Save.**  
The Quota Configurations and Default Quotas related lists appear.

4. **Click New** in the Quota Configurations related list, enter a unique and meaningful **Group Name**, and then fill in the form:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group Name</td>
<td>Provide a name for the configuration group.</td>
</tr>
<tr>
<td>Group Maximum Limit</td>
<td>Enter a maximum limit for the quota.</td>
</tr>
<tr>
<td>Quota Definition Type</td>
<td>The quota definition name.</td>
</tr>
<tr>
<td>Per User Limit</td>
<td>Enter the maximum limit for each user.</td>
</tr>
</tbody>
</table>

5. **Click Submit.**

6. **You can specify optional default quotas that will be set on the resource block by clicking** **New** **in the Default Quotas related list, and then filling in the form:**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group Maximum Limit</td>
<td>Enter a maximum limit for the quota.</td>
</tr>
<tr>
<td>Quota Definition</td>
<td>The quota definition for which you are setting the default values.</td>
</tr>
<tr>
<td>Per User Limit</td>
<td>Enter the number of users that this quota applies to.</td>
</tr>
</tbody>
</table>

7. **Click Submit.**

**Budget-based notification and approval**

Administrators can assign a budget for a group and a user within the group. When the user or group reaches the budget limit threshold, notifications are sent alerting them about it.

Administrators can assign a budget (in USD) on a weekly, monthly, quarterly, or yearly basis. The budget set for a user and for a group are independent of each other. For example, a group consisting of five users can have a budget of 100 dollars and each user in that group can be assigned a limit of 25 dollars. An organization decides on the frequency of the budget and all the groups in that organization follow the same frequency. For example, if an organization decides on a monthly budget, then all the groups and users in that organization follow a monthly budget. See **Configure budgets.**

A default budget is given to each new group and new user. A new group gets a default budget of 1000 dollars and a new user gets a default budget of 100 dollars.

Administrators can increase or decrease the budget at any given time. Notifications are sent to the user and the group when the budget limit reaches its threshold limits. Notifications trigger as part of the billing process. Billing discovery is scheduled for each user and group. At the end of
the billing discovery, a comparison is made between the budget limit and the actual cost and if the threshold has reached or has exceeded, notifications are triggered.

Administrators can set up a policy whereby if the budget limit reaches a particular threshold or exceeds the limit, the administrator gives an approval for the user or the group to continue using the resources. For example, the administrator can create a policy for a group whereby when the group's budget threshold reaches 90%, an approval is required for the group to continue consuming resources. If the administrator does not set up a policy for the budget, the user or the group can continue using the resources.

You can view the budget details on the at Analyze > Budget Consumption. You can view the budget consumption details for a user as well as for groups.

Configure budgets
You can configure budgets for groups and users within that group. You can set up a budget period for the group, allocate a budget limit to a group and to each user within that group.

Role required: admin
1. In the Cloud Admin Portal, navigate to Govern > Budget.
2. Click New next to Budget Configuration.
3. Fill in the form fields (as shown in the table)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group Name</td>
<td>Select a group from the list.</td>
</tr>
<tr>
<td>Budget Period</td>
<td>Select a budget period for the group: weekly, monthly, quarterly, or yearly.</td>
</tr>
<tr>
<td>Group Max Limit</td>
<td>Enter a budget limit for the group. By default, the budget limit for each new group is 1000 dollars.</td>
</tr>
<tr>
<td>Per User Limit</td>
<td>Enter a budget limit for each user in that group. By default, the budget limit for each new user is 100 dollars.</td>
</tr>
</tbody>
</table>

4. Click Submit.

Use the Cloud Operations Dashboard
The Cloud Operations Dashboard breaks down cloud service requests from your end users and cloud stacks that you offer in the Cloud User Portal.

Role required: sn_cmp.cloud_operator or sn_cmp.cloud_admin
1. In the Cloud Admin Portal, navigate to Operate > Cloud Operations Dashboard.

The Cloud Operation Dashboard appears, showing you Cloud Service Requests and Stacks. Requests are also broken down by requester in the bar chart below. Stacks are broken down by datacenters.
An example Cloud Operations Dashboard

2. Do any of the following to obtain the tag data you want on the report:

<table>
<thead>
<tr>
<th>Goal</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td>See data grouped by another attribute</td>
<td>Select a value in the <strong>Group by</strong> choice list for either chart.</td>
</tr>
<tr>
<td>See updated data</td>
<td>Point to the top of any of the charts until the <strong>refresh icon</strong> (⇘) appears, and then click the icon.</td>
</tr>
<tr>
<td>Save an image of a chart</td>
<td>Point to any of the charts until the options icon (≡) appears, and then select <strong>Save as PNG</strong> or <strong>Save as JPEG</strong>.</td>
</tr>
</tbody>
</table>
Use Cloud Root Cause Analysis reports
Root Cause Analysis reports help you troubleshoot issues with Cloud Management. Use the reports to view details about the Cloud Orchestration Trail and the Cloud API Trail.

Role required: sn_cmp.cloud_operator or sn_cmp.cloud_admin

1. In the Cloud Admin Portal, navigate to **Operate > Root Cause Analysis Dashboard**.

   The Root Cause Analysis dashboard appears, with the **Cloud Root Cause Analysis Dashboard** displayed by default. This gives you a graphical summary of the Cloud Orchestration Trail with trail records under the reports. These charts group records by different attributes:

   - **Trails**: groups data by the template, which is the component, such as a resource block or blueprint, on which a Cloud Management action was applied.
   - **Stages**: groups data by the stage, which identifies when the transaction took place.
   - **Components**: groups data by the component in the system that was involved in the transaction.
   - **Steps**: groups data by the step, which is the descriptive step associated with a stage and component.

   See [The Cloud Orchestration Trail](#) for a list of possible steps.

   Requests are also broken down by requester in the bar chart below. Stacks are broken down by datacenters.

2. Do any of the following to obtain the tag data you want on the report:
Goal | Do this
---|---
**Filter the data** | Select from the options, such as the **Level**, **Date**, and the **Request Item**.

**See updated data** | Point to the top of any of the charts until the refresh icon ( ) appears, and then click the icon.

**Save an image of a chart** | Point to any of the charts until the options icon ( ) appears, and then select **Save as PNG** or **Save as JPEG**.

3. **Click any Cloud Orchestration API ** | **Number** to view that specific record. See *The Cloud Orchestration Trail* for field descriptions.

4. **To view reports about the Cloud API Trail, click the ** | **Cloud API Dashboard** tab.

   This dashboard shows you several reports for the Cloud API Trail grouped by provider, status, and connectors. You can also see information the methods that were invoked and the API invocations today.
5. Click any the data in the graphs to open the matching Cloud API Trail records. See The Cloud API Trail for descriptions of the Cloud API Trail form fields.

The Cloud Orchestration Trail
The Cloud Orchestration Trail is an activity log for all cloud resource activity on the instance.
### Cloud Orchestration Trail contents

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>An auto-generated number for the trail entry.</td>

</tr>
<tr>
<td>Message Details</td>
<td>&quot;Failed to execute API - Failed with status code and message: 400: {&quot;error&quot;: &quot;code&quot;: &quot;NoRegisteredProviderFound&quot;, &quot;message&quot;: &quot;No registered resource provider 'eastus' and API version '2017-07-29' for type 'storageAccounts'. The supported api-views are 'preview', 2018-02-01, 2017-10-01, 2017-06-01, 2016-12-01, 2016-05-01, 2016-01-01, 2015-11-01, 2015-10-01, 2015-06-01} (script_include:Cloud)&quot;</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Level</td>
<td>One of the following:</td>
</tr>
<tr>
<td></td>
<td>· Debug</td>
</tr>
<tr>
<td></td>
<td>· Info</td>
</tr>
<tr>
<td></td>
<td>· Warn</td>
</tr>
<tr>
<td></td>
<td>· Error</td>
</tr>
<tr>
<td>Template</td>
<td>The component, such as a resource block or blueprint, on which a Cloud Management action was applied.</td>
</tr>
<tr>
<td>Template Instance</td>
<td>The datacenter in which the cloud resource is located.</td>
</tr>
<tr>
<td>User</td>
<td>The user involved in the transaction.</td>
</tr>
<tr>
<td>User group</td>
<td>The user group that the user belongs to.</td>
</tr>
<tr>
<td>Created</td>
<td>The date and time that the system created the entry.</td>
</tr>
<tr>
<td>Milestone</td>
<td>If this transaction is a milestone. You can configure the form to see this field.</td>
</tr>
<tr>
<td>Request Item</td>
<td>The service catalog request generated for the transaction.</td>
</tr>
<tr>
<td>Step</td>
<td>The step that identifies additional information about the transaction, including the component and the stage. You can configure the form to see this field.</td>
</tr>
<tr>
<td>Catalog Item</td>
<td>The catalog item, if any, that was involved in the execution.</td>
</tr>
<tr>
<td>Message</td>
<td>The error message or successful completion message. This could include items like the ID of the corresponding message in the Cloud API Trail record or the Cloud API that was invoked.</td>
</tr>
<tr>
<td>Message details</td>
<td>Details about the error, such as an HTTP error.</td>
</tr>
</tbody>
</table>

An example of an error message detail is as follows:

```
Failed to list loadbalancer Failed : HTTP error code : 403
```

This indicates that the credentials were incorrect, and Discovery could not access the cloud resource. The load balancer interface throws the first error because the load balancer device is the first device that allows access to the cloud resource.

A corresponding error on the MID-Server is captured in the Cloud API Trail.

**Steps, stages, and components**

Each Cloud Orchestration entry has identifying attributes that explain what the triggering transaction was about. *Steps* group these attributes together and identify the *component* in the system that was involved in the transaction and the *stage* at which the transaction took place.

You can configure the Cloud Orchestration Trail form to show the *Step* field if it is not already visible.

See [Use Cloud Root Cause Analysis reports](#) for instructions on how to access reports related to the Cloud Orchestration Trail.

Open the Cloud Orchestration Trail

Open the Cloud Orchestration Trail to debug and troubleshoot issues like a failed policy or failed discovery of cloud resources.

Role required: sn_cmp.cloud_operator or sn_cmp.cloud_admin

1. In the Cloud Admin Portal, navigate to **Operate > Trails**.
2. On the **Cloud Orchestration Trail** tab, filter and sort the list of Orchestration API Trail records as needed. If you are looking for something like a failed Discovery, filter the list so the **Level** column shows only entries with **Error**.
3. Click a link in the **Created** column to open the Orchestration API Trail record.
4. In the CAPI Trail Logs related list, open the log record that displays the information you want. For example, open **route_error** or **error_detail** to debug a failed operation.

*The Cloud API Trail*

The Cloud API Trail is an activity log for all activity that uses the Cloud API and goes through the MID Server.
Cloud API Trail contents

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic route ID</td>
<td>An auto-generated ID number for the entry.</td>
</tr>
<tr>
<td>Mid name</td>
<td>The name of the MID Server through which the Discovery was performed.</td>
</tr>
<tr>
<td>Route status</td>
<td>Whether or not the Discovery operation run by the API was successful. Possible values are:</td>
</tr>
<tr>
<td></td>
<td>• success</td>
</tr>
<tr>
<td></td>
<td>• error</td>
</tr>
<tr>
<td></td>
<td>• executing</td>
</tr>
<tr>

<td>The interface operation from the Cloud API that processed this record.</td>
</tr>
<tr>
<td>Provider name</td>
<td>The cloud provider.</td>
</tr>
<tr>
<td>Version</td>
<td>The version specified in the Cloud API.</td>
</tr>
</tbody>
</table>

**CAPI Trail Logs**

The CAPI Trail Logs related list provides more details about Cloud API trail entry. The following types of log keys are available:

<table>
<thead>
<tr>
<th>Log key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>route_data</td>
<td>Information about the Cloud API calls.</td>
</tr>
<tr>
<td>dynamic_route</td>
<td>Information about the actual route the data took, including URIs.</td>
</tr>
<tr>
<td>route_result</td>
<td>The payload received by the instance, or a description of the result of the data transfer. The payload</td>
</tr>
<tr>
<td>chunk_number</td>
<td>The number of data chunks that the instance received.</td>
</tr>
<tr>
<td>route_status</td>
<td>Whether or not the route connection and payload transfer was successful.</td>
</tr>
<tr>
<td>route_error</td>
<td>The error that occurred. For example, the error Failed to list loadbalancer Failed: HTTP error code : 403 means that your credentials were incorrect and Discovery could not access the cloud resource.</td>
</tr>
<tr>
<td>error_detail</td>
<td>More details about the error, including the Cloud Management API and connector that was used in the attempted Discovery, and the errors that the cloud provider threw.</td>
</tr>
</tbody>
</table>

An example of a route_error is as follows:

```
Failed to list loadbalancer Failed : HTTP error code : 403
```

An example of the error_detail entry for the same error is as follows:

```
com.snc.cmp.connector.cloud.loadbalancer.component.LoadBalancerException: Failed to list loadbalancer Failed : HTTP error code : 403
at com.snc.cmp.connector.cloud.loadbalancer.customizer.impl.AWSLoadBalancerCustomizer.listLoadBalancers(AWSLoadBalancerCustomizer.java:56)
at com.snc.cmp.connector.cloud.loadbalancer.component.LoadBalancerProducer.process(LoadBalancerProducer.java:46)
```
These two entries indicate that the credentials were incorrect, and Discovery could not access the cloud resource. The load balancer interface throws the first error because the load balancer device is the first device that allows access to the cloud resource. The org.apache.camel errors indicated routing errors on the Amazon Web Services side.

The corresponding error on the instance side is captured in the Cloud Orchestration Trail.

Open the Cloud API Trail
Open the Cloud API Trail to debug and troubleshoot issues like a failed policy or failed Discovery of cloud resources.

Role required: sn_cmp.cloud_operator or sn_cmp.cloud_admin
1. In the Cloud Admin Portal, navigate to **Operate** > **Trails**.
2. On the Cloud Api Trail tab, filter and sort the list of Cloud API Trail records as needed. If you are looking for something like a failed Discovery, filter the list so the Route Status column shows only entries with error.
3. Click a link in the Created column to open the Cloud API Trail record.
4. In the CAPI Trail Logs related list, open the log record that displays the information you want. For example, open route_error or error_detail to debug a failed operation.

Cloud Management dashboards and reports
Dashboards enable cloud admins and cloud users to view reports like cloud billing data and cloud tag usage.

View cloud costs on the Billing dashboard
The Billing dashboard provides rich summary information on cloud usage, cost trends, and cost aggregates.

Role required: sn_cmp.cloud_admin
1. In the Cloud Admin Portal, navigate to **Analyze** > **Billing** > **Billing Dashboard**.
   The Billing dashboard shows the Cloud Cost tab by default. This tab displays these two graphs:
   - **Cost Trend**: A line graph showing daily costs over time for the selected Usage Date.
   - **Cost Aggregate**: Total costs for each tag value for the selected Group by tag.
Cloud Cost tab on the Billing dashboard

2. Do any of the following to obtain the tag data you want on the report:

<table>
<thead>
<tr>
<th>Goal</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td>Update the billing period</td>
<td>Select a new option from the Usage Data choice list.</td>
</tr>
<tr>
<td>See data grouped by another tag</td>
<td>Select a value in the Group by choice list under either chart.</td>
</tr>
<tr>
<td>Filter by tag values</td>
<td>Select a tag value from the list.</td>
</tr>
<tr>
<td>Save an image of a chart</td>
<td>Point to either donut chart until the options icon ( ) appears, and then select <strong>Save as PNG</strong> or <strong>Save as JPEG</strong>.</td>
</tr>
</tbody>
</table>
3. To view the areas with the highest level of spending, click the **Top Spends** tab. 
Bar charts showing the total cost for each tag display by default. You can further filter the data by **Service Category**, **Provider**, and **Datacenter**.

4. Click any part of the charts to see cost records for the selected criteria.
The list view of the cost records appear. You can view information such as usage quantity and specific cost per usage date.

![Example cost records](image)

**View tagged resources on the Tag dashboard**

The Tag dashboard shows all tagged resources. Use the Tag dashboard to see specific tag values for a group of resources such as stacks or virtual machines.

Role required: sn_cmp.cloud_admin

1. In the Cloud Admin Portal, navigate to **Analyze > Tag**.

The **Tag Dashboard** tab displays the Tag dashboard where all tagged resources are broken down by tag.

The Tag dashboard

2. Do any of the following to obtain the tag data you want on the report:

<table>
<thead>
<tr>
<th>Goal</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td>See tag values for a specific resource group</td>
<td>Click a section of the <strong>Tagged Resources</strong> donut chart.</td>
</tr>
<tr>
<td>See data grouped by another tag</td>
<td>Select a value in the <strong>Group by</strong> choice list under the <strong>Assigned Tag Values</strong> donut chart.</td>
</tr>
<tr>
<td>See updated data</td>
<td>Point to the top of either chart until the refresh icon ( reloading ) appears, and then click the icon.</td>
</tr>
<tr>
<td>Save an image of a chart</td>
<td>Point to either chart until the options icon ( saving ) appears, and then select <strong>Save as PNG</strong> or <strong>Save as JPEG</strong>.</td>
</tr>
</tbody>
</table>

3. To view a specific tag history record, click any section in the **Assigned Tag Values** chart. A list of tag histories appears that matches the CI class for the selected tag value.
## A tag history record

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created</td>
<td>The date the tag history was created.</td>
</tr>
<tr>
<td>Current</td>
<td>If selected, indicates if the current record is the most current.</td>
</tr>
<tr>
<td>CMDB CI</td>
<td>The actual CI in the CMDB. Click the record icon to see the CI form.</td>
</tr>
<tr>
<td>User group</td>
<td>The group tag associated with this CI.</td>
</tr>
<tr>
<td>User</td>
<td>The user tag associated with this CI.</td>
</tr>
<tr>
<td>Application</td>
<td>The application tag associated with this CI.</td>
</tr>
<tr>
<td>Stack</td>
<td>The stack tag associated with this CI.</td>
</tr>
<tr>
<td>Business service</td>
<td>The business service tag associated with this CI.</td>
</tr>
<tr>
<td>ServiceNow instance</td>
<td>The instance tag associated with this CI.</td>
</tr>
<tr>
<td>Cost center</td>
<td>The cost center tag associated with this CI.</td>
</tr>
<tr>
<td>Time provisioned</td>
<td>The date the machine was provisioned.</td>
</tr>
<tr>
<td>Project</td>
<td>The project tag associated with this CI.</td>
</tr>
<tr>
<td>Custom values</td>
<td>Any custom values tagged to the CI.</td>
</tr>
</tbody>
</table>
Tags for cloud resources
Tags categorize cloud resources to provide richer and more detailed tracking and billing report data.

Create tags to enable Cloud Management to automatically categorize cloud resources after they are provisioned. Each tag associates a specific key:value pair with a requested cloud resource, such as Cost Center=Retail. The Cost Center tag, for example, enables you to group billing data on the Cost Trend report by Cost Center.

After the cloud resource is provisioned, the key:value information in tags become part of the resource's metadata and are saved along with all other parameters about the resource. Because a cloud resource can have multiple tags, you can view cost items from multiple perspectives.

Tag definitions
Tag definitions are records that associate a tag name with a value type. These value types are available:

<table>
<thead>
<tr>
<th>Value type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable</td>
<td>A value that user enters or selects from a choice list. This value is stored as a service catalog variable. If a table is associated with a variable tag, the values in the field marked as the Display field are displayed to the user when they request the instance. In most cases, this is the Name field. For example, the names of the business services in the Service table display to the user. If no table is specified in the tag definition, the user is presented with a text field.</td>
</tr>
<tr>
<td>Order field</td>
<td>A value that the user submits, but is not presented as a service catalog variable. The available values are taken from the Orders (sn_cmp_order) table.</td>
</tr>
<tr>
<td>Script</td>
<td>A script that obtains a value from the instance, such as the current time on the instance. The script must obtain the value via the base-system API and return the value to the answer variable. For example, to obtain the current time on the instance, the script would be:</td>
</tr>
</tbody>
</table>

```java
answer = new GlideDateTime().getValue();
```

Default tags
These tags are provided by default:

<table>
<thead>
<tr>
<th>Default Cloud Tags</th>
</tr>
</thead>
<tbody>
<tr>
<td>Label</td>
</tr>
<tr>
<td>Application</td>
</tr>
</tbody>
</table>
Cloud administrators can also create custom tags to suit your specific needs. For example, you can create a Location tag can to track the location of the resource.

**AWS tags**

Tags generated for Amazon Web Services (AWS) resources are sent to AWS and are also available from your AWS console.

Create a custom tag for cloud resources

Cloud Administrators can create custom tags in addition to the default tags to categorize cloud resources.

Role required: sn_cmp.cloud_admin

If a resource was provisioned prior to the existence of a particular tag, then that tag must be manually added to the record for that resource.

1. In the Cloud Admin Portal, navigate to **Analyze > Tag > Tag Management > Tag Definitions**.
2. Click **New**.
3. Fill out the form fields (see table):

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Label</td>
<td>Name to display on screen for the cloud user.</td>
</tr>
<tr>
<td>Name</td>
<td>Name of the key. The name is stored in all tables, along with the value.</td>
</tr>
<tr>
<td>Value type</td>
<td>The <em>type of value</em> for this tag.</td>
</tr>
<tr>
<td>Variable name</td>
<td>The name of the variable. This option appears if you select the Variable value type.</td>
</tr>
<tr>
<td>Table (optional)</td>
<td>The table that provides the choices for the Variable value type field. Select a table from the system. If you do not select a table, cloud users are presented with an empty text field for the variable.</td>
</tr>
<tr>
<td>Order field</td>
<td>The field on the request form. Click the down arrow next to <strong>Click to select</strong>, and then select the field from the Orders [sn_cmp_order] table.</td>
</tr>
<tr>
<td>Active</td>
<td>An indicator that specifies if the tag is in use. Select this option to apply the tag to all new requests.</td>
</tr>
</tbody>
</table>
Troubleshooting tools for Cloud Management

The Cloud Management application provides several tools to help you troubleshoot errors you might encounter during the Discovery of cloud accounts, the provisioning and managing of cloud resources, and the updating of the CMDB.

These troubleshooting tools are available:

Cloud Orchestration Trail

The Cloud Orchestration Trail is an activity log for all cloud resource activity on the instance. Use the Cloud Orchestration Trail to find errors that occur with cloud resources, such as credential errors during Discovery or API execution errors.

See Open the Cloud Orchestration Trail for instructions.

Cloud API Trail

The Cloud API Trail is an activity log for all activity that uses the Cloud API and goes through the MID Server. Use the Cloud API Trail to see API invocations and errors related to the route data, specific API route errors, and Java runtime exceptions.

See Open the Cloud API Trail for instructions.

Root Cause Analysis Dashboard

The Root Cause Analysis Dashboard brings together records from the cloud orchestration trail and cloud API trail and presents them in useful, filterable, lists and charts.

See Use Cloud Root Cause Analysis reports for instructions.

Cloud Orchestrations

Cloud Orchestrations are the orders that your instance processed for each attempted operation on a stack. Use Cloud Orchestration records to view status messages for operations that are run on cloud resources and for details about each API step.

See Open cloud orchestrations for instructions.

The Cloud Orchestration Trail

The Cloud Orchestration Trail is an activity log for all cloud resource activity on the instance.

Cloud Orchestration Trail contents

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>An auto-generated number for the trail entry.</td>
</tr>
<tr>
<td>Level</td>
<td>One of the following:</td>
</tr>
<tr>
<td></td>
<td>• Debug</td>
</tr>
<tr>
<td></td>
<td>• Info</td>
</tr>
<tr>
<td></td>
<td>• Warn</td>
</tr>
<tr>
<td></td>
<td>• Error</td>
</tr>
<tr>
<td>Template</td>
<td>The component, such as a resource block or blueprint, on which a Cloud Management action was applied.</td>
</tr>
<tr>
<td><strong>Field</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Template Instance</td>
<td>The datacenter in which the cloud resource is located.</td>
</tr>
<tr>
<td>User</td>
<td>The user involved in the transaction.</td>
</tr>
<tr>
<td>User group</td>
<td>The user group that the user belongs to.</td>
</tr>
<tr>
<td>Created</td>
<td>The date and time that the system created the entry.</td>
</tr>
<tr>
<td>Milestone</td>
<td>If this transaction is a milestone. You can configure the form to see this field.</td>
</tr>
<tr>
<td>Request Item</td>
<td>The service catalog request generated for the transaction.</td>
</tr>
<tr>
<td>Step</td>
<td>The step that identifies additional information about the transaction, including the component and the stage. You can configure the form to see this field.</td>
</tr>
<tr>
<td>Catalog Item</td>
<td>The catalog item, if any, that was involved in the execution.</td>
</tr>
<tr>
<td>Message</td>
<td>The error message or successful completion message. This could include items like the ID of the corresponding message in the Cloud API Trail record or the Cloud API that was invoked.</td>
</tr>
<tr>
<td>Message details</td>
<td>Details about the error, such as an HTTP error.</td>
</tr>
</tbody>
</table>

An example of an error message detail is as follows:

Failed to list loadbalancer Failed : HTTP error code : 403

This indicate that the credentials were incorrect, and Discovery could not access the cloud resource. The load balancer interface throws the first error because the load balancer device is the first device that allows access to the cloud resource.

A corresponding error on the MID-Server is captured in the Cloud API Trail.

**Steps, stages, and components**

Each Cloud Orchestration entry has identifying attributes that explain what the triggering transaction was about. Steps group these attributes together and identify the component in the system that was involved in the transaction and the stage at which the transaction took place.

You can configure the Cloud Orchestration Trail form to show the Step field if it is not already visible.

<table>
<thead>
<tr>
<th><strong>Step</strong></th>
<th><strong>Component</strong></th>
<th><strong>Stage</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Apply API Parameter</td>
<td>CAPI Probe</td>
<td>Cloud API Orchestration</td>
</tr>
<tr>
<td>Apply Config Parameter</td>

<td>Cloud Orchestration</td>
</tr>
</tbody>
</table>

See #unique_1199 for instructions on how to access reports related to the Cloud Orchestration Trail.

Open the Cloud Orchestration Trail

Open the Cloud Orchestration Trail to debug and troubleshoot issues like a failed policy or failed Discovery of cloud resources.

Role required: sn_cmp.cloud_operator or sn_cmp.cloud_admin

1. In the Cloud Admin Portal, navigate to **Operate > Trails**.
2. On the **Cloud Orchestration Trail** tab, filter and sort the list of Orchestration API Trail records as needed. If you are looking for something like a failed Discovery, filter the list so the **Level** column shows only entries with **Error**.

3. Click a link in the **Created** column to open the Orchestration API Trail record.

4. In the CAPI Trail Logs related list, open the log record that displays the information you want. For example, open `route_error` or `error_detail` to debug a failed operation.

**The Cloud API Trail**
The Cloud API Trail is an activity log for all activity that uses the Cloud API and goes through the MID Server.

### Cloud API Trail contents

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic route ID</td>
<td>An auto-generated ID number for the entry.</td>
</tr>
<tr>
<td>Mid name</td>
<td>The name of the MID Server through which the Discovery was performed.</td>
</tr>
<tr>
<td>Route status</td>
<td>Whether or not the Discovery operation run by the API was successful. Possible values are:</td>
</tr>
<tr>
<td></td>
<td>- success</td>
</tr>
<tr>
<td></td>
<td>- error</td>
</tr>
<tr>
<td></td>
<td>- executing</td>
</tr>
<tr>
<td>Input parameters</td>
<td>The input parameter that generated the API trail record. This value is usually the datacenter in which the Discovery was run.</td>
</tr>
<tr>
<td>Interface name</td>
<td></td>
</tr>
<tr>
<td>Invoked by</td>
<td>This value is always <strong>CMP</strong> when running Discovery.</td>
</tr>
<tr>
<td>Method name</td>
<td>The interface operation from the Cloud API that processed this record.</td>
</tr>
<tr>
<td>Provider name</td>
<td>The cloud provider.</td>
</tr>
<tr>
<td>Version</td>
<td>The version specified in the Cloud API.</td>
</tr>
</tbody>
</table>

**CAPI Trail Logs**
The CAPI Trail Logs related list provides more details about Cloud API trail entry. The following types of log keys are available:

<table>
<thead>
<tr>
<th>Log key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>route_data</td>
<td>Information about the Cloud API calls.</td>
</tr>
<tr>
<td>dynamic_route</td>
<td>Information about the actual route the data took, including URIs.</td>
</tr>
<tr>
<td>route_result</td>
<td>The payload received by the instance, or a description of the result of the data transfer. The payload</td>
</tr>
<tr>
<td>Log key</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>chunk_number</td>
<td>The number of data chunks that the instance received.</td>
</tr>
<tr>
<td>route_status</td>
<td>Whether or not the route connection and payload transfer was successful.</td>
</tr>
<tr>
<td>route_error</td>
<td>The error that occurred. For example, the error Failed to list loadbalancer Failed : HTTP error code : 403 means that your credentials were incorrect and Discovery could not access the cloud resource.</td>
</tr>
<tr>
<td>error_detail</td>
<td>More details about the error, including the Cloud Management API and connector that was used in the attempted Discovery, and the errors that the cloud provider threw.</td>
</tr>
</tbody>
</table>

An example of a route_error is as follows:

```
Failed to list loadbalancer Failed : HTTP error code : 403
```

An example of the error_detail entry for the same error is as follows:

```
com.snc.cmp.connector.cloud.loadbalancer.component.LoadBalancerException: Failed to list loadbalancer Failed : HTTP error code : 403
at com.snc.cmp.connector.cloud.loadbalancer.customizer.impl.AWSLoadBalancerCustomizer.list
at com.snc.cmp.connector.cloud.loadbalancer.component.LoadBalancerProducer.process
at org.apache.camel.util.AsyncProcessorConverterHelper$ProcessorToAsyncProcessorBridge.process
at org.apache.camel.processor.SendProcessor.process
```

These two entries indicate that the credentials were incorrect, and Discovery could not access the cloud resource. The load balancer interface throws the first error because the load balancer device is the first device that allows access to the cloud resource. The `org.apache.camel` errors indicated routing errors on the Amazon Web Services side.

The corresponding error on the instance side is captured in the Cloud Orchestration Trail.

Open the Cloud API Trail

Open the Cloud API Trail to debug and troubleshoot issues like a failed policy or failed Discovery of cloud resources.

Role required: sn_cmp.cloud_operator or sn_cmp.cloud_admin

1. In the Cloud Admin Portal, navigate to Operate > Trails.
2. On the Cloud Api Trail tab, filter and sort the list of Cloud API Trail records as needed. If you are looking for something like a failed Discovery, filter the list so the Route Status column shows only entries with error.
3. Click a link in the Created column to open the Cloud API Trail record.
4. In the CAPI Trail Logs related list, open the log record that displays the information you want. For example, open route_error or error_detail to debug a failed operation.

Use Cloud Root Cause Analysis reports

Root Cause Analysis reports help you troubleshoot issues with Cloud Management. Use the reports to view details about the Cloud Orchestration Trail and the Cloud API Trail.
Role required: sn_cmp.cloud_operator or sn_cmp.cloud_admin

1. In the Cloud Admin Portal, navigate to **Operate > Root Cause Analysis Dashboard**.

   The Root Cause Analysis dashboard appears, with the **Cloud Root Cause Analysis Dashboard** displayed by default. This gives you a graphical summary of the Cloud Orchestration Trail with trail records under the reports. These charts group records by different attributes:

   - **Trails**: groups data by the template, which is the component, such as a resource block or blueprint, on which a Cloud Management action was applied.
   - **Stages**: groups data by the stage, which identifies when the transaction took place.
   - **Components**: groups data by the component in the system that was involved in the transaction.
   - **Steps**: groups data by the step, which is the descriptive step associated with a stage and component.

   See [The Cloud Orchestration Trail](#) for a list of possible steps.

   Requests are also broken down by requester in the bar chart below. Stacks are broken down by datacenters.

2. Do any of the following to obtain the tag data you want on the report:

<table>
<thead>
<tr>
<th>Goal</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td>Filter the data</td>
<td>Select from the options, such as the Level, Date, and the Request Item.</td>
</tr>
</tbody>
</table>
### Goal | Do this
---|---
**See updated data** | Point to the top of any of the charts until the refresh icon (⟳) appears, and then click the icon.

**Save an image of a chart** | Point to any of the charts until the options icon (⋮) appears, and then select **Save as PNG** or **Save as JPEG**.

---

3. Click any Cloud Orchestration API **Number** to view that specific record. See [The Cloud Orchestration Trail](#) for field descriptions.

4. To view reports about the Cloud API Trail, click the **Cloud API Dashboard** tab. This dashboard shows you several reports for the Cloud API Trail grouped by provider, status, and connectors. You can also see information the methods that were invoked and the API invocations today.
5. Click any the data in the graphs to open the matching Cloud API Trail records. See *The Cloud API Trail* for descriptions of the Cloud API Trail form fields.

*Open cloud orchestrations*
Cloud orchestration records show you the orders that your instance processed for each attempted operation on a stack. They also show you the values of the fields that the user submitted through the Cloud User Portal. Use cloud orchestrations to troubleshoot issues that occur when a user provisions a cloud resource or runs another operation on an existing cloud resource.

Role required: sn_cmp.cloud_operator or sn_cmp.cloud_admin

1. On the instance (not the Cloud User Portal), enter the following text into the application filter:
The list of Cloud Orchestrations appear.

2. Sort and filter the list to find the error or other message you are looking for.

   For example, to sort the list by date, click the **Order Date** column. To show only errors that occurred, right-click **Error** in a cell and select **Show Matching**.

3. Open a cloud orchestration record by clicking the **Order Date** field.

4. Review the form fields:
The example form shows you the type of message you can see when an operation fails due to the incorrect credentials. The OrderForm Data field shows the Sys ID of the credential record and the service account ID.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service Request Item</td>
<td>A service catalog request, if any, associated with this transaction.</td>
</tr>
<tr>
<td>Context Key</td>
<td>A key identifier for this message.</td>
</tr>
<tr>
<td>Context Object</td>
<td>This field is typically empty.</td>
</tr>
<tr>
<td>Context Instance</td>
<td>The blueprint used in transactions on a stack or the resource block used in transactions on a cloud resource.</td>
</tr>
<tr>
<td>Owner Instance</td>
<td>The Owner Instance is the resource block on which the transaction took place. This field is only populated when the Entity Type is Resource.</td>
</tr>
<tr>
<td>Owner Table</td>
<td>The owner table is always Stack (sn_cmp_stack) for the provisioning of a stack. Otherwise, the table is the CI type of the resource, such as Virtual Machine (sn_cmp_vm_instance).</td>
</tr>
<tr>
<td>Entity Type</td>
<td>Whether the transaction occurred on Blueprint or a Resource (resource block).</td>
</tr>
<tr>
<td>Operation Name</td>
<td>The interface and operation that is triggered.</td>
</tr>
<tr>
<td>Order Date</td>
<td>The date of the transaction.</td>
</tr>
<tr>
<td>OrderForm Data</td>
<td>The data submitted through the user form.</td>
</tr>
<tr>
<td>Tag values</td>
<td>Any tag values involved in the transaction.</td>
</tr>
<tr>
<td>Resource</td>
<td>The resource block on which the operation took place. This field is populated only when the value of the Entity type field is Resource.</td>
</tr>
<tr>
<td>Status</td>
<td>The status of the message. If you are viewing an error, the Error option is listed.</td>
</tr>
<tr>
<td>Stack</td>
<td>The stack that the resource belongs to.</td>
</tr>
<tr>
<td>Status Message</td>
<td>The status message that explains the issue. Search the cloud provider documentation for the status codes and messages that appear in this field. The cloud provider might provide solutions available to you.</td>
</tr>
<tr>
<td>User</td>
<td>The user who triggered the operation.</td>
</tr>
<tr>
<td>Mid name</td>
<td>This field can show the name of the MID Server involved in the transaction. It is often left blank.</td>
</tr>
</tbody>
</table>

**Scoped applications for Cloud Management**

Create scoped applications using the standard Cloud Management entities to support new cloud providers and new configuration management providers. For example, you can create a scoped application for a third-party platform that provisions a virtual machine, such as the Google Compute Engine service.

Use the ServiceNow®Studio to create scoped applications on a regular cadence and publish them to a repository or the ServiceNow Store. Studio specifies plugin dependencies, specifies licensing requirements, and publishes scoped applications to a repository, to any instance, or to the ServiceNow Store. See the ServiceNow Store documentation for details on publishing an application.
Content entity types that are supported for creating scoped applications

- CMDB CI classes
- CMDB CI identifiers
- CMDB relations
- CMDB CI identification entries
- Custom tables
- Cloud APIs
- Resource blocks
- Policies
- Blueprints
- Script includes
- Pools and filters
- MID Server script files
- MID Server capabilities
- Credentials
- Provider credentials mapping
- Provider types (Puppet configuration management provider only)

Create a Puppet Enterprise scoped application for Cloud Management

Create a Puppet Enterprise scoped application for Cloud Management by using a virtual machine (for example, a Linux virtual machine). Creating a scoped application and publishing the application to the ServiceNow Store makes finding the application more efficient.

- See the ServiceNow Store documentation for prerequisites for publishing.
- Create a repository in a version control system like the GitHub hosting service.
- Test the connection to make sure that the Puppet Enterprise server can communicate with the Puppet Enterprise agents.
- Provision a virtual machine (for example, Linux virtual machine) from a blueprint.
- Verify that the Puppet Enterprise configuration management provider is up and running.
- Role required: sn_cmp.cmp_root_admin

1. Create an application in the ServiceNow Studio.
2. Switch to the newly created application to set dependencies and create application settings for the new application.
3. Create a table for storing credential information to access the Puppet Enterprise server.
4. To manage all your Puppet Enterprise instances, create a configuration item (CI) class.
5. Create a cloud API provider.
6. Create cloud APIs.
7. Create script includes to be used by the cloud APIs to communicate with the Puppet Enterprise server.
8. Create a CI class for an environment.
    An environment can be a production, development, or a test environment.
9. Add identification rules to the CI class.
10. Configure metadata rules to create a relationship between the Puppet Enterprise CI class and the Puppet Enterprise environment CI class.
11. Create a resource block.
12. Configure cloud script templates to install a Puppet Enterprise agent on a virtual machine once the virtual machine is provisioned.
13. Create a workload provider type.
14. Create a capability for the Puppet Enterprise provider in the MID Server.
A capability is required for each MID Server to work with the Cloud Management application.

15. Test the scoped application.
16. Publish the scoped application to the ServiceNow Store.

Your Puppet Enterprise scoped application for Cloud Management is created and published to the ServiceNow Store.

Create an application for Puppet provider in the ServiceNow Studio

Create an application for Puppet provider in the ServiceNow Studio. Create all your Puppet provider configuration information in the form of an application using the ServiceNow Studio. Once the configuration information is in an application, you can use the files in your application, create new files, and modify application files in a tabbed environment.

Role required: sn_cmp.cmp_root_admin

1. Navigate to System Applications > Studio.
   The Load Application pop-up window appears.
2. In the Load Application pop-up window, click Create Application.
   The Create Application dialog box appears.
3. In the Create custom application section, click Create.
4. On the form, fill in the fields.

Create Application form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name for the application.</td>
</tr>
<tr>
<td>Scope</td>
<td>Scope of the application. The scope appears automatically.</td>
</tr>
<tr>
<td>Menu</td>
<td>Menu file name. By default, the menu file name is the name of the application and appears automatically.</td>
</tr>
<tr>
<td>User Role</td>
<td>Required user role. By default, the scope determines the user role and appears automatically.</td>
</tr>
</tbody>
</table>

5. To create a table associated with the application:
   a) Enable the Create Table feature.
   b) On the form, fill in the fields.

Table form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Label</td>
<td>Name of the table.</td>
</tr>
<tr>
<td>Name</td>
<td>File name of the table.</td>
</tr>
<tr>
<td>Module</td>
<td>Module associated with the table.</td>
</tr>
<tr>
<td>Extends Table</td>
<td>Table to be extended.</td>
</tr>
<tr>
<td>Extensible</td>
<td>Indication of whether the table can be extended.</td>
</tr>
<tr>
<td>Live Feed</td>
<td>Indication of whether live feed is in use.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Auto-number</td>
<td>Indication of whether the table is automatically numbered. If selected, prompts for prefix, number, and number of digits.</td>
</tr>
</tbody>
</table>

6. Click **Create**. The Confirm Application dialog box appears.

7. In the Confirm Application dialog box, click **OK**. A successful completion message appears. After the application is successfully created, the Application Creation window opens with the message 'Puppet' service has been created.

Your Puppet provider configuration information is in the form of an application.

**Set dependencies on the Puppet scoped application**

Set dependencies on the Puppet scoped application

Set dependencies and create application settings on the newly created puppet scoped application. Setting dependencies and creating application settings lets you customize the application and helps you manage the application.

Role required: sn_cmp.cmp_root_admin

1. Navigate to **System Applications > Studio** and click **Create Application**. The Load Application window appears.
2. Select the application that you created (for example, **Config Management Puppet**). The Welcome to Studio home page appears.
3. Navigate to **File > Settings**. The Application Settings record appears.
4. From the **Runtime Access Tracking** list, select **None**.
5. Click **Update**.
6. Click the Dependencies related list.
7. Click **Edit**.
8. Associate the plugins with the Config Management Puppet application by moving the desired plugins to the **Dependencies** list.
9. Click **Save**.

All the plugins, added as dependencies, appear in the Dependencies related list.

**Create a table for storing Puppet credential information**

Create a table for storing Puppet credential information

Create a table for storing credential information pertaining to the Puppet provider. The credential information is used to connect to the Puppet server. Having this information in a table helps you manage the information about the connection.

Role required: sn_cmp.cmp_root_admin

1. Navigate to **System Definition > Tables**.
2. Click **New**.
3. On the form, fill in the fields.
### Table form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Label</td>
<td>Label for the table (for example, Puppet Enterprise Credentials). The label appears in the list and form views for the table.</td>
</tr>
<tr>
<td>Name</td>
<td>Table file name (for example, x_sn_config_puppet_puppet_enterprise_credentials). This name is automatically populated based on the table label and a prefix. For a table in a scoped application, the name is prefixed with a namespace identifier to indicate that it is part of an application.</td>
</tr>
</tbody>
</table>
| Extends table      | Table to extend (for example, Credentials). Extending a base table incorporates all the fields of the original table and creates system fields for the new table. You can extend tables that are marked as extensible under one of the following conditions:  
- Both tables are in the same scope.  
- Both tables enable configuration from other scopes. |
| Application        | Applications associated with the table. Global is the default. |
| Create module      | Option for creating a module. This check box is selected by default. |
| Create mobile module | Option for creating a mobile module. This check box is selected by default. If you clear the Create module check box, this check box disappears. |
| Add module to menu | Menu for the new module. If you clear the Create module check box, this check box disappears. |
| New menu name      | Name for the new menu. If you clear the Create module check box, this check box disappears. |

4. Change the names of the table columns.  
   a) Click the Columns related list. The Table Columns form appears.  
   b) On the form, fill in the fields.  

**Note:** You may need to modify the Table Columns form to see the heading names. To modify the form, click the personalize list icon ( ). Move the desired heading names to the Selected list and select the check box options as needed, then click OK.
Table Columns form

<table>
<thead>
<tr>
<th>Column Label</th>

</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. Right-click anywhere in the Table form title bar and click Save.
6. Modify the user privileges.
   a) Click your user name or role in the banner and select Elevate Roles.
   b) Select the security_admin check box and click OK.
   The Tables form appears.
   c) Open the Puppet Enterprise Credentials table.
   d) On the Puppet Enterprise Credentials table record, click the Access Controls related list.
   The list of credential records appears.
   e) Open the record listed with the read operation.
   f) In the Required role section, add a role with the value, mid_server, to the Access Control record.
   g) Click Save and then click Update.

A table containing the Puppet credentials information appears in the Tables list view using the column headings you specified.

Create a CI class for the Puppet provider

Create a CI class for your Puppet provider instances to make managing the provider instances more efficient.

Role required: sn_cmp.cmp_root_admin

1. Navigate to Configuration > CI Class Manager.
2. To display the CI classes list, click Hierarchy.
4. To create a new child class, click **Add Child Class**. The Create Class window appears in the Provide Basic Info stage.
5. In the **Display name** field, enter a name (for example, **Puppet Enterprise**) for the class.

6. To advance to the Add Attributes stage, click **Next**.
   The Create Class window appears in the Add Attributes stage.

7. In the Add Attributes stage, click **Next**.
   The Create Class window appears in the Set Identification Rule stage.
Set Identification Rule stage

8. To create an identification rule, click **Add**. The Create Identification Rule dialog box appears.
9. In the Create Identification Rule dialog box, accept the default values and click **Save**.

10. Click **Next** through each remaining stage until you return to the Config Management Workload Provider form.

The class and the identification rule have been created and are available for you to use.

**Create a cloud API provider for Puppet**

Create a cloud API provider for Puppet. The cloud API provider improves the interaction between Cloud Management and the Puppet provider.

Role required: **sn_cmp.cmp_root_admin**

1. Navigate to **Cloud Management > Cloud Management Portal > Design > Cloud API**. The Cloud API window appears.

2. Click the **Providers** tab if it is not already selected.

3. Add a provider.
   a) In the Cloud API window, click **New**.
   b) On the form, fill in the fields.
Add Cloud Provider form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud Provider</td>
<td>Name of the cloud provider.</td>
</tr>
<tr>
<td>Description</td>
<td>Short description for the Puppet cloud provider.</td>
</tr>
<tr>
<td>Datacenter class</td>
<td>Datacenter class selected for the Puppet cloud provider.</td>
</tr>
</tbody>
</table>

c) Click **Submit**.
The Cloud Provider record displays details about the provider.

4. Add a new cloud product.
   a) In the Cloud Products related list, click **New**.
   b) On the form, fill in the fields.

Cloud Product form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name for the cloud product.</td>
</tr>
<tr>
<td>Service Category</td>
<td>Service category selected.</td>
</tr>
</tbody>
</table>

c) Click **Submit**.

The new cloud product appears in the Cloud Provider record.

Create a cloud API for Puppet

Create a cloud API for Puppet
Create a cloud API for the Puppet configuration management provider. The cloud API helps integrate Cloud Management services with the Puppet provider.

Role required: sn_cmp.cmp_root_admin

1. In the Cloud Admin Portal, navigate to **Design > Cloud API**.
   To access the Cloud Admin Portal, navigate to **Cloud Management > Cloud Admin Portal**.
2. Click **API** and then click **New**.
3. On the form, fill in the fields.

Add Cloud API form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud API</td>
<td>Name of the Cloud API (for example, Puppet Enterprise Configuration API).</td>
</tr>
<tr>
<td>Interface</td>
<td>Interface selected for the cloud API (for example, Configuration Management Interface).</td>
</tr>
<tr>
<td>Connector</td>
<td>Name of the connector. This field is automatically set by default.</td>
</tr>
<tr>
<td>Product</td>
<td>Product for the Cloud API.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Version</td>
<td>Version of the cloud API (for example, 1.0).</td>
</tr>
<tr>
<td>Scripted</td>
<td>Option used to indicate if the API is scripted. This check box is selected by default.</td>
</tr>
<tr>
<td>Script Type</td>
<td>Type of script used by the Cloud API.</td>
</tr>
<tr>
<td>ExecuteScriptOn instance</td>
<td>Option used to indicate whether to execute the script on the instance.</td>
</tr>
</tbody>
</table>

4. Click **Submit**. The record for the new Cloud API appears.

5. Click the **API Config Overrides** related link and then click **New**. The API Config Overrides form appears.

6. Create three API overrides; one for credentials, one for endpoint, and one for identity. Follow the same procedure for each one.
   a) To create the API overrides for credentials, fill in the form.

   **API Config Override for Credential form**

<table>
<thead>
<tr>
<th>Config parameter</th>
<th>Override value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enter <strong>Credentials</strong> and then click the lookup list icon (🔍) and select the Config parameter name <strong>Credentials</strong> that corresponds to the Endpoint, <strong>cfg-mgmt</strong>.</td>
<td>$(CloudCredential.password)</td>
</tr>
</tbody>
</table>

   b) Click **Submit**.

   c) To create the API overrides for endpoints, fill in the form.

   **API Config Override for Endpoint form**

<table>
<thead>
<tr>
<th>Config parameter</th>
<th>Override value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enter <strong>Endpoint</strong> and then click the lookup list icon (🔍) and select the Config parameter name <strong>Endpoint</strong> that corresponds to the Endpoint, <strong>cfg-mgmt</strong>.</td>
<td>$(CloudCredential.URL)</td>
</tr>
</tbody>
</table>

   d) Click **Submit**.

   e) To create the API overrides for identity, fill in the form.
API Config Override for Identity form

<table>
<thead>
<tr>
<th>Config parameter</th>
<th>Override value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enter <strong>Identity</strong> and then click the lookup list icon (🔍) and select the Config parameter name <strong>Identity</strong> that corresponds to the Endpoint, <strong>cfg-mgmt</strong>.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>$(CloudCredential.user_name)</td>
</tr>
</tbody>
</table>

f) Click **Submit**.

The three API config overrides, credentials, endpoint, and identity are created. Enter scripts for the Cloud API Interface operations: Discover, BootstrapNode, DeregisterNode, ExecuteConfigPackages, and RegisterNode.

**Note:** For the content you can use for the API interface operations, see [Sample scripts for Cloud API interface operations](#).

7. Click the CAPI Method Mappers related list and then click **Discover**.
   a) In the **Request Script** field, click the information icon (🔍) to open the record.
   b) Enter the script, **puppet-enterprise-1.0-Discover**, in the **Script** field and click **Update**.

8. In the CAPI Method Mappers related list, click **BootstrapNode**.
   a) In the **Request Script** field, click the information icon (🔍) to open the record.
   b) Enter the script, **puppet-enterprise-1.0-BootstrapNode**, in the **Script** field and click **Update**.

9. In the CAPI Method Mappers related list, click **DeregisterNode**.
   a) In the **Request Script** field, click the information icon (🔍) to open the record.
   b) Enter the script, **puppet-enterprise-1.0-DeregisterNode**, in the **Script** field and click **Update**.

10. In the CAPI Method Mappers related list, click **ExecuteConfigPackages**.
   a) In the **Request Script** field, click the information icon (🔍) to open the record.
   b) Enter the script, **puppet-enterprise-1.0-ExecuteConfigPackage**, in the **Script** field and click **Update**.

11. In the CAPI Method Mappers related list, click **RegisterNode**.
   a) In the **Request Script** field, click the information icon (🔍) to open the record.
   b) Enter the script, **puppet-enterprise-1.0-RegisterNode**, in the **Script** field and click **Update**.

A cloud API for puppet is created.

Create script includes for a Puppet scoped application
Sample scripts for Cloud API interface operations

By default, sample scripts are provided by the Cloud Management application for the cloud API interface operations: Discover, BootstrapNode, DeregisterNode, ExecuteConfigPackages, and RegisterNode.

**puppet-enterprise-1.0-Discover**

For the Discover cloud API, use the following script:

```javascript
discoverPuppetEnterprise();

function discoverPuppetEnterprise() {
    try {
        var discoveryPayload = {};
        var additionalParameters = this.parameters.get('AdditionalParameters');
        var additionalParams = new JSON().decode(additionalParameters);
        var discoveryParameter = additionalParams.entity;
        ms.log("$$ discoveryParameter : " + discoveryParameter);

        if (discoveryParameter == "environment") {
            // invoke Environments Discovery
            var peE = new PuppetEnterpriseEnvironments(this.parameters, this.headers);
            var environments = peE.discoverEnvironments();
            discoveryPayload['environments'] = environments.environments;
            discoveryPayload['objectId'] = environments.objectId;
        }

        if (discoveryParameter == "group") {
            // invoke Environments Discovery
            var peG = new PuppetEnterpriseClassification(this.parameters, this.headers);
            var groups = peG.discoverGroups();
            discoveryPayload['groups'] = groups.groups;
            discoveryPayload['objectId'] = groups.objectId;
        }

        if (discoveryParameter == "inventory") {
            // invoke Inventories Discovery
            var peI = new PuppetEnterpriseInventory(this.parameters, this.headers);
            var inventories = peI.discoverInventories();
            discoveryPayload['inventories'] = inventories.inventories;
            discoveryPayload['facts'] = inventories.facts;
            discoveryPayload['objectId'] = inventories.objectId;
        }

        if (discoveryParameter == "unsigned_certificate") {
            // invoke Unsigned Certificates Discovery
            var peC = new PuppetEnterpriseUnsignedCerts(this.parameters, this.headers);
            var unsignedCertificates = peC.discoverUnsignedCert();
            discoveryPayload['unsignedCertificates'] = unsignedCertificates.unsigned_certs;
            discoveryPayload['objectId'] = unsignedCertificates.objectId;
        }

        if (discoveryParameter == "moduleClasses") {

        }
    }
```
puppet-enterprise-1.0-BootstrapNode

For the cloud API, BootstrapNode, use the following script:

```javascript
bootstrapNode();

function bootstrapNode()
{
    // install the puppet agent at host in cloud
    var invObj = new PuppetEnterpriseInventory(this.parameters, this.headers);
    var bootStrapNodePayload = invObj.installAgentAtNode();
    // return bootstrapNodePayload;
}
```

puppet-enterprise-1.0-DeregisterNode

For the cloud API, DeregisterNode, use the following script:

```javascript
var peI = new PuppetEnterpriseInventory(this.parameters, this.headers);
peI.unsignCertANode();
```

puppet-enterprise-1.0-ExecuteConfigPackages

For the cloud API, ExecuteConfigPackages, use the following script:

```javascript
// Compare Group Class parameters, if it is same, continue to create job ::
else update group parameter's value and create job.
var pc = new PuppetEnterpriseClassification(this.parameters, this.headers);
pc.compareGroupParameterValue();
var pj = new PuppetEnterpriseJob(this.parameters, this.headers);
pj.launchAJob();
```

puppet-enterprise-1.0-RegisterNode

For the cloud API, RegisterNode, use the following script:

```javascript
registerNode();
```
function registerNode() {
// accept certificate of host at Puppet Enterprise
    var invObj = new PuppetEnterpriseInventory(this.parameters,
                                          this.headers);
    var registerNodePayload = invObj.acceptCertRequest();

    //return registerNodePayload;
}
initialize: function(parameters, headers) {
  // define Macros
  this.puppetTargetRunCount = 50;
  this.puppetWaitPeriod = 20000;

  this.logger = new PuppetEnterpriseLogger();
  this.parameters = parameters;

Create a CI class for an environment

Create a configuration item (CI) class for an environment and add identification rules to the CI class. Creating a class and adding identification rules makes managing the CIs more efficient. An environment can be a production, development, or a test environment.

Role required: sn_cmp.cmp_root_admin

1. Navigate to Configuration > CI Class Manager.
2. To display the CI classes list, click Hierarchy.
3. Search for and open the Config Entity (cmdb_ci_config_entity) CI class.
4. To create a new child class, and move to the Provide Basic Info stage, click Add Child Class.
5. In the Provide Basic Info stage, enter a name (Puppet Enterprise Environment) for the class in the Display Name field.
6. Click Next until you reach the Set Identification Rule stage.
7. Create an identification rule.
   a) Click Add.
      The Create Identification Rule dialog box appears.
   b) Click Dependent and click Save.
   c) To create an identifier entry, click Add in the Identifier Entries section.
   d) Move Object ID to the Selected list.
   e) Click Save.

A class is created for the environment and identification rules have been created.

Configure Metadata Rules for Puppet provider

Configure metadata rules to create a relationship between the Puppet enterprise CI class and the Puppet enterprise environment CI class.
Role required: sn_cmp.cmp_root_admin

1. Navigate to Metadata Editor.
2. Click Hosting Rules and then click Add New Rule.
   Add Top Level Hosting Rule dialog box appears.

3. Select Puppet Enterprise Environment from the Configuration Item Type list box and click Create
   Puppet Enterprise Environment is listed in the Metadata Editor window.
4. Search for Puppet Enterprise Environment and click the plus icon (Add hosting rule) next to it.
   The Add Hosting Rule to Puppet Enterprise Environment dialog box appears.
5. Select Puppet Enterprise from the Configuration Item Type list box.
6. De-select the Reverse Relationship Direction check box. By default, this check box is enabled.
7. Click Create.

Create a resource block for Puppet provider

Create a resource block for Puppet provider
Create a resource block for the Puppet provider based on a CI type from the CMDB.

Role required: sn_cmp.cmp_root_admin

1. In the Cloud Admin Portal, navigate to Design > Resource Blocks.
2. Click New.
   The Create Resource Block dialog box appears.
3. Fill in the form fields (as shown in the table). For a detailed description of each field, see Create a custom resource block.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a name (Puppet Enterprise) for the resource block.</td>
</tr>
<tr>
<td>Layer</td>
<td>Select the type of resource block (Virtual Infrastructure).</td>
</tr>
<tr>
<td>CI Type</td>
<td>Select the CI type (Puppet Enterprise) that the resource block represents.</td>
</tr>
<tr>
<td>Guest Interface</td>
<td>Select a default guest interface (Puppet Enterprise Interface) to use when you add a resource block to a blueprint.</td>
</tr>
</tbody>
</table>
4. Click **Submit**.
   The resource block information appears.

5. Click the **Operations** sub tab and then click the plus icon to add an operation.
   The Add Operation dialog box appears.

6. Fill in the form fields (as shown in the table).

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Interface</td>
<td>Select the check box to create a custom guest interface.</td>
</tr>
</tbody>
</table>

7. Click **Submit**.

8. Click the **Edit Operation** icon (next to the **Operation** list box) to add operation parameters.
   The Edit Operations dialog box appears.

9. Click the plus icon next to **OperationParameters**.

10. Enter the **Name** and **Type** parameters as mentioned in the table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CfgMgmtEndpoint</td>
<td>String</td>
</tr>
<tr>
<td>ConfigMgmtProviderInfo</td>
<td>String</td>
</tr>
<tr>
<td>WorkloadConfigProvider</td>
<td>String</td>
</tr>
</tbody>
</table>

11. Click **Close**.
    You need to add input parameters for the Discover operation.

12. Click the plus icon next to **Generate Catalog**.

13. Enter parameters and their corresponding mappings. Please ensure that you enter the exact mapping values as shown in the table.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Mapping</th>
</tr>
</thead>
<tbody>
<tr>
<td>CfgMgmtEndpoint</td>
<td>${ci.cmdb_ci_workload_config_provider($parameter.WorkloadConfigProvider)}</td>
</tr>
<tr>
<td>ConfigMgmtProviderInfo</td>
<td>${parameter.ConfigMgmtProviderInfo}</td>
</tr>
<tr>
<td>WorkloadConfigProvider</td>
<td>${ci.cmdb_ci_workload_config_provider($parameter.WorkloadConfigProvider)}</td>
</tr>
</tbody>
</table>

14. Click **Save Changes** (next to **Generate Catalog**).

15. Click **Steps** and then click the plus icon to add operation steps to discover environments.
    The Add Operation Steps dialog box appears.

16. Fill out the form fields (as shown in the table).

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operation Type</td>
<td>Select <strong>Invoke Cloud API</strong> from the list.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>API Provider</td>
<td>Select <strong>Puppet Enterprise</strong> from the list.</td>
</tr>
<tr>
<td>API Interface</td>
<td>Select <strong>Configuration Management Interface</strong> from the list.</td>
</tr>
<tr>
<td>API Method</td>
<td>Select <strong>Discover</strong> from the list.</td>
</tr>
<tr>
<td>CAPI Version</td>
<td>Enter the value <strong>1.0</strong> in the field.</td>
</tr>
</tbody>
</table>

17. Click **Submit**.
18. For the parameter, **AdditionalParameters**, enter
   ```json
   {
   "organization": "${parameter.Organization}"
   },
   "entity": "environment"
   ```
in the **Value** field.
19. Click the **Resource Script** sub tab and then click **New**.
20. Enter a name, type, and define a script and then click **Submit**. You need to define the script titled, **Discover_Puppet_Environments**. See **Resource Scripts for Puppet Provider** located at the end of this topic.
21. Click the **Operations** sub tab and click **Steps**.
22. Click **Response Processor** and then click the plus icon. The Add Response Processor dialog box appears.
23. Select **Discover_Puppet_Environment** from the **Script Name** list and click **Submit**.
24. Click the plus icon again to add operation steps to discover groups. Use the same values that you used in step 16.
25. For the parameter **AdditionalParameters**, enter
   ```json
   {
   "organization": "${parameter.Organization}"
   },
   "entity": "group"
   ```
in the **Value** field.
26. Click the **Resource Script** sub tab and then click **New**.
27. Enter a name, type, and define a script and then click **Submit**. You need to enter two resource scripts (**Discover_Puppet_Config_Installables** and **Discover_Puppet_Create_Application_Template**). See **Resource Scripts for Puppet Provider** located at the end of this topic.
28. Click the **Operations** sub tab and click **Steps**.
29. Click **Response Processor** and then click the plus icon. The Add Response Processor dialog box appears.
30. Select **Discover_Puppet_Config_Installables** from the **Script Name** list and click **Submit**.
31. Click the plus icon again to enter another response processor. Select **Discover_Puppet_Create_Application_Template** from the **Script Name** list and click **Submit**.
32. Reset the order of the response processors as shown in the table and click **Save Changes**.

<table>
<thead>
<tr>
<th>Script Name</th>
<th>Execution Order</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discover_Puppet_Config_Installables</td>
<td>0</td>
</tr>
<tr>
<td>Discover_Puppet_Create_Application_Template</td>
<td></td>
</tr>
</tbody>
</table>

**Create cloud script templates for Puppet provider**

Resource scripts for Puppet provider

Several sample resource scripts are provided, by default, by the Cloud Management application for the Puppet provider.
Discover_Puppet_Environments

function processResponse(response, cloudServiceAccountId, ldc) {
    var PuppetModelString = [];
    var discoveryResponse = global.JSON.parse(response);
    gs.info("^*^*^uppet Environment Discovery Response ^*^*^"+response);
    var respIndex = 0;
    var tableName = "";

    //environment
    var environmentResponse = discoveryResponse.environments;
    for(respIndex= 0, environments_size = environmentResponse.length;
        respIndex <environments_size ; respIndex++){
        //hosting table = Enterprise for Environment
        tableName = getPuppetTableName("Puppet Enterprise Environment");
        var hostingTable = {};
        hostingTable.name = getPuppetTableName("Puppet Enterprise");
        hostingTable.identifier = "object_id";
        hostingTable.identifierValue = discoveryResponse.objectId;

        var envObjectId = discoveryResponse.objectId + "_"+
        environmentResponse[respIndex].name;
        var environmentTable = new BuildTableData(tableName,envObjectId,
        hostingTable);
        //add attributes for the table
        environmentTable[tableName].attributes.name =
        environmentResponse[respIndex].name;
        PuppetModelString.push(environmentTable);
    }
    return global.JSON.stringify(PuppetModelString);
}

function BuildTableData(tableName, id, hostingTable){
    this[tableName] = {};
    this[tableName].validator = "PuppetEnterpriseResponseValidator" ;
    this[tableName].validator_overrides = {};
    this[tableName].identification = {};
    this[tableName].identification [tableName] = {};
    this[tableName].identification[tableName].criterion= {};
    this[tableName].identification[tableName].criterion.object_id = id.toString();

    //attach hosting table identification
    this[tableName].identification[hostingTable.name] =
    buildTableIdentification(hostingTable);
    this[tableName].attributes = {};
}

function buildTableIdentification(hostingTable){
    var identification = {};
    identification[hostingTable.name] = {};
    identification[hostingTable.name].criterion = {};
    identification[hostingTable.name].criterion[hostingTable.identifier] =
    hostingTable.identifierValue;
    return identification[hostingTable.name];
}

function getPuppetTableName(name){
    var dbObjectGr = new GlideRecord('sys_db_object');

    return '';  
}
```

Create cloud script templates for Puppet provider

Create cloud script templates to install a puppet agent on a virtual machine once the virtual machine is provisioned.

Role required: sn_cmp.cmp_root_admin

1. In the Cloud Admin Portal, navigate to Design > Cloud Scripts > Cloud Script Templates.
2. Click New. Create two script templates (as shown in the table).
<table>
<thead>
<tr>
<th>Name of the script</th>
<th>Script</th>
</tr>
</thead>
</table>
| **InstallPuppetAgent** | ```bash
#!/bin/sh
MASTER_ENDPOINT=#CfgMgmtEndpoint#
sed -i '/search/d' /etc/resolv.conf
curl -k "$MASTER_ENDPOINT:8140/packages/current/install.bash"| sudo bash
CMD="export PATH=$PATH:/opt/puppetlabs/puppet/bin:/opt/puppetlabs/puppet/lib:/opt/puppetlabs/puppet/bin/gem"
CMD="service puppet start"
PUPPET_STATUS=$(service puppet status)
echo "PUPPET_AGENT_STATUS : "$PUPPET_STATUS"
``` |
| **UnsignCertOfPuppetAgent** | ```bash
#!/bin/sh
MASTER_ENDPOINT=#CfgMgmtEndpoint#
sed -i '/search/d' /etc/resolv.conf
curl -k "$MASTER_ENDPOINT:8140/packages/current/install.bash"| sudo bash
CMD="export PATH=$PATH:/opt/puppetlabs/puppet/bin:/opt/puppetlabs/puppet/lib:/opt/puppetlabs/puppet/bin/gem"
CMD="service puppet start"
PUPPET_STATUS=$(service puppet status)
echo "PUPPET_AGENT_STATUS : "$PUPPET_STATUS"
``` |

3. Click **Submit** after creating each script template.

*Create a workload provider type for Puppet*

Create a workload provider type for Puppet.

Create a workload provider type information for the Puppet provider.

Role required: sn_cmp.cmp_root_admin.

1. In the Cloud Admin Portal, navigate to **Manage > Config Management > Workload Config Provider Types**.

   The Workload Config Provider Type window appears.
2. Click New.
3. Fill in the form fields (as shown in the table).

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a name (<strong>Puppet Enterprise</strong>) for the workload config provider type.</td>
</tr>
<tr>
<td>Product Type</td>
<td>Select (<strong>Puppet Enterprise</strong>) from the list.</td>
</tr>
<tr>
<td>Config CI</td>
<td>Select (<strong>u_cmdb_ci_puppet_enterprise</strong>) from the list.</td>
</tr>
<tr>
<td>Credential Resolver</td>
<td>Select (<strong>PuppetEnterpriseCredentialResolver</strong>) from the list.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------</td>
</tr>
<tr>
<td>Server Type</td>
<td>Enter Enterprise, Opensource in this field.</td>
</tr>
<tr>
<td>Version</td>
<td>Enter the version number 1.0.</td>
</tr>
<tr>
<td>Credential Type</td>
<td>Enter the name (sn_puppet_config_puppet_enterprise_credentials) of the credentials table for this workload config provider type. The name of the credentials table can vary based on application.</td>
</tr>
</tbody>
</table>

4. In the Workload Provider Properties section, insert a new row with the following values:

<table>
<thead>
<tr>
<th>Key</th>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Environment</td>
<td>Test</td>
<td>Production</td>
</tr>
</tbody>
</table>

5. Click Submit.

6. Open the Puppet Enterprise record. In the Provider Cloud Template Mappings section, update the Cloud Script Template field (for the BootstrapNode provider operation) with the value InstallPuppetAgent.
7. Click **Update**.

*Create a MID Server capability for a Puppet provider.*

Create a MID Server capability for a Puppet provider
Create a capability for the Puppet provider in your MID Server and associate this capability with a MID Server. A capability is required for each MID Server to work with the Cloud Management application.

Role required: sn_cmp.cmp_root_admin.

1. Navigate to MID Server > Capabilities.
2. Click New to create a capability with the name Puppet.
3. Click Submit.
   - Associate the Puppet capability with the MID Server.
5. Open your MID Server record and in the Related Links, click the Capabilities sub tab.
6. Click New.
7. Select Puppet from the Capability list and click Submit.

Create Puppet credentials for a Cloud Management scoped app.

Create Puppet credentials for a Cloud Management scoped app
Create credentials for the Puppet provider you created in this Cloud Management application example.

Role required: sn_cmp.cmp_root_admin.

1. In the Cloud Admin Portal, navigate to Manage > Credentials.
2. Click New and select Puppet Enterprise Credentials.
   - The Puppet Enterprise Credentials window appears.
3. Click the Additional actions icon and navigate to **Configure > Form Layout**.
4. Select the following attributes from the **Available** column, move them to the **Selected** column, and click **Save**.
   - Name
   - Active
   - MID Servers
   - Order
   - Username
   - Password
   - Machine Username
   - Machine Password

5. Fill in valid values in the form fields in the Puppet Enterprise Credentials window and click **Submit**.

Create a Puppet configuration management provider
Create a Puppet configuration management provider
Create a Puppet configuration management provider and run Discovery on the Puppet provider to discover its resources.
Role required: sn_cmp.cmp_root_admin.

1. In the Cloud Admin Portal, navigate to Manage > Config Management.
2. Click New.
3. Fill out valid values in the form fields and click Submit.
   The Puppet configuration management provider is created.
4. In the Cloud Admin Portal, navigate to Manage > Config Management.
5. Open the Puppet configuration management record and click Discover Now.
   The discovered resources for Puppet appear under Entities.

Create a blueprint for a Puppet provider

Create a blueprint for a Puppet provider

Create a blueprint to provision virtual machine instances for the Puppet provider.

Role required: sn_cmp.cmp_root_admin

1. In the Cloud Admin Portal, navigate to Design > Blueprint.
2. Click New.
3. Give the blueprint a name and select a category for the blueprint and click Save.
   The blueprint is created and appears in the Deployment Model tab.
4. Add the resources, vSphere Datacenter and virtual server, to the blueprint.
5. Create associations to the Blueprint container resource to virtual server and the virtual server to the vSphere Datacenter.
6. Click Logical Datacenter and add the following constraints:
   - vSphere Datacenter
   - AWS Datacenter
7. Click the Operations tab and select Provision to display steps associated with the blueprint.
   The attributes appear in the right side of the window.
9. Select the attributes WorkloadConfigProvider and WorkloadConfigProvider Type and click Save.
10. Click New to add the BootstrapNode resource operation and update the following operation attributes with their respective mappings.
    - ScriptParameters:
      - "WorkloadConfigProviderType":"${parameter.WorkloadConfigProviderType}"
      - CfgMgmtEndpoint:
        - "${ci.cmdb_ci_workload_config_provider[${parameter.WorkloadConfigProvider}].url}"
11. Click Save.
12. Click New to add RegisterNode and ExecuteConfigpackages resource operations one by one.
13. After the three resource operations are added, click Publish to Catalog.

Publish the Puppet scoped application

Publish the Puppet scoped application

After you create the cloud API scoped application for the Puppet provider, validate the scoped application and then publish it to the ServiceNow Store.

You have to meet certain prerequisites before you can publish to the ServiceNow Store. See Publish an application to the ServiceNow Store.

Once you publish the scoped application to the ServiceNow Store, the application can be imported and is ready to be used by everyone.
Create a Google Cloud Platform scoped application for Cloud Management

This example shows you how to create a scoped application for Google Cloud Platform with the Cloud Management application.

- Role required: sn_cmp.cmp_root_admin
- Ensure that you have met all the prerequisites to publish applications in the ServiceNow Store. See the ServiceNow Store documentation for the required details.
- Creation of a repository in a version control system like Github
- an active google compute account
- Successful MID Server communication with Google compute cloud.

You can publish this scoped application to the ServiceNow Store. A Linux virtual machine is used in this example.

Sequentially perform the following tasks to successfully create a Google Cloud Platform scoped application.

1. Create an application in the Studio.
2. Switch to the newly created application to set dependencies and create application settings for the new application.
3. Create a table for storing credential information to access the Google Cloud Platform server.
4. Create a CI class to manage all your Google Cloud Platform instances.
5. Create a capability for the Google Cloud Platform provider in MID Server. A capability is required for each MID Server to work with the Cloud Management application.
6. Create script includes to be used by the cloud APIs to communicate with the Google Cloud Platform server.
7. Configure MID Server jar files.
8. Map the Google Cloud Platform provider to credentials.
9. Create a cloud API provider for Google Cloud Platform.
10. Create cloud APIs.
11. Create a resource block.
12. Add Google datacenter as a host to the Virtual Server resource block.
13. Create a blueprint.
14. Test the scoped application.
15. Publish the scoped application to the ServiceNow Store.

Create an application for Google Cloud Platform in Studio

Create all your Google Cloud Platform configuration information in the form of an application using the Studio.

Role required: sn_cmp.cmp_root_admin

1. Navigate to System Applications > Studio.
   The Load Application pop-up window appears.
2. Click Create Application.
   The Create Application dialog box appears.
3. Click **Create** in the **Create Custom Application** section.
4. Fill in the form fields (as shown in the table).

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Specify a name (GCP demo) for the application.</td>
</tr>
<tr>
<td>Scope</td>
<td>The scope of the application, (sn_gcp_demo*), automatically appears.</td>
</tr>
</tbody>
</table>

5. Click **Create**.
   A confirmation dialog box appears.

6. Click **OK**.
   An application creation pop-up window appears on the successful creation of the application.

**Set dependencies on Google Cloud Platform application**
Set dependencies on Google Cloud Platform application
Create application settings and set dependencies to associate Cloud Management plugins with the Google Cloud Platform scoped application.

Role required: sn_cmp.cmp_root_admin

1. Click **System Applications > Studio**.
2. From the Applications list, click the application you created, **GCP demo**.
The Welcome to Studio home page appears.

3. Navigate to **File > Settings**.
   The Application Settings window appears.
### Custom Application

**GCP Credentials**

<table>
<thead>
<tr>
<th>Name</th>
<th>GCP Credentials</th>
<th>Version</th>
<th>1.0.0</th>
</tr>
</thead>
</table>

**Application Scoping**

Application scope will provide better protection for any system installing this application. Leave empty to create your application in the global scope. Enable Application administration to prevent System Administrators from accessing the application.

<table>
<thead>
<tr>
<th>Scope</th>
<th><code>x_snca_grp_credential</code></th>
</tr>
</thead>
</table>

**Design and Runtime**

Changing these options may affect how your application runs once it's been installed on a target instance.

<table>
<thead>
<tr>
<th>JavaScript Mode</th>
<th>ES5 Standards Mode</th>
<th>Runtime Access Tracking</th>
<th>Tracking</th>
<th>Restrict Table Choices</th>
</tr>
</thead>
</table>

**Subscription Management**

If this application is licensable, set the subscription requirement and model.

<table>
<thead>
<tr>
<th>Licensable</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Subscription requirement</td>
<td>Monitor</td>
</tr>
<tr>
<td>Subscription Model</td>
<td>Not applicable</td>
</tr>
</tbody>
</table>

**Primary menu**

Enter a new or choose an existing name to define the primary menu in the navigator for this application. Any module created for this app will reside by default in this menu.

<table>
<thead>
<tr>
<th>Menu</th>
<th>GCP Credentials</th>
</tr>
</thead>
</table>
4. In the Runtime Access Tracking list, select None. The default value is Tracking.
5. Click Update.
6. In Related Lists, click the Dependencies tab.
7. Click Edit. Select the following plugins from the Collection list and move them to the Dependencies list, to associate the plugins with the Google Cloud Platform scoped application.
   - Cloud API
   - Cloud Management
   - Cloud Config Management
   - Cloud Management Core
8. Click Save.
   All the plugins, added as dependencies, appear under the Dependencies tab.

Create table for storing Google Cloud Platform credential information
Create a table for storing credential information pertaining to the Google Cloud Platform provider. This information is used to connect to the Google Cloud Platform server.

Role required: sn_cmp.cmp_root_admin.
1. Navigate to System Definition > Tables.
2. Click New.
3. Fill in the form fields (as shown in the table below).
Field | Description
--- | ---
Label | Enter a unique label for the table (GCP Credentials). The label appears on list and form views for the table.
Name | The table name is automatically populated based on the table label and a prefix. Ensure the table name reads `sn_gcp_demo_gcp_credentials`. For a table in a scoped application, the name is prefixed with a namespace identifier to indicate that it is part of an application.
Extends table | Select the table to extend (Credentials). Extending a base table incorporates all the fields of the original table and creates system fields for the new table. You can extend tables that are marked as extensible if they are in the same scope or if they allow configuration from other scopes.

4. Right-click the header and select Save. The GCP credentials table appears.
5. Click Application Access to define the scope protection for the table.
6. Select the following check-boxes:
   - Can Create
   - Can Update
   - Can Delete
7. Right-click the header and select Save. You need to add information for the PrivateKey column.
8. Click Columns and then click New (next to Table Columns).
9. Fill in the form fields (as shown in the table below):

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Select String from the list.</td>
</tr>
<tr>
<td>Column Label</td>
<td>Enter a label (PrivateKey) for the column.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Enter a name (private_key) for the column.</td>
</tr>
<tr>
<td>Max Length</td>
<td>Enter the value 4000.</td>
</tr>
<tr>
<td>Active</td>
<td>Select this check box.</td>
</tr>
<tr>
<td>Mandatory</td>
<td>Select this check box.</td>
</tr>
</tbody>
</table>

10. Click Submit. You now need to add information for the Client Email column.
11. Click New.
12. Fill in the form fields (as shown in the table below):

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Select String from the list.</td>
</tr>
<tr>
<td>Column Label</td>
<td>Enter a label (Client Email) for the column.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Enter a name (Client_email) for the column.</td>
</tr>
</tbody>
</table>
13. Click **Submit**.
    You now need to add information for the **Project Name** column.

14. Click **New**.
15. Fill in the form fields (as shown in the table below):

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Max Length</td>
<td>Enter the value <strong>100</strong>.</td>
</tr>
<tr>
<td>Active</td>
<td>Select this check box.</td>
</tr>
<tr>
<td>Mandatory</td>
<td>Select this check box.</td>
</tr>
</tbody>
</table>

16. Click **Submit**.
17. Click the **User Menu** list and select **Elevate Roles**.
18. Select the **security_admin** check box and click OK.
19. In the **GCP Credentials** table, scroll down to **Related Links > Access Controls** and open the record with the read operation.
20. Select ***** in the list next to the **Name** list to allow access to records in the Credentials table.
21. In the **Requires role** section, add a role with the value, **mid_server**, to the Access Control record.
22. Click **Save** and then click **Update**.
    The Verify Security Rules dialog box appears.
23. Click **Continue**.
24. Scroll down in the table to Related Links and click **Show List**.
25. Click **New**, next to GCP Credentials.
26. Click the **Additional actions** icon and then select **Configure > Form Layout**.
    The Configuring GCP Credentials form window appears.
27. Select the following from the Available column and move them to the Selected column.
    - PrivateKey
    - ProjectName
    - ClientEmail
28. Click **Save**.

**Create CI class provider for Google Cloud Platform**
Create CI class provider for Google Cloud Platform
Create a CI class (table) to manage all your Google Cloud Platform instances.
Role required: **sn_cmp.cmp_root_admin**

1. Navigate to **CI Class Manager**.
2. Click **Hierarchy** and search for **Logical Datacenter**.

3. Click the Open Menu icon (next to **Logical Datacenter**) and select **Add Child Class** to create a new child class.

4. Enter a name (**Google Datacenter**) for the class in the **Display Name** field.

5. Keep clicking **Next** till you reach **Done**.
6. Click **Done** to create the Google Datacenter.

**Create a capability in MID Server for Google Cloud Platform**
Create a capability in MID Server for Google Cloud Platform
Create a capability for the Google Cloud Platform provider in MID Server and associate this capability with a MID Server. A capability is required for each MID Server to work with the Cloud Management application.

Role required: sn_cmp.cmp_rootAdmin.

1. Navigate to **MID Server > Capabilities**.
2. Click **New** to create a capability with the name **Google**.
3. Click **Submit**.
   - You need to associate the **Google** capability with a MID Server.
4. Navigate to **MID Server > Servers**.
5. In the Related Links, click the **Capabilities** sub tab.
6. Click **New**.
7. Select **Google** from the **Capability** list and click **Submit**.

**Create script includes for Google Cloud Platform**
Create script includes for Google Cloud Platform
Create script includes to be used by the cloud APIs to communicate with the Google Cloud Platform server.

Role required: sn_cmp.cmp_rootAdmin

1. Navigate to **Mid Server > Script Includes**.
2. Click **New**.
3. Fill in the form details for each script include and click **Submit**. See **Script includes**.
   - You need to create two script includes (GoogleAPIInvoker and GoogleComputeVirtualMachine) for the cloud APIs to communicate with the Google Cloud Platform server. See **Sample script includes for Google Cloud Platform**.

**Create a MID Server JAR file for Google Cloud Platform**
Sample script includes for Google Cloud Platform
Several sample scripts are provided, by default, by the Cloud Management application. You need these script includes for the cloud APIs to communicate with the Google Cloud Provider server.

**GoogleAPIInvoker**

```javascript
var GoogleAPIInvoker = Class.create();

GoogleAPIInvoker.prototype = Object.extendsObject( CloudRESTAPIInvoker, { 
  initialize: function(url, scope, clientEmail, privateKey) { 
    CloudRESTAPIInvoker.prototype.initialize.call(this);
    this.endpointUrl = url;
    this.scope = scope;
    this.clientEmail = clientEmail;
    this.privateKey = privateKey;
  },

  setHeaders: function(headers) {
    this.headers = headers;
  },

  /* Other methods */

} )
```

setParameters: function(parameters) {
  this.parameters = parameters;
},

getEndpointUrl: function() {
  return this.endpointUrl;
},

ggetToken: function() {
  var tokenGenerator = new Packages.com.snc.cmp.connector.util.GoogleJwsUtil();
  this.info("GoogleAPIInvoker::getToken::scope  = " + this.scope + "
clientEmail = " + this.clientEmail + " privateKey  = " + this.privateKey);
  var accessToken = tokenGenerator.getToken(this.scope, this.clientEmail, this.privateKey);
  this.info("obtained accessToken : " + accessToken);
  return accessToken;
},

getHeaders: function(headers) {
  headers["User-Agent"] = "ServiceNow-Jakarta";
  headers["Content-Type"] = "application/json";
  headers["Authorization"] = "Bearer " + this.getToken();

  if (!JSUtil.nil(this.headers)) {
    for (var header in this.headers) {
      parameters[header] = this.headers[header];
    }
  }
},

getParameters: function(parameters) {
  if (!JSUtil.nil(this.parameters)) {
    for (var param in this.parameters) {
      parameters[param] = this.parameters[param];
    }
  }
},

type: "GoogleAPIInvoker"
});

GoogleComputeVirtualMachine

var GoogleComputeVirtualMachine = Class.create();

GoogleComputeVirtualMachine.prototype = Object.extendsObject(CloudAPIBase, {
  CloudComputeDTO: Packages.com.snc.cmp.connector.dto.CloudCompute,
  scope: "https://www.googleapis.com/auth/cloud-platform",

  initialize: function(parameters, headers) {
    CloudAPIBase.prototype.initialize.call(this);

    this.parameters = parameters;
    this.headers = headers;
    this.clientEmail = parameters.get('ClientEmail');
    this.privateKey = parameters.get('PrivateKey');
  },

  createVirtualMachine: function(projectId, location, instanceRequest, params) {

var jsonObj = new JSON();

// send the request to GCP
var computeEndpoint = "https://www.googleapis.com/compute/v1/projects/" + projectId + "/zones/" + location + "/instances";
var apiInvoker = new GoogleAPIInvoker(computeEndpoint, this.scope, this.clientEmail, this.privateKey);

var responseStr = apiInvoker.invokePost(jsonObj.encode(instanceRequest));
var responseObj = apiInvoker.getResponse(responseStr);

// sleep for a few seconds to let the vm initialize
Packages.java.lang.Thread.sleep(20000);

// fetch the details of the vm
computeEndpoint = "https://www.googleapis.com/compute/v1/projects/" + projectId + "/zones/" + location + "/instances/" + instanceRequest.name;
apiInvoker = new GoogleAPIInvoker(computeEndpoint, this.scope, this.clientEmail, this.privateKey);
responseObj = new JSON().decode(apiInvoker.invokeGet());
var computeNode = new this.CloudComputeDTO();

// setup the node properties
computeNode.setLocation(location);
computeNode.setNodeName(instanceRequest.name);
computeNode.setNodeId(responseObj.id);
computeNode.setState(responseObj.status);
computeNode.setHardwareId(params.hardwareId);
computeNode.setImageId(params.imageId);

return computeNode;
}

Create a MID Server JAR file for Google Cloud Platform

MID Server JAR Files allow you to upload a JAR file to an instance and synchronize it to all MID Servers. The JAR file provides REST APIs to communicate with Google cloud.

- Role required: sn_cmp.cmp_root_admin
- You should have downloaded the JAR file, gcp-util-1.0.jar, onto your local system.

1. Navigate to **MID Server > JAR Files**.
2. Click **New**.
3. Enter a name (**JSON Web Signature Util**) and a version (**1.0**) in the **Name** and **Version** fields.
4. Click the Manage Attachments icon to attach the JAR file, **gcp-util-1.0.jar**.
5. Click **Update**.

Create a cloud API provider for Google Cloud Platform

Create a cloud API provider for Google Cloud Platform

Role required: sn_cmp.cmp_root_admin

1. In the Cloud Admin Portal, navigate to **Design > Cloud API**.
2. Click **New**.
   - The Add Cloud Provider dialog box appears.
3. Fill in the form details (as shown in the table below).
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud Provider</td>
<td>Enter the name (Google) of the cloud provider.</td>
</tr>
<tr>
<td>Description</td>
<td>Enter a short description for the cloud provider.</td>
</tr>
<tr>
<td>Datacenter class</td>
<td>Select a datacenter class (Google Datacenter) for the provider.</td>
</tr>
</tbody>
</table>

4. Click Submit.  
The Cloud Provider details appear.

5. Click New next to Cloud Products.

6. Fill in the form fields (as shown in the table below).

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a name (Google Compute) for the cloud provider.</td>
</tr>
<tr>
<td>Service Category</td>
<td>Select a service category (Compute) for the cloud provider.</td>
</tr>
</tbody>
</table>

7. Click Submit.

8. Open the Google Compute record.

9. Click New, next to Cloud Resources Types.

10. Fill in the form fields (as shown in the table below).

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a name (Compute.Engine/VM Instances) for the resource type.</td>
</tr>
<tr>
<td>CI Class</td>
<td>Enter a CI class (cmdb_ci_vm_instance) for the resource type.</td>
</tr>
</tbody>
</table>

11. Click Submit.

---

**Create a cloud API for Google Cloud Platform**

Create a cloud API for Google Cloud Platform
Create a cloud API for the Google Cloud Platform provider.

Role required: sn_cmp.cmp_root_admin.

1. In the Cloud Admin Portal, navigate to Design > Cloud API.
2. Click API and then click New.
   The Add Cloud API dialog box appears.
3. Fill in the form details (as shown in the table below).

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud API</td>
<td>Enter a name (Google Compute Platform API) for the cloud API.</td>
</tr>
<tr>
<td>Interface</td>
<td>Select an interface (Compute Interface) for the cloud API.</td>
</tr>
<tr>
<td>Product</td>
<td>Select a product (Google Compute) for the cloud API.</td>
</tr>
</tbody>
</table>
4. Click **Submit**. The Google Compute Platform API information appears.

5. In the CAPI Method Mappers tab, search for **CreateNode** and open the **CreateNode** record.

6. In the **Request Script** field, click the information icon to open the record.

7. Fill in the form fields (as shown in the table below).

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a name (google-compute-1.0-CreateNode) for the script.</td>
</tr>
<tr>
<td>Active</td>
<td>Select the check box.</td>
</tr>
<tr>
<td>Description</td>
<td>Enter a description (Script for CAPI - Google Compute Platform API1.CreateNode) for the script.</td>
</tr>
</tbody>
</table>
Script

function createVirtualMachine() {
    var jsonObj = new JSON();

    var location = this.parameters.get('Location');
    var vmName = "" + this.parameters.get('NodeName');
    var computeProfile = this.parameters.get('ComputeProfile');
    var osProfile = this.parameters.get('OsProfile');

    var mappedHardware = jsonObj.decode(computeProfile);
    var hardwareId = mappedHardware.HardwareId;
    var localStorage = mappedHardware.LocalStorage;

    var mappedOsProfile = jsonObj.decode(osProfile);
    var imageId = mappedOsProfile.ImageId;

    var projectName = this.parameters.get('Project');
    var gcpvm = new GoogleComputeVirtualMachine(this.parameters,
    this.headers);

    ms.log('google-compute-1.0-
CreateNode::createVirtualMachine
  + 'location = ' + location + '
  + vmName = ' + vmName + '

        location, instanceRequest,
        params);
    } catch (e) {
        ms.log(e);
        throw e;
    }

    return vm;
}
8. Click **Update**.
The CAPI Method Mapper window appears.
9. Click the back icon, next to CAPI Method Mapper, to get back to the Cloud API window.
10. Click the **API Config Overrides** sub tab and then click **New**.
The API Config Overrides window appears.
11. Click the search icon next to the **Config Parameter** list.
12. Click **New** to create a config parameter.
13. Fill in the form fields (as shown in the table below).
   
   You need to create three API config overrides; one for PrivateKey, one for ClientEmail, and one for Project.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config Parameter Name</td>
<td>Enter a name for the config parameter.</td>
</tr>
<tr>
<td></td>
<td>• PrivateKey</td>
</tr>
<tr>
<td></td>
<td>• ClientEmail</td>
</tr>
<tr>
<td></td>
<td>• Project</td>
</tr>
<tr>
<td>Default value</td>
<td>Enter a default value for a config parameter.</td>
</tr>
<tr>
<td></td>
<td>• $(CloudCredential.private_key) for PrivateKey</td>
</tr>
<tr>
<td></td>
<td>• $(CloudCredential.client_email) for ClientEmail.</td>
</tr>
<tr>
<td></td>
<td>• $(CloudCredential.project_name) for Project</td>
</tr>
<tr>
<td>Config data type</td>
<td>Select a config data type from the list.</td>
</tr>
<tr>
<td></td>
<td>For all the three config parameters, (PrivateKey, ClientEmail, and Project), select <strong>String</strong>.</td>
</tr>
<tr>
<td>Config type</td>
<td>Select a config type from the list.</td>
</tr>
<tr>
<td></td>
<td>For all the three config parameters, (PrivateKey, ClientEmail, and Project), select <strong>Config</strong>.</td>
</tr>
</tbody>
</table>

14. Click **Update**.
The API Config Overrides window appears.
15. Enter a value in the **Override value** field. Based on the config parameter you created, enter the appropriate value.

<table>
<thead>
<tr>
<th>Config Parameter</th>
<th>Override value</th>
</tr>
</thead>
<tbody>
<tr>
<td>PrivateKey</td>
<td>$(CloudCredential.private_key)</td>
</tr>
<tr>
<td>ClientEmail</td>
<td>$(CloudCredential.client_email)</td>
</tr>
<tr>
<td>Project</td>
<td>$(CloudCredential.project_name)</td>
</tr>
</tbody>
</table>

16. Click **Submit**.

**Create a resource block for Google Cloud Platform**
Create a resource block for Google Cloud Platform

Resource blocks are the building blocks of cloud catalog items. Create a resource block for the Google Cloud Platform provider, based on a CI type from the CMDB.
Role required: sn_cmp.cmp_root_admin

1. In the Cloud Admin Portal, navigate to Design > Resource Blocks.
2. Click New to open the Create Resource Block dialog box and then fill in the form. For a detailed description of each field, see Create a custom resource block.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a name (Google Datacenter) for the resource block.</td>
</tr>
<tr>
<td>Layer</td>
<td>Select the type of resource block (Logical Datacenter).</td>
</tr>
<tr>
<td>CI Type</td>
<td>Select the CI type (Google Datacenter) that the resource block represents.</td>
</tr>
<tr>
<td>Guest Interface</td>
<td>Select a default guest interface (Compute Interface) to use when you add a resource block to a blueprint.</td>
</tr>
</tbody>
</table>

3. Click Submit. The resource block information appears.
4. Click the Resource Script sub tab and then click New.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a name (Create_VM_GCP_Response_Processor) for the resource script.</td>
</tr>
<tr>
<td>Type</td>
<td>Select a type (Response Processor) for the script.</td>
</tr>
</tbody>
</table>
Enter the following script:

```javascript
function processResponse(response, cloudServiceAccountId, ldc, correlationId, step, requestorContext) {
    var cloudModelString = [];
    var apiObj = global.JSON.parse(step);
    var vmResponse = global.JSON.parse(response);
    var reqContext = global.JSON.parse(requestorContext);
    var status_map = {'RUNNING': 'on',
                      'SUSPENDED': 'paused',
                      'STOP': 'off',
                      'TERMINATED': 'terminated',
                      'ERROR': 'error',
                      'UNRECOGNIZED': 'off',
                      'PENDING': ''
                     }
    if(Array.isArray(vmResponse))
        vmResponse = vmResponse[0];

    var vmInfo = {
        'cmdb_ci_vm_instance': {
            'validator': 'virtual_machine_create_update_validator',
            'identification': {
                'cmdb_ci_cloud_service_account': {
                    'criterion': {
                        'object_id': cloudServiceAccountId
                    }
                },
                'u_cmdb_ci_google_datacenter': {
                    'criterion': {
                        'object_id': apiObj.ldcObjectId
                    }
                }
            },
            'cmdb_ci_vm_instance': {
                'criterion': {
                    'object_id': vmResponse.nodeId
                }
            },
            'attributes': {
                'name': vmResponse.nodeName,
                'object_id': vmResponse.nodeId,
                'state': status_map[vmResponse.state],
                'ip_address': vmResponse.publicIps[0],
                'assigned_to': reqContext.userId,
                'assignment_group': reqContext.groupId
            }
        }
    }
    cloudModelString.push(vmInfo);
    return global.JSON.stringify(cloudModelString);
}
```
5. Click **Submit**.
6. Click the **Operations** sub tab and then click **Steps**.
7. Select **ConnectAndCreateVirtualMachine** from the **Operations** list.
8. Click the **Add a Step** plus icon to open the Add Operation Steps dialog box and then fill in the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operation Type</td>
<td>Select <strong>Invoke Cloud API</strong> from the list.</td>
</tr>
<tr>
<td>API Provider</td>
<td>Select <strong>Google Compute</strong> from the list.</td>
</tr>
<tr>
<td>API Interface</td>
<td>Select <strong>Compute Interface</strong> from the list.</td>
</tr>
<tr>
<td>API Method</td>
<td>Select <strong>CreateNode</strong> from the list.</td>
</tr>
<tr>
<td>CAPI Version</td>
<td>Enter the value <strong>1.0</strong> in the field.</td>
</tr>
</tbody>
</table>

9. Click **Submit**.
10. Click **Response Processor** and then click the plus icon. The Add Response Processor dialog box appears.
11. Select **Create_VM_GCP_Response_Processor** from the **Script Name** list and click **Submit**.
12. Click the **Draft** toggle button. The Google Datacenter resource block moves from the draft to the published state and no further changes can be made to the resource block. Changes to a resource block can be made only if the status is set to **Draft**.

**Configure a virtual server for Google Cloud Platform**

Configure a virtual server for Google Cloud Platform
Add the Google Datacenter as a host to the Virtual Server resource block.

Role required: sn_cmp.cmp_root_admin.

1. In the Cloud Admin Portal, navigate to **Design > Resource Blocks**.
2. Search for the Virtual Server resource block and open the Virtual Server resource block record.
3. Click **Published** to move the resource block to draft mode.
4. Click **Host Resource** and then click **New**.
5. From the **GuestResource** list, select **Virtual Server**.
6. From the **HostResource** list, select **Google Datacenter**.
7. Click **Submit**.
8. Navigate to the Virtual Server resource block.
9. Click the **Draft** toggle button to move the resource block to a published state.

   Google Datacenter is listed as a host resource for Virtual Server in the Host Resource tab.

**Create credential mapping for Google Cloud Platform provider**

Create credential mapping for Google Cloud Platform provider
Map the Google Cloud Platform provider to the GCP credentials table. Each credential is mapped to a particular provider.

Role required: sn_cmp.cmp_root_admin.

1. In the Cloud Admin Portal, navigate to **Manage > Credentials > Provider Credential Mapping**.
2. Click **New**.
3. Fill in the form fields (as shown in the table).
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

4. Click **Submit**.

Create a blueprint for Google Cloud Platform
Create a blueprint for Google Cloud Platform
Create a blueprint to provision virtual machine instances in the Google compute engine.

Role required: sn_cmp.cmp_root_admin.

1. In the Cloud Admin Portal, navigate to **Design > Blueprint**.
2. Click **New**, enter a name (**GCE VM Instance**), and then select a category (**Compute**).
3. Click **Submit**.
   The blueprint information appears.
4. Click the + icon next to Resources, search for Virtual Server and click **Virtual Server**.
   Virtual Server is added to the layout pane.
5. Search for Logical Datacenter in Resources and click **Logical Datacenter**.
   Logical Datacenter is added to the layout pane.
6. Connect the Blueprint container resource to the Virtual Server. To create a connection between resources, select the parent resource (Blueprint Container), click the connection pad in the resource, and then drop the connection in the Virtual Server with a dotted outline.
7. Connect the Virtual Server to the Logical Datacenter.
8. Click **Operations** and then click **Provision**.
9. Ensure that you select the check boxes for the following attributes:
   - Application
   - Business Service
   - Cloud Account
   - Cost Center
   - Lease End Date
   - Location
   - ScheduleProfile
   - ScheduleTimezone
   - StackName
   - UserGroup

10. Click **Virtual Server** and then click **Provision** to view Virtual Server attributes.
11. Select the check boxes for the following attributes:
   - ComputeProfile
- NodeName
- OSProfile
- SSHKey

12. Click **Publish to Catalog** to generate catalog forms.
13. Click **GCE VM Instance** under Request Operation.
   Operation inputs of GCE VM Instance blueprint appear.
14. Click **Form** and then click **Location**.
15. Scroll down to **Rules** section.
16. Click **TriggerChangeEvent Virtual_Server_OSProfile** to edit it.
17. On the **Actions** tab, click **New**, and then fill in the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a name <em>(Reload from pool)</em> for the action.</td>
</tr>
<tr>
<td>Action Type</td>
<td>Select a type of action <em>(Reload)</em> from the list.</td>
</tr>
<tr>
<td>Datasource</td>
<td>Select a datasource <em>(Reload From pool)</em> from the list.</td>
</tr>
<tr>
<td>TargetField</td>
<td>Select a target field <em>(Virtual_Server_OSProfile)</em> for the list.</td>
</tr>
</tbody>
</table>

18. Scroll down and enter the following two keys and their values.

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>CloudAccount</td>
<td>CloudAccount</td>
</tr>
<tr>
<td>Location</td>
<td>Location</td>
</tr>
</tbody>
</table>

19. Click **Submit**.
20. Click **Location** under **Form Parameters**.
21. In the **Rules** section, click **TriggerChangeEvent Virtual_Server_ComputeProfile** to edit it.
22. Click the **Actions** tab, click **New**, and then fill in the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a name <em>(Reload from pool)</em> for the action.</td>
</tr>
<tr>
<td>Action Type</td>
<td>Select a type of action <em>(Reload)</em> from the list.</td>
</tr>
<tr>
<td>Datasource</td>
<td>Select a datasource <em>(Reload From pool)</em> from the list.</td>
</tr>
<tr>
<td>TargetField</td>
<td>Select a target field <em>(Virtual_Server_ComputeProfile)</em> for the list.</td>
</tr>
</tbody>
</table>

23. Scroll down and enter two keys and their values. See step 18 for the keys and their values.
24. Click **Submit**.

The blueprint is created successfully and can provision a virtual machine in Google Datacenter.

*Publish the Google Cloud Platform scoped application*

Publish the Google Cloud Platform scoped application

After you create the cloud API scoped application for the Google Cloud Platform provider, validate the scoped application and then publish it to the ServiceNow Store.
Certain prerequisites need to be met before you can publish to the ServiceNow Store. See Publish an application to the ServiceNow Store.

After you test the scoped application and then publish the application to the ServiceNow Store, the application is ready to be used by everyone.

Create a Google Cloud Platform scoped application for demo purposes
Create a scoped application for Google Cloud Platform, push it to your local repository, and continue working on it. This application can be used for demo or testing purposes.

Role required: sn_cmp.cmp_root_admin.

1. Create an application in the ServiceNow Studio.
2. Create credentials to be used in provisioning a virtual machine instance in Google Cloud Platform.
3. Create a capability for Google Cloud Platform in the MID Server and associate this capability with a MID Server. A capability is required for each MID Server to work with the Cloud Management application.
4. Create a cloud account and a service account.
5. Configure a datacenter.
6. Create an OS template, a compute template, an OS profile and a compute profile.
7. Create capacity configurations for Google datacenter.
8. Create application files. Application files can be moved from one environment to another.
9. Create a blueprint for a scoped application and test the blueprint.
10. Test the newly created scoped application.
11. Push the newly created scoped application to your local repository.

Your scoped application is ready to be used for demo and testing purposes.

Moving Cloud Management content across environments
You can move the content in the Cloud Management application from one environment to the other. For example, develop an application in an environment and then move the application and all its dependencies to another environment for testing or production.

Content entities that can be moved
The Cloud Management application consists of code, resources, content, and configurations.
You can move the following content entities across environments:
- Blueprints
- Resource blocks
- Cloud APIs

Use the update sets to move the content entities. Update sets, which are XML files, group all the content into named sets and then moves these sets, as a unit, to other systems for testing or deployment. For information on how system update sets work, see System update sets.

Content entity dependencies
Each of the content entities has some direct dependencies that are automatically moved with the content to the new environment.

The direct dependencies for each of these content entities are:
<table>
<thead>
<tr>
<th>Content entity</th>
<th>Dependencies</th>
</tr>
</thead>
</table>
| Blueprint      | - Resource blocks  
|                | - Cloud APIs  
|                | - MID scripts  
|                | - Resource pools

| Cloud API      | - MID scripts  |

**Move a blueprint from one environment to another**

Use update sets to move a blueprint and its dependencies from one environment to another. Update sets let you group a blueprint and its dependencies into a named set and then move them as a unit to other systems for testing or deployment. For example, you can move a blueprint from a development environment to a production environment.

Role required: sn_cmp.cloud_service_designer or admin

- Users with the sn_cmp.cloud_service_designer role can only export update sets.
- Users with the admin role can export and import update sets.

Package the blueprint as an update set. Then export the update set from its current environment and import it to another environment.

1. In the Cloud Admin Portal, navigate to **Design > Blueprints**.
   All blueprints, in published and draft mode, appear in the Blueprints window.
2. Export the blueprint.
   a) Click the Export icon (Leod) for the blueprint that you want to export.
   The Blueprint Exporter window appears.
<table>
<thead>
<tr>
<th>Type</th>
<th>Policies</th>
<th>Policy Name</th>
<th>Policy Trigger</th>
<th>Target Entity</th>
<th>Status</th>
<th>Updated by</th>
<th>Updated</th>
</tr>
</thead>
<tbody>
<tr>
<td>MD Server Script Includes</td>
<td></td>
<td>Scheduling Default</td>
<td>on Catalog Item launch</td>
<td>Published</td>
<td>system</td>
<td>2018-11-05 14:36:44</td>
<td></td>
</tr>
</tbody>
</table>
The Blueprint Exporter window has a list of all the indirect dependencies (Policy, MID Server Script Includes, MID Server Script Files, Script Includes, and Workflows) for the blueprint. Objects such as policies, pools, MID scripts, script includes, and workflows are not directly a part of a blueprint, but a blueprint might depend on these objects to work correctly.

b) In the Blueprint Exporter window, click an object in the Type column. In the right column, select the object's corresponding entries that you want to export with the blueprint. For example, if you select MID Server Script Includes, all the corresponding script includes appear in the right column.

If a workflow contains subworkflows, select the parent workflow and all the subworkflows in order for the workflow to be exported. If there are any custom activities associated with a workflow, export those activities first and then export the workflow.

c) Click **Next**.

A window opens with a summary of the indirect dependencies that you chose to include in the export update set.

d) Click **Export Update Set**.

The Blueprint Exporter window opens with the **Success** check box selected in green indicating that the blueprint has been successfully exported along with all its dependencies. By default, all the files listed under Exported Update Set(s) get downloaded onto your system automatically. However, if the files are not automatically downloaded, follow these steps.
Blueprint Exporter - blueprint1

✅ Success

**Exported Update Set(s):**
- blueprint1 2018-05-02 17:57:51
- blueprint1 2018-05-02 17:57:53

**Metadata:**
- blueprint1 2018-05-02 17:57:53_metadata

**Log:**
- blueprint1 2018-05-02 17:57:53_log
Note: The number of update sets created is based on the scope of records that are being exported. For example, the blueprint that you are exporting has 100 records in all: 60 records are in scope one, 20 records are in scope two, and the remaining 20 records are in scope three. In such a scenario, three update sets are created. One update set for each scope.

3. Make sure that the files are downloaded. If the files are not downloaded, complete these steps.
   a) Click the metadata file.
      The metadata file mentions the order in which the exported files should be imported. In this example, the file blueprint10 is the first file to be exported followed by the file blueprint11.
   b) Based on the order mentioned in the metadata file, click the appropriate file to open it. A window opens with a list of all the files contained in the update set.
   c) To download the first XML file (in this example, the file is blueprint10) onto your system, click Export to XML. Import all the exported files into another environment. Users with the admin role can import the files. For example, you may have created the export update set in a system that runs the development environment and want to import it into another system that runs the production environment.
   d) Open the other XML file (in this example, the file is blueprint11) and download that file onto your system, too.

4. Import the blueprint.
   a) In the environment and the new instance where you want to import the files, enter Retrieved Update Sets in the filter navigator and then press the Enter key.
   b) Click the Import Update Set from XML related link.
   c) In the Import XML window that appears, click Choose File, select the export file, and click Upload.

Note: If a blueprint that you exported from the source environment exists in the target environment, and both the blueprints have a different sys_id, when you import the blueprint, an error appears and the import process stops. Export a different blueprint from the source environment or delete the blueprint with the same name in the target environment. If a blueprint that you exported from the source environment exists in the target environment and both the blueprints have the same sys_id, then the blueprint in the target environment gets updated with the blueprint that you exported from the source environment.

5. To verify that the blueprint is imported into the new environment, go to your instance in the new environment and in the Cloud Admin Portal, navigate to Design > Blueprints. The blueprint you imported should appear in the listed blueprints.

Move a resource block from one environment to the other
Use update sets to move a resource block and its dependencies from one environment to another. Update sets let you group a resource block and its dependencies into a named set and then move them as a unit to other systems for testing or deployment. For example, you can move a resource block from a development environment to a production environment.

Role required: sn_cmp.cloud_service_designer or admin
• Users with the sn_cmp.cloud_service_designer role can only export update sets.
• Users with the admin role can export and import update sets.

Package the resource block as an update set. Then export the update set from its current environment and import it to the other environment.

**Note:** If a resource block that you export from the source environment exists in the target environment, when you import this resource block, it results in two resource blocks with the same name: one resource block that existed before the import and another resource block which you just imported. For example, if you export the AWS Datacenter resource block from the development environment and you already have a resource block with the same name in the production environment, then when you import the AWS Datacenter resource block to the production environment, two resource blocks with the same name, AWS Datacenter, reside in the production environment.

1. In the Cloud Admin Portal, navigate to **Design > Resource Blocks.**
   All resource blocks, in published and draft mode, appear in the Resource Blocks window.
2. Export the resource block.
   a) Click the Export Resource block icon (Export Resource block icon) for the resource block to export. The Resource Block Exporter window appears.
a) In the Resource Block Exporter window, click an object in the Type column. In the right column, select the corresponding entries for the object that you want to export with the
resource block. For example, if you select MID Server Script Includes, all the corresponding script includes appear in the right column.

If a workflow contains subworkflows, select the parent workflow and all the subworkflows in order for the workflow to be exported. If there are any custom activities associated with a workflow, export those activities first and then export the workflow.

b) Click **Next**.
A window opens with a summary of the indirect dependencies that you chose to include in the export update set.

c) Click **Export Update Set**.

The Resource Block Exporter window opens with the **Success** check box selected in green indicating that the resource block has been successfully exported along with all its dependencies. By default, all the files listed under Exported Update Set(s) get downloaded onto your system automatically.
Resource Block Exporter - Azure Datacenter

☑ Success

Exported Update Set(s):
  Azure Datacenter0 2018-05-03 20:09:36
  Azure Datacenter1 2018-05-03 20:09:38

Metadata:
  Azure Datacenter 2018-05-03 20:09:38_metadata

Log:
  Azure Datacenter 2018-05-03 20:09:38_log

[ResourceBlock Exporter LOG] 2018-05-03 20:09:36:Exporting resource script - Stop_Azure_Datacenter0
[ResourceBlock Exporter LOG] 2018-05-03 20:09:36:Exporting resource script - Start_Azure_Datacenter0
3. Make sure that the files are downloaded. If the files are not downloaded, complete these steps.
   a) Click the metadata file.
      The metadata file mentions the order in which the exported files should be imported. In this example, the file Azure Datacenter is the first file to be exported followed by the file Azure Datacenter.
   b) Based on the order mentioned in the metadata file, click the appropriate file to open it.
      A window opens with a list of all the files contained in the update set.
   c) To download the first XML file (in this example, the file is Azure Datacenter) onto your system, click Export to XML.
   d) Open the other XML file (in this example, the file is Azure Datacenter1), and download that file onto your system.
      You must import all the exported files into another environment. For example, you may have created the export update set in a system that runs the development environment and want to import it into another system that runs the production environment.

4. Import the resource block.
   a) In the environment and the new instance where you want to import the files, enter Retrieved Update Sets in the filter navigator and then press the Enter key.
   b) Click the Import Update Set from XML related link.
   c) In the Import XML window that appears, click Choose File, select the export file, and click Upload.

Note: If a resource block that you exported from the source environment exists in the target environment, and both the resource blocks have a different sys_id, when you import the resource block, an error appears and the import process stops. Export a different resource block from the source environment or delete the resource block with the same name in the target environment. If a resource block that you exported from the source environment exists in the target environment and both the resource blocks have the same sys_id, then the resource block in the target environment gets updated with the resource block that you exported from the source environment.

5. To verify that the resource block is imported into the new environment, go to your instance in the new environment and in the Cloud Admin Portal, navigate to Design > Resource Blocks.
   The resource block you imported should appear in the listed resource blocks.

Move a cloud API from one environment to the other
Use update sets to move a cloud API from one environment to another. Update sets let you group a cloud API and its dependencies into a named set and then move them as a unit to other systems for testing or deployment. For example, you can move a cloud API from a development environment to a production environment.

Role required: sn_cmp.cloud_service_designer or admin
- Users with the `sn_cmp.cloud_service_designer` role can only export data sets.
- Users with the `admin` role can export and import update sets.

Package the cloud API as an update set. Then export the update set from its current environment and import it to the other environment.

**Note:** If a cloud API that you export from the source environment exists in the target environment, when you import this cloud API, it results in two cloud APIs with the same name: one cloud API that existed before the import and another cloud API which you just imported. For example, if you export the Ansible Configuration API from the development environment and you already have a cloud API with the same name in the production environment, when you import the Ansible Configuration API to the production environment, two cloud APIs with the same name, Ansible Configuration API, reside in the production environment.

1. In the Cloud Admin Portal, navigate to **Design > Cloud API > API**. All cloud APIs appear in the Cloud API window.
2. Export the cloud API.

   a) Click the Export Cloud API icon (\[\]) for the cloud API to export.
   
   The Cloud API Exporter window appears.
b) In the Cloud API Exporter window, click an object in the Type column. In the right column, select the corresponding entries for the object that you want to export with the cloud API. For example, if you select MID Script, all the corresponding MID scripts appear in the right column.

c) Click Next.
   A window opens with a summary of the indirect dependencies of the cloud API that you chose to include in the export update set.

d) Click Export Update Set.
   The Cloud API Exporter window opens with the Success check box selected in green indicating that the cloud API has been successfully exported along with all its dependencies. By default, all the files listed under Exported Update Set(s) get downloaded onto your system automatically.
Cloud API Exporter - Ansible Tower Configuration API

✅ Success

Exported Update Set(s):
- Ansible Tower Configuration API0 2018-05-03 22:38:41
- Ansible Tower Configuration API1 2018-05-03 22:38:43

Metadata:

Log:

3. Make sure that the files are downloaded. If the files are not downloaded, complete these steps.
   a) Click the metadata file.
      The metadata file mentions the order in which the exported files should be imported. In this example, the file titled Ansible Tower Configuration API0 is the first file to be exported, followed by the file titled Ansible Tower Configuration API1.
   b) Based on the order mentioned in the metadata file, click the appropriate file to open it.
      A window opens with a list of all the files contained in the update set.
   c) To download the first XML file (in this example, the file is API0 2018-05-03) onto your system, click Export to XML.
   d) Open the other XML file (in this example, the file is API1 2018-05-03), and download that file onto your system.
      You must import all the exported files into another environment. For example, you may have created the export update set in a system that runs the development environment and want to import it into another system that runs the production environment.

4. Import the cloud API.
   a) In the environment and the new instance where you want to import the files, enter Retrieved Update Sets in the filter navigator and then press the Enter key.
   b) Click the Import Update Set from XML related link.
   c) In the Import XML window that appears, click Choose File, select the export file, and click Upload.
      The cloud API gets imported to your new environment.

5. To verify that the blueprint is imported into the new environment, go to your instance in the new environment and in the Cloud Admin Portal, navigate to Design > Cloud API > API. The cloud API you imported should appear in the list of cloud APIs.

Cloud API (CAPI)
The Cloud API (CAPI) enables you to integrate Cloud Management with cloud providers using REST APIs.

CAPI components
Integration with cloud providers is performed through REST calls, such as PUT, GET, POST, and DELETE. CAPI provides the framework for you to integrate a cloud vendors REST API so that your instance can communicate with the cloud provider to manage cloud resources.

CAPI contains these components:
Providers

Cloud providers are the clouds that you can connect to. By default, Cloud Management includes the most commonly used providers, such as AWS, Azure, and VMware. Each provider has many products, each of which provide resource types. Each resource type maps to a single CI type. For example, the AWS provider includes the AWS Elastic Compute Cloud product, which includes the AWS::EC2::Instance resource type. This resource type is one of the most common cloud resources that you can create. It maps directly to the Virtual Machine Instance (cmdb_ci_vm_instance) CI type, where virtual machines are saved in the CMDB.

Interfaces

Interfaces define the framework that the system needs to structure the REST calls that the cloud provider APIs expect. Interfaces define operations, also called methods, and the parameters that each method requires.

Interfaces are reusable. If you extend CAPI to include new products and APIs, you can use existing interfaces to make the same REST calls.
APIs

CAPI APIs are the core component of CAPI that ties a product and interface together. The APIs include the actual code that the system executes.

Each CAPI API includes these components:

- **CAPI Method Mappers** provide the methods that are mapped to the operations defined in the interface. From CAPI method mappers, you create MID Server script includes in JavaScript to tell the cloud provider exactly what to do. It is through the script includes that the connection to the cloud provider occurs.

  **Note:** If you create custom CAPI APIs, the system provides an empty script include for you to customize. You can also modify existing script includes on method mappers if necessary. However, many of the default APIs that come with the Cloud Management application do not use modifiable script includes. The connections are hard-coded in Java. You can still use these APIs in new resource blocks that you create, but you cannot modify the APIs.

- **API Config Overrides** contain the identity, such as a key, and credentials, such as the secret key, and other important parameters required by the cloud provider. These parameters help the cloud provider perform the operations in the CAPI Method Mappers related list. API Config Overrides are necessary because, when the system calls the cloud provider API via REST, credential data is not included. Resource blocks use the parameters and values that you define in the API Config Overrides to query the credential store. When your API executes, the attributes are made available to all method calls in your script includes.

  The overrides are scoped only for this API. The overrides do not override anything in other APIs.

Because you can define multiple versions of a CAPI API with slight variations, you can extend (without overwriting) an existing API while retaining desired functionality.

This image illustrates the components of CAPI that are used when you provision an Azure virtual machine using the default CAPI settings provided with Cloud Management:
In this example, the Microsoft.Compute product is contained in the Azure provider. Azure uses the Microsoft.Compute product for virtual machines. In your instance, the Microsoft.Compute product maps to the Microsoft.Compute/virtualMachines resource type, which is associated to the Virtual Machine Instance CI type in the CMDB.

The Compute interface contains definitions for methods like CreateNode, which defines how to create the actual virtual machine. Of the many parameters that CreateNode uses, Location captures the datacenter where the virtual machine resides.

The Azure Compute API pulls together the Microsoft.Compute product and the structure defined in the Compute interface. The implementation of the CreateNode method calls the azure-compute-1.0-CreateNode MID Server script include, which calls the AzureComputeVirtualMachine MID Server script include. The script includes make the actual calls to the Azure API. To access the Azure account, the SecretKey, ClientID, TenantID, and other methods are passed in Config Overrides.
How CAPI integrates with the instance

CAPI integrates these components in your instance:

Cloud Management resource blocks

A resource block represents a single cloud resource, such as a virtual server, virtual server storage, or a datacenter. You can also think of it as a CI type in the CMDB. You put many resource blocks together in a blueprint, which appears as a catalog item (also called a stack) to your users in the Cloud Catalog.

In the system, each resource block is like a container that references CAPI, and links responses from the cloud provider to a specific CI. Resource blocks use:

- Operational steps that call CAPI for each operation, such as the provision operation, and pass along necessary parameter values that the cloud provider needs to execute the operation.
- Response processors that process and parse the REST response from the provider and update records in the CMDB.

The CMDB

Each resource block is based on a CI type from the CMDB. For Cloud Management, all cloud-related CI types are based on the Virtual Machine Object CI class, which provides all the attributes that you need for all the cloud resources supported by default. If a CI type for a cloud resource does not exist in the base system, you must create a new CI class and add the necessary attributes.

If you do create a new CI class, you must also create:

- A CI class for each of the resources that are available to your users. All CI classes are based on the virtual machine object class.
- An identification rule that specifies an Object ID. Whenever components of Cloud Management refer to a specific cloud resource in the CMDB, they need the Object ID to find the correct cloud resource.
- A relationship rule that specifies how the CI class for the resource is related to other CI classes. For example, a virtual server CI must have a Hosted on::Hosts relationship with a datacenter CI. These relationship rules are necessary for CI uniqueness when processed by the Identification and Reconciliation Engine (IRE). The combination of the service account, the object ID of the resource, and the datacenter (or location) where the resource is located determines the uniqueness.

MID Server script include

Each operation in the CAPI API has a MID Server script include that you configure. The script include calls the JavaScript classes that are already in other script includes in the system, or JavaScript classes that you create. Eventually, the invoker class is called to trigger the REST call. MID Server script includes are configured on your ServiceNow instance, but run on the MID Server.

This image illustrates how the components work together when a user provisions a resource from the Cloud User Portal:
REST calls to the cloud provider

REST calls to the cloud provider are triggered from the MID Server script includes that are referenced from scripted CAPI Method Mappers inside CAPI API records. To create your own CAPI APIs, or to create custom MID Server script includes (which are part of CAPI Method Mappers), you must understand:

- The classes that are available for you to call in MID Server script includes. See [CAPI classes in MID Server script includes](#).
- How the cloud provider implements REST. See:
  - [Azure REST API Reference](#)
  - [AWS Guides and API References](#)

For example, to learn how to make a REST call to Azure to create a resource group, review this Azure topic: [Resource Groups - Create Or Update](#). You can find the endpoint, parameters, and request body that Azure requires, and the responses it provides. You can see that:

- The endpoint is `management.azure.com`
- The method to call with a PUT operation is `subscriptions/{subscriptionId}/resourcegroups/{resourceGroupName}?api-version=2018-02-01`, where you specify the subscription ID, the resource group name, and the API version.

Remember that the REST API calls take place inside the MID Server script includes that are associated with CAPI API method mappers. Call the methods that CAPI already makes available for you by using the classes extended from `CloudAPIBase` and `CloudRESTAPIInvoker`. You can also create more script includes to extend these base classes and create your own classes. Familiarize yourself with these base classes and the methods available within them.

Get started here

1. [Review CAPI APIs that are provided with Cloud Management by default](#).
2. [Review the CAPI classes that are provided by default](#). These classes can be called from the MID Server script includes in your CAPI API operations.
3. Walk through the provisioning of an [Azure virtual machine](#) and an [AWS virtual machine](#) to see how the components work together. The Azure walkthrough uses a MID Server script include so you can see the various CAPI classes used in the provision operation. The AWS walkthrough does not use a MID Server script include.
4. [Add a product to an existing provider in CAPI](#).
5. [Create a CI class for a virtual cloud resource](#).
6. [Create or extend a CAPI interface](#).
7. [Create a CAPI API](#), and a custom MID Server script include that makes the REST calls to the cloud provider. An empty MID Server script include is always generated for new CAPI APIs. Modify it with the calls to other JavaScript classes and methods, such as the methods in the Invoker class.

Default CAPI APIs

Several CAPI APIs are provided by default with the Cloud Management application.
CAPI APIs refer to the API records that link a CAPI product and a CAPI interface. They do not refer to the CAPI classes that you can call from MID Server script includes in CAPI APIs. For an overview of CAPI classes, see CAPI classes in MID Server script includes.

View Cloud APIs by navigating to Cloud API > Library in the base system instance interface, or by navigating to Design > Cloud API in the Cloud Admin Portal.

</table>

*You can customize how scripted APIs make REST calls to the cloud provider.

**CAPI classes in MID Server script includes**

Cloud Management provides several JavaScript classes that make REST calls to cloud providers. These classes are called from MID Server script includes (for Azure by default) or from Java calls in the system (for AWS by default). If you create custom providers, interfaces, or CAPI APIs (for any cloud provider), you can use MID Server script includes to call the classes.
**Note:** In CAPI APIs, there are no MID Server script includes (in Method Mappers) that you can customize to call the AWS classes. By default, the CAPI APIs for AWS make Java calls to then call the AWS classes. However, if you create CAPI APIs, you can also create custom script includes to call the classes.

View CAPI classes by navigating to **MID Servers > Script Includes** in the base system instance interface (not the Cloud Admin Portal). You search for the name of a class in the **Go to** search box using the **Name** column:

---

**Base classes**

These base classes are available by default. They form a basis for the Azure and AWS classes that make the actual REST calls.

**CloudAPIBase**

CloudAPIBase is a provider-agnostic API that communicates with all types of cloud APIs. It provides functions for basic debugging and logging, and for collecting proxy information on the MID Server. It also defines Headers, Parameters, Endpoints, and this.parameter.

**AWSCloudAPIBase**

This class is extended from CloudAPIBase and provides functions that call the invoker to make GET, PUT, POST, and DELETE requests. The class provides the option of an executeAction method, which is an AWS implementation of GET, or the invoke method, which provides REST API calls.

**AzureCloudAPIBase**

This class is extended from CloudAPIBase and provides functions that do these actions:

- Fetch resource IDs.
- Fetch endpoint properties.
- List resources.
- Call the invoker to make GET, PUT, POST, and DELETE requests.

AzureCloudAPIBase utilizes the _invokeRequest method to make REST API calls to Azure using the standard REST API calls.
Invoker classes

Invoker classes perform the actual REST calls to the cloud provider. If you create a custom CAPI interface and API, you should extend `CloudRestAPIInvoker` to create your REST calls.

CloudRestAPIInvoker

This class is an abstracted class for making REST API calls. If there are headers and/or parameters to send with a request, classes that implement the invoker must extend this object. They also must provide overrides for `getEndpointUrl` to return the targeted endpoint, and for `getHeaders` and `getParameters`. For example, with Azure REST APIs, authentication requires the passing of a token as a header. The extension implementing it should provide a response from `getHeaders` that performs the token creation or retrieval and sets it. This base object invokes `getHeaders` and sends whatever it gets back with the request. This class also provides a `getResponse` method to handle the response from the cloud provider.

If you create a custom CAPI API, you should extend `CloudRestAPIInvoker` to make REST calls to the cloud provider.

AmazonWebServicesAPIInvoker

This class is extended from `CloudRestAPIInvoker` and provides methods for making REST API calls to the cloud provider.

AzureAPIInvoker

This class is extended from `CloudRestAPIInvoker` and provides functions that make these REST API calls to Azure Resource Manager:

- Sets the Service Principal, headers, and parameters for REST calls.
- Gets the endpoint URL, token (client ID, tenant ID, and secret key), and headers/parameters.
- Retrieves and decodes the JSON response body from the cloud provider.

AzureEAAPIInvoker

This class returns the token for access to the Azure Enterprise Agreement (EA) REST API.

AzureStorageAPIInvoker
This class makes REST calls for Azure storage. The functions in this class can get the token, response, headers, and parameters.

This graphic illustrates how these base classes are used to extend AWS-specific and Azure-specific classes:

- **AmazonWebServicesAPIInvoker**
- **CloudRESTAPIInvoker**
- **AzureAPIInvoker**
- **CloudAPIBase**

### Exceptions

**RESTAPIException**
This base class handles exceptions that might occur during the REST call. It returns the response code from the cloud provider.

**AWSAPIException**
This class handles exceptions that might occur during the REST call.

**AzureAPIException**
This class throws a runtime exception when needed during Azure API invocation.
Handling exceptions

Classes for credentials

CloudRESTRequestSigningUtil
This class uses overrides that are specified in CAPI API Config Overrides. The AmazonWebServicesRequestSigner class extends this class. For Azure, many signers are built into the MID Server script includes for Method Mappers in Azure CAPI APIs.

AmazonWebServicesRequestSigner
This class sets up a secure session for the REST API call by taking information about a request, and creating a signature v4-signed string for the request. This class is extended from CloudRESTRequestSigningUtil.

Other Azure classes

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>

<td>Class to import and manipulate key pairs.</td>
</tr>
<tr>
<td>AWSS3</td>
<td>Handler for AWS S3 API calls.</td>
</tr>
<tr>
<td>AWSTopics</td>
<td>Class with AWS topics.</td>
</tr>
</tbody>
</table>

### Azure VM provisioning walkthrough

This example walks you through the components of Cloud Management that function during the provisioning of a virtual machine in an Azure datacenter. Topics covered include blueprints, resource blocks, the Cloud API (CAPI), and MID Server script includes.

**Role required:** admin

This walkthrough starts with a Linux VM that a user already provisioned in Azure. Next, it walks you through the blueprint with the VM, the resource blocks, and then the CAPI calls specified from the resource blocks. Finally, the walkthrough shows you how a MID Server script include eventually, through several CAPI calls, makes the actual REST calls to the Azure API.

This example uses default resource blocks and script includes that are available in your instance. Therefore, although you might not have a provisioned VM on your instance, you can still follow these steps and view the components used in this example to understand how the components work.

For an example of how a custom CAPI API can be used with custom resource blocks, see the following topics:

- Create a Google Cloud Platform scoped application for Cloud Management
- Create a resource block for Google Cloud Platform
- Sample script includes for Google Cloud Platform

For an example of a VM in AWS, see AWS VM provisioning walkthrough.
Note: The terms virtual machine, VM, and virtual server are used interchangeably in this example.

1. Look at a provisioned VM in the Cloud User Portal, and focus on some of the details about the VM:
   a) In the base system instance interface, open the Cloud User Portal (Cloud Management > Cloud User Portal).
   b) On the Cloud User Portal, view a provisioned VM in a stack, such as this VM, by clicking Stacks, and then clicking the name of the stack.
      In this example, the stack is named MyAzureVM.
   c) Under Resources, click the VM in the stack.
      
      ![Virtual Server]
      
      Virtual Server
      Virtual Server
      State On

   d) View the properties of the VM, and notice that it is in an Azure Datacenter in region eastus.
2. Look at the blueprint on which the VM is based:
   a) Navigate to Design > Blueprints, and then open a blueprint with a virtual server in the Azure datacenter. The Deployment Model tab appears by default, showing you the various components of the blueprint.

   This example blueprint has three components: the container, the virtual server, which is the actual VM that is provisioned, and the Azure datacenter.
b) Click the **Operations** tab on the bottom, and then click **Provision**.

The Provision operation is the operation that the system triggered when it created the VM. Other default operations are available, but this example focuses on the Provision operation.

c) Click the **Provision** block for Blueprint Container Resource.
d) On the right, notice that one of the parameters in the Inputs list is Location. This parameter holds the value eastus, which is where the VM lives in the datacenter.

Inputs can be specified on the container, as it is in this example, or on any other resource block. By default, the Location parameter is already specified for you in the Blueprint Container resource block, so that you can use it in every blueprint like this one. If you switch the blueprint to Draft, you can add more parameters to the Blueprint Container resource block. You cannot add parameters to the Virtual Server resource block. For this walkthrough, no additional parameters are necessary.

3. View the Virtual Server and Datacenter resource blocks used in this blueprint:
   a) In the Cloud Admin Portal, navigate to Design > Resource Blocks.
   b) Search for and open the Virtual Server resource block, which is provided by default with Cloud Management.
c) On the Resource Block form, click the Host Resource related list to view the list of supported host resource blocks.

d) Notice the host interface and host resource that are already specified:
• The **Host Interface** field specifies the interface that must match the guest interface in the resource block that hosts this virtual machine. In this case, the host interface is the Compute Interface, which is also the guest interface on the Azure Datacenter resource block. By default, the datacenter resource blocks provide several guest interfaces that other resource blocks like virtual storage can use to connect to the datacenter.

• The **HostResource** column in the Host Resource related list already specifies **Azure Datacenter**, which means that the Azure datacenter resource block is a valid host for this VM.

e) Click the **Operations** tab, and then click the **Steps** subtab.

f) Select **Provision** from the **Operation** list.

Remember that the Provision operation is the operation that the system used to create the VM. Other default operations are available, but this example focuses on the Provision operation.

g) Notice the step that appears in the list and the full step description that appears above the input parameters:

• **Host Resource Operation**: indicates that this step calls an operation on the host resource (the Azure datacenter in this example).

• **Compute Interface** is the guest interface on the Azure datacenter that this step is using.

• **ConnectAndCreateVirtualMachine** is the operation in the Azure datacenter that this step calls.
Note: In this case, the step calls an operation from another resource block: the Azure datacenter. Steps can also call CAPI directly, and then CAPI can execute REST calls to the cloud provider API. You can see that when you look at the Azure datacenter resource block.

h) Navigate back to Design > Resource blocks.

i) Open the Azure Datacenter resource block, which is the host resource block that the virtual server is connected to.

j) Notice the supported guest interfaces in the Guest Interface related list:

These guest interfaces are the interfaces that the Azure datacenter makes available to other resource blocks. The Compute Interface is provided so that the Virtual Server...
resource block, which specifies the Compute Interface as its host interface, can connect to the datacenter.

k) Click the Operations tab, and then click the Steps subtab.

![Virtual Server Resource Block](image)

l) In the Interface list, select Compute Interface if it is not already selected.

Remember that this interface is specified in the Virtual Server resource block.

m) In the Operation list, search for and select ConnectAndCreateVirtualMachine.

![Operation List](image)

Remember that this operation is specified in the Virtual Server resource block.

n) Notice the CAPI call that is used in the only step for the ConnectAndCreateVirtualMachine operation:
- **Cloud API**: indicates that this step calls CAPI, so that CAPI can execute a REST call to the cloud provider, which in this case is Azure.
- **Compute Interface** specifies the CAPI interface that this step calls.
- **CreateNode** indicates the method that is executed. As the name suggests, this method tells the cloud provider to create the virtual machine.

**o)** To open the step configuration: With the resource block in the **Draft** state, point to the highlighted (blue) step, and then click the **Edit Step** icon that appears.

**p)** Look at the step configuration and notice the settings that integrate with CAPI:
Edit Operation Steps

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operation Type</td>
<td>Invoke Cloud API specifies that this step should call the CAPI via the specified provider, interface, and method.</td>
</tr>
<tr>
<td>API Provider (which is actually the product)</td>
<td>Microsoft.Compute is a product (not the actual provider) that belongs to the Azure provider as defined in CAPI.</td>
</tr>
<tr>
<td>API Interface</td>
<td>Compute Interface is a product that belongs to the Azure provider as defined in CAPI.</td>
</tr>
<tr>
<td>API Method</td>
<td>CreateNode is the method that calls Azure to create the VM.</td>
</tr>
</tbody>
</table>

Note: The CAPI API definition ties together the provider (Azure), the product (Microsoft.Compute), the interface (Compute Interface), and the method (CreateNode).

a) Close the window.

r) With the Compute Interface.CreateNode step selected, click the Response Processor tab, and notice the Create_Virtual_Server_Response_Processor script.
This script is the response processor that updates the CMDB in your instance after the virtual machine is created.

s) For an explanation of the script, see Create a Response Processor and the example that is part of the topic. When you finish reviewing that topic, return to this topic.

4. Look at the CAPI components that work together to provision the VM:
   a) In the Cloud Admin Portal, navigate to Design > Cloud API.
   b) Click the API tab and then search for an open Azure Compute API.
   c) Look at how this CAPI API ties together an interface and a product:
Cloud API Name: Azure Compute API

Cloud API Interface: Compute Interface

Connector: Script Connector

Version: 1.0

Product: Microsoft.Compute

Service Category: Compute

Description: API that works with azure for compute resources

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud API Interface</td>
<td>Compute Interface is the same interface that you can see specified in the resource block. The interface contains the definition for methods, including the CreateStack method.</td>
</tr>
<tr>
<td>Connector</td>
<td>Script Connector indicates that this CAPI provides a MID Server script include for each operation. The script include calls the API. You can modify the script include or even create a new one.</td>
</tr>
<tr>
<td>Version</td>
<td>1.0 indicates the version of the API. You could have multiple versions of this API with different version numbers. Remember that in the step in the datacenter resource block that creates the VM, a Version field is provided. Although it was blank in this example because there is only one version of this API, you can specify a different version number.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>-------------</td>
</tr>
<tr>
<td>Product</td>
<td><strong>Microsoft.Compute</strong> is the product that belongs to the provider in CAPI. This product is provided by default with Cloud Management, and is one of the most commonly used products for creating VMs on Azure.</td>
</tr>
</tbody>
</table>

d) In the CAPI Method Mappers related list, click the record preview icon for the **CreateNode** record, and then click **Open Record**.

e) Look at the **CreateNode** method mapper:
Notice that the Endpoint operation is Execute Script, which indicates that a customizable script include is used to call functions in CAPI, which eventually makes the REST calls to Azure. The azure-compute-1.0-CreateNode MID Server script include is specified in the Request script field.

This graphic illustrates how the components — from the resource block to the script include — are connected:
Click the record icon ( ) for the Request script. The azure-compute-1.0-CreateNode MID Server script include opens.

Review the contents of the script.

```javascript
createNode();
function createNode(){
  var acp = new AzureComputeVirtualMachine(this.parameters,
      this.headers);
  var vm = acp.createVirtualMachine();

  return vm;
}
```

The script calls the createVirtualMachine function in the AzureComputeVirtualMachine class. It returns the virtual machine that is created. The AzureComputeVirtualMachine class extends AzureCloudAPIBase, which is one of the base APIs in Cloud Management.

To see the AzureComputeVirtualMachine class, which is a MID Server script include, open the base system instance interface (not the Cloud Admin Portal), and then navigate to MID Server > Script Includes.

Search for and open AzureComputeVirtualMachine.
Review the `createVirtualMachine` function:

The function defines many variables that are required to create a VM, including the `Location` (datacenter) and the name of the VM, and so on.

```javascript
var location = this.parameters.get('Location');
var vmName = this.parameters.get('NodeName');
...
```

This line of code calls the `_performVMOperation` function in this same script include and passes in the parameters that are necessary. Notice that an empty value '' is passed for the `action` parameter:

```javascript
var response = this._performVMOperation(subscriptionId, resourceGroup,
vmName, '', 'PUT', jsonObj.encode(params));
```

The `_performVMOperation` function calls the function `_invokeRequest`, which is located in the `AzureCloudAPIBase` class:

```javascript
return this._invokeRequest(this.pathDefault, param, method,
requestBody);
```

The PUT method for the REST call is specified in the `method` parameter.

Look at the `AzureCloudAPIBase` MID Server script include. The `_invokeRequest` function first calls the `_getEndpoint` function to get the endpoint and the `_getAPIInvoker` function to identify the `AzureAPIInvoker` class as the class that invokes the actual PUT call:

```javascript
var apiInvoker = this._getAPIInvoker(apiEndpoint, this.apiVersion);
```

`AzureAPIInvoker` is extended from `CloudRESTAPIInvoker`, which provides the base functions for all invokers. Once the correct invoker class is identified, a `response` variable is created to hold the value returned from `invokePut` function in the `CloudRESTAPIInvoker`:

```javascript
response = apiInvoker.invokePut(requestBody);
```

Look at the `CloudRESTAPIInvoker`, which is the base class for all invokers. The `invokePut` function specifies the PUT method and calls `getRequest`, and it returns the response from the `getResponse` function, which gets a status code and the response from Azure. This invoker class is where the connection to Azure is made.

Return to the `AzureComputeVirtualMachine` MID Server script include and find these lines:

```javascript
var response = this._performVMOperation(subscriptionId, resourceGroup,
vmName, '', 'PUT', jsonObj.encode(params));
this._compareVMState(response.id, 'PowerState/running');
var nodeResponse = this.getVirtualMachine(response.id);
```

Remember that the variable `response` is returned from the call to `_performVMOperation`, which has the response from the API invoker that triggered the PUT method. The `nodeResponse` variable holds the response from the `getVirtualMachine` function, which is passed the ID of the virtual machine that is in the response. The `getVirtualMachine` function calls `_getVMInfo`, which calls the same `_invokeRequest` function that was called earlier. This call is another connection to the invoker, which performs the actual
REST calls. In this case, the REST call is a GET REST call to Azure to obtain the identify of the VM.

The `return nodeResponse;` line returns `nodeResponse` in the `createVirtualMachine` function, which was called from the MID Server script included on the `createNode` operation.

This graphic illustrates the classes involved:

k) Navigate back to the Azure Compute API form.

l) Click the API Config Overrides related list, and review the items that are required for authentication.

<table>
<thead>
<tr>
<th>Config Parameter and Override Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ClientID $(CloudCredential.client_id)</td>
<td>The client ID is necessary to identify the application.</td>
</tr>
<tr>
<td>EndpointURL $(CloudCredential.URL)</td>
<td>The endpoint URL is the authorizing input in Azure.</td>
</tr>
<tr>
<td>SecretKey $(CloudCredential.secret_key)</td>
<td>The secret key is used to authorize the client.</td>
</tr>
<tr>
<td>TenantID $(CloudCredential.tenant_id)</td>
<td>The tenant ID is the globally unique identifier for your tenant.</td>
</tr>
<tr>
<td>Config Parameter and Override Value</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>EnrollmentNumber</td>
<td>$(CloudCredential.sn_cmp_ea_credential.enrollment_number)</td>
</tr>
<tr>
<td>EnrollmentToken</td>
<td>$(CloudCredential.sn_cmp_ea_credential.access_key)</td>
</tr>
</tbody>
</table>

See *Store the Azure service principal credentials in the instance* for more information on the Azure information that is used in these overrides.

m) Navigate back to Design > Cloud API, and then click the Interface tab.

n) Search for and open Compute Interface.

o) Review the contents of the interface.

Notice that the interface provides REST response structures for methods like CreateNode. You typically do not need to modify existing interfaces.
Note the service category and the operations:

<table>
<thead>
<tr>
<th>Field or related list</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service Category</td>
<td>The service category classifies the interface. The category for the Compute Interface is also <strong>Compute</strong>.</td>
</tr>
<tr>
<td>CAPI Interface Operations</td>
<td>The interface operations define the JSON structure for the REST call and the parameters that are required for the interface.</td>
</tr>
</tbody>
</table>

p) Click the **CreateNode** CAPI interface operation. This operation is the operation that provides the framework for creating the EC2 virtual server.

q) Review the components of the operation:
<table>
<thead>
<tr>
<th>Field or related list</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Response structure</td>
<td>The response structure is the JSON framework for REST API call. It provides a list of attributes that the provider can use to create the virtual resource with empty values.</td>
</tr>
<tr>
<td>Interface Operation Parameters</td>
<td>These parameters are also the parameters that the CAPI interface needs from the system so it can pass it in the REST call to the cloud provider.</td>
</tr>
</tbody>
</table>
This record is in the **Cloud API application**, but **Global** is the current application. To edit this record, you need to change the application.

**Operation name**: CreateNode

**Cloud API Interface**: Compute Interface

**Response structure**:

```json
{
    "nodeId": "",
    "nodeName": "",
    "imageld": "",
    "nodeGroup": "",
    "state": "",
    "location": "",
    "scope": "",
    "availabilityZone": "",
    "hostName": "",
    "hostServer": "",
    "osName": "",
    "osVersion": "",
    "osVendor": "",
    "userId": "",
    "userName": "",
    "privateKey": "",
    "password": "",
    "hardwareId": "",
    "hardwareProvider": "",
    "ram": "",
    "processors": [{
        "cores": "",
        "speed": ""
    }]
}
```
r) Navigate back to **Design > Cloud API** and then click the **Provider** tab.

s) Open the **Azure** provider.

   The Azure Cloud Provider form opens, showing you that this provider is based on an existing CMDB class: **Azure Datacenter (cmdb_ci_azure_datacenter)**.

t) Click the Cloud Products related list, and sort the list by the **Name** column.

Notice that several Azure products are available by default. One of the most commonly used Azure products created from templates is **Microsoft.Compute**.

u) Click **Microsoft.Compute** in the **Name** column. Notice that the product specifies many resource types, each of which is mapped to a CI class.
These resource types indicate some of the CIs, but not all, that are related to the virtual machine. The response processor in the resource block populates CIs with data when the cloud provider provisions the VM.

5. To see the important CIs that are related to the VM:
a) On the Cloud User Portal, click **Stacks**, and then open the stack containing the VM.

b) Click the **View Dependency** icon.

The dependency map displays the stack CI at the top, the VM in the middle, and the various related CIs, such as the image, at the bottom.

c) To view the form for the VM in the CMDB, right-click the arrow next to any CI.
d) From the menu, select **View Form**.

The CI form opens, showing you much of the information is already available on the Cloud User Portal when you view the properties of the VM.
The VM CI form

VM properties in the Cloud User Portal

AWS VM provisioning walkthrough

This example walks you through the components of Cloud Management that function during the provisioning of a virtual machine in an AWS datacenter. Topics covered include blueprints, resource blocks, the Cloud API (CAPI), and MID Server script includes.

Role required: admin

This walkthrough starts with a Windows VM that a user already provisioned in AWS. Next it walks you through the blueprint with the VM, the resource blocks, and then the CAPI calls specified from the resource blocks. Finally, the walkthrough shows you how a base MID Server script include makes the actual calls to the AWS API.

This example uses default resource blocks and script includes that are available in your instance. Therefore, although you might not have a provisioned VM on your instance, you can still follow these steps and view the components used in this example to understand how the components work.

For an example of a VM in Azure, see Azure VM provisioning walkthrough.

Note: The terms virtual machine, VM, and virtual server are used interchangeably in this example.

1. Look at a provisioned VM in the Cloud User Portal, and focus on some of the details about the VM:
   a) On your instance, open the Cloud User Portal (Cloud Management > Cloud User Portal).
   b) View a provisioned VM in a stack, such as this Windows VM, by clicking Stacks, and then clicking the name of the stack.
      In this example, the stack is named MyStack.

   c) Under Resources, click the VM in the stack.
d) View the properties of the VM, and notice that it is in region us-east-1 in an AWS Datacenter.
2. Look at the blueprint on which the VM is based:
   a) Navigate to Design > Blueprints, and then open a blueprint with a virtual server in the Azure datacenter. The Deployment Model tab appears by default, showing you the various components of the blueprint.

   This example blueprint has three components: the container, the virtual server, which is the actual VM that is provisioned, and the AWS datacenter.
b) Click the **Operations** tab on the bottom, and then click **Provision**.

The Provision operation is the operation that the system triggered when it created the VM. Other default operations are available, but this example focuses on the Provision operation.

c) Click the **Provision** block for Blueprint Container Resource.
d) On the right, notice that one of the parameters in the Inputs list is Location. This parameter holds the value eastus, which is where the VM lives in the datacenter.

Inputs can be specified on the container, as it is in this example, or on any other resource block. By default, the Location parameter is already specified for you in the Blueprint Container resource block, so that you can use it in every blueprint like this one. If you switch the blueprint to Draft, you can add more parameters to the Blueprint Container resource block. You cannot add parameters to the Virtual Server resource block. For this walkthrough, no additional parameters are necessary.

3. Look at the Virtual Server and AWS Datacenter resource blocks used in this blueprint:
   a) In the Cloud Admin Portal, navigate to Design > Resource Blocks.
   b) Search for and open the Virtual Server resource block, which is provided by default with Cloud Management.
c) On the Resource Block form, click the **Host Resource** related list to view the list of supported host resource blocks.

d) Notice that the host interface and host resource are already specified:
• The **Host Interface** field specifies the interface that must match the guest interface in the resource block that hosts this virtual machine. In this case, the host interface is the Compute Interface, which is also the guest interface on the AWS Datacenter resource block. By default, the datacenter resource blocks provide several guest interfaces that other resource blocks like virtual storage can use to connect to the datacenter.

• The **HostResource** column in the **Host Resource** related list already specifies **AWS Datacenter**, which means that the AWS datacenter resource block is a valid host for this VM.

e) Click the **Operations** tab, and then click the **Steps** subtab.
f) Select **Provision** from the **Operation** list.

Remember that the Provision operation is the operation that the system used to create the VM. Other default operations are available, but this example focuses on the Provision operation.

g) Notice the step that appears in the list and the full step description that appears above the input parameters:

- **Host Resource Operation**: indicates that this step calls an operation on the host resource (the AWS datacenter in this example).
- **Compute Interface** is the guest interface on the AWS datacenter that this step is using.
- **ConnectAndCreateVirtualMachine** is the operation in the AWS datacenter that this step calls.

**Note**: In this case, the step calls an operation from another resource block: the AWS datacenter. Steps can also call CAPI directly, and then CAPI can execute REST calls to the cloud provider API. You can see that when you look at the AWS datacenter resource block.

h) Navigate back to **Design > Resource blocks**.

i) Open the **AWS Datacenter** resource block, which is the host resource block that the virtual server is connected to.

j) Notice the supported guest interfaces in the **Guest Interface** related list:
These guest interfaces are the interfaces that the AWS datacenter makes available to other resource blocks. The **Compute Interface** is provided so that the Virtual Server resource block, which specifies the Compute Interface as its host interface, can connect to the datacenter.

k) Click the **Operations** tab, and then click the **Steps** subtab.
l) In the **Interface** list, select **Compute Interface** if it is not already selected.

Remember that this interface is specified in the Virtual Server resource block.

m) In the **Operation** list, search for and select **ConnectAndCreateVirtualMachine**.

Remember that this operation is specified in the Virtual Server resource block.

n) Notice the CAPI call that is used in the only step for the **ConnectAndCreateVirtualMachine** operation:
- **Cloud API**: indicates that this step calls CAPI, so that CAPI can execute a REST call to the cloud provider, which in this case is AWS.

- **Compute Interface** specifies the CAPI interface that this step calls.

- **CreateNode** indicates the method that is executed. As the name suggests, this method tells AWS to create the virtual machine.

o) With the resource block in the Draft state, point to the highlighted (blue) step and then click the **Edit Step** icon to open the step configuration.

p) Look at the step configuration, and notice the settings that integrate with CAPI:
Edit Operation Steps

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operation Type</td>
<td><strong>Invoke Cloud API</strong> specifies that this step should call the CAPI via the</td>
</tr>
<tr>
<td></td>
<td>given provider, interface, and method.</td>
</tr>
<tr>
<td>API Provider</td>
<td><strong>AWS Elastic Compute Cloud</strong> is a product (not that actual provider) that</td>
</tr>
<tr>
<td></td>
<td>belongs to the AWS provider as defined in CAPI.</td>
</tr>
<tr>
<td>API Interface</td>
<td><strong>Compute Interface</strong> is a product that belongs to the AWS provider as</td>
</tr>
<tr>
<td></td>
<td>defined in CAPI.</td>
</tr>
<tr>
<td>API Method</td>
<td><strong>CreateNode</strong> is the method that calls AWS to create the VM.</td>
</tr>
</tbody>
</table>

**Note:** The CAPI API definition ties together the provider (AWS), the product (AWS Elastic Compute Cloud), the interface (Compute Interface), and the method (CreateNode).
q) Close the window.

r) With the **Compute Interface.CreateNode** step selected, click the **Response Processor** tab, and notice the **Create_Virtual_Server_Response_Processor** script.

This script is the response processors that updates the CMDB in your instance after the virtual machine is created in AWS.

s) For an explanation of this script, see *Create a Response Processor* and the example that is part of that topic. After you finish reviewing that topic, come back to this one.

4. Look at the CAPI components that work together to provision the VM:
   a) In the Cloud Admin Portal, navigate to **Design > Cloud API**.
   b) Click the **API** tab.
   c) Search for an open **AWS Compute API**.
      There are two AWS Compute API records. Open the first one in the list that matches the image in the next step.
   d) Look at how this CAPI API ties together an **interface** and a **product**:
Field | Description
--- | ---
Cloud API Interface | **Compute Interface** is the same interface that you can see specified in the resource block. The interface contains the definition for methods, including the **CreateNode** method.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connector</td>
<td><strong>Cloud Compute Connector</strong> indicates that this CAPI makes Java calls to the system, which then calls the AWS API. This connector is not scripted. If this were a scripted connector, it was have a MID Server script include that calls the AWS API.</td>
</tr>
<tr>
<td>Version</td>
<td>1.0 indicates the version of the API. You could have multiple versions of this API with different version numbers. Remember that in the step in the AWS Datacenter resource block that creates the VM, a Version field is provided. Although it was blank in this example because there is only one version of this API, you could specify a different version number.</td>
</tr>
<tr>
<td>Product</td>
<td><strong>AWS Elastic Compute Cloud</strong> is the product that belongs to the AWS provider in CAPI. This product is provided by default with Cloud Management, and is one of the most commonly used products for creating VMs on AWS.</td>
</tr>
</tbody>
</table>

**Note:** Most AWS-related APIs that are provided in the Cloud Management application by default are not scripted, like this one, and cannot be modified. But you can create your own scripted APIs.

e) In the CAPI Method Mappers related list, click the record preview icon for the **CreateNode** record, and then click **Open Record**.
f) Look at the **CreateNode** method mapper:
Notice that the Endpoint operation is not **Execute Script**. This value indicates that the CreateNode method is using a Java call within the Cloud Management application on your instance to make a REST call to the AWS API. Therefore, you cannot modify how the CreateNode method works. If the value was **Execute Script**, you would see a MID Server script include specified in the **Request** script field. You would be able to modify that script include, or specify a new one, to customize the REST calls to the AWS provider.

g) Scroll down and look at parameters in the CAPI Parameter Mappers related list. Notice that important parameters, such as **Location**, are provided.

h) Navigate back to the AWS Compute API form.

i) Click the **API Config Overrides** related list, and review the items that are required for authentication:

<table>
<thead>
<tr>
<th>Config Parameter and Override Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AccountAliasName $(CloudCredential.Alias)</td>
<td>The account alias is an optional value that you can create in your AWS account. It is a secondary name for your account ID. See the AWS documentation for more information.</td>
</tr>
<tr>
<td>Config Parameter and Override Value</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>Credentials $(CloudCredential.secret_key)</td>
<td>The secret key is used with the access key for authentication. You configured this value in your AWS credential record during setup. To refer to that procedure, see <a href="#">Create the credentials that enable Cloud Management to access your AWS data</a>.</td>
</tr>
<tr>
<td>Endpoint $(CloudCredential.URL)</td>
<td>The endpoint is the URL that your users must log in to and authenticate. It uses the account ID or the account alias. See the <a href="#">AWS documentation</a> for more information.</td>
</tr>
<tr>
<td>Identity $(CloudCredential.access_key)</td>
<td>The Identify record holds the AWS access key, which AWS requires for authentication.</td>
</tr>
</tbody>
</table>

j) Navigate back to Design > Cloud API, and then click the Interface tab.

k) Search for and open Compute Interface. This interface is the interface specified in the resource block and the AWS Compute API CAPI API.

l) Review the contents of the interface.
Notice that the interface provides REST response structures for methods like `CreateNode`. You typically do not need to modify existing interfaces.

Note the service category and the operations:

<table>
<thead>
<tr>
<th>Field or related list</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service Category</td>
<td>The service category classifies the interface. The category for the Compute Interface is also <code>Compute</code>.</td>
</tr>
<tr>
<td>CAPI Interface Operations</td>
<td>The interface operations define the JSON structure for the REST call and the parameters that are required for the interface.</td>
</tr>
</tbody>
</table>

m) Click the `CreateNode` CAPI interface operation. This operation is the one that provides the framework for creating the EC2 virtual server in AWS.
n) Review the components of the operation:

<table>
<thead>
<tr>
<th>Field or related list</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Response structure</td>
<td>The response structure is the JSON framework for REST API call. It provides a list of attributes that AWS can use to create the virtual resource with empty values.</td>
</tr>
<tr>
<td>Interface Operation Parameters</td>
<td>These parameters are also the parameters that the CAPI interface needs from the system so it can pass it in the REST call to the cloud provider.</td>
</tr>
</tbody>
</table>
This record is in the **Cloud API application**, but **Global** is the current application. To edit this record, **Global** must be the current application.

**Operation name**: CreateNode

**Cloud API Interface**: Compute Interface

**Response structure**:

```json
{
    "nodeId": "",
    "nodeName": "",
    "imageId": "",
    "nodeGroup": "",
    "state": "",
    "location": "",
    "scope": "",
    "availabilityZone": "",
    "hostName": "",
    "hostServer": "",
    "osName": "",
    "osVersion": "",
    "osVendor": "",
    "userId": "",
    "userName": "",
    "privateKey": "",
    "password": "",
    "hardwareId": "",
    "hardwareProvider": "",
    "ram": "",
    "processors": [{
        "cores": "",
        "speed": ""
    }
}
```
o) Navigate back to **Design > Cloud API**, and then click the **Provider** tab.

p) Open the **AWS** provider.

The AWS Provider form opens, showing you that this provider is based on an existing CMDB class: **AWS Datacenter (cmdb_ci_aws_datacenter)**.

q) Click the Cloud Products related list if it is not already selected, and sort the list by the **Name** column.

Notice that several AWS products are already available by default. One of the most commonly used AWS products is **Elastic Compute Cloud (EC2)**.
r) Click **AWS Elastic Compute Cloud** in the **Name** column. Notice that the product specifies many resource types, each of which is mapped to a CI class.
These resource types indicate some of the CIs, but not all, that are related to the virtual machine. The response processor in the resource block populates CIs with data when AWS provisions the VM.

5. To see the important CIs that are related to the VM:
   a) On the Cloud User Portal, click **Stacks**, and then open the stack containing the VM.
   b) Click the View Dependency icon.
The dependency map displays the stack CI at the top, the VM in the middle, and the various related CIs, such as the image, at the bottom.

c) To view the form for the VM in the CMDB, right-click the arrow next to any CI, such as the VM.

d) From the menu, select View Form.
The CI form opens, showing you that much of the information is already available on the Cloud User Portal when you view the properties of the VM.
Add a product to an existing provider in CAPI

The Cloud Management Cloud API (CAPI) offers many providers, such as AWS and Azure, and products, such as EC2 instances. However, you can add products to existing providers for new types of cloud resources.

- Role required: admin
- Review Default CAPI APIs and make sure the provider and product that you want to create are not already provided.
Familiarize yourself with the cloud provider API so that you know how to create REST calls to the provider. If you are not familiar with the headers, authentication requirements, endpoint, and data that you can pass into the provider API, you cannot build your own CAPI components.

This topic provides general instructions for extending an existing cloud provider, product, and resource type. For a complete example, see Create CI class provider for Google Cloud Platform and Create a CI class for the Puppet provider. These examples are part of the Scoped applications for Cloud Management scenarios that show you in detail how to create scoped apps. The examples also cover the configuration of CAPI, resource blocks, blueprints, and credential mappings.

1. In your instance (not in the Cloud Admin Portal), enter the following text into the application filter:

   sn_capi_product.list

2. Press ENTER.

   The list of products that belong to all providers appears. You can filter the list to verify that the product you want to create is not already provided.

3. Click New and then enter a name and choose one of the existing service categories that is most appropriate.

4. Click Submit.

   The list of products appears again.

5. Find the product that you created, and then double-click the empty cell in the Provider column.

6. Add the correct provider.

7. Add a unique provider name: Double-click the cell in the Provider Name field and then change the name.

   The system can auto-generate a provider name for you, but you should modify it to avoid conflicts with existing provider names.
8. In the Cloud Admin Portal, navigate to **Design > Cloud API**.
9. Click the tile for the provider to which you added the new product.
10. Verify that your product is in the **Cloud Products** related list.
11. Click the information icon ( ) for the cloud product, and then click **Open Record**.
12. In the Cloud Resource Types related list, click **New** and then fill in the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a descriptive name.</td>
</tr>
<tr>
<td>Product</td>
<td>Verify that the resource type is for the correct product.</td>
</tr>
<tr>
<td>CI Class</td>
<td>Select a CMDB table. If you do not see the correct CMDB table, see <a href="#">Create a CI class for a virtual cloud resource</a> for instructions on how to create one.</td>
</tr>
</tbody>
</table>

You can ignore the **Pattern** and **Dependency sequence** fields.

13. Click **Submit**.

*Create a CI class for a virtual cloud resource* if necessary, or *Create or extend a CAPI interface*

Create a CI class for a virtual cloud resource

If the base system does not provide a CI type for cloud-based virtual resources, you can create a CI class based on the virtual machine object class.

Role required: admin
This topic provides general instructions for extending an existing cloud provider, product, and resource type. For a complete example, see Create CI class provider for Google Cloud Platform and Create a CI class for the Puppet provider. These examples are part of the Scoped applications for Cloud Management scenarios that show you in detail how to create scoped apps. The examples also cover the configuration of CAPI, resource blocks, blueprints, and credential mappings.

1. Navigate to Configuration > CI Class Manager.
2. Click Open Hierarchy.

3. On the CI Classes pane, enter Virtual Machine Object in the search field, and then select Virtual Machine Object.

4. Click the Virtual Machine Object link.
5. Click Add Child Class.

6. In the Provide Basic Info step that appears, enter a name and a description.

When you move the focus of the cursor away from the Display Name field, the Table Name field automatically populates with the same name in lower case. For a table in a scoped application, the name is prefixed with a namespace identifier to indicate that it is part of an application. For a table in the global application, the name is prefixed with the string u_cmdb_ci. You cannot modify the prefix; however, you can modify the rest of the table name. The name can contain only lowercase alphanumeric ASCII characters and underscores (_). The maximum string length is 80 characters.

7. Click Next.

8. On the Add Attributes step, click Derived, and then review the attributes that are inherited from the Virtual Machine Object class.

Most attributes that you need are provided.

9. Optional: To add an attribute:
   a) Double-click the Insert a new row text in the Column label field.
   b) Enter a name for the column and then click the green arrow.
   c) Fill out the rest of the fields in the row. See Dictionary Entry Form for a description of all the fields.

10. Click Next.

11. On the Set Identification Rule step, create an identification rule that specifies a unique Object ID, which is required for identification.

    Important: Cloud Management depends on the Object ID to uniquely identify an instance of the CI Class Type.

    a) Click Replace on the default rule under Identification Rule.
    b) Enter a name for the rule and select the Dependent option.
    c) Click Save.
    d) Under Identifier Entries, click Add.
e) Move **Object ID** from the **Available** column to the **Selected** column.
f) Click **Save**.

12. Click **Next**.
13. On the **Add Dependent Relationships** step, click **Override Dependencies**.
14. Configure the relationship between this virtual resource and the logical datacenter on which it resides:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rule Type</td>
<td>Hosting</td>
</tr>
<tr>
<td>Relationship</td>
<td>Hosted on (Hosted on::Hosts)</td>
</tr>
<tr>
<td>Target Class</td>
<td>Logical Datacenter</td>
</tr>
</tbody>
</table>

15. Click **Save**.
16. Click **Next**.
17. Click **Next** again to skip the **Add Reconciliation Rules** step, and then click **Done** to skip the **Add Suggested Relationships** step.

Use the CI class in a resource type for a cloud provider. See [Add a product to an existing provider in CAPI](#) for instructions.

Your response processor, which is part of the resource block, must also specify the necessary CI class types so it can update the CMDB. Usually, the response processor needs the object ID, the specific datacenter, and the cloud service account. See [Virtual server response processor example](#) for example response processor code that uses CI classes.

**Create or extend a CAPI interface**

You can create a new CAPI interface or extend an existing one by adding new operations.

- **Role required:** admin
- Review [Default CAPI APIs](#) and make sure the provider and product that you want to create do not exist.
- Familiarize yourself with the cloud provider API so that you know how to create REST calls to the provider. If you are not familiar with the headers, authentication requirements, endpoint, and data that you can pass into the provider API, you cannot build your own CAPI components.

Usually, you can use the default interfaces that are provided in the Cloud Management application. To create a custom interface, base it on an existing one that is similar.

1. In the Cloud Admin Portal, navigate to **Design > Cloud API**, and then click the **Interface** tab.
2. Click **New**.
3. In the Add Cloud interface window, enter a name for the interface, a helpful description, and select the most relevant category to which the API interface should belong.

This example shows an interface for Azure storage:

**Add Cloud Interface**

<table>
<thead>
<tr>
<th>Cloud Interface</th>
<th>Azure Block Blob Storage Interface</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>An interface for storage storage of objects for Azure</td>
</tr>
<tr>
<td>category</td>
<td>Storage</td>
</tr>
</tbody>
</table>

4. In the CAPI Interface Operations related list, click **New**.

Each operation that you create corresponds to a different REST API call.
5. Provide a name for the operation that corresponds to the API you want to call in the provider. For example, you can create an operation called **CreateContainer** that corresponds to the Create Container operation in Azure.

6. Right-click the header and select **Save**.

7. In the Interface Operation Parameters related list, click **New**.

8. Create a parameter that the operation needs as defined by the cloud provider REST API documentation. If you do not know the parameters, the operation fails.

   In the Azure storage example, the **CreateContainer** operation must have the name of the container that is referred to here as **ContainerName**.

9. Click **Submit**.

10. Add as many parameters as you need for the operation, and then add all the operations you need.

    **Create a CAPI API**

**Create a CAPI API**

If the existing CAPI APIs do not integrate with the CAPI interface for a provider, you can create an API. The steps in resource blocks can call your API methods when operations are executed.
• Role required: admin
• Review Default CAPI APIs and make sure the provider and product that you are creating do not exist.
• Familiarize yourself with the cloud provider API so that you know how to create REST calls to the provider. If you are not familiar with the headers, authentication requirements, endpoint, and data that you can pass into the provider API, you cannot build your own CAPI components.

This topic provides instructions for creating a CAPI API. For a complete example, see Create a cloud API for Puppet and Create a cloud API for Google Cloud Platform. Both of those examples are part of the Scoped applications for Cloud Management scenarios that show you in detail how to create scoped apps. They also cover the configuration of CAPI, resource blocks, blueprints, and credential mappings.

1. In the Cloud Admin Portal, navigate to Design > Cloud API.
2. Click the API tab.
3. Click New.
4. Fill out the form fields (see table):

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud API</td>
<td>Provide a descriptive name.</td>
</tr>
<tr>
<td>Interface</td>
<td>Select from among the existing interfaces that provide the operations you need.</td>
</tr>
<tr>
<td>Connector</td>
<td><strong>Script Connector</strong> appears in this field if the connector is a Java connector that is available out-of-box and cannot be modified. You do not need to modify these script connectors.</td>
</tr>
<tr>
<td>Product</td>
<td>Select the product that is part of the provider. The product includes resource types in the CMDB.</td>
</tr>
<tr>
<td>Version</td>
<td>Provide a version number to identify this API. Enter 1.0 if this API is the first version. You can create several versions of the same API and then refer to the specific versions in the operation steps of resource blocks.</td>
</tr>
<tr>
<td>Scripted</td>
<td>This field is selected if the Interface value is Script Connector.</td>
</tr>
<tr>
<td>Script Type</td>
<td>Select the language for the script.</td>
</tr>
<tr>
<td>ExecuteScriptOnInstance</td>
<td></td>
</tr>
<tr>
<td>Description</td>
<td>Provide a description for this API.</td>
</tr>
</tbody>
</table>

5. Verify that all the operations you need appear in the CAPI Method Mappers related list.

The operations in the CAPI Method Mappers list are the same operations in the interface that you selected. They are bound to this API. You cannot add or remove any operations from the list. Some of the operations, especially Azure operations, use MID Server script includes

© 2020 ServiceNow, Inc. All rights reserved. ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
that perform the actual implementation for the API. The script includes a call to the REST API for the provider, such as AWS or Azure. You should be able to find the API in the provider's documentation.

6. To see the script include for a CAPI Method Mapper:
   a) Click the gear icon (⚙️) on the CAPI Method Mappers related list, add the Request Script field to the Selected column, and then click OK.

   The MID Server script includes now appear in the list of method mappers.

   b) Click the name of a script to view the script include.
   
   In this example, the `CreateNode` operation uses the `azure-compute-1.0-CreateNode` script include.
That script include contains the following code:

```javascript
createNode();
function createNode()
{
    var acp = new AzureComputeVirtualMachine(this.parameters,
        this.headers);
    //this passes the parameters and headers into the
    AzureComputeVirtualMachine script include.
    var vm = acp.createVirtualMachine();

    return vm;
}
```

Notice that the code calls the `AzureComputeVirtualMachine` script include, which is available by default with the Cloud Management application. It contains all the API calls to Azure against virtual machines.

7. Create an API config override to pass the necessary credential information to the cloud provider. You also need to pass header information required by the cloud provider REST API.
API config overrides are necessary because credential data is not included when your instance makes the REST call to the cloud provider API.

Tip: If you do not know which API config overrides to create, look at a similar API that exists in CAPI, and use the same overrides. For example, if you are creating an API for something like AWS storage, look at other AWS APIs such as AWS Block Storage or AWS Compute.

a) In the API Config Override related list, click New.

b) Click the lookup icon and select an existing config parameter. Many useful parameters are provided by default, such as Identity, Credentials, and so on.

c) Enter an Override value.

You can set a static value, or you can pull a value from the system in the form of $(CloudCredential.attribute_name). The CloudCredential portion unlocks it from the credential store. The attribute_name portion is an attribute that depends on the particular credential or alias or endpoint URL that you are trying to retrieve.

If you navigate to Connections and Credentials > Credentials and open your AWS credential, you can right-click the Access Key ID field and see the name of the column in the Credentials table where the access key is stored. In this case, the access key is stored in the access_key column. So your Override value should be $(CloudCredential.access_key).
8. If you need to create a configuration parameter to use in the API Config Override, follow this procedure:
   a) On the API Config Override form, click the lookup icon in the **Config Parameter** field.
   b) Click **New** on the Configuration Parameter window and then fill in the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config parameter name</td>
<td>Enter a descriptive name.</td>
</tr>
<tr>
<td>Default value</td>
<td>Set an optional default value.</td>
</tr>
<tr>
<td>Endpoint</td>
<td>This field is read only.</td>
</tr>
<tr>
<td>Description</td>
<td>Enter a helpful description.</td>
</tr>
<tr>
<td>Config data type</td>
<td>Select the type of data:</td>
</tr>
<tr>
<td></td>
<td>· String</td>
</tr>
<tr>
<td></td>
<td>· DateTime</td>
</tr>
<tr>
<td></td>
<td>· Date</td>
</tr>
<tr>
<td></td>
<td>· Long</td>
</tr>
<tr>
<td></td>
<td>· Password</td>
</tr>
<tr>
<td></td>
<td>· Boolean</td>
</tr>
<tr>
<td>Config type</td>
<td>Select the type of configuration:</td>
</tr>
<tr>
<td></td>
<td>· Header: Use this value to pass the override values as headers. If your have a MID Server script include as part of your API and it uses <code>this.headers</code> as a parameter, the override values are passed to the provider API.</td>
</tr>
<tr>
<td></td>
<td>· Config</td>
</tr>
<tr>
<td></td>
<td>· URI Config</td>
</tr>
</tbody>
</table>

9. If necessary, modify the script includes that execute the operations against the cloud provider API:
   a) On the Cloud API form, in the CAPI Method Mappers related list, click the information icon ( ) next to the CAPI interface operation. Do not click the CAPI Interface Operation name itself.
   b) Click **Open Record**.
   c) On the operation form, you can modify the following field values:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Endpoint operation</td>
<td>Keep the default <code>Execute Script</code> endpoint operation.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Supported in version</td>
<td>You typically do not need to change this value. Change the <strong>Supported in</strong> version to use the method mapper in a different version of the API. By default, the method mappers are set to the same version number as the API they belong to.</td>
</tr>
</tbody>
</table>

**d)**

In the **Request Script** field, click the information icon ( información icon ( ) next to the placeholder MID Server script include to modify it.

**e)** On the script include form, create your script.

The following example JavaScript lists Azure load balancers. Note the helpful comments:

```javascript
getResourceInfo();

function getResourceInfo() {
  var anpi = new AzureLoadBalancer(this.parameters, this.headers);

  //this calls the 'AzureLoadBalancer' MID Server script include, which in turn
  //calls the 'AzureCloudAPIBase' script include, both of which
  //are already in your instance by default.
  //The 'AzureCloudBase' script include runs a query for
  //resources of a given type in a
  //specified region.

  var items = anpi.listResourcesByRegionOrIDs();
  //This function is in the 'AzureCloudAPIBase' script include. It calls the Azure API.

  return items;
}
```

The overrides provided for this operation are what Azure needs to find the load balancers: the Client ID, Tenant ID, the Secret Key, and the Endpoint URL:
For other examples of MID Server script includes that you can use in CAPI APIs, see Sample scripts for Cloud API interface operations and Sample script includes for Google Cloud Platform.

**Note:** For the Google Cloud integration example, a MID Server JAR file is also needed.

f) Click **Submit**.

g) Modify the script include for each operation.

### Cloud User Portal

The Cloud User Portal gives you immediate access to all day-to-day cloud activities.

**Cloud User Portal**

Use the Cloud User Portal to perform the following actions:

- Monitor your quota, costs, budget, life cycle events, stack health, and requests.
- Request stacks from the service catalog and track requests.
- Request life cycle operations for stacks and resources (for example, stop, start, or deprovision).
- Create and track incidents.
Using the `Overview` page

</tr>
<tr>
<td>Stacks</td>
<td>Lists all stacks that are assigned to you. Select a catalog item to view the stacks that the item launches. Click a stack to view details—all resources, resource properties, activities, and life cycle operations. See <a href="#">Manage a stack</a>.</td>
</tr>
<tr>
<td>Resources</td>
<td>Lists individual resources of the provisioned stacks that are assigned to you, regardless of who requested the stack. See <a href="#">Manage a resource</a>.</td>
</tr>
<tr>
<td>Activities</td>
<td>Stack requests, change requests, cloud life cycle events (if configured), and incidents that are associated with your stacks and resources. SSH keys that you created or that were generated for you. See <a href="#">View Activities</a>.</td>
</tr>
<tr>
<td>Dashboard</td>
<td>Provides insight on cloud costs and usage. See <a href="#">Cloud Management user dashboards</a>.</td>
</tr>
</tbody>
</table>

**Cloud Management user dashboards**

The **Dashboard** tab provides insight on cloud costs and usage. Select the dashboard to view from the list.
Cost Trend
Trend lines showing the daily costs of the user's resources in each Service Category (or other selected grouping) over the filtered time frame.

Cost Aggregate
Chart showing the division of the user's total resource usage cost between Service Categories (or another selected grouping) over the filtered time frame.

Cloud Tag Values dashboard
Tagged Resources
Set of tagged resources owned by the logged-in user, grouped by resource type.
Assigned Tag Values

Division of assigned tag values among the resources for a selected tag name ("Stack" by default).

**Search the Cloud User Portal**

The Search page returns search results and provides filters that help you to zoom in on the results.

Role required: sn_cmp.cloud_service_user

1. On any portal page, enter text in the **Search** text box and press **Return**.
2. To filter the search results on the **Cloud Search** page, click a category.

   In this example, only **Stacks** that include the search text **s** appear in the **Search results** list:
Launch a stack

Launching a stack of cloud resources means submitting a request for an item in the service catalog. You can launch a stack from the Cloud User Portal overview page.

Role required: sn_cmp.cloud_service_user
When you submit a request for an item in the service catalog, the system typically provisions the stack immediately. Sometimes, your request must be approved first.

If a resource on a stack that you request requires credentials when being accessed via SSH, then you must create an SSH key pair before you can launch the stack. See Create an SSH key and Download an SSH key.

1. Open the request form using either of the following methods:
   - On the overview page, click Launch a Stack. By default, all catalog items in all service categories are listed. Select a Service Category, and then click a catalog item Name.
   - Open the Catalog page. By default, all catalog items in all service categories are listed. Select a Service Category and then click Launch on the catalog item.

2. In each section of the form, enter the values that configure your request. The form fields differ for each catalog offering. Contact your Cloud Management administrator if you have any questions about the fields.

3. Click the section header to move to the next section.
   The remaining quota is updated based on the user group that you select. For mandatory fields, the system selects the first item in the list by default and you can select any value that you need.

4. Click Submit to request the stack.
   - The Activities page opens to the Status tab on the Track > Requests activity. The tab displays the progress and status of the request. The following color codes show the stage of the request:
     - Green: Completed or Approved.
     - Orange: Processing.
     - Red: Rejected, Error, or Canceled.
   - If approval is required, then when the administrator approves your request, the system launches the stack and updates the Request Status.
   - Select another request to view its Request Status and Stack Status.
   - To view a summary of all your pending requests, click the Pending Requests link in the title bar at any time.
<table>
<thead>
<tr>

Track a stack request
The system generates a request when you submit the form to launch a stack.

Role required: sn_cmp.cloud_service_user
If no approval policy is defined, requests are auto-approved. If a policy is defined, then a user on the approver list must approve the request.

1. Go to the Activities page or navigate to Overview > View Activities, then select Track > Requests.
The following color codes show you the status of the request:
- Green: Completed or Approved.
- Orange: Processing.
- Red: Rejected, Error, or Canceled.

2. In the Requests list, click an entry.

| Status tab | Request Status | Actions taken on the request. Click the down-arrow (▼) to toggle between:
| --- | --- | --- |
|  |  | •Verbose mode that describes each action and the status of the action
|  |  | •Icon-only mode that indicates only the status (pass/fail) of an action.

| Status tab | Stack Status | Status of each stack request. If deployment fails, errors from cloud orchestration are listed.
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

| Comments / Work Notes tab | Item requested and request number | Log of comments and notes made for the request. The itil role is required to add a comment or work note.
To add a comment or work note:
1. Enter text.
2. Select the Work notes check box to add a work note.
3. Click Send.

| Request Details tab | Values that the requester submitted on the stack request form.

| Tasks tab | Lists all the catalog tasks created for stacks that failed to provision. Click on a catalog task to view more details about that task. See Resubmit a failed stack request.

Resubmit a failed stack request
The Cloud Management application creates a remediation or a catalog task when a request for a stack fails to provision. You can resubmit the failed request or assign it to the Cloud Operator group to handle it for you.

Roles required: sn_cmp.cloud_service_user and sn_cmp.cloud_operator.
Task remediation captures every remediation applied to a failed request. You can view the remediation carried out for a failed request and all the major milestones in the Comments/Work Notes sub tab in the Cloud User Portal. Task remediation is available only for new provisioning of stacks and not for life cycle or any other operation.
A stack may fail to provision for many reasons. A stack may fail if you have exceeded your cloud quota, datacenter capacity, or have entered an invalid parameter in the request form (such as a duplicate NIC).

If a stack fails to provision, a catalog task is created and assigned to you. An error message pertaining to the failed request is displayed in the Status sub tab in the Cloud User Portal.

1. In the Cloud User Portal, navigate to **View Activities > Requests > Tasks**.
2. Click the catalog task to resubmit.
3. Based on your preference, select an action:
   - **Retry**: Resubmits the failed request. You can try to resubmit the failed request by resolving the error if possible. If the error is due to exceeding the quota limit, you can try to deprovision some resources that are not currently in use and then click **Retry**. When you click **Retry**, the original request is resubmitted. A new request is not created.
     - **Note**: Any policy associated with a resource operation is re-executed.
   - **Ask for Help**: Creates a new catalog task and assigns it to the Cloud Operator group to resubmit the failed request. The Cloud Operator group can look more closely into the error and try to resolve it for you. Every time the comments or work notes in the catalog task gets updated by the Cloud Operator group, the changes are reflected in the **Comments/Work Notes** sub tab in the Cloud User Portal. If necessary, the operator can cancel the failed request.
   - **Cancel Order**: Cancels the failed request and deprovisions all partially-provisioned resources.

Manage a stack

Use the Stack Details page to view details and status for a stack and to perform life cycle operations on a stack.

Role required: sn_cmp.cloud_service_user

1. Use one of the following methods to open the **Stack Details** page:
   - Click **Stacks** on the toolbar.
   - Use the **Search** text box to search for the stack.
   - On the home page, click a stack in the **Recent Stacks**, or the **Stack Health** section.
   - On the home page, click **Manage Stacks**.

By default, all stacks in all service categories are listed.

2. In the **Stacks** list, select a stack category, and then click a stack **Name**.
   The **Stack Details** page displays the following information:
• Breadcrumb navigation
Name of the stack. Click View Dependency to view the dependency map for the stack, Manage Stack to view the resources, properties, and activities of the stack, and the Track Operations to view the list of lifecycle operations performed on the stack and its resources.

Status information
List of all resources in the stack. Click a resource to view details in the Properties section. Color codes indicate status of the stack:
- Green: On/Active.
- Yellow: Turned off or Processing.
- Red: Terminated or Error.

List of the stack properties. Some properties are set in the stack request form and others are set by policy.

Activities associated with the stack. Click a tab to view:
- Change requests that are associated with the stack. See Track a change request.
- Incidents that were raised for the stack. See Submit an incident for a stack and Track an incident.
- Cloud events that are associated with the stack. Cloud Events appears only when a resource is selected. See View cloud events.
- Catalog tasks associated with the stack. See Resubmit a failed stack request.
- Upcoming business hours schedule operations associated with the stack. You can skip an upcoming operation or cancel a schedule associated with the stack. See Modify business schedule operations for a stack.

Operations you can perform on a stack. See Perform a life-cycle operation on a stack or resource.

Text box used to search the Cloud User Portal for stacks, resources based on types, stack requests, change requests, incidents, keys, and catalog items.

### Stack properties

<table>

Manage a resource
Use the Resource Details page to view details and status for a resource and to perform life cycle operations on a resource.

Role required: sn_cmp.cloud_service_user

1. Click Resources on the toolbar.
   The Resources page lists all resource types in the left pane.
| Name            | Status | State  | Assigned to        | Assignment group             | Owned by  | CPUs | GBs | Memory (MB) | Network adapters | Object ID         | Terminated On | Terminated | |
|-----------------|--------|--------|--------------------|------------------------------|-----------|------|-----|-------------|------------------|------------------|----------------|-------------|
| AWS Datacenter  |        |        |                    |                              |           |      |     |             |                  |                  |                |             | |
| Virtual Machine Instance |    |        |                    |                              |           |      |     |             |                  |                  |                |             | |
| Load Balancer   |        |        |                    |                              |           |      |     |             |                  |                  |                |             | |
| Cloud Load Balancer |    |        |                    |                              |           |      |     |             |                  |                  |                |             | |
| Network         |        |        |                    |                              |           |      |     |             |                  |                  |                |             | |
| Cloud Subnet    |        |        |                    |                              |           |      |     |             |                  |                  |                |             | |
| Compute Security Group |  |        |                    |                              |           |      |     |             |                  |                  |                |             | |
| Internet Gateway |      |        |                    |                              |           |      |     |             |                  |                  |                |             | |
| Cloud Network   |        |        |                    |                              |           |      |     |             |                  |                  |                |             | |
| Storage         |        |        |                    |                              |           |      |     |             |                  |                  |                |             | |
| 1               | Terminated |        | System Administrator | Team Development Code Reviewers |           | 1    | 1   | 627         |                  | 03b7e6c60087760c6 | False          | False      | |
| 2               | Terminated |        | System Administrator | Team Development Code Reviewers |           | 1    | 1   | 627         |                  | 03b7e6c60087760c6 | False          | False      | |
| 3               | Terminated |        | System Administrator | Team Development Code Reviewers |           | 0    | 1   | 628         |                  | 03b7e6c60087760c6 | False          | False      | |
| 4               | Terminated |        | System Administrator | Team Development Code Reviewers |           | 1    | 1   | 627         |                  | 03b7e6c60087760c6 | False          | False      | |
| 5               | Terminated |        | System Administrator | Team Development Code Reviewers |           | 0    | 1   | 628         |                  | 03b7e6c60087760c6 | False          | False      | |
| 6               | Terminated |        | System Administrator | Team Development Code Reviewers |           | 1    | 1   | 627         |                  | 03b7e6c60087760c6 | False          | False      | |
| 7               | Terminated |        | System Administrator | Team Development Code Reviewers |           | 0    | 1   | 628         |                  | 03b7e6c60087760c6 | False          | False      | |
| 8               | Terminated |        | System Administrator | Team Development Code Reviewers |           | 1    | 1   | 627         |                  | 03b7e6c60087760c6 | False          | False      | |
| 9               | Terminated |        | System Administrator | Team Development Code Reviewers |           | 0    | 1   | 628         |                  | 03b7e6c60087760c6 | False          | False      | |
| 10              | Terminated |        | System Administrator | Team Development Code Reviewers |           | 1    | 1   | 627         |                  | 03b7e6c60087760c6 | False          | False      | |
2. Navigate to the appropriate resource type to see the list of resources that you are interested in and then click a resource name to view specific details about that resource.
The resource details screen contains the following information:

- Breadcrumb navigation
- All properties specific to the resource
- Activities associated with the resource. Click a tab to view:
  - Change requests that are associated with the resource. See Track a change request.
  - Incidents that were raised for the resource. See Submit an incident for a stack and Track an incident.
  - Cloud events that happened to the resource. See View cloud events.
- Text box used to search the Cloud User Portal for stacks, resources based on types, stack requests, change requests, incidents, keys, and catalog items.

**Perform a life-cycle operation on a stack or resource**

Operations like Start/Stop, Deprovision, and ExecuteScript are called life-cycle operations or day-2 operations. When you request a life-cycle operation on a stack or resource, the system generates a change request. An approval policy specifies either that the change is auto-approved or that a user on the approver list must approve the change.

Life-cycle operations require the user with sn_cmp.cloud_service_user role who owns the resource. A user with the root_admin, admin, or sn_cmp.cloud_admin role can also perform the operation.

- As noted in the descriptions, not all operations are supported for all providers or for all service categories (resource types).
- All other configuration management providers: If a stack or resource requires login, then you must download the associated SSH key before you can access the resource. See Download an SSH key.

1. Select a stack or resource.
2. While viewing the Stack Details page, select the operation from the Select Stack Operation or Select Resource Operation list.
   
   For full descriptions of the operations, see Life-cycle operations in Cloud Management.
3. Some operations require settings (for example, the name of a script or new schedule settings). Enter the settings and then click OK.
   
   The system submits a change request and the Activities > Change Requests page displays the progress and status of the request.

**Life-cycle operations in Cloud Management**

Operations like Start/Stop, Deprovision, and ExecuteScript are called life-cycle operations or day-2 operations. When you request a life-cycle operation on a stack or resource, the system generates a change request. An approval policy specifies either that the change is auto-approved or that a user on the approver list must approve the change.

To perform an operation, you select a stack or resource and then click Select Stack Operation or Select Resource Operation. The list includes only appropriate operations for the selected resource or stack. Some operations are provided by configuration management systems like Ansible or Terraform.

**Operations in the base system**

**Start**

The Start operation starts selected VM. The resource status changes to On.
No setting is required.

**Stop**

The Stop operation stops the selected VM. The resource status changes to Off.

No setting is required.

**Deprovision**

The Deprovision operation terminates the selected stack and sends a notification to the stack owner.

No setting is required.

**Virtual Machine 'Store Extension Interface' operations**

The Virtual Machine Store Extension Interface operations are supported by Google Cloud Platform and IBM Cloud only. The Terraform Connector ServiceNow Store app supplies the operations.

**Virtual Machine Store Extension Interface.ExecuteScript**

The ExecuteScript operation runs a script on the selected Windows or Linux VM. For example, a script might install an application on a resource. See KB0756431 for detailed instructions.

*Note: To run the ExecuteScript operation, a VM must include credentials. Linux VMs inherit management key credentials when they are provisioned. For Windows VMs, use the InfuseKey operation to add credentials to the VM.*

In the popup, specify:

- **ScriptType**: Shell and PowerShell scripts are supported.
- **Script**: Name of the script.

**Virtual Machine Store Extension Interface.InfuseKey**

For Windows VMs, the InfuseKey operation adds key credentials (public and private key pair values) to the VM.

As a result, you can view the credentials on the Properties list of the Windows VM and can use the credentials to perform VM operations. For instructions on generating a key, see Create an SSH key.

To add key credentials to a Windows VM:

1. Select the Windows VM.
2. In the Select Resource Operation list, select Virtual Machine Store Extension Interface.InfuseKey.
3. In the popup, specify the key to use in the UserKey field and then click OK.

**Virtual Machine Store Extension Interface.Execute Job Template**

Ansible supplies the Execute Job Template operation. The operation enables you to attach a node to an Ansible server and execute a package on that VME. For example, a script might install an application on a resource. In the popup, specify:

- **WorkloadConfigProviderType**
<table>
<thead>
<tr>
<th>WorkloadConfigProvider</th>
<th>Inventory</th>
</tr>
</thead>
<tbody>
<tr>
<td>HostGroup</td>
<td>The list includes all possible applications (called <em>groups</em> in Ansible), not just the applications that the configuration management provider supports. Therefore, if users select an unsupported application, the provisioning fails.</td>
</tr>
<tr>
<td>ApplicationProfile</td>
<td>Select the application profile to execute on the selected resource.</td>
</tr>
</tbody>
</table>

- **ScriptType**: For Google Cloud Platform, **Shell** is supported.
- **Script**: Name of the script.

**Virtual Machine Store Extension Interface: Resize**

The *Resize* operation changes the *Size* setting for a VM (called **HardwareType** in the CI definition). In the popup, specify the new size in the **HardwareType** field.
‘Compute Security Group Store Extension Interface’ operations

The Compute Security Group Store Extension Interface operations are supported for IBM Cloud only. The Terraform ServiceNow Store app supplies the operations.

Compute Security Group Store Extension Interface.Deprovision

The Deprovision operation terminates the selected compute security group resource and sends a notification to the owner.

No setting is required.

The Status of the network interface changes to Terminated. In the Stack Health section of the home page, the status of the stack indicates that some resources are down.
'Load Balancer Store Extension Interface' operations

**Load Balancer Store Extension Interface.Deprovision**

The **Deprovision** operation terminates the selected load balancer and sends a notification to the stack owner.

No setting is required.

The **Status** of the load balancer changes to **Terminated**. In the Stack Health section of the home page, the status of the stack indicates that some resources are down.

'Network Store Extension Interface' operations

'Network Store Extension Interface.Deprovision'

The **Deprovision** operation terminates the selected network store and sends a notification to the stack owner.

No setting is required.

The **Status** of the network store changes to **Terminated**. In the Stack Health section of the home page, the status of the stack indicates that some resources are down.

'Storage Volume Store Extension Interface' operations

The **Storage Volume Store Extension Interface** operations are supported for IBM Cloud only. The Terraform ServiceNow Store app supplies the operations.

**Storage Volume Store Extension Interface.Create Snapshot**

The **Create Snapshot** operation generates a read-only copy of the specified volume.

In the popup, specify the **SnapshotName** to use as the label for the snapshot.

The snapshot is saved in the **(cmdbc.ci_storage_vol_snapshot_list)** table.

If approval is not required, the system immediately takes the snapshot. If approval is required, there may be a delay while an admin approves the change. You receive email when the admin approves. After the admin approves, return to the VM Instance form and click the **Proceed with Change** related link.

**Note:** If the VM is running, the VM is shut down at the start of the snapshot process and then restarted when the process finishes. The system auto-deletes the oldest snapshot when the **Snapshot eviction policy** limit is exceeded.

**Storage Volume Store Extension Interface.Restore From Snapshot**

The **Restore From Snapshot** operation restores the image from the specified snapshot.

Select the **SnapshotID** to use to restore the volume.

**Storage Volume Store Extension Interface.Delete Snapshot**

The **Delete Snapshot** operation deletes the selected snapshot.

**Storage Volume Store Extension Interface.Attach**

The **Attach** operation attaches a VM to the selected volume.
1. Select the volume to attach. The **Status** of the volume must be **Available**.

2. Select the **Storage Volume Store Extension Interface.Attach** operation.

3. In the **NodeId** field on the popup, select the **Instance ID** of the server to attach to the volume.

   The status of the volume changes from Available to In Use.

---

**Storage Volume Store Extension Interface.Detach**

The **Detach** operation detaches a VM from the selected volume.

1. Select the volume to attach. The **Status** of the volume must be **In Use**.

2. Select the **Storage Volume Store Extension Interface.Detach** operation.

3. In the **NodeId** field on the popup, select the **Instance ID** of the host to detach from the volume.

   If this VM is the last or the only VM that is detached, then the status of the volume changes from In Use to Available.

---

**Storage Volume Store Extension Interface.Deprovision**

The **Deprovision** operation terminates the selected volume and sends a notification to the stack owner.

No setting is required.

- The billing item for the storage resource is removed.
- The **Status** of the volume changes to **Terminated**. In the Stack Health section of the home page, the status of the stack indicates that some resources are down.
- For IBM Cloud: The storage volume is available in the IBM Cloud Console for an extended period to enable the user to reclaim the storage volume.

---

**Submit an incident for a stack**

Submit an incident for a stack when it is not working as expected or you have questions. When the user responds or solves the issue, the incident is closed.

**Role required:** sn_cmp.cloud_service_user

You can submit an incident for a stack or for an individual resource.

You can also submit an incident through the **Incident application**. Make sure that the **Category** field is set to the value **Cloud Management**. The configuration item should be the stack name against which the incident should be raised and the caller name should be the name of the person for whom this incident is created.

1. View the stack details page using either of the following methods:

   - On the **Stack Details** page, click the **Incidents** tab in the **Activities** section.
   - On the **Activities** page, click **Track > Incidents**.

   The **Activities** section lists all submitted incidents for the stack.

---

| Activities # Incidents | View and submit incidents of all types, for any stack or resource. |
2. Click **New Incident** and fill in the form:

<table>
<thead>
<tr>
<th>Incident type</th>
<th>Type that best matches your need.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stack / Resource (related fields)</td>
<td>Stack and resource that the incident applies to.</td>
</tr>
<tr>
<td></td>
<td>From the Activities page: Select the Stack from the list of active stacks. Leave the Resource field blank if the issue is not associated with a particular resource.</td>
</tr>
<tr>
<td></td>
<td>From the Stack Details page: The Stack value is the current stack.</td>
</tr>
<tr>
<td></td>
<td>From the Resource page: The Resource value is the current resource.</td>
</tr>
<tr>
<td>Describe the issue</td>
<td>Describe the issue that you are experiencing or enter your question. Give full information on the behavior that is the issue.</td>
</tr>
<tr>
<td>What is the business impact</td>
<td>Specify how the incident affects your work and the work of others, including your customers.</td>
</tr>
<tr>
<td>Attach screenshots, logs, and so on</td>
<td>Click or drop to add files that clarify the issue or question.</td>
</tr>
</tbody>
</table>

3. Click **Submit**.

The system generates the incident. The **Incidents** tab on the **Activities** page displays a summary.

To view a list of all submitted incidents, navigate to **Activities > Incidents**.

**Using the Activities page**

Use the Activities page to view and manage details of your cloud actions.
Tasks
Catalog tasks created when a request for a stack fails to provision. See Resubmit a failed stack request.

Lease Operations
View a list of all your stacks that are nearing their lease end dates. You can extend the end date of a lease for any of the stacks listed. See Modify the lease for a stack.

Business Schedule Operations
View a list of upcoming business hours schedule operations associated with stacks. You can skip an upcoming operation or cancel a schedule associated with a particular stack. See Modify business schedule operations for a stack.

Monitor
Cloud Events
List of life cycle events that affect resources assigned to you or to a user in your group. See View cloud events.

Manage
Keys
View existing SSH keys that are assigned to you or generate a key. See Create an SSH key.

Track a change request
The system generates a change request when you perform a life cycle operation on a stack or resource.

Role required: sn_cmp.cloud_service_user

Each change request is either approved by default or, if an approval policy is in place, is approved by a user that is on the approver list.

1. Go to the Activities page or navigate to Overview > View Activities, then select Track > Change Requests.

<table>
<thead>
<tr>
<th>Number</th>
<th>Unique auto-generated number.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Config item</td>
<td>The affected CI.</td>
</tr>
<tr>
<td>Category</td>
<td>Cloud Management</td>
</tr>
<tr>
<td>Short description</td>
<td>Text that was entered by the requester.</td>
</tr>
<tr>
<td>Approval</td>
<td>Status.</td>
</tr>
</tbody>
</table>

2. In the Change Requests list, click an entry to view full details.

Track an incident
Before an incident is resolved and closed, you can view the state of the incident.

Role required: sn_cmp.cloud_service_user

1. View the Incidents page using either of the following methods:
   - On the Activities page, click Track > Incidents.
   - On the Stack Details page, click the Incidents tab in the Activities section.

   The Activities section lists all submitted incidents for the stack.

2. In the Incidents list, click an entry to view details.

<table>
<thead>
<tr>
<th>Number</th>
<th>Unique auto-generated number.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Category</td>
<td>Cloud Management.</td>
</tr>
</tbody>
</table>
View cloud events
You can view the events that are generated from your cloud resources if your administrator configured Cloud Management to monitor them. All events are listed on the Cloud Events tab on the stack details page.

Role required: sn_cmp.cloud_service_user

1. View the cloud events page using either of the following methods:
   - On the Activities page, click Monitor > Cloud Events.
   - On the Stack Details page, click the Cloud Events tab in the Activities section.

The Cloud Events section lists all events for the stack.

<table>
<thead>
<tr>
<th>Created</th>
<th>Timestamp of the arrival of the event.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source</td>
<td>Source of the event:</td>
</tr>
<tr>
<td>Event name</td>
<td>Name that is provided by Amazon, Azure, or VMware.</td>
</tr>
<tr>
<td>Subject</td>
<td>Text that describes the event.</td>
</tr>
<tr>
<td>Event time</td>
<td>Timestamp of the event.</td>
</tr>
<tr>
<td>Resource ID</td>
<td>Unique ID of the resource that received the life cycle state change or configuration change event.</td>
</tr>
</tbody>
</table>

2. Click an entry to view full details.

Create an SSH key
A stack might include a virtual machine that requires an SSH key for access. To request such a stack, you can either use a key pair that is assigned to you or you can generate another key.
Role required: sn_cmp.cloud_service_user

1. On the Cloud User Portal, click Activities.
2. In the Activities list, select Manage > Keys.
3. In the SSH Key Pair list, click Generate Key Pair, specify a Name for the key, and then click OK.

The system generates the key pair with the Name that you specified.

Download an SSH key
If a resource on a stack requires login, then you must download the associated SSH key before you can access the resource.

Role required: sn_cmp.cloud_service_user

1. On the Cloud User Portal, click Activities.
2. In the Activities list, select Manage > Keys.
3. Click a key in the SSH Key Pair list and then click Download Private Key in the SSH private key section.

Business hour scheduling
You can set up business hour scheduling on all virtual machines in a stack. Business hour scheduling can be set up on stacks at the time of provisioning or on existing stacks.

Schedules can be set for when a stack should be started, stopped, and/or deprovisioned by defining parameters such as business hours, holidays, long weekends.

The administrator can create schedule profiles in the Cloud Admin Portal. See Resource profiles.

While provisioning a stack in the Cloud User Portal, use the Schedule Profile list to select a profile that has already been created by the administrator. Select a time zone in the Schedule Time Zone list which defaults to your system's time zone and indicates the time zone in which the schedule's business hour time frames is enforced.

You can also define the lease end dates for a stack during provision. The lease end date for a stack can be modified at any time. See Modify the lease for a stack.

Once you provision a stack with a schedule and/or lease dates, a series of operations (start, stop, deprovision) occur at the appropriate time set by you. You can skip a business schedule operation or cancel the business schedule operations associated with a stack. See Modify business schedule operations for a stack.

Modify the lease for a stack
When a stack reaches the end of its lease, the system notifies the stack owner and deprovisions the stack. You can modify the lease for a stack before it approaches its end date.

Role required: sn_cmp.cloud_service_user

A lease end date is assigned to all provisioned stacks. A built-in policy titled Lease End ServiceNow with an on Lease end policy trigger has rules defining notifications and operations that are performed before, at, and after the end date of the lease. Lease dates can be modified for active stacks. The system sends a notification to the stack owner one day prior to the end of the lease. On the day the lease ends, the system stops the stack and sends another notification. Seven days after the lease has ended, the stack is terminated and a final notification is sent to the stack owner. You can modify the actions taken and the timings of these actions by modifying the Lease End ServiceNow policy. You can modify the default lease duration for all new stacks, going forward, by modifying the associated action script in the Scheduling Defaults built-in policy.

1. Navigate to Overview > View Activities, then select Lease Operations.
   A list of stacks with upcoming lease-related operations is displayed.
2. Click the Select Action list associated with the stack and then select Modify Lease.
   The Modify Lease option is also available from the stack details list in Manage Stacks.
3. Set a new date and time for the lease to expire and then click OK.

Modify business schedule operations for a stack
Business hours scheduling can be performed on stacks at the time of provisioning or on existing stacks.

Role required: sn_cmp.cloud_service_user.

Once a stack is set up with a business schedule, the system generates a series of tasks for starting and stopping the stack. You can view these tasks and can modify the business schedule for any stack.

1. Navigate to Overview > View Activities, then select Business Schedule Operations. A list of stacks with upcoming business schedule operations is displayed.
2. From the Select Action list associated with the stack, perform either of the two operations:
   - Skip Operation- Click to skip a single business schedule operation on a stack. A confirmation message appears. Click OK.
   - Cancel Schedule- Click to cancel business hour scheduling on a stack. A confirmation message appears. Click OK.

For modifying the schedule of an existing stack, navigate to the stacks details list in Manage Stacks and select Modify Schedule from the Select Stack Operation list.

Manage personal and group resources

You can view and manage your resources as well as the resources assigned to the group you belong to. If you belong to more than one group, you can view and manage all resources assigned to those groups.

Role required: sn_cmp.cloud_group_admin

1. On the Cloud User Portal, click the Views filter.
2. Select an option:
   - Mine: View and manage only resources that are assigned to you.
   - My Groups: View and manage all resources that are assigned to you and that are assigned to all members of all groups that you belong to.

Only the Root Admin and the Sys Admin have access to all three filters: Mine, My Groups, and All.

Cloud Management troubleshooting

There are several methods to troubleshoot issues with Discovery and the management of cloud resources.

Schemas of Cloud Management tables

The tables are cloud-agnostic and can therefore hold data for any cloud provider.

Load balancer table

The load balancer table (cmdb_ci_cloud_load_balancer) extends from (cmdb_ci_vm_object), which extends from (cmdb_ci). Click to enlarge the image.
Key native attributes of the cmdb_ci_cloud_load_balancer table

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_id</td>
<td>Identifier that typically holds the load balancer name as the value.</td>
</tr>
<tr>
<td>canonical_hosted_zone_id</td>
<td>ID of the Amazon Route 53 hosted zone for the load balancer.</td>
</tr>
<tr>
<td>canonical_hosted_zone_name</td>
<td>DNS name of the load balancer.</td>
</tr>
<tr>
<td>dns_name</td>
<td>Public DNS name of the load balancer.</td>
</tr>
<tr>
<td>fqdn</td>
<td>DNS name as fully qualified domain name. Can also be a CNAME record pointed to the DNS name.</td>
</tr>
<tr>
<td>state</td>
<td>State of the load balancer: available or terminated.</td>
</tr>
</tbody>
</table>

Network resource table

The network resource table (cmdb_ci_network) extends from (cmdb_ci_vcenter_object), which extends from (cmdb_ci_vm_object), which extends from (cmdb_ci). Click to enlarge the image.
**Key native attributes of the cmdb_ci_network table**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_id</td>
<td>Identifier that typically holds the network ID as the value. Uniquely identifies an object within a cloud.</td>
</tr>
<tr>
<td>name</td>
<td>Name of the network.</td>
</tr>
<tr>
<td>cidr</td>
<td>IP Address range. Classless inter-domain routing is a set of internet protocol standards that is used to create unique identifiers for networks.</td>
</tr>
<tr>
<td>default_gateway</td>
<td>Holds InternetGatewayID if we attach InternetGateway to the network. A default gateway serves as an access point or IP router that a networked computer uses to send information to a computer in another network or Internet. The specified gateway is used by default unless an application specifies a different gateway.</td>
</tr>
<tr>
<td>Broadcast_address</td>
<td>IP address used to transmit messages and data packets to network systems.</td>
</tr>
<tr>
<td>Is_shared</td>
<td>Boolean. true: Network shared across other projects. false: Network not shared across other projects.</td>
</tr>
<tr>
<td>max_ports</td>
<td>Maximum number of hosts that can be connected to the network.</td>
</tr>
<tr>
<td>Is_external</td>
<td>Boolean. true: Network is external. false: Network is internal.</td>
</tr>
<tr>
<td>terminated_on</td>
<td>Time that the network was de-provisioned.</td>
</tr>
<tr>
<td>state</td>
<td>State of the network: <strong>available</strong> or <strong>terminated</strong>.</td>
</tr>
<tr>
<td>netmask</td>
<td>Type of CIDR. 32-bit mask that divides an IP address into subnets and specify the hosts that are available on the network.</td>
</tr>
<tr>
<td>dhcp_enabled</td>
<td>Boolean. true: Dynamic IP address is assigned to host false: Static IP address is assigned to host</td>
</tr>
</tbody>
</table>

**Storage volume resource table**

The storage volume resource table (cmdb_ci_storage_volume) extends from (cmdb_ci). Click to enlarge the image.
Key native attributes of the cmdb_ci_storage_volume table

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_id</td>
<td>Identifier that typically holds the object ID as the value. Uniquely identifies an object within a cloud.</td>
</tr>
<tr>
<td>volume_id</td>
<td>Identifier that typically holds the volume ID as the value. Uniquely identifies an object within a cloud.</td>
</tr>
<tr>
<td>volume_container</td>
<td>For NetApp only, LUN becomes the volume and NetApp volume becomes the volume container.</td>
</tr>
<tr>
<td>sharable</td>
<td>Boolean. true: Volume is shared by multiple VMs. false: Volume is not shared by multiple VMs.</td>
</tr>
<tr>
<td>storage_type</td>
<td>Type of storage. • AWS: Block • Azure: PageBlob • vSphere: VMware vdisk</td>
</tr>
<tr>
<td>size</td>
<td>Total capacity of the volume.</td>
</tr>
<tr>
<td>free_space</td>
<td>Available space of the volume</td>
</tr>
<tr>
<td>state</td>
<td>State of the volume: available or in_use.</td>
</tr>
<tr>
<td>share_count</td>
<td>Number of VMs that are shared by the volume.</td>
</tr>
</tbody>
</table>

Virtual server resource table

The virtual server resource table (cmdb_ci_vm_instance) extends from (cmdb_ci_vm_object), which extends from (cmdb_ci). Click to enlarge the image.
Key native attributes of the cmdb_ci_vm_instance table

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_id</td>
<td>Identifier that typically usually holds the VM instance ID. Uniquely identifies an object within a cloud.</td>
</tr>
<tr>
<td>name</td>
<td>Name of the VM.</td>
</tr>
<tr>
<td>state</td>
<td>State of the VML: on, off, or terminated.</td>
</tr>
<tr>
<td>cpus</td>
<td>Number of CPUs.</td>
</tr>
<tr>
<td>memory</td>
<td>Memory size in megabytes.</td>
</tr>
<tr>
<td>disks</td>
<td>Number of disk drives.</td>
</tr>
<tr>
<td>disk_size</td>
<td>Total size of disks in gigabytes.</td>
</tr>
<tr>
<td>nics</td>
<td>Number of network interface adapters.</td>
</tr>
<tr>
<td>terminated_on</td>
<td>Time that the instance was terminated.</td>
</tr>
<tr>
<td>termination_protection</td>
<td>Boolean. Default value is false. Can prevent the instance from being accidentally terminated using Amazon EC2. false: Cannot prevent the instance from being accidentally terminated using Amazon EC2.</td>
</tr>
</tbody>
</table>

Cloud Optimization: Cloud Insights application

The ServiceNow® Cloud Optimization: Cloud Insights application, available in the ServiceNow Store, helps you to analyze the full range of costs associated with cloud assets so you can identify and take action on opportunities to save money and optimize operations. Release 1.0 ad 1.1 support Amazon Web Services (AWS) only. Release 1.2 also supports Azure.S

Request apps on the Store

Upgrade Cloud Insights from release 1.0 to release 1.1

You upgrade Cloud Insights by upgrading each required app. Cloud Insights release 1.1 is supported on New York and Orlando platforms.

Role required: Cloud Insights Admin (sn_clin_core.insights_admin)

1. Navigate to System Applications > All Available Applications > All.
2. In the search box, enter *cloud.
3. Find Cloud Integrations Core.
   The selection list displays 1.0 (Installed).
4. In the selection list, select 1.1 and then click Upgrade.
5. Repeat the process to perform the upgrade for each application in exactly the following order:
   - Cloud Integrations AWS
   - Cloud Spend Reports Core
   - Cloud Spend Reports AWS
   - Cloud Insights Core
   - Cloud Insights AWS
   - Cloud Insights

6. Orlando instances only: Install the sn_itom_pattern application.

Cloud Insights release 1.1 is ready to use.

Cloud Insights setup guide
The Cloud Insights app is available on the ServiceNow Store.
Requirements and limitations

- You must have AWS Management Console administrator permissions to work in the AWS Management Console.
- The Cloud Insights app operates entirely independently of the Cloud Management application. The Cloud Management application is available as a separate subscription and requires the Cloud Management plugin (com.snc.cloud.mgmt).
- Cloud Insights is not supported on mobile devices.
- The Unassigned Resources, Business Hours Reports, and Rightsizing Recommendations features support only Amazon Elastic Compute Cloud (EC2) virtual machine (VM) instances.
- Values in reports might vary slightly from provider billing values due to currency conversion or rounding.
- Domain separation is not supported in this application. For more information, see Application support for domain separation.
## Setting up Cloud Insights

1. **Get the app.**
   - Get the Cloud Insights app from the ServiceNow Store.
   - **Do this:** Visit the ServiceNow Store website to get the Cloud Insights app and supporting apps.

2. **Activate plugins.**
3. **Assign roles.**
4. **Create credentials.**
5. **Configure MID Servers.**
6. **Discover your resources.**
7. **Schedule download jobs.**
8. **Set up insights features.**

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
<th>Do this</th>
</tr>
</thead>
</table>
| ![Activate all supporting plugins and applications.](image) | Activate all supporting plugins and applications. | For instructions, see:  
  - Request a plugin  
  - Activate a plugin |

When you first open the app, the home page shows the areas to configure. (After you configure the system, the page shows overview data and gives quick access to reports.)

Cloud Insights provides visibility, management, and governance for your cloud infrastructure and your business.

Follow the instructions in the table. The buttons on the Home page provide shortcuts to some setup activities:

- When you click the **Set up Discover Schedule** button in the Configure Accounts and Discovery section, the Discover Schedules form opens.
- When you click the **Set up Download Schedule** button in the Configure Billing section, the Billing Download Jobs form opens.
- When you click the **Set up Download Schedule** button in the Configure Price Sheets section, the Price Sheets Download Jobs form opens.

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td>![Checkmark]</td>
<td>Schedule and manage the jobs that download price sheets.</td>
<td></td>
</tr>
</tbody>
</table>

When you click the **Set up Download Schedule** button in the Configure Price Sheets section, the Price Sheets Download Jobs form opens. A Price Sheet Download job downloads and stores price sheet data. Rightsizing processes use price sheet data when generating rightsizing recommendations.

Configure the insights features:
- Rightsizing
- Business Hours
- Unassigned Resources

- A Business Hours job applies Business Hours policies to identify resources that are running when they should be powered off, reports them, and can start and stop them on the schedule that you specify. Running only during specified business hours can significantly reduce your cloud spend.
  - The Rightsizing feature analyzes resource usage to recommend better sizes for resources that are wasting money by being over-provisioned or underused. A confidence rating and predicted savings support each recommendation to rightszie a resource.
  - Unassigned Resources policies help you to identify the resources that are not associated with an assignment group and to assign them appropriately. When a resource is assigned to the correct group, the resource can be appropriately governed even as it goes through stages such as patching, upgrading, and reconfiguring.

- **Business Hours**: Ensuring resources run only when required
- **Rightsizing**: Implementing cost-effective sizing for resources
- **Identifying unassigned resources to ensure accurate reporting**

**Roles for Cloud Insights users**

You assign Cloud Insights roles to user groups and to individual users based on user activities and responsibilities.
## Role relationships in Cloud Insights

![Diagram showing role relationships in Cloud Insights]

<table>
<thead>
<tr>

<td>The role is in the Cloud Integrations Core plugin.&lt;br&gt;• Configure Billing Download jobs and Price Sheet Download jobs.&lt;br&gt;• All rights of the API Integrator role.&lt;br&gt;• All rights of the (flow_operator) role.&lt;br&gt;• All rights of the (discovery_admin) role.</td>
</tr>
</tbody>
</table>
Create the credentials that enable Cloud Insights to access your AWS data

To enable Discovery to access your AWS account, you create a programmatic user in the AWS Management Console. You specify the credentials of the user when you configure the MID Servers that communicate with your cloud provider.

You should be familiar with AWS policies. If you use IAM, you must know how to create an IAM user and set up a user policy. See the AWS documentation on IAM for details.

Roles required:
- On the AWS Management Console: AWS Management Console administrator
- Cloud Insights: admin or sn_cmp.cloud_admin

You create the credentials in the AWS Management Console and then create a record of them in Cloud Insights.

1. On the AWS Management Console, enter IAM in the AWS services search box to open the Identity and Access Managements (IAM) service.
2. On the IAM Resources portal, click Users.
3. Click Add user.
4. On the Details page, configure the user settings as shown and then click Next.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>User name</td>
<td>Name for the programmatic user, for example, servicenowcloud.</td>
</tr>
<tr>
<td>Access type</td>
<td>Programmatic access.</td>
</tr>
</tbody>
</table>

5. On the Permissions page, configure the following settings and then click Next.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set permissions for &lt;username&gt;</td>
<td>Attach existing policies directly.</td>
</tr>
</tbody>
</table>

ServiceNow    New York    IT Operations Management

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attach one or more policies</td>
<td>The appropriate policy.</td>
</tr>
</tbody>
</table>

**Note:** The AdministratorAccess policy has the most powerful permission level, including permission to provision cloud resources. The policy enables the same access that would be granted to the instance as if you were not using IAM and used your AWS account Access Key ID and Secret Access Key. You might instead prefer to create a policy or combine multiple policies to grant the appropriate permission level. See [Create an IAM user policy for Cloud Insights](#) for details.

6. On the Review page, verify your selections and then click **Create user**.

7. On the Complete page, click **Download .csv** to save a CSV backup file that contains the user name, Access key ID, and the Secret access key value. You create the file as a backup in case you lose those values. Verify that the file was created and then store the file securely.

8. Create a record of the credentials in Cloud Insights.
   a) In Cloud Insights, navigate to **AWS Settings > Credentials**.
   b) On the AWS Credentials form, click **New**, enter a unique and meaningful **Name** (for example, **AWS Billing Credentials**), and then fill in the form.

   **AWS Credentials form fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Input value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a unique and descriptive name for the AWS credentials.</td>
</tr>
<tr>
<td>Active</td>
<td>Select the check box to use the credential.</td>
</tr>
<tr>
<td>Access Key ID</td>
<td>Enter the <strong>Access key ID</strong> that you generated on the AWS Management Console, such as: <code>APIAIOFODNN7EXAMPLE</code>.</td>
</tr>
<tr>
<td>Secret Access Key</td>
<td>Enter the <strong>Secret access key</strong> that you generated on the AWS Management Console, such as: <code>wPalrXUtnFEMI/K7MDENG/bPxfRfiCYEXAMPLEKEY</code>.</td>
</tr>
</tbody>
</table>
   c) Click **Update** or **Submit**.

**Create an IAM user policy for Cloud Insights**

If you manage users with IAM, you must create an IAM user profile that enables Discovery to access AWS data.

You must know how to create an IAM user and set up a user policy. See the [AWS documentation on IAM](#) for details.

Use an auto-generated access key. You need the key information when you configure AWS credentials in the instance.
Roles required:

- On the AWS Management Console: AWS Management Console administrator
- Cloud Insights: admin or sn_cmp.cloud_admin

1. Log in to the AWS Management Console and create a new user in IAM.
2. Save the Access Key ID and Secret Access Key.
3. Open the user record in the instance for appropriate user.
4. Define a user policy in AWS using either of the following methods:

   - Grant Administrator Access to the instance, which is essentially the same access that would be granted to the instance as in the case that you were not using IAM and used your AWS account Access Key ID and Secret Access Key. Attach the AdministratorAccess policy to the user profile.

   - Create a custom policy with a descriptive name and the following code in the Policy Document field in the user policy. Be sure to see the code listed in this topic.

   ```json
   {
     "Version": "2012-10-17",

      "Action": ["ce:GetCostAndUsage", "ce:GetCostForecast"],
      "Resource": "*"
    }
  ]
}
```

Configuring MID Servers to connect Cloud Insights to AWS accounts

To ensure secure and reliable communications, the Discovery process communicates with your cloud provider accounts and cloud resources through one or more MID Servers. You can set up the MID Servers on your network or in one of your cloud networks.
Requirements

There must be an internal network connection between the MID Servers and the AWS Cloud API endpoints: *.amazonaws.com.

Using a proxy server

You can use a proxy server for the Cloud Insights MID Server. See Proxy server configuration for your Cloud Insights MID Server.

MID Server settings

<table>

</tbody>
</table>

Proxy server configuration for your Cloud Insights MID Server

You can configure any MID Server to use a proxy server for Cloud Insights operations. Proxy servers support all cloud-based activities such as running Discovery, Billing Download jobs, and Price Sheet Download jobs.

Proxy server limitations

- Only Windows or Linux platforms are supported.
- The Google Cloud Platform integration is not supported.
- The VMware integration is not supported.
- Remote PowerShell scripts cannot be executed.
- Custom APIs might not work.

Discovering your AWS cloud resources

When you create a schedule with the Discovery Manager wizard, you select the service accounts to discover, the credentials for accessing the accounts, and the MID Servers that scan the resources. The wizard greatly simplifies the configuration process for discovering cloud attributes.

Initial set up from the Home page

During initial installation, on the Home page, when you click the Set up Discover Schedule button in the Configure Accounts and Discovery section, the Discover Schedules form opens. Click Cloud Discovery to proceed.
About Cloud Discovery

The Cloud Discovery plugin includes the necessary components from Cloud Management to perform Cloud Discovery. See [Cloud Discovery](#) for detailed instructions for configuring Cloud Discovery.

Cloud Discovery finds the following cloud attributes for access to your AWS account:

- **Service accounts, subaccounts, and logical datacenters (LDCs):** Cloud Discovery finds all logical datacenters and subaccounts in a cloud service account.
- **Cloud resources:** Cloud Discovery by IP ranges finds all virtual machines in a cloud service account. Select a MID Server configured for Cloud Discovery and create the schedule. Cloud Discovery determines the IP addresses to scan based on the IP ranges in your cloud service account. Make sure that you have one or more MID Servers up and running that can access those addresses.
- **Tracking Cloud Discovery results:** The instance displays all results from a Cloud Discovery on both the cloud account page in Cloud Management and on the Cloud Discovery home page. You can drill down into specific schedules and lists of discovered devices, cloud resources, and errors. Sort these results for a closer look and view Cloud Discovery trends for the devices you find. [Error results](#) give you specific suggestions for fixing any problems you encounter.

Schedule and manage the jobs that download AWS billing data

Billing Download jobs download, organize, and store billing data for each payer account. The system analyzes the data to make recommendations for changes in your cloud operations that can lead to cost savings.

- For each provider, run Discovery on each service account.
- Role required: Cloud Spend Admin (sn_cld_spend_core.spend_admin) or Cloud Integrations Admin (sn_cld_intg_core.cloud_integrations_admin)

On the Home page,

**Note:** If the Cloud Management application is installed on your instance: Both Cloud Management and Cloud Insights download billing data. The two download jobs are completely separate processes and they do not interfere with each other.

- To ensure accurate reporting and recommendations, make sure that Discovery runs before the scheduled execution.
- The Billing Download job updates the billing node data table (sn_cld_intg_aws_cost_usage) with the CIs in the CMDB that correspond to each resource ID.
- Each update of billing data triggers the Business Hours and Rightsizing jobs to analyze spend and usage data and to update the actionable recommendations in reports.
- You can create only one Billing Download job for each payer account.
- For AWS accounts, only costs of unblended type are supported.
- When the scheduled time arrives, job execution happens in multiple stages (for example, connect to the provider, download the data, perform post-import sort, and so on). The system logs status and results on the Job Executions dashboard for each stage.
- Billing data is downloaded in reverse chronological order by month. For example, if the range is from March to June, data for June is downloaded first.
- To ensure meaningful results for the first billing data download, the app downloads data for at least 30 days. For example, if today is June 10 and you specify June for download, the system downloads data for both May and June to ensure at least 30 days of data for analysis. You can download data only for the most recent six months.
To optimize performance, the instance downloads only changes to the bill since the most recent download.

1. If you currently have an AWS Cost and Usage Report, review the settings in this step to ensure that the settings on the report meet the requirements for Cloud Insights. On the AWS Management Console, define an AWS Cost and Usage Report, as follows:
   a) Follow the instructions for “Creating an AWS Cost and Usage Report” in the AWS documentation and use the following settings:
      • Select the Include resource IDs check box.
      • Select the Automatically refresh your Cost and Usage Report when check box.
      • Report path prefix: optional
      • Set Time granularity to Hourly.
      • Set Report versioning to Create new report version.
      • Set Compression type to GZIP or ZIP. Cloud Insights does not support Parquet.
   b) Keep track of the following values because you will enter them into a Cloud Insights form in a moment.
      • Report name.
      • Report prefix.
      • Name of the S3 bucket that is the data storage area for the daily detailed billing records on the AWS account.
      • The cost type that your AWS account generates (unblended or blended). You set this value on the Advanced Options section of the AWS Billing and Cost Management console.

2. During initial installation, on the Home page, when you click the Set up Download Schedule button in the Configure Billing section, the Billing Download Jobs form opens. Navigate to Cloud Insights > AWS Settings > Billing Download Jobs.

3. Click New and then fill in the form.

### Billing Download Job form

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Meaningful name for the scheduled execution of the Billing Download job.</td>
</tr>
<tr>
<td>Provider</td>
<td>The provider.</td>
</tr>
<tr>
<td>Service account</td>
<td>The AWS payer account.</td>
</tr>
</tbody>
</table>
Bucket

Amazon S3 bucket that is the data storage area for the daily detailed billing records on the AWS account. Ensure that the credentials associated with the service account have access to the S3 bucket from which the bills are downloaded.

To obtain the value:

1. Log in to the AWS Management Console and select **My Billing Dashboard** in the menu.
2. Select **Reports**.
3. Copy the value from the **S3 bucket** column into the **Bucket** field on the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Report prefix</td>
<td>The <strong>report-prefix</strong> value that appears in your AWS Cost and Usage Report.</td>
</tr>
<tr>
<td>Report name</td>
<td>The <strong>report-name</strong> value that appears in your AWS Cost and Usage Report.</td>
</tr>
<tr>
<td>Active</td>
<td>Option for activating the job. Only active jobs are executed.</td>
</tr>
<tr>
<td>Field</td>
<td>Value</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Notify users / Notify groups</td>
<td>The users or groups to notify by email of the status of the job execution (for example, download failure). The system does not send a notification for success. Users or groups with the Billing Admin (sn_cld_intg_core.cloud_billing_admin) role are well suited to handle these issues. To update the email template, navigate to System Notification &gt; Email &gt; Notifications and open the Notify on billing job execution error template. For information on configuring the email, see Create an email template.</td>
</tr>
<tr>
<td>Run</td>
<td>Frequency to execute the job. Default: Daily</td>
</tr>
<tr>
<td>Time</td>
<td>Time of day to execute the job.</td>
</tr>
<tr>
<td>Last successful execution</td>
<td>Read-only field. The timestamp of the most recent execution.</td>
</tr>
<tr>
<td>Current execution status</td>
<td>Read-only field. The status of the execution that is currently running.</td>
</tr>
<tr>
<td>Current execution details</td>
<td>Read-only field. Execution details for the execution that is currently running.</td>
</tr>
</tbody>
</table>

4. Click Test Connection.
   The Test Connection workflow uses the configured settings to attempt to access the provider account, displays a progress pop-up, and then displays a success message or an error message that suggests actions to fix the configured settings.

5. After the connection succeeds, you can execute immediately or save the scheduled job:

<table>
<thead>
<tr>
<th>Choice</th>
<th>Resulting actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Click Submit.</td>
<td>Create the schedule for the Billing Download job.</td>
</tr>
<tr>
<td>Click Execute Now.</td>
<td>Execute the Billing Download job immediately. The Billing Download Job dialog box opens.</td>
</tr>
<tr>
<td></td>
<td>1. In the Start month field, enter the first month of data to download.</td>
</tr>
<tr>
<td></td>
<td>2. In the End month field, enter the last month of data to download.</td>
</tr>
<tr>
<td></td>
<td>3. To overwrite data from an earlier download attempt, select the Re-import data check box.</td>
</tr>
<tr>
<td></td>
<td>4. Click Download.</td>
</tr>
</tbody>
</table>
The following events happen when the job executes:

- After downloading the data, Cloud Insights updates the billing node data table (sn_cld_intg_aws_cost_usage) with the CIs in the CMDB that correspond to each resource ID. If a CI does not exist, the system generates a placeholder CI. On subsequent discovery, the system reconciles the placeholder CI. (The CI placement process associates downloaded cost and usage data with the appropriate CIs. See Add a class type to the Billing query table for details.)

- Cloud Insights generates a log entry for each stage of the execution. See Monitoring executions of download and reporting jobs for details on the logged information.
Cancel a Billing Download job

A Billing Download job downloads billing data from each payer account for each provider. You can cancel any Billing Download job individually.

Role required: Cloud Insights Admin (sn_clin_core.insights_admin)

1. Navigate to **Cloud Insights > AWS Settings > Billing Download Jobs**.
2. Click the execution to cancel (either currently running or scheduled).
3. Cancel the execution:
   - To cancel a currently running execution: On the Billing Download Job form, click **Cancel Execution**.
   - To cancel a scheduled execution:
     1. On the Billing Download Job form, click the execution in the Scheduled Executions related list.
     2. Click **Cancel**.

Add a class type to the Billing query table

The CI placement process is a part of Billing Download job execution. The CI placement process associates downloaded cost and usage data with the appropriate CIs. Specify the details of a new CI or CI type to enable the process to correctly assign cost and usage data.

Role required: Cloud Insights Admin (sn_clin_core.insights_admin)

The Billing Download jobs store downloaded billing data in the billing node table. The Class Type table holds CI type definitions for the cost usage table. Cloud Insights executes the CI placement process to associate the billing and usage data with CIs in the CMDB. The CI placement process queries the billing node table using the CI type definitions that reside in the CI placement type table.

The AWS CI placement type table (sn_cld_intg_aws_ci_placement_type) that is included in the Cloud Insights base system inherits from the Core CI placement type table, shown here:
The following procedure describes how to add a new class type definition to an existing CI placement type table. The step examples use the AWS table (sn_cld_intg_aws_ci_placement_type_list).

1. Go to the CI placement type table and click **New**.
2. Fill in the form.
### CI Placement Type Information Form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Class type</td>
<td>The class type table that this type of CI is stored in. New CIs of this type are added to the table.</td>
</tr>
<tr>
<td>Name</td>
<td>Name of the CI type.</td>
</tr>
<tr>
<td>Query table</td>
<td>The billing node table that the CI placement process queries to find instances of the CI type.</td>
</tr>
<tr>
<td>Query params</td>
<td>The parameter values in the billing node table that uniquely define the CI type.</td>
</tr>
</tbody>
</table>

3. Add a new CI placement type table.
   a) Inherit from (sn_cld_intg_core_ci_placement_type) and call it (for example):
      [sn_cld_intg_<provider-name>_ci_placement_type]
   b) Add or modify class type definitions as needed.

### Schedule and manage the jobs that download price sheets

A Price Sheet Download job downloads and stores price sheet data. Rightsizing processes use price sheet data when generating rightsizing recommendations.

- For each provider, run Discovery on each service account.
• Role required: Cloud Insights Admin (sn_clin_core.insights_admin)

On the Home page, when you click the **Set up Download Schedule** button in the Configure Price Sheets section, the Price Sheets Download Jobs form opens.

• You create a scheduled Price Sheet Download job for each provider.
• Each execution of a Price Sheet Download job runs multiple execution items. Each execution item imports and stores the price sheet for one region.
• To ensure accurate reporting and recommendations, make sure that Discovery runs before the scheduled execution.
• When the scheduled time arrives, job execution happens in multiple stages (for example, connect to the provider, download the data, perform post-import sort, and so on). The system logs status and results on the Job Executions dashboard for each stage.

### Tables that store price sheet data

<table>
<thead>
<tr>
<th>Table type</th>
<th>Tables</th>
</tr>
</thead>
</table>
| Cloud integrations AWS tables   | • sn_cld_intg_aws_price_sheet_info  
                                | • sn_cld_intg_aws_product_details_ec2  
                                | • sn_cld_intg_aws_product_offering_ec2 |
| Cloud integrations core tables  | • sn_cld_intg_core_ps_schedule  
                                | • sn_cld_intg_core_ps_download_request  
                                | • sn_cld_intg_core_ps_download_request_items |

1. During initial installation, on the Home page, when you click the **Set up Download Schedule** button in the Configure Price Sheets section, the Price Sheets Download Jobs form opens. After initial setup, you navigate to **Cloud Insights > AWS Settings > Price Sheet Download Jobs**.

2. Click **New** and then fill in the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Meaningful name for the Price Sheet Download job.</td>
</tr>
<tr>
<td>Provider</td>
<td>The cloud provider.</td>
</tr>
<tr>
<td>Last successful execution</td>
<td>Read-only field. The timestamp of the most recent execution of the job.</td>
</tr>
<tr>
<td>Active</td>
<td>Option for activating the job. Only active jobs are executed.</td>
</tr>
<tr>
<td>Run</td>
<td>Frequency to execute the job. Default: Daily</td>
</tr>
<tr>
<td>Time</td>
<td>Time of day to execute the job.</td>
</tr>
<tr>
<td>Current execution status</td>
<td>Read-only field. The status of the execution that is currently running.</td>
</tr>
</tbody>
</table>

**Note:** Depending on the value that you select, additional fields appear. For example, if you select a **Run** value of **Monthly**, a **Day** field appears. A value of 3 would mean the third day of the month.
### 3. You can execute the job immediately or save the scheduled job:

<table>
<thead>
<tr>
<th>Choice</th>
<th>Resulting actions</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Click Submit.</strong></td>
<td>Create the schedule for the Price Sheet Download job.</td>
</tr>
<tr>
<td><strong>Click Execute Now.</strong></td>
<td>Execute the Price Sheet Download job immediately.</td>
</tr>
</tbody>
</table>

The Price Sheet Download Job dialog box opens.

1. In the **Start month** field, enter the first month of data to download.
2. In the **End month** field, enter the last month of data to download.
3. To overwrite data from an earlier download attempt, select the **Re-import data** check box.
4. Click **Download**.

During execution, Cloud Insights downloads and stores the data. The app logs status and results on the Job Executions dashboard for each execution item. If there is no new data, the execution is marked Skipped. If the download process is stuck, the execution is marked as Canceled. See [Monitoring executions of download and reporting jobs](#) for details on the logged information.

### Cancel a Price Sheet Download job

A Price Sheet Download job downloads price sheet data from each provider. You can cancel any Price Sheet Download job individually.

- For each provider, run Discovery on each service account.
- Role required: Cloud Insights Admin (sn_clin_core.insights_admin)

Cloud Insights downloads price sheet data from each provider one region at a time. If you cancel a running price sheet download job, the current region finishes downloading and the system cancels download for the remaining regions. If you cancel a scheduled job execution, then all regions are marked as canceled.

1. **Navigate to Cloud Insights > AWS Settings > Price Sheet Download Jobs.**
2. **Click the job execution to cancel** (either currently running or scheduled).
3. **Cancel the execution:**
   - To cancel a currently running execution: On the Price Sheet Download Job form, click **Cancel Execution**.
   - To cancel a scheduled execution:
     1. On the Price Sheet Download Job form, click the execution in the Scheduled Executions related list.
     2. **Click Cancel**.

Exclude a resource from Cloud Insights reports

To ensure that cost data for a particular resource does not appear in a report, you exclude the resource by adding it to the Excluded Resource list.

- A cloud account with a service account and associated datacenters is required.
- Role required: Cloud Insights Admin (sn_clin_core.insights_admin)

- Excluding a resource from a report means only that the resource will not appear in the report. This setting does not affect analysis of data for the resource.
- At any time, you can unexclude a resource (remove the resource from the Excluded Resources list).
- Production resources are examples of resources that you might exclude. Because production resources must always be active, you might, for example, want to exclude production resources from Business Hours reports.

Exclude a resource either from a single report type or from all reports.

- Exclude a resource from a single report type: On any Resources or Recommendation tab, select the resource and click Exclude. The resource is excluded from the current report and is added to the Excluded Resources list for the report.
- Exclude a resource from all reports (add a resource to the global Excluded Resources list):
  1. Navigate to Cloud Insights > Global Settings > Global Exclusions.
  2. On the Excluded Resources page, click New and fill in the form. Click Save. The resource will then be excluded from all Cloud Insights reports.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resource</td>
<td>The resource to exclude. Only VM resources appear in the list.</td>
</tr>
<tr>
<td>Description</td>
<td>The reason for excluding the resource.</td>
</tr>
</tbody>
</table>

Remove a resource from the Excluded Resource list

At any time, you can unexclude a resource (remove the resource from the Excluded Resources list).

- A cloud account with a service account and associated datacenters is required.
- Role required: Cloud Insights Admin (sn_clin_core.insights_admin)

When you remove a resource from the Excluded Resources list, the resource appears in the appropriate reports.

Remove a resource from the Excluded Resources list.

- To remove a resource from the Excluded Resources list for a single report type: On the Excluded Resources tab for the report, select the resource and click Remove from Excluded Resources list.
- To remove a resource from the global Excluded Resources list:
  1. Navigate to Cloud Insights > Global Settings > Global Exclusions.
  2. Select the resources to remove.
3. In the Actions on selected rows list, select **Delete** and then confirm deletion.

**Configuring Cloud Insights system properties**

Some properties are available on a system properties form, but some lesser-used properties are available only from the System Property (sys_properties) table.

**System properties for Billing Download jobs**

**sn_cld_intg_core.ci_placement_threads_number**

Number of threads that are used by CI placement flow to create CIs in the billing process.
- **Type:** integer
- **Default value:** 4
- **Location:** System properties

**sn_cld_intg_aws.max_unprocessed_records_for_ci_placement**

Maximum number of records to read in one batch from the AWS Cost And Usage Bill Data table for CI Placement.
- **Type:** integer
- **Default value:** 300000
- **Location:** System properties

**sn_cld_intg_aws.min_unprocessed_records_for_ci_placement**

Minimum number of records to read in one batch from the AWS Cost And Usage Bill Data table for CI Placement.
- **Type:** integer
- **Default value:** 100000
- **Location:** System properties

**System properties for Spend analysis**

**sn_cld_spend_core.metricbase_transform_limit**

Maximum number of Billing records to use in one Metric Base transform.
- **Type:** integer
- **Default value:** 100000
- **Location:** System properties

**sn_cld_spend_core.spend_report_flow_launcher_chunk_size**

Number of non-empty CI chunks to send to the spend flow launcher.
- **Type:** integer
- **Default value:** 40
- **Location:** System properties
**sn_cld_spend_core.spend_report_per_chunk_workload_size**
Number of workloads (CI ranges and metadata) for each chunk in the spend flow launcher.
- Type: integer
- Default value: 1000
- Location: System properties

**sn_cld_spend_aws.num_months_forecast**
Number of future months after the current month for which the AWS Forecast spend is retrieved during every execution of the Spend job.
- Type: integer
- Default value: 2
- Location: System properties

**System properties for Business Hours**

Note: The collection of data for a single download of billing or price sheet data is called a *workload*. Data in a workload is held in sets of data called *chunks*. You can specify the size of each chunk and the number of chunks in a workload.

**sn_clin_core.bh_report.batch_size**
The number of resources to include in a Business Hours report batch.
- Type: integer
- Default value: 5000
- Location: System properties

**sn_clin_core.bh_recom_max_chunk_size**
Number of records used to create workload chunks of rightsizing recommendations. If you set a value greater than `glide.db.max_view_records`, then the `glide.db.max_view_records` value is used instead. A smaller number means more chunks and a larger number means fewer chunks.

Records considered in one execution of generating recommendations = (number of chunks) * (data records/chunk)
- Type: integer
- Default value: 10000
- Location: System properties

**sn_clin_core.bh_recom_num_chunks_per_workload**
Number of chunks per workload. This value times the value of `sn_clin_core.bh_recom_max_chunk_size` is the total number of records per workload when generating rightsizing recommendations.

Records considered in one execution of generating recommendations = (number of chunks) * (data records/chunk)
- Type: integer
- Default value: 10
Cloud Insights admin guide

The Cloud Insights application, available in the ServiceNow Store, helps you to analyze the full range of costs associated with cloud assets so you can identify and take action on opportunities to save money and optimize operations.

How Cloud Insights works

Cloud Insights continuously monitors your cloud infrastructure to analyze costs so you can identify and take action on resources to save money and optimize operations.

Benefits for Executives

To help ensure that your cloud usage is in line with your organization's budget, vision and goals, Cloud Insights provides the following benefits:

- Accurate, current, and easy-to-digest information.
- The ability to tie cloud use (what is used and when, who has access and for how long) into measurable outcomes, which enables you to predict the need for investment and to meet and exceed customer demand with timely releases.

Benefits for Cloud Administrators

You need to set up and monitor cloud usage, to track metrics such as changes in integration or the number of code or infrastructure changes, to review forecasting and weekly trends to determine better provisioning strategies, to share usage reports with management and execs, and to shut down or rights size resources when appropriate. Cloud Insights enables you to accomplish the following tasks:

- Set up data collection and usage policies.
- Monitor usage and shut down or rights size resources as needed.
- Design custom reports that display clear and actionable information.
- Confidently share reports with management.
- View weekly trends with forecasting tools.

Benefits for Cloud Managers

You need to define project and portfolio goals, understand how and why resources are being provisioned, monitor and act on burn rates, forecast your cloud spend and then share cost and forecast info with your team and with execs. Cloud Insights lets you accomplish those tasks:

- View dashboards with burn rates and insight into events and trends on costs and usage.
- Design dynamic reports for execs and upper-level managers.
- Proactively identify potential issues and then take action to avoid them.

Questions that you need answers to

How much am I spending in the public cloud? Am I paying for resources that are over-provisioned or underused? Am I paying for resources that have no known function (or are unused)?

- Cloud Spend Analytics reports help you to identify opportunities to reduce cloud costs. See the Cloud spend: Last 30 Day Spend reports, Cloud spend: Monthly Spend reports, and Cloud spend: Forecast reports.
- The Rightsizing feature analyzes resource usage to recommend better sizes for resources that are wasting money by being over-provisioned or underused. A confidence rating and predicted savings support each recommendation to rightsize a resource. See Rightsizing: Implementing cost-effective sizing for resources.

Do all my cloud assets follow my policies? Which assets can I not track accurately because they are not properly tagged with an assignment group? Am I paying for resources that are not "owned" by a cost center or department?

To ensure that the information on usage and spending is accurate, Unassigned Resources policies identify resources that do not belong to an assignment group. For such resources, the policy can auto-assign an assignment group to a resource, require a member of the assignment group to approve the assignment, or add the resource to a report and take no further action. See Identifying unassigned resources to ensure accurate reporting.

Which assets are operating outside the hours that they should be operating?

A Business Hours job applies Business Hours policies to identify resources that are running when they should be powered off, reports them, and can start and stop them on the schedule that you specify. Running only during specified business hours can significantly reduce your cloud spend. See Business Hours: Ensuring resources run only when required.

Service category names in Cloud Insights and Amazon AWS Cloud

Use this information to determine the name of the AWS service category (resource type) that corresponds to a service category name that appears in Cloud Insights.

Cloud Insights home page

After you have configured the Cloud Insights app, the home page displays a scannable overview of areas where you might save money and improve utilization of resources.

Cloud Insights home page

On the home page (Cloud Insights > Home), you can quickly scan costs associated with various aspects of your cloud infrastructure. Just click one of the View buttons to access reports and view job execution status. Cloud Insights reports are scannable dashboards that present trends and forecasts on cloud spending and help you to understand where and how you currently spend on cloud resources.
Cloud Insights

Cloud Insights provides visibility, management, and governance for your cloud infrastructure and your business.

1. Cloud Spend Analytics reports:
   
   - **Cloud spend: Last 30 Day Spend reports**: The Last 30-Day Spend tab displays a chart of spending for the most recent 30-day period grouped by service category (resource type) or over the time period that you specify. You can filter the data that appears in the chart.
   
   - **Cloud spend: Monthly Spend reports**: The Monthly Spend tab displays an overview of cloud costs. The tab displays a chart of your cloud spend over a date range that you specify. You can filter the data that appears in the chart and group the data by category like region or service category (resource type).
   
   - **Cloud spend: Forecast reports**: The Forecast tab displays forecasted cloud costs for the current month and for upcoming months.

2. **Unassigned Resources overview**: Unassigned Resources policies help you to identify the resources that are not associated with an assignment group and to assign them appropriately. When a resource is assigned to the correct group, the resource can be appropriately governed even as it goes through stages such as patching, upgrading, and reconfiguring. The Unassigned Resources Overview tab highlights the number of resources that do not have an assignment group and the status of your Unassigned Resources policies. The Cloud Discovery process triggers Unassigned Resources analysis and updates recommendations in reports.

3. **Rightsizing overview**: The Rightsizing Overview tab highlights the resources that waste the largest portion of your cloud spend. It also includes reports that show how many resources are scheduled for rightsizing and how many additional resources might benefit from rightsizing.

4. **Business Hours overview**: The Business Hours Overview tab identifies the top five opportunities to improve business-hours usage and costs and the number of resources in each state of adjustment of business-hours.

5. **Job Executions dashboard**: The Job Executions dashboard displays status information on each type of job that Cloud Insights executes. The various jobs download, store, and analyze cost and usage data and generate reports that present actionable recommendations.

---

**Cloud spend: Last 30 Day Spend reports**

The Last 30-Day Spend tab displays a chart of spending for the most recent 30-day period grouped by service category (resource type) or over the time period that you specify. You can filter the data that appears in the chart.

**Viewing the Last 30 Day Spend reports**

Use one of the following methods to view the reports:

- Click Analytics > Cloud Spend and then click the Last 30 Day Spend tab.
- Click Home. In the Cloud Spend Analytics section, click View Details. The Cloud Spend page opens in a new tab. Click the Last 30-Day Spend tab.

**Working with the data**

- All data is auto-updated so there are no settings to configure.
- Click anywhere in a report or chart to view supporting data.
- By default, reports display combined data for all providers. Filter settings control the sources of data for the charts and reports. To display targeted data, change a filter setting. For example, to view data only for a particular service account, select the account in the Service Account filter. The Master Service Account filter limits the data to the AWS payer account that you
specify. You can narrow or widen the range of dates for the data in the chart using the Date Range filter.

- All reports present money values rounded and in reasonable increments. Numbers greater than 10000 are shown as factors of one thousand (k) or one million (m) with two trailing decimal places. For example, €123542 appears as €123.54k and ¥1234567 appears as ¥1.23m.
- To save a chart as an image, click the menu icon
  
  ![Menu Icon](image)

and select the image type.
Last 30 Day Spend tab

- The Last 30 Day Spend chart shows the full spend for the preceding 30 days, color-coded by service category (resource type). Color codes appear under the Spend by Service Category chart.
• The Spend by Service Category chart shows the spend for each service category for the preceding 30 days. You can use the **Date Range** filter to specify the time period to present on the chart.

**Note:** Because Cloud Insights supports multiple providers, it uses general terms for many service categories. For information about which terms apply, see Service category names in Cloud Insights and Amazon AWS Cloud.

Cloud spend: Monthly Spend reports

The **Monthly Spend** tab displays an overview of cloud costs. The tab displays a chart of your cloud spend over a date range that you specify. You can filter the data that appears in the chart and group the data by category like region or service category (resource type).

**Viewing the Monthly Spend reports**

Use one of the following methods to view the reports:

- Click **Analytics > Cloud Spend** and then click the **Monthly Spend** tab.
- Click **Home**. In the Cloud Spend Analytics section, click **View Details**. The Cloud Spend page opens in a new tab. Click the **Monthly Spend** tab.

**Working with the Monthly Spend data**

- All data is auto-updated so there are no settings to configure.
- By default, reports display combined data for all providers. Filter settings control the sources of data for the charts and reports. To display targeted data, change a filter setting. For example, to view data only for a particular service account, select the account in the **Service Account** filter. The Master Service Account filter limits the data to the AWS payer account that you specify. You can narrow or widen the range of dates for the data in the chart using the Date Range filter.
- All reports present money values rounded and in reasonable increments. Numbers greater than 10000 are shown as factors of one thousand (k) or one million (m) with two trailing decimal places. For example, €123542 appears as €123.54k and ¥1234567 appears as ¥1.23m.
- Click anywhere in a report or chart to view supporting data.
- To save a chart as an image, click the menu icon and select the image type.
### Monthly Spend tab

#### Current Month Spend
- **$4,242.00**

#### Last Month Spend
- **$6,803.00**
- The Last Month Spend value is the value from Amazon Web Services of your costs for the entire previous month.
- The Month-by-Month Spend chart shows the full spend up to today for the current month, color-coded by the setting that you specify for the Group by filter. Descriptions of the color codes appear under the chart. Specify the time period of data to display using the Date Range filter.
- Click the menu icon

```
(   )
```
to save a chart as an image.

Cloud spend: Forecast reports
The Forecast tab displays forecasted cloud costs for the current month and for upcoming months.

Viewing the reports

Use one of the following methods to view the reports:
- Navigate to Cloud Insights > Analytics > Cloud Spend and then click the Forecast tab.
- Navigate to Cloud Insights > Home. In the Cloud Spend Analytics section, click View Details. The Cloud Spend page opens in a new tab. Click the Forecast tab.

Working with the data

- All data is auto-updated so there are no settings to configure.
- The Master Service Account filter limits the data to the AWS payer account that you specify.
- All reports present money values rounded and in reasonable increments. Numbers greater than 10000 are shown as factors of one thousand (k) or one million (m) with two trailing decimal places. For example, €123542 appears as €123.54k and ¥1234567 appears as ¥1.23m.
- Click anywhere in a report or chart to view supporting data.
Cloud Spend Forecast tab

Current Month Forecast

$8,372.00

Next Month Forecast

$7,142.00

Month-by-Month Forecast

- Oct/2019
- Nov/2019
- Dec/2019
• The Next Month Forecast value is your expected cost for the entire following month. Amazon Web Services calculates the forecast based on past costs.
• The Month-by-Month Forecast chart shows the projected costs for the next three months.
• Click the menu icon

( )
to save a chart as an image.

Spend optimization: Overall spend reports

The Cloud Insights Optimization reports present trends and forecasts on cloud spending and help you to understand where and how you currently spend on cloud resources. The Overall tab identifies and ranks cloud spend by owners and groups.

Working with the data

• All data is auto-updated so there are no settings to configure.
• Click anywhere in a report or chart to view supporting data.
• All reports present money values rounded and in reasonable increments. Numbers greater than 10000 are shown as factors of one thousand (k) or one million (m) with two trailing decimal places. For example, €123542 appears as €123.54k and ¥1234567 appears as ¥1.23m.
• By default, reports display combined data for all providers. Filter settings control the sources of data for the charts and reports. To display targeted data, change a filter setting. For example, to view data only for a particular service account, select the account in the Service Account filter. You can narrow or widen the range of dates for the data in the chart using the Date Range filter.
• To save a chart as an image, click the menu icon

( )
and select the image type.

Spend Optimization: Overall tab

Navigate to Cloud Insights. Click Analytics > Spend Optimization and then click the Overall tab. The Overall tab identifies and ranks cloud spend by owners and groups.
**Total Cloud Spend**
Spend for the last 30 days.

**Top Cloud Spend by Assignment Group**
Ordered list of assignment groups that spent the most over the last 30 days.

**Note:** Cloud Insights uses the Assignment Group value of a resource to show trends in spending. The Unassigned Resources feature identifies resources that are not associated with an assignment group so you can assign them. See [Identifying unassigned resources to ensure accurate reporting](#).

**Top Cloud Spend by Owner**
List of resource owners that spent the most over the last 30 days.

**Spend optimization: Business Hours reports**
The Business Hours reports help you to identify resources that waste money by being powered on for a significant time when they should be powered off.

**Viewing the reports**
Use one of the following methods to view the reports:

- Click Analytics > Spend Optimization and then click the Business Hours tab.
- Click Cost Optimization > Business Hours. On any tab on the Business Hours page, click Business Hours Analytics. The tab opens in a new browser tab.
Working with the data

- All data is auto-updated so there are no settings to configure.
- By default, reports display combined data for all providers. Filter settings control the sources of data for the charts and reports. To display targeted data, change a filter setting. For example, to view data only for a particular service account, select the account in the Service Account filter. The Master Service Account filter limits the data to the AWS payer account that you specify. You can narrow or widen the range of dates for the data in the chart using the Date Range filter.
- Click anywhere in a report or chart to view supporting data.
- All reports present money values rounded and in reasonable increments. Numbers greater than 10000 are shown as factors of one thousand (k) or one million (m) with two trailing decimal places. For example, €123542 appears as €123.54k and ¥1234567 appears as ¥1.23m.
- To save a chart as an image, click the menu icon and select the image type.

Business Hours tab

In this example, the filter settings limit the reports to show data only for the service account named Insight aws and only for resources that match the AutoApply policy.
$6,178.77  $10.00  $22.00  10
Total cloud spend. The Policy filter does not apply for this chart.

**Total Business Hours Spend**
Total spend for resources that are on during business hours (as determined by Business Hours policies).

**Total Non-Business Hours Spend**
Total spend for resources that are on during non-business hours (as determined by Business Hours policies).

**Total Resources**
Number of resources in your cloud infrastructure.

**Business vs. Non-Business Hours Spend**
Timeline of spend for resources. The report groups spend during business hours and during non-business hours.

**Top Predicted Savings by Owner**
Ordered by resource owner: The biggest savings that could result if all recommended business hours changes are implemented.

**Top Predicted Savings by Assignment Group**
Ordered by assignment group for resources: The biggest savings that could result if all recommended business hours changes are implemented.

**Cost optimization: Rightsizing reports**
Reports on the Rightsizing tab help you to identify the users, user groups, or locations that are wasting money by running over-provisioned or underused resources. Other reports on the tab present your expected savings if you were to take action to rightsize the identified resources.

**Viewing the reports**
Use one of the following methods to view the reports:

- Click Analytics > Spend Optimization and then click the Rightsizing tab.
- Click Cost Optimization > Rightsizing. On any tab on the Rightsizing page, click Rightsizing Analytics. The tab opens in a new browser tab.

**Working with the data**
- All data is auto-updated so there are no settings to configure.
- Click anywhere in a report or chart to view supporting data.
- All reports present money values rounded and in reasonable increments. Numbers greater than 10000 are shown as factors of one thousand (k) or one million (m) with two trailing decimal places. For example, €123542 appears as €123.54k and ¥1234567 appears as ¥1.23m.
- By default, reports display combined data for all providers. Filter settings control the sources of data for the charts and reports. To display targeted data, change a filter setting. For example, to view data only for a particular service account, select the account in the Service Account filter. You can narrow or widen the range of dates for the data in the chart using the Date Range filter.

- To save a chart as an image, click the menu icon and select the image type.

**Rightsizing tab**

![Rightsizing tab](image)

**Total Cloud Spend**

Total cloud spend. The **Job** filter does not apply to this chart.
**Total Predicted Savings**

Total savings to expect if all rightsizing recommendations are applied.

**Total Recommended Resources**

Number of resources that have a rightsizing recommendation.

**Rightsizing Monthly Savings**

Each of the possible states of a rightsizing recommendation appears as a bar on the chart:

- **New**: Potential savings for resources that the most recent analysis has recommended for rightsizing.
- **In-progress**: Potential savings for resources where the Rightsizing change request has not yet been approved.
- **Rejected**: Potential savings for resources where the Rightsizing change request was rejected.
- **Failed**: Potential savings for resources where the Rightsizing change request failed.

**Rightsizing Resources**

Each of the possible states of a rightsizing recommendation appears as a bar on the chart:

- **New**: Potential savings for resources that the most recent analysis has recommended for rightsizing.
- **In-progress**: Number of resources where the Rightsizing change request has not yet been approved.
- **Rejected**: Number of resources where the Rightsizing change request was rejected.
- **Failed**: Number of resources where the attempt to rightsize the resource failed.

**Top Predicted Savings by Owner**

Each bar represents the potential savings for a resource owner.

**Top Predicted Savings by Assignment Group**

Each bar represents the potential savings for an assignment group.

**Monitoring executions of download and reporting jobs**

The Job Executions dashboard displays status information on each type of job that Cloud Insights executes. The various jobs download, store, and analyze cost and usage data and generate reports that present actionable recommendations.

**Reports on the Job Executions dashboard**

The Job Executions dashboard displays reports on the jobs that Cloud Insights executes.

- **Billing Download jobs** download, organize, and store billing data for each payer account. The system analyzes the data to make recommendations for changes in your cloud operations that can lead to cost savings.
- **A Price Sheet Download job** downloads and stores price sheet data. Rightsizing processes use price sheet data when generating rightsizing recommendations.
- **Spend jobs** analyze cost and usage data to generate analytics reports on your cloud costs and trends.
- **Each update of billing data** triggers the Business Hours and Rightsizing jobs to analyze spend and usage data and to update the actionable recommendations in reports.
- **The Cloud Discovery process** triggers Unassigned Resources analysis and updates recommendations in reports.
To specify the time period that the reports should cover, use the Date Range filter.
Click any report to view status and log data for executions.

Accessing the Job Executions dashboard

Use one of the following methods to view the reports:

- Navigate to Cloud Insights > Monitoring > Job Executions.
- Navigate to Cloud Insights > Home and then click the Job Executions button.

**Job execution logs**

When you click any report on the dashboard, the list of execution records with the selected job execution status appears.

- In Progress: The job is executing (running).
- Failed: At least one of the processes that the job performs failed to run to completion.
- Canceled: A user canceled the job before it could run to completion.
- Completed: The job ran to completion successfully.

**Billing Download jobs**

The following example shows a Billing Download Executions table for a failed execution. The execution records can help you to determine why a particular execution failed. Each execution has an associated progress bar.
The execution of a billing job proceeds in several stages. Each stage performs one or more actions on the data (import data, sort the data, update the CMDB, store the data, and so on). For example, the Post-Import of Billing Data stage reconciles the resource identifiers from the billing data with the corresponding CIs in the CMDB. Each execution record in the list identifies the stage that is currently running or the last stage that ran. Click an execution Start time to view the stages that make up the execution. In the following example, the execution failed in the Importing Billing Data stage.
Click a stage to view its details. Click an extension to view the execution details for the extension.
The Extension Executions (Download Cloud Integrations AWS Cost Usage Report and CI Placement Extension) show the extensions that ran as part of the stage. Each stage has logs and each log has a level.
### Execution Stage Logs (31)

Customizing the Job Executions dashboard

Because the Job Executions dashboard is a standard report, you can change the reports or add or rearrange widgets as needed. Click the + icon to customize the page. If you customize the page, keep in mind that the invisible building block near the top of the page is there to ensure that the rows in the reports line up neatly.

Business Hours: Ensuring resources run only when required

A Business Hours job applies Business Hours policies to identify resources that are running when they should be powered off, reports them, and can start and stop them on the schedule that you specify. Running only during specified business hours can significantly reduce your cloud spend.

How the Business Hours feature works

Each update of billing data triggers the Business Hours and Rightsizing jobs to analyze spend and usage data and to update the actionable recommendations in reports. Business Hours jobs follow this process:
Define a business hours policy

Finance department policy
Applies to:
Resources tagged "finance"
Business hours schedule:
8:00 - 5:00
Policy actions:
Apply business schedule to every matching VM

Admin

Apply the policy
Find all the resources in the CMDB that match the policy conditions

System

Repeat this process when new billing data appears

Perform the actions specified by the policy
Apply the business hours schedule to each matching resource

© 2020 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
1. For each Business Hours policy, examine the CMDB to identify resources that match the policy criteria. (Policies are described in the following sections.)

2. For each resource that matches a policy, generate a change request to enforce the on/off schedule that is defined in the policy. Alternatively, generate a single change request that applies to all CIs that match the policy.

3. Update Business Hours reports with resources that match a policy and with approved, rejected, and failed changes.

4. When a change request is approved, apply the on/off schedule that is defined in the policy to the associated resources.

5. Repeat this process whenever billing data is updated.
Business Hours policy

Policy name: Finance department

Policy is: Active

Policy type: Auto-apply after approval

Business hours schedule: 8:00 AM to 5:00 PM

Power-on flow: Launch VM Start

Power-off flow: Launch VM Stop

Resource criteria:

Service Accounts
Specify the accounts to apply the policy to.

Providers

AWS

Service accounts
Billing 15970

Resources
Specify the tags that determine which resources match the policy.

This condition must be met

Department is Finance
The Finance department policy example has the following settings:

- The policy is active — it is applied every time billing data is updated.
- The policy type is Auto-apply after approval, which means that, after a qualified user approves the change request, the schedule for resources that match the policy is adjusted.
- The Business Hours (on/off) schedule is "on" from 8:00 AM to 5:00 PM.
- The power-on and power-off flows are specified.
- Only resources that meet the following resource criteria match the policy:
  - The cloud provider is AWS and the service account is Billing 15970.
  - The resource has a tag with the name Department with the value Finance.

After the policy is applied, for each resource that matches the policy (and the change request is approved), the system starts the resource at 8:00AM and stops it at 5:00PM.

**Note:** The actual start and stop times vary slightly due to changes in system demand and the time it takes for the resource to start and stop.

### Business Hours policy types

For each resource that matches the policy criteria, the actions that the policy takes depend on the policy type:

**Auto-apply policy type**

- Generate a recommendation to apply the specified business hours and add the resource to Business Hours reports.
- Generate and auto-approve a change request for the assignment group.
- Apply the Business Hours schedule to the resource.

**Auto-apply after approval**

- Generate a recommendation to apply the specified business hours and add the resource to Business Hours reports.
- Generate a change request for members of the assignment group.
- Add the resource to Business Hours reports.
- Any member of the group with the ITIL role can approve the schedule (through the change request).
- When approved, apply the Business Hours schedule to the resource.

**Report-only**

- Generate a recommendation to apply the specified business hours.
- Add the resource to Business Hours reports.

**Configure Business Hours operations**

You can choose to use or to disable Business Hours features and specify the amount of non-business hour spend that triggers notifications to users or groups. Controlling unnecessary resource use can help reduce costs.

- A cloud account with a service account and associated datacenters is required.
- Role required: Cloud Insights Admin [sn_clin_core.insights_admin]

1. Navigate to **Cloud Insights > Cost Optimization > Business Hours**.
2. On any tab, click **Settings** and then configure the following settings as needed.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable business hours</td>
<td>Option for enabling the Business Hours feature. All active policies are applied when data becomes available. Deselect the check box to disable the Business Hours feature. No policies are applied regardless of the Active setting for a policy.</td>
</tr>
</tbody>
</table>

**Note:** When you disable the Business Hours feature, all schedules that were applied by policies are deactivated and resources return to their original schedules.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Notify when unassigned resources exceed (%) of total CIs</td>
<td>The percentage of overall cloud spend for non-business hour usage that triggers email notification of the users or groups that you specify.</td>
</tr>
<tr>
<td>Notify users / Notify groups</td>
<td>The users or groups to notify by email when the non-business hour spend exceeds the specified percentage of overall cloud spend. If you do not specify users or groups, then no notification is sent.</td>
</tr>
</tbody>
</table>
3. Optional: Specify whether to generate a single change request that applies to all CIs that
match a policy (the default setting) or a separate change request for each CI.
   a) Select the Advanced check box.
   b) Select or clear the Single change request check box.

<table>
<thead>
<tr>
<th>Setting of the Single change request check box</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Selected (default)</td>
<td>The system generates a single change request that applies to all CIs that match the policy. For the Auto-apply after approval policy type, the Maximum CIs per change field appears. Specify the maximum number of resources to associate with a single change request. If the maximum is reached, the system generates a new change request.</td>
</tr>
<tr>
<td>Not selected</td>
<td>The system generates a change request for each CI that matches the policy.</td>
</tr>
</tbody>
</table>

4. Optional: Follow this procedure to create a custom script include.
   The default change request templates that the system uses to generate change requests work well in most applications. Some attributes of the change request template have static/constant values that cannot be changed. Some attributes (for example, risk and work_notes) have dynamic values that you can set using a script include.
   a) Select the Advanced check box.
   b) Select the tab for the policy type to configure.
   c) Specify the script include that sets values in the change template that is used for the change requests for resources that match the policy.
      To change or add values in the template, create a new script include based on one of the default script includes. In the new script include, override the settings in the setValues function. Creating a new script include simplifies upgrades.
      - Auto-apply policies (The Assignment group is derived from the Standard Change template and cannot be overridden): Default: CLINBHStandardChangeRequestUtil
      - Auto-apply after approval policies: Default: CLINBHNormalChangeRequestUtil

5. Click Submit or Update.

Define or update a Business Hours policy
A Business Hours job applies Business Hours policies to identify resources that are running when they should be powered off, reports them, and can start and stop them on the schedule that you specify. Running only during specified business hours can significantly reduce your cloud spend.
   - A cloud account with a service account and associated datacenters is required.
   - Role required: Cloud Insights Admin (sn_clin_core.insights_admin)
   - You can create as many policies as needed.
   - When you deactivate a policy, the resources that met the policy criteria might match a different policy (the matching policy with lowest run order) and therefore move to another schedule. In this case, the system generates a new change request. If a resource no longer meets any policy, the system attempts to power on the resource using the specified Power-on flow setting.

1. Navigate to Cloud Insights > Cost Optimization > Business Hours.
2. On the **Policies** tab, click **New**. Alternatively, edit an existing policy by clicking a policy card or a policy name in the list.

3. On the **Set Policy Properties** page, configure the general settings and the actions that the policy performs on resources that match the policy (meet the policy criteria).

**General section on the Set Policy Properties page**

<table>
<thead>

</tr>
<tr>
<td></td>
<td>Select a schedule from the list or define a schedule by navigating to Cloud Insights &gt; Global Settings &gt; Schedules. For more information, see Define a schedule.</td>
</tr>
<tr>
<td></td>
<td>If you update the time, day, or frequency of a schedule, then the system generates new change requests for the new schedule within 24 hours.</td>
</tr>
<tr>
<td>Power-on flow / Power-off flow</td>
<td>Auto-apply and Auto-apply after approval policy types only. The flows that perform the on/off operations on the resources that match the policy.</td>
</tr>
</tbody>
</table>

4. Click **Next** to move to the **Set Policy Criteria** page.
   A resource matches the policy if the criteria on the **Set Policy Criteria** page are met.

5. In the Service Accounts section, specify the service accounts to apply the policy to.
   a) Select the provider.
   b) Move the required service accounts to the **Selected** list.

6. In the Resources section, specify the conditions (combinations of tag values) that define which resources match the policy.
   - The values come from the Key Value (cmdb_key_values) table.
   - A resource matches the policy if the criteria on the **Set Policy Criteria** page are met.
   - The following example has two conditions. The first condition consists of two required subconditions.
7. Click Save.

The policy appears as a card on the Policies tab. See Viewing Business Hours policies for additional information on the cards.

When the Discovery and billing data update executions finish, the system applies active policies to identify matching resources and then performs the policy actions on the resources.

Viewing Business Hours policies
When you create a Business Hours policy, the policy settings are represented on a card or in a list on the Business Hours Policies tab.

Opening the Business Hours Policies page

Use one of the following methods to access the page:

- Navigate to Cloud Insights > Cost Optimization > Business Hours.
- Navigate to Cloud Insights > Home. In the Business Hours section, click View Details.

Click the Policies tab.

**Note:** When a policy is created or updated with changes other than to its name or description, a notification appears on the tab. Click the Reapply Policies button to apply the changed policy and recalculate the reported data.
Policy cards and lists

- Click the view icon to switch between card view and list view.
- The list view displays additional information like the number of resources in each approval state and creation information for the policy.
- Changes to the name or description of a policy do not change the Last Updated timestamp of a policy.

1. Name.
   - Expected savings and schedules and status of change requests.
   - Run order for the policy.

   **Note:** Run order values for Unassigned Resources policies and Business Hours policies do not interfere with each other.

2. Policy type.
   - Auto: Auto-apply or Auto-apply after approval.
   - Report: Report-only.

3. Hold the cursor here to perform an action:
   - View Report.
   - Clone the policy.
   - Delete the policy.

4. Click anywhere to edit.

5. Active / Not Active.

Viewing the overall state of business hours usage
The Business Hours **Overview** tab identifies the top five opportunities to improve business-hours usage and costs and the number of resources in each state of adjustment of business-hours.
Accessing the Business Hours Overview page

Use one of the following methods to access the page:

- Navigate to Cloud Insights > Cost Optimization > Business Hours.
- Navigate to Cloud Insights > Home. In the Business Hours section, click View Details.

Click the Overview tab.

Working with Business Hours usage data

- All data is auto-updated so there are no settings to configure.
- Data appears on reports only when at least one policy is active.
- By default, reports display combined data for all providers. Filter settings control the sources of data for the charts and reports. To display targeted data, change a filter setting. For example, to view data only for a particular service account, select the account in the Service Account filter.
- Each update of billing data triggers the Business Hours and Rightsizing jobs to analyze spend and usage data and to update the actionable recommendations in reports.
- Because updates to a policy can change the reported data, click Re-Evaluate Policies whenever you have updated a policy. The button is enabled only if all active policies are valid or if any recommendations are still pending.
- All reports present money values rounded and in reasonable increments. Numbers greater than 10000 are shown as factors of one thousand (k) or one million (m) with two trailing decimal places. For example, €123542 appears as €123.54k and ¥1234567 appears as ¥1.23m.

Business Hours Overview page

The sections on the Overview tab show the savings that are possible when you implement Business Hours policies.

In the example shown in the figure, the filter settings limit the reports to show data only for the service account named Billing 884788 and only for resources that match the QualityEng policy.

Reports on the Business Hours Overview tab

Overall Cost Savings section

- Top 5 business-hours savings opportunities: The five resources that generate the most cost by running outside their specified business hours. Click See All to view details on the Business Hours Resources page. See Managing your business hours processes for more information.
- Your spend and savings from resources in policies: Your total spend over the last 30 days plus your potential savings if the recommended business-hours adjustments are made.

Current status savings and details section

- Resources scheduled for business hour adjustment: The number of resources for which change requests will be generated during the next execution, plus your potential savings for the next 30 days if the recommended business hours adjustments are made. Click See All to view details on the Scheduled Resources tab. See Managing your business hours processes for more information.
- Resources not yet scheduled for business hour adjustment: The number of resources for which change requests are not yet approved plus your potential savings for the next 30 days if the recommended business hours adjustments are made. Click See All to view details on the Pending Resources tab on the Business Hours Resources page. See Managing your business hours processes for more information about working on the Business Hours tab.
- Declined business hour adjustments: The number of resources for which the change requests were rejected, plus the cost of non-business hours operation for the resources over the next 30 days. Click See All to view details on the Declined Resources tab on the Business Hours Resources page. See Managing your business hours processes for more information on working on the Business Hours tab.
- Failed business hour adjustments: The number of resources for which the adjustments failed, plus the cost of non-business hours operation for the affected resources over the next 30 days. Click See All to view details on the Failed Resources tab on the Business Hours Resources page. See Managing your business hours processes for more information on working on the Business Hours tab.
- Resources that match Report-only policies: The number of resources for which no action is being taken plus your potential savings for the next 30 days if business hour adjustments are made on the affected resources. Click See All to view details on the Report-Only Resources on the Business Hours Resources page. See Managing your business hours processes for more information about working on the Business Hours tab.

Managing your business hours processes

Use the information in the Business Hours Resources tab to assess and manage your ongoing efforts to ensure that resources run only when they should run.

Opening the Resources page

Use one of the following methods to access the page:

- Navigate to Cloud Insights > Cost Optimization > Business Hours.
- Navigate to Cloud Insights > Home. In the Business Hours section, click View Details.

Click the Resources tab.
Tabs on the Business Hours Resources page

Because updates to a policy can change the reported data, click **Re-Evaluate Policies** whenever you have updated a policy. The button is enabled only if all active policies are valid or if any recommendations are still pending.

<table>
<thead>
<tr>
<th>Tab</th>
<th>Description</th>

</tbody>
</table>

**Rightsizing: Implementing cost-effective sizing for resources**

The Rightsizing feature analyzes resource usage to recommend better sizes for resources that are wasting money by being over-provisioned or underused. A confidence rating and predicted savings support each recommendation to rightsize a resource.

**How rightsizing works**

To generate accurate rightsizing recommendations for resources, Cloud Insights follows this procedure every time billing data is updated:

1. Obtain costs from the updated billing data tables.
2. Collect the CPU and memory usage data for each resource for the preceding 14 days.
3. Obtain rates for resource types and sizes the price sheet data tables.
4. Obtain percentage discount rates from the discount tables and apply the appropriate discounts to the rates on the price sheet.
5. Compare calculated potential costs to actual billed costs and then generate rightsizing recommendations.
6. For each approved change, resize the resource. For a resource in the ON state, stop the resource, resize it, and then restart it. If the attempt to resize fails, perform a rollback, as described in **Rollback on failed Rightsizing attempts**.
7. Update the Rightsizing reports with new recommendations and with approved, rejected, and failed changes.

The recommended memory size is calculated so that the peak usage during the analysis period is no more than 80% of the recommended size. For example, say a resource currently has 16GB and the available sizes are 4GB, 8GB, and 16GB. If the resource used a peak of 3.9GB over the analysis period, then the recommendation would be 8GB.
AWS: Resources that are not considered for rightsizing

Resources with the following AWS attributes are not considered for rightsizing:

- Not in a VPC
- Not backed by an EBS root volume
- Part of Auto-scaling-group
- Does not have enhanced network support
- Virtualization type is not HVM
- Spot instance

Overview: Implementing Rightsizing processes

You follow this general process to define a rightsizing job:

1. On the Rightsizing Recommendations page: Select the resources to rightsize based on the rightsizing recommendations.
2. Add the resources to a Rightsizing job.
3. Specify the time for the job to run and the action to take (auto-rightsize or auto-rightsize after the appropriate user approves the change request).
4. Save the job.

The system immediately generates the change requests. Later, at the scheduled time, the system runs the job to rightsize all approved resources. For change requests that are rejected, failed for some reason, or still pending, you can reschedule the resources into another job.

Ensuring that rightsizing reports and recommendations are current

To ensure that rightsizing reports and recommendations are up-to-date, follow these guidelines:

- Run Discovery on each service account.
- Ensure that the Billing Download job has completed for each provider.
- Ensure that the Price Sheet Download job has completed for each provider.

Confidence levels in rightsizing recommendations

Each recommendation that the system makes to rightsize a resource has an associated confidence level. You consider the confidence level when making the decision of whether to rightsize a resource. Confidence levels reflect the following factors:

- High confidence requires the following conditions:
  - The system has at least 10 days of usage data for the resource.
  - The current and recommended family/generation are identical.

- Medium confidence requires the following conditions:
  - The system has less than 10 days of usage data for the resource.
  - The current and recommended family/generation are identical.

- Low confidence: The current and recommended family/generation are different.
Specify rate discounts to enable accurate pricing for rightsizing recommendations
To generate an accurate rightsizing recommendation, the system analyzes usage data for the last 14 days, obtains prices from the price sheet data tables, and then applies appropriate discounts. To enable the calculations, you specify the provider’s discount rate for each service account.

Role required: Cloud Insights Admin (sn_clin_core.insights_admin)

1. Navigate to **Cloud Insights > AWS Settings > Price Discounts**.
2. Click **New** and then fill in the form.

AWS Price Discount form

<table>
<thead>
<tr>
<th>Service account</th>
<th>The service account that the specified discount applies to.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discount (%)</td>
<td>The percentage discount for the specified service account.</td>
</tr>
</tbody>
</table>

3. Repeat the process for each service account.

Configure Rightsizing operations
The Rightsizing feature recommends better sizes for resources that are wasting money by being over-provisioned or underused. Use the Settings page to configure Rightsizing processes and specify the amount of potential rightsizing savings that triggers notifications.

- Run Discovery on each service account.
- Ensure that the Billing Download job has completed for each provider.
- Ensure that the Price Sheet Download job has completed for each provider.
- Role required: Cloud Insights Admin (sn_clin_core.insights_admin)

1. Navigate to **Cloud Insights > Cost Optimization > Rightsizing**.
2. On any tab, click **Settings**.
3. On the **General** tab, specify the following settings.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable Rightsizing</td>
<td>Option for enabling Rightsizing activities. Clearing the check box disables Rightsizing. Default: Enabled</td>
</tr>
<tr>
<td>After resize, exclude resource for (days)</td>
<td>The number of days to place a resized resource in the Excluded Resources list. The app monitors resized resources for the specified period to verify that the new size is appropriate. When the period expires, the app removes the resource from the list and rightsizing analysis resumes. [<strong>Note:</strong> During this monitoring period, you cannot remove the resource from the Excluded Resources list.]</td>
</tr>
<tr>
<td>Do not recommend if savings are below threshold</td>
<td>The minimum cost over a 30-day period to use when deciding whether to rightsize. For example, a setting of ¥100 means that the app should ignore any rightsizing recommendation that would result in less than ¥100 in savings over 30 days.</td>
</tr>
</tbody>
</table>
Field | Value
--- | ---
Notify when potential rightsizing savings exceed (%) of total spend | The percentage of overall cloud spend of resources that are sized incorrectly that triggers email notification to the users or groups that you specify. The value is calculated using the amount that could be saved if all rightsizing recommendations are followed.

Notify users / Notify groups | The users or groups to notify by email when the spend for incorrectly sized resources exceeds the specified percentage of overall cloud spend. For information on configuring the email, see Create an email template.

4. The default change request templates that the system uses to generate change requests work well in most applications. To specify non-default change templates, follow this procedure.
   a) Select the Advanced check box.
   b) Select the tab for the policy type to configure.
   c) Specify the script include to use for change requests when a resource matches a policy of the specified type.

   Default values:
   - Auto-apply policies (The Assignment group is derived from the Standard Change template and cannot be overridden): CLINRSSStandardChangeRequestUtil
   - Auto-apply after approval policies: CLINRSNormalChangeRequestUtil

   Note: You cannot modify the content of the default scripts.

5. Click Submit.

Define memory metrics (AWS only)
To enable accurate memory usage data for use in generating rightsizing recommendations, you first define memory metrics in your AWS account. You then define a custom memory metric in Cloud Insights.

- Run Discovery on each service account.
- Ensure that the Billing Download job has completed for each provider.
- Ensure that the Price Sheet Download job has completed for each provider.
- Role required: Cloud Insights Admin (sn_clin_core.insights_admin)

AWS does not automatically collect memory metric statistics. On the AWS Management Console, you specify the statistics to collect and push the data to Amazon CloudWatch. Cloud Insights accesses the data through CloudWatch, and verifies that the combination of namespace and metric name is defined correctly. To recommend resources for rightsizing, Cloud Insights analyzes the memory usage data for the custom metric. If no data is returned, the analysis uses the maximum memory of the resource.

1. Navigate to Cloud Insights > Cost Optimization > Rightsizing.
2. Click Settings.
3. On the AWS Memory Metrics subtab on the Memory Metrics tab, click New.
4. Fill in the form and then right-click in the header and select Save.
### Field | Value
--- | ---
Unit | Memory unit of the value.
Namespace | CloudWatch namespace that holds the resource and usage data.
Metric name | Unique name that identifies the custom metric to monitor for rightsizing analysis. Use the name that appears for the metric in CloudWatch.
Resource key dimension | CloudWatch Dimension name that maps to the unique objectID of the VM in your instance, for example, InstanceId.

5. To ensure that the settings that you entered enable the system to access and parse the data correctly, validate the settings against a single region.
   a) Click **Validate**.
   b) In the dialog box, enter the **Service account** and **Region** values to use for validation and then click **Validate**.

After a successful validation, the next cycle of rightsizing analysis uses the custom metric. The custom metric appears in the list on the **AWS Memory Metrics** tab. Error messages for unsuccessful validations recommend corrective actions.

6. Click **Submit** to add the definition to rightsizing analysis.

After a cycle of rightsizing analysis runs, the **Discovered Instances** tab displays the list of resources that meet the custom metric conditions.
1. objectID of the VM
2. Name of the VM
3. Name of the custom metric
4. Name of the CloudWatch dimension

Managing Rightsizing recommendations
Use the Rightsizing Recommendations tab to determine how to manage new recommendations for rightsizing and to manage ongoing rightsizing operations.

Opening the Rightsizing Recommendations page

Use one of the following methods to access the page:

- Navigate to Cloud Insights > Cost Optimization > Rightsizing.
- Navigate to Cloud Insights > Home. In the Rightsizing section, click View Details.

Click the Recommendations tab.
Rightsizing Recommendations page

To take action on a resource, select the recommendation in the list and click one of the actions. For details, see Schedule a resource to be rightsized, Move a resource to a different Rightsizing job, and Exclude a resource from Rightsizing analysis.

<table>
<thead>
<tr>
<th>Tab</th>
<th>Description</th>
<th>Available actions on selected recommendations</th>
</tr>
</thead>
</table>
| New Recommendations        | Resources that are candidates for rightsizing. Each update of billing data triggers the Business Hours and Rightsizing jobs to analyze spend and usage data and to update the actionable recommendations in reports. | • Exclude  
• Add to Job  
• Schedule Job |
| Scheduled Recommendations   | Resources that are scheduled in Rightsizing jobs.                                              | • Schedule Job  
• Add to Job  
• Remove from Job |
| Declined Recommendations   | Resources that owners did not want to resize (declined the change request).                    | • Exclude  
• Reschedule in a New Job  
• Reschedule in Another Job |
| Completed Recommendations  | Resources that were rightsized by the Rightsizing job.                                         | None                                                             |
| Failed Recommendations     | Resources for which the Rightsizing operation was not successful. For failed attempts, the Rightsizing operation performs a rollback, as described in Rollback on failed Rightsizing attempts. | • Exclude  
• Reschedule in a New Job  
• Reschedule in Another Job |
| Excluded Resources         | Resources that are configured not to be considered for rightsizing.                           | Remove From Excluded Resources List                              |
## Values on the tabs

The following values appear on the appropriate tabs:

### Values on the New, Scheduled, Declined, Completed, and Failed Recommendations tabs

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configuration item</td>
<td>Unique identifier of the resource.</td>
</tr>
<tr>
<td>Current size</td>
<td>Size of the resource that was analyzed for rightsizing — the size that you are currently paying for.</td>
</tr>
<tr>
<td>Recommended size</td>
<td>The size that is operationally and cost-wise most appropriate for the resource, based on the analysis of provisioning and usage levels over the last 14 days.</td>
</tr>
<tr>
<td>Override size</td>
<td>Size to use instead of the recommended size. By default, the system uses the <strong>Recommended size</strong> when rightsizing. Specify a different size by specifying an <strong>Override size</strong>.</td>
</tr>
<tr>
<td>Rationale</td>
<td>The reason that the system recommends resizing, based on the analysis of provisioning and usage levels over the last 14 days.</td>
</tr>
<tr>
<td>Monthly savings</td>
<td>Predicted savings if the resource is resized to the <strong>Recommended size</strong>.</td>
</tr>
<tr>
<td>Confidence</td>
<td>The confidence level in a recommendation.</td>
</tr>
<tr>
<td></td>
<td>• High confidence requires the following conditions:</td>
</tr>
<tr>
<td></td>
<td>• The system has at least 10 days of usage data for the resource.</td>
</tr>
<tr>
<td></td>
<td>• The current and recommended family/generation are identical.</td>

Schedule a resource to be rightsized

To rightsize a resource, add it to a Rightsizing job and specify when the job should run. You can also move resources out of one scheduled job into a new job.

- Run Discovery on each service account.
- Ensure that the Billing Download job has completed for each provider.
- Ensure that the Price Sheet Download job has completed for each provider.
- Role required: Cloud Insights Admin (sn_clin_core.insights_admin)

1. Navigate to **Cloud Insights > Cost Optimization > Rightsizing**.
2. Click the **Recommendations** tab.
3. In the list on the appropriate tab, select the check boxes for the resources to rightszie.
   - To create a Rightsizing job for resources that are new candidates for rightsizing: On the **New Recommendations** tab, select the resources and then click **Schedule Job**.
   - To create a new job for resources that had previously been scheduled but were not resized: On the **Declined Recommendations** tab or the **Failed Recommendations** tab, select the resources and then click **Reschedule in a New Job**.
4. Fill in the dialog box and then click **Schedule**.

<table>

<td>----------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| Policy type      | **Auto-rightsize after approval:** Generates a change request for a member of the assignment group to resize the resource and continues to list the resource in the appropriate Rightsizing reports.  
- Until a member of the assignment group approves/rejects the change, the resource state is set to Pending, the resource remains listed on reports, and no other action is taken.  
- If a member of the assignment group approves the request, the state is set to Approved and the resource is added to the list of resources that the job will resize.  
- If a member of the assignment group rejects the request, the resource state is set to Declined, the resource remains listed on reports, and no action is taken.  
**Auto-rightsize:** Generates and auto-approves a change request to resize the resource. The system also sends the approved change request to the assignment group. The resource is added to the list of resources that the job will resize.  
- For the **Change template** field, specify the change request template (Standard Change type) to use for Auto-rightsize recommendations.  
- If no template appears in the list, you must create one. See [Create a change request template](#). |

The Rightsizing job is created and will run at the scheduled time.

Move a resource to a different Rightsizing job

You can add resources to a currently scheduled job, move resources from one job to another, or remove resources from a job.

- Run Discovery on each service account.
- Ensure that the Billing Download job has completed for each provider.
- Ensure that the Price Sheet Download job has completed for each provider.
- Role required: Cloud Insights Admin (sn_clin_core.insights_admin)

1. Navigate to **Cloud Insights > Cost Optimization > Rightsizing**.
2. Click the **Recommendations** tab.
3. In the list on the appropriate tab, select the check boxes for the resources that are recommended for rightsizing and then specify the action to take.
   - To add the selected resources to an already scheduled job, click **Add to Job**. In the dialog box, select the job and then click **Confirm**. The resources are added to the job.
   - To add resources that have failed rightsizing or have been previously declined for rightsizing to an already-scheduled job, click **Reschedule in Another Job**. In the dialog box, select the job and then click **Confirm**. The resources are added to the job.
To remove the selected resources from a job that is scheduled to run, click **Remove from Job**. In the dialog box, select the job and then click **Confirm**. The resources are removed from the job.

Exclude a resource from Rightsizing analysis
To ensure that a particular resource is not considered or recommended for rightsizing, add the resource to the Excluded Resource list. The system continues to collect cost and usage data but does not analyze the resource data for rightsizing.

- Run Discovery on each service account.
- Ensure that the Billing Download job has completed for each provider.
- Ensure that the Price Sheet Download job has completed for each provider.
- Role required: Cloud Insights Admin (sn_clin_core.insights_admin)

1. Navigate to **Cloud Insights > Cost Optimization > Rightsizing**.
2. On the appropriate tab on the **Recommendations** tab, select the check boxes for the resources and then click **Exclude**.
   The resources are added to the Excluded Resources list. To remove a resource from the list, select it and then click **Remove From Excluded Resources List**.

Rollback on failed Rightsizing attempts
If a Rightsizing action fails, the system immediately performs a rollback to return the resource to its original size, restarts the resource if needed, updates the change request with full details, and updates Rightsizing report data.

In a successful Rightsizing job, the system resizes each resource that has an approved change request. If a resource is in the ON state, the process stops the resource, resizes (modifies) it, and then restarts it. If a resource is in the OFF state, the process resizes the resource but does not start it.

A resource might fail to restart, for example, if the new size would exceed the quota limit for a resource type or for a constrained availability zone.

A Rightsizing job proceeds in batches of resources, grouped by provider/service account/region. If any modified resource in a batch fails to restart, then each resource in the batch is rolled back to its original size and then restarted. The system then updates the change requests for the resources and sets the **Rightsizing recommendation** status on Rightsizing reports to **Failed**.

Resources in a batch that were in the OFF state are not rolled back or marked as failed.

Viewing the overall state of Rightsizing efforts
The Rightsizing **Overview** tab highlights the resources that waste the largest portion of your cloud spend. It also includes reports that show how many resources are scheduled for rightsizing and how many additional resources might benefit from rightsizing.

Opening the Rightsizing Overview page
Use one of the following methods to access the page:

- Navigate to **Cloud Insights > Cost Optimization > Rightsizing**.
- Navigate to **Cloud Insights > Home**. In the Rightsizing section, click **View Details**.

Click the **Overview** tab.
Working with the data

- All data is auto-updated so there are no settings to configure.
- By default, reports display combined data for all providers. Filter settings control the sources of data for the charts and reports. To display targeted data, change a filter setting. For example, to view data only for a particular service account, select the account in the Service Account filter.
- All reports present money values rounded and in reasonable increments. Numbers greater than 10000 are shown as factors of one thousand (k) or one million (m) with two trailing decimal places. For example, €123542 appears as €123.54k and ¥1234567 appears as ¥1.23m.
- Each update of billing data triggers the Business Hours and Rightsizing jobs to analyze spend and usage data and to update the actionable recommendations in reports.

Rightsizing Overview page

The sections on the Overview tab show how much you are spending on underused or over-provisioned resources and your potential savings if the resources are rightsized.

In the example shown in the figure, the filter settings limit the reports to show data only for the service account named Billing 884788 and only for recommendations with confidence levels of High or Medium.

Viewing scheduled Rightsizing jobs
View and manage upcoming rightsizing jobs on the Rightsizing **Jobs** tab.

Opening the Rightsizing Jobs page

Use one of the following methods to access the page:
- Navigate to **Cloud Insights > Cost Optimization > Rightsizing**.
- Navigate to **Cloud Insights > Home**. In the Rightsizing section, click **View Details**.

Click the **Jobs** tab.

Rightsizing Scheduled Jobs page

On the **Jobs** page, select the **Scheduled Jobs** tab.

The following values appear on the tabs. Click a job name to view the job record in the form view.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the scheduled job. Typically auto-generated.</td>
</tr>
<tr>
<td>Planned date</td>
<td>Time that the job will execute.</td>
</tr>
</tbody>
</table>
Viewing completed Rightsizing jobs
When a rightsizing job finishes, the job is listed on the Rightsizing Completed Jobs tab.

Opening the Rightsizing Jobs page
Use one of the following methods to access the page:

- Navigate to Cloud Insights > Cost Optimization > Rightsizing.
- Navigate to Cloud Insights > Home. In the Rightsizing section, click View Details.

Click the Jobs tab.

Rightsizing Completed Jobs page
On the Jobs tab, select the Completed Jobs tab.

The following values appear on the tabs. Click a job name to view the job record in the form view.

### Field | Value
--- | ---
Name | Name of the scheduled job. Typically auto-generated.
Planned date | Time that the job will execute.
Job Status | The status of job execution.
Created by | Name of the admin who created the job.

Identifying unassigned resources to ensure accurate reporting
Unassigned Resources policies help you to identify the resources that are not associated with an assignment group and to assign them appropriately. When a resource is assigned to the correct group, the resource can be appropriately governed even as it goes through stages such as patching, upgrading, and reconfiguring.

How Unassigned Resources policies work
For cloud billing information to be accurate, it must include all resources in your managed cloud infrastructure. An Unassigned Resources policy analyzes all resources to identify resources that are not assigned to an assignment group. The policy can then auto-assign the appropriate assignment group to the resources.

Requirements and limitations
- The Cloud Discovery process triggers Unassigned Resources analysis and updates recommendations in reports.
- The Unassigned Resources feature supports AWS EC2 instances only.
• Terminated, retired, or canceled resources are not considered.
• Data appears on reports only when at least one policy is active. The base system includes a default Unassigned Resources policy. See Viewing Unassigned Resources policies for details.
• When a policy is created or updated with changes other than to its name or description, a notification appears on the tab. Click the Reapply Policies button to apply the changed policy and recalculate the reported data.

Unassigned Resources — Policies tab

To ensure that the information on usage and spending is accurate, Unassigned Resources policies identify resources that do not belong to an assignment group. For such resources, the policy can auto-assign an assignment group to a resource, require a member of the assignment group to approve the assignment, or add the resource to a report and take no further action.

You create and manage Unassigned Resources policies on the Policies tab. See Define or update an Unassigned Resources policy.

Unassigned Resources — Resources tab

Use the Resources tab on the Unassigned Resources page to assess and manage your ongoing efforts to ensure that all resources are associated with an assignment group. Accurately assigned resources gives you greater understanding of and control over your cloud spend.

Configure Unassigned Resources operations

To ensure that the billing data used by Cloud Insights is accurate, the Unassigned Resources feature identifies resources that do not belong to an assignment group. You can choose to use or to disable Unassigned Resources features, and can specify the percentage of unassigned resources that triggers a notification.

• For each provider, run Discovery on each service account.
• Role required: Cloud Insights Admin (sn_clin_core.insights_admin)

1. Navigate to Cloud Insights > Spend Optimization > Unassigned Resources.
2. On any tab, click Settings and then configure the following settings as needed.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable Unassigned Resources</td>
<td>Option for enabling the Unassigned Resources feature. All active policies are applied when data becomes available. Deselect the check box to disable the Unassigned Resources feature. No policies are applied regardless of the Active setting for a policy.</td>
</tr>
<tr>
<td>Notify when unassigned resources exceed (% of total CIs)</td>
<td>Level of unassigned resources as a percentage of all CIs in the CMDB that triggers email notification of the users or groups that you specify. For information on configuring the email, see Create an email template.</td>
</tr>
<tr>
<td>Notify users / Notify groups</td>
<td>Users or groups to notify by email when the percentage of unassigned resources spend exceeds the specified limit.</td>
</tr>
</tbody>
</table>
3. Optional: Specify whether to generate a single change request that applies to all CIs that match a policy (the default setting) or a separate change request for each CI.
   a) Select the Advanced check box.
   b) Select or clear the Single change request check box.

<table>
<thead>
<tr>
<th>Setting of the Single change request check box</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Selected (default)</td>
<td>The system generates a single change request that applies to all CIs that match the policy. For the Auto-apply after approval policy type, the Maximum CIs per change field appears. Specify the maximum number of resources to associate with a single change request. If the maximum is reached, the system generates a new change request.</td>
</tr>
<tr>
<td>Not selected</td>
<td>The system generates a change request for each CI that matches the policy.</td>
</tr>
</tbody>
</table>

4. Optional: Follow this procedure to create a custom script include that sets attribute values in the change request template.

The default change request templates that the system uses to generate change requests work well in most applications. Some attributes of the change request template have static/constant values that cannot be changed. Some attributes (for example, risk and work_notes) have dynamic values that you can set using a script include.

   a) Select the Advanced check box.
   b) Select the tab for the policy type to configure.
   c) Specify the script include that sets values in the change template that is used for the change requests for resources that match the policy.

   To change or add values in the template, create a new script include based on one of the default script includes. In the new script include, override the settings in the setValues function. Upgrades are simplified when you create a new script include.

   - Default for Auto-apply policies (The Assignment group is derived from the Standard Change template and cannot be overridden): CLINUnassignedStandardChangeRequestUtil
   - Default for Auto-apply after approval policies: CLINUnassignedNormalChangeRequestUtil

5. Click Submit or Update.

Define or update an Unassigned Resources policy
To ensure that the information on usage and spending is accurate, Unassigned Resources policies identify resources that do not belong to an assignment group. For such resources, the policy can auto-assign an assignment group to a resource, require a member of the assignment group to approve the assignment, or add the resource to a report and take no further action.

   - For each provider, run Discovery on each service account.
   - Role required: Cloud Insights Admin (sn_clin_core.insights_admin)

   - When a policy is created or updated with changes other than to its name or description, a notification appears on the tab. Click the Reapply Policies button to apply the changed policy and recalculate the reported data.
• The **Cloud Insights** application includes an example policy named Default Unassigned Policy.

1. Navigate to **Cloud Insights > Spend Optimization > Unassigned Resources**.
2. On the **Policies** tab, click **New** or edit an existing policy by clicking a policy card or a policy name in the list.
3. On the **Set Policy Properties** tab, configure the general settings and the actions that the policy performs for resources that meet the policy criteria.

**General section of the policy definition**

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Active</strong></td>
<td>The option to apply the policy. Select the <strong>Active</strong> check box to apply the policy whenever billing data is updated.</td>
</tr>
<tr>
<td><strong>Policy name / Description</strong></td>
<td>A unique and descriptive name and description for the policy.</td>
</tr>
<tr>
<td><strong>Run order</strong></td>
<td>The order to apply the policies. Policies are applied low-to-high. <strong>Note:</strong> Run order values for Unassigned Resources policies and Business Hours policies do not interfere with each other.</td>
</tr>
</tbody>
</table>
| **Policy type**        | Action to take on resources that match the policy. **Auto-apply:**  
  - Generate a recommendation to assign the specified assignment group and add the resource to Unassigned Resources reports.  
  - Generate and auto-approve a change request for a member of the assignment group. **Auto-apply after approval:**  
  - Generate a recommendation to assign the specified assignment group and add the resource to Unassigned Resources reports.  
  - When the policy is saved, generate a change request for members of the assignment group. Any member of the group with the ITIL role can approve the change.  
  - When a change is approved, the system assigns the resource to the specified assignment group. **Report-only:** Generate a recommendation to assign the specified assignment group and add the resource to assignment group reports. Perform no other action. |
4. Click **Next** to move to the **Set Resource Criteria** page.
   
   A resource matches the policy if the criteria on the **Set Resource Criteria** page are met.

5. In the Service Accounts section, specify the service accounts to apply the policy to.
   
   a) Select the provider.
   
   b) Move the required service accounts to the **Selected** list.

6. In the Resources section, specify the conditions (combinations of tag values) that define which resources match the policy.

   The tag values come from the Key Value (cmdb_key_values) table.

   A policy applies if any of the specified conditions is met. The following example has two conditions. The first condition consists of two required subconditions.
7. Click **Save**.

The policy appears as a card on the **Unassigned Resources > Policies** tab. For more information on the cards, see **Viewing Unassigned Resources policies**.

The Cloud Discovery process triggers Unassigned Resources analysis and updates recommendations in reports.

**Viewing Unassigned Resources policies**

When you create an Unassigned Resources policy, the policy settings are represented on a card or in a list on the Unassigned Resources **Policies** page.

**Opening the Unassigned Resources Policies page**

Use one of the following methods to access the page:

- Navigate to **Cloud Insights > Cost Optimization > Unassigned Resources**.
- Navigate to **Cloud Insights > Home**. In the Unassigned Resources section, click **View Details**.

Click the **Policies** tab.

**Policy cards and lists**

- Click the view icon
  
  ![View Icon]

  to switch between card view and list view.

  ![List View]

  The list view displays additional information like the number of resources in each approval state and creation information for the policy.

- Changes to the name or description of a policy do not change the Last Updated timestamp of a policy.

1. Name of the policy.
2. Resources that meet policy criteria and assignment status.
3. Run order for the policy.

   **Note:** Run order values for Unassigned Resources policies and Business Hours policies do not interfere with each other.

2. Policy type.
   - Auto: Auto-apply or Auto-apply after approval.
   - Report: Report-only.

3. Hold the cursor here to perform an action:
   - View resources.
   - Clone the policy.
   - Delete the policy.

4. Click anywhere to edit.

5. Active / Inactive.

### The default Unassigned Resources Policy

At least one Unassigned Resources policy must be active for the Unassigned Resources feature to operate. The base system includes a default Unassigned Resources policy with the following settings:

<table>
<thead>
<tr>
<th>Policy property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Default Unassigned Policy</td>
</tr>
</tbody>
</table>
### Viewing overall progress on unassigned resources

The Unassigned Resources **Overview** tab highlights the number of resources that do not have an assignment group and the status of your Unassigned Resources policies. The Cloud Discovery process triggers Unassigned Resources analysis and updates recommendations in reports.

### Opening the Unassigned Resources Overview page

Use one of the following methods to access the page:

- Navigate to **Cloud Insights > Cost Optimization > Unassigned Resources**.
- Navigate to **Cloud Insights > Home**. In the Unassigned Resources section, click **View Details**.

Click the **Overview** tab.

### Working with the data

- All data is auto-updated so there are no settings to configure. The Cloud Discovery process triggers Unassigned Resources analysis and updates recommendations in reports.
- Because updates to a policy can change the reported data, click **Re-Evaluate Policies** whenever you have updated a policy. The button is enabled only if all active policies are valid or if any recommendations are still pending.
- By default, reports display combined data for all providers. Filter settings control the sources of data for the charts and reports. To display targeted data, change a filter setting. For example, to view data only for a particular service account, select the account in the **Service Account** filter.

### Unassigned Resources Overview page

- The sections on the **Overview** tab show how many resources are still unassigned and how many resources have been identified by the policies that you have defined.
• On this page, each See All button opens the Unassigned Resources > Resources page to the appropriate tab. See Managing how resources are associated with assignment groups for information on working on the Resources tab.

• In the following example, the filter settings limit the reports in the Policy Overview section to show data only for the service account named Billing 884788 and only for resources that match the QualityEng policy.
UNASSIGNED RESOURCES OVERVIEW

Unassigned Resources Overview section

- Unassigned resources in the CMDB: The number and percentage of resources that do not have an assignment group. The report is not affected by filter settings. Click See All to open the Unassigned Resources page to the Unassigned Resources tab.

Policy Overview section

- Assigned resources: The number of resources that matched a policy and were assigned to an assignment group. Click See All to open the Assigned Resources tab.
- Pending assignments: The number of resources that matched a policy and have been flagged for assignment, but the change request has not yet been approved or the action hasn’t been taken. To work on the resources, click See All to open the Pending Resources tab.
- Declined assignments: The number of resources where the approver rejected the change request. To work on the resources, click See All to open the Unassigned Resources page to the Resources > Declined Resources tab.
- Failed assignments: The number of resources that matched a policy but failed to be assigned. To work on the resources, click See All to open the Unassigned Resources page to the Resources > Failed Assignment tab. You can work with the resources on that tab.
- Report-only: The number of resources that matched a Report-only policy type. To work on the resources, click See All to open the Unassigned Resources page to the Resources > Report-only tab.

Managing how resources are associated with assignment groups

Use the Resources tab on the Unassigned Resources page to assess and manage your ongoing efforts to ensure that all resources are associated with an assignment group. Accurately assigned resources gives you greater understanding of and control over your cloud spend.

Opening the Resources page

Use one of the following methods to access the page:

- Navigate to Cloud Insights > Cost Optimization > Unassigned Resources.
- Navigate to Cloud Insights > Home. In the Unassigned Resources section, click View Details.

Click the Resources tab.

Tabs on the Resources page

Because updates to a policy can change the reported data, click Re-Evaluate Policies whenever you have updated a policy. The button is enabled only if all active policies are valid or if any recommendations are still pending.
Select a resource and click **Exclude** to exclude it from reports. See [Exclude a resource from Cloud Insights reports](#).

<table>
<thead>
<tr>
