<td>• <strong>Published:</strong> The synonym is saved with all changes published.</td>
</tr>
</tbody>
</table>

| Active         | Option to activate the synonym for use in the synonym dictionary. To        |
|                | deactivate the synonym, clear the **Active** check box.                    |

5. Click **Submit**.

The new synonym appears in the AI Search Dictionary Terms related list.

6. Optional: Repeat the preceding steps for each additional synonym that you want to create.

7. Choose one of the following actions.

   • To save the modified dictionary and refresh its active synonyms in all linked search profiles, click **Publish**.
   • To save the modified dictionary without refreshing its active synonyms in all linked search profiles, click **Update**.

**Define a synonym with equivalent words and phrases**

This example shows a synonym defining *vacation*, *holiday*, *PTO*, and the phrase *time off* as equivalent.
Clone a synonym dictionary

Create a copy of an existing synonym dictionary.

Role required: ais_admin

Cloning a synonym dictionary copies the source dictionary's settings and all of its all defined synonym terms. This process can save you time when you need multiple synonym dictionaries that have many synonym terms in common.

1. Navigate to **AI Search > Search Query Settings > Dictionaries**.
2. Expand the Synonym record group if necessary and edit the synonym dictionary that you want to clone.
3. Click **Clone**.
4. In the Set Dictionary Label dialog box, enter a label for the new synonym dictionary in the **Cloned dictionary label** field and click **OK**.

The new synonym dictionary form opens. All synonym terms defined in the source dictionary appear in the AI Search Dictionary Terms related list.

Link a synonym dictionary to a search profile

Link an existing synonym dictionary to one or more search profiles.

Role required: ais_admin

You can link a single synonym dictionary to multiple search profiles.

1. Navigate to **AI Search > Search Experience > Search Profiles**.
2. Edit the search profile that you want to link the synonym dictionary to.
3. In the Synonyms related list, click **Link Existing**.
4. On the AI Search Profile Dictionary M2M form, follow these steps.
   a) Click the reference lookup icon (🔍) for the Dictionary field.
   b) Select the synonym dictionary that you want to link to the search profile.
   c) Click Submit.

The selected synonym dictionary appears in the search profile’s Synonyms related list.

To make the new synonym dictionary linking take effect, publish the search profile. For more information on publishing a search profile, see Publish a search profile.

Unlink a synonym dictionary from a search profile

Remove a synonym dictionary from a search profile.

Role required: ais_admin

Unlinking a synonym dictionary from a search profile does not delete the dictionary. To delete a synonym dictionary, you must first unlink it from all search profiles. For steps to delete a synonym dictionary, see Delete a synonym dictionary.

1. Navigate to AI Search > Search Experience > Search Profiles.
2. Edit the search profile that you want to unlink the synonym dictionary from.
3. In the Synonyms related list, select the option for the synonym dictionary that you want to unlink from the search profile.
4. Click Unlink Selected.

The selected synonym dictionary disappears from the search profile’s Synonyms related list.

To make the change in synonym dictionary linking take effect, publish the search profile. For more information on publishing a search profile, see Publish a search profile.

Delete a synonym dictionary

Remove a synonym dictionary that is not linked from any search profile.

Role required: ais_admin

1. Navigate to AI Search > Search Query Settings > Dictionaries.
   The AI Search Dictionaries list appears with a [Type] [!=] [Spell Check] filter condition applied and records grouped by dictionary type.
2. Expand the Synonym record group if necessary and edit the synonym dictionary that you want to delete.
3. Click Delete.

   **Note:** If the synonym dictionary is still linked to any search profiles, deletion fails and an error message lists the linked profiles. Unlink the dictionary from these search profiles, then repeat the preceding steps. For details on unlinking a synonym dictionary from a search profile, see Unlink a synonym dictionary from a search profile.

The selected synonym dictionary disappears from the AI Search Dictionaries list.

Stop words

Stop words remove search query terms that do not produce meaningful results. Improve search precision and relevancy by configuring stop word dictionaries and defining stop words.

Stop words are common terms that appear on a large proportion of indexed records. Examples of such terms can include articles, conjunctions, personal pronouns, and prepositions. By defining these terms as stop words, you can improve search precision and result relevancy for users.
You can define stop words in the default stop word dictionary for a search profile, or create your own stop word dictionaries linked to search profiles. Create and publish stop words for each dictionary. Publish the dictionary to make your stop words take effect for searches that use linked search profiles.

You can delete stop word dictionaries that are not linked to any search profiles.

**Stop word usage in search**

When a search query includes a term defined as a stop word, AI Search removes the term from the search query.

For example, a stop word might remove the term *my* from a search query for *upgrade my laptop*. This modified search query only matches records containing the more relevant terms *upgrade* and *laptop*.

**Conditions for stop word eligibility**

To operate on a search query, a stop word must meet these conditions:

- It must be active.
- It must be included in a published stop word dictionary.
- The parent stop word dictionary must be linked to the search profile specified for the search query.
- The language of the parent stop word dictionary must match the language of the search query.

**Multi-word phrases**

A stop word term can include either a single word or a multi-word phrase. AI Search removes multi-term phrases when the words in the search query exactly match the order and proximity of the words in the stop word definition. If a user searches with these words in a different arrangement, no term removal occurs.

For example, if you define a *retirement account* stop word, AI Search removes these terms from a search for *401k retirement account* but does not remove them from a search for *retirement 401k account*.

**Case sensitivity**

By default, AI Search ignores letter case when comparing stop words with search query terms. You can enable case sensitivity for a stop word dictionary. This option affects all stop words defined in the dictionary.

When case sensitivity is enabled, stop words in the dictionary only match search query terms or phrases that include the same combination of uppercase and lowercase letters.

For example, if you define a *RAID* stop word in a dictionary with case sensitivity enabled, AI Search ignores the search query term *RAID* but treats the search query term *raid* normally.

**Punctuation sensitivity**

By default, AI Search ignores punctuation when comparing stop words with search query terms. You can enable punctuation sensitivity for a stop word dictionary. This option affects all stop words defined in the dictionary.

When punctuation sensitivity is enabled, stop words in the dictionary only match search query terms or phrases that include the same punctuation.

For example, if you define a *one-half* stop word in a dictionary with punctuation sensitivity enabled, AI Search removes the search query term *one-half* but does not remove the search query term *one half*. 
Language dependence

Stop word removal is language-dependent. You specify a language for each stop word dictionary, and this language applies to all stop words defined in the dictionary. Only stop words from dictionaries with the same language as the search query are eligible for removal.

AI Search supports stop word dictionaries for English, French Canada, French, German, Japanese, and Spanish. You can only link one stop word dictionary per language to a given search profile.

Interaction with other features

The following table describes interactions between stop words and other features that modify search queries or results.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Interaction with stop words</th>
</tr>
</thead>
<tbody>
<tr>
<td>Genius Results</td>
<td>If a search query term that matches a Genius Result configuration's Term trigger is defined as a stop word, evaluates the trigger before removing the stop word from the search query.</td>
</tr>
<tr>
<td>Lemma and Unicode normalization</td>
<td>If a search query term is defined as a stop word, removes the term without normalizing it.</td>
</tr>
<tr>
<td>Result improvement rules</td>
<td>If a search query term that matches a result improvement rule's Query trigger is defined as a stop word, evaluates the rule trigger before removing the stop word from the search query.</td>
</tr>
</tbody>
</table>
| Synonyms                       | If a synonym expands a search query's terms to include a term defined as a stop word, removes the stop word before computing results for the expanded search query.  
                                    For example, suppose you define paas as a stop word and saas##paas as a synonym. If a user searches for saas, the synonym expands the search query term to saas OR paas, but removes the paas stop word before computing the search's results. |
| Typo handling                  | If a misspelled search query term is defined as a stop word, auto-corrects the term normally instead of removing it. Ignores terms defined as stop words when determining an auto-correction for a misspelled search query term. For example, if you define email as a stop word, does not offer email as an auto-correction when you search for emial. |

Publishing stop word dictionaries

Publishing a stop word dictionary makes its settings and active stop words take effect in all linked search profiles.

Publishing a search profile updates the profile's stop word dictionary links but does not update the dictionary's settings or active stop words in AI Search.

Create a stop word dictionary linked to a search profile
Define a new stop word dictionary and link it to a search profile.

Role required: ais_admin

To make a stop word dictionary affect search behavior, you must link it to a search profile, either at creation time or afterward. You can only link one stop word dictionary per language to a given search profile. To learn about linking a saved stop word dictionary to a search profile, see Link a stop word dictionary to a search profile.

1. Navigate to **AI Search > Search Experience > Search Profiles**.
2. Edit the search profile that you want to link the new stop word dictionary to.
3. In the Stop Words related list, click **Create and Link**.
4. On the form, fill in the fields.

### Dictionary form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Label</td>
<td>Unique label for the dictionary.</td>
</tr>
<tr>
<td>Dictionary name</td>
<td>Name for the dictionary. This field is automatically set based on the <strong>Label</strong> field value.</td>
</tr>
<tr>
<td>Language</td>
<td>Language for all stop words defined in the dictionary. AI Search only considers stop words with the same language as the search query. You can only link one stop word dictionary with a given language to a search profile.</td>
</tr>
<tr>
<td>Type</td>
<td>Dictionary type. This field is automatically set to <strong>Stop Word</strong>.</td>
</tr>
<tr>
<td>State</td>
<td>Current state of the dictionary.</td>
</tr>
<tr>
<td></td>
<td>• <strong>New</strong>: The dictionary has never been published.</td>

</tr>
</tbody>
</table>

5. To save the new stop word dictionary and link it to the specified search profile, click **Submit**.

The new stop word dictionary appears in the Stop Words related list.

To make new or updated stop word dictionary settings take effect, publish the search profile that you edited. For details on publishing a search profile, see Publish a search profile.

Create stop words

Define terms to remove from search queries.

Role required: ais_admin
You must have already created a stop word dictionary. For information on creating stop word dictionaries, see Create a stop word dictionary linked to a search profile.

1. Navigate to **AI Search > AI Search Engine > Dictionaries**.
2. Edit the stop word dictionary that you want to add the new stop word to.
3. In the AI Search Dictionary Terms related list, click **New**.
4. On the form, fill in the fields.

### Dictionary Term form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dictionary</td>
<td>Name of the dictionary containing the stop word. This field is automatically set based on the stop word dictionary that you selected.</td>
</tr>
<tr>
<td>Term</td>
<td>Term to define as a stop word.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate the stop word for use in the stop word dictionary. To deactivate the stop word, clear the <strong>Active</strong> check box.</td>
</tr>
</tbody>
</table>

5. Click **Submit**.
   The new stop word appears in the AI Search Dictionary Terms related list.

6. Optional: Repeat the preceding steps for each additional stop word that you want to create.

7. Choose one of the following actions.
   - To save the modified dictionary and refresh its active stop words in all linked search profiles, click **Publish**.
   - To save the modified dictionary without refreshing its active stop words in all linked search profiles, click **Update**.

### Clone a stop word dictionary

Create a copy of an existing stop word dictionary.

Role required: ais_admin

Cloning a stop word dictionary copies the source dictionary's settings and all of its all defined stop word terms. This process can save you time when you need multiple stop word dictionaries that have many stop word terms in common.

1. Navigate to **AI Search > Search Query Settings > Dictionaries**.
2. Expand the Stop Word record group if necessary and edit the stop word dictionary that you want to clone.
3. Click **Clone**.
4. In the Set Dictionary Label dialog box, enter a label for the new stop word dictionary in the **Cloned dictionary label** field and click **OK**.

The new stop word dictionary form opens. All stop word terms defined in the source dictionary appear in the AI Search Dictionary Terms related list.

### Link a stop word dictionary to a search profile

Link an existing stop word dictionary to one or more search profiles.

Role required: ais_admin

You can link a single stop word dictionary to multiple search profiles. You can only link one stop word dictionary per language to a given search profile.

1. Navigate to **AI Search > Search Experience > Search Profiles**.
2. Edit the search profile that you want to link the stop word dictionary to.
3. In the Stop Words related list, click **Link Existing**.
4. On the AI Search Profile Dictionary M2M form, follow these steps.
   a) Click the reference lookup icon (🔍) for the Dictionary field.
   b) Select the stop word dictionary that you want to link to the search profile.
   c) Click Submit.

The selected stop word dictionary appears in the search profile's Stop Words related list.

To make the new stop word dictionary linking take effect, publish the search profile. For more information on publishing a search profile, see Publish a search profile.

Unlink a stop word dictionary from a search profile

Remove a stop word dictionary that is not linked from any search profile.

Role required: ais_admin

Unlinking a stop word dictionary from a search profile does not delete the dictionary. To delete a stop word dictionary, you must first unlink it from all search profiles. For steps to delete a stop word dictionary, see Delete a stop word dictionary.

1. Navigate to AI Search > Search Experience > Search Profiles.
2. Edit the search profile that you want to unlink the stop word dictionary from.
3. In the Stop Words related list, select the option for the stop word dictionary that you want to unlink from the search profile.
4. Click Unlink Selected.

The selected stop word dictionary disappears from the search profile's Stop Words related list.

To make the change in stop word dictionary linking take effect, publish the search profile. For more information on publishing a search profile, see Publish a search profile.

Delete a stop word dictionary

Remove a stop word dictionary that is not linked from any search profile.

Role required: ais_admin

1. Navigate to AI Search > Search Query Settings > Dictionaries.
   The AI Search Dictionaries list appears with a [Type] [!=] [Spell Check] filter condition applied and records grouped by dictionary type.
2. Expand the Stop Word record group if necessary and edit the stop word dictionary that you want to delete.
3. Click Delete.

   Note: If the stop word dictionary is still linked to any search profiles, deletion fails and an error message lists the linked profiles. Unlink the dictionary from these search profiles, then repeat the preceding steps. For details on unlinking a stop word dictionary from a search profile, see Unlink a synonym dictionary from a search profile.

The selected stop word dictionary disappears from the AI Search Dictionaries list.

Typo handling

AI Search replaces misspelled search query terms with auto-correction terms derived from indexed content. Configure typo handling dictionary settings to control derivation of auto-correction terms.

To define auto-correction terms for a search profile, modify settings in the profile's linked typo handling dictionary. The typo handling dictionary derives a list of auto-correction terms from indexed content found in search sources linked to its search profile. Update the typo handling dictionary to save its settings. Publish the linked search profile to make auto-correction terms available for searches that use the profile.
AI Search automatically creates a typo handling dictionary for a search profile when you link search sources to that profile. You cannot delete a typo handling dictionary, unlink it from its search profile, or link it to any other search profile.

To disable typo handling auto-correction for a search application, deselect the **Enable Typo Handling** option in the search application configuration. For more details on search application configuration settings, see [Create a search application configuration for AI Search](#).

**Conditions for auto-correction term eligibility**

When deriving its list of auto-correction terms, the typo handling dictionary only considers indexed terms that satisfy the following conditions:

- The term includes at least 3 characters and no more than 255 characters.
- The term appears at least once in indexed records from the search profile's linked search sources.

**Auto-correction of search query terms**

When a search query includes a term not present in the typo handling dictionary, AI Search looks for terms in the dictionary with similar spelling. If it finds a good match, it automatically replaces the original search query term with the dictionary term.

For example, a search for `emial`, which is not present on any indexed record, might auto-correct to the similarly spelled term `email` which exists on multiple indexed records and thus appears in the typo handling dictionary.

A notification message displays the auto-corrected term. Users can click the link in this message to repeat their search with the original query term.

**Showing results for email**

*Search instead for emial*

**Terms excluded from auto-correction**

Auto-correction ignores search query terms that satisfy any of the following conditions:

<table>
<thead>
<tr>
<th>Condition</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Search query term less than 3 characters in length</td>
<td>Auto-correction ignores search query terms below 3 characters in length.</td>
</tr>
<tr>
<td></td>
<td>For example, AI Search does not auto-correct the search query term <code>gi</code>.</td>
</tr>
<tr>
<td>Search query term includes only uppercase letters</td>
<td>To enable search for abbreviations, auto-correction ignores search query</td>
</tr>
<tr>
<td></td>
<td>terms that contain only uppercase letters.</td>
</tr>
<tr>
<td></td>
<td>For example, AI Search does not auto-correct the search query term <code>PINN</code>,</td>
</tr>
<tr>
<td></td>
<td>even if it auto-corrects the lowercase form <code>pinn</code> to <code>pin</code>.</td>
</tr>
<tr>
<td>Condition</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Search query term includes one or more numeric digits</td>
<td>To enable search for numbers and alphanumeric identifiers, auto-correction ignores search query terms that include numeric digits. For example, AI Search does not auto-correct the search query term 4 0 2 K.</td>
</tr>
<tr>
<td>Search query term excluded from typo handling dictionary</td>
<td>Auto-correction ignores search query terms excluded from the typo handling dictionary. For instructions on excluding terms from a typo handling dictionary, see Exclude a term from a typo handling dictionary.</td>
</tr>
</tbody>
</table>

**Automatic refresh of auto-correction term lists**

Each typo handling dictionary automatically refreshes its list of auto-correction terms after a set interval. The refresh operation has the same effect as republishing the dictionary's linked search profile.

By default, typo handling dictionaries refresh every 24 hours. If you want the term list refreshed less frequently, you can increase this interval in the dictionary settings.

**Language dependence**

Typo handling is language-dependent. AI Search derives a separate list of auto-correction terms for each supported language found in the search sources' indexed content.

AI Search supports derivation of auto-correction terms for English, French Canada, French, German, and Spanish. Typo handling auto-correction term derivation is not supported for Japanese.

**Interaction with other features**

The following table describes interactions between typo handling and other features that modify search queries or results.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Interaction with typo handling</th>
</tr>
</thead>
<tbody>
<tr>
<td>Genius Results</td>
<td>Auto-corrected search query terms cannot trigger Genius Result configurations with Term trigger conditions.</td>
</tr>
<tr>
<td>Lemma and Unicode normalization</td>
<td>performs lemma and Unicode normalization on auto-corrected search query terms.</td>
</tr>
<tr>
<td>Result improvement rules</td>
<td>An auto-corrected search query term can trigger a result improvement rule if it matches the rule's Query trigger.</td>
</tr>
</tbody>
</table>
Feature | Interaction with typo handling
--- | ---
Stop words | If a misspelled search query term is defined as a stop word, auto-corrects the term normally instead of removing it. Ignores terms defined as stop words when determining an auto-correction for a misspelled search query term. For example, if you define `email` as a stop word, does not offer `email` as an auto-correction when you search for `email`.

Synonyms | If a misspelled search query term is defined as a synonym, expands the synonym without auto-correcting it.

Modify settings for a typo handling dictionary
Modify typo handling dictionary settings for a search profile.

Role required: ais_admin

Each typo handling dictionary is linked to a search profile. For more information about search profiles, see Search profiles.

1. Navigate to **AI Search > Search Experience > Search Profiles**.
2. Edit the search profile that contains the typo handling dictionary that you want to modify.
3. In the Typo Handling related list, edit the record for the typo handling dictionary.
4. On the form, update the fields.

### AI Search Dictionary form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Label</td>
<td>Unique label for the typo handling dictionary.</td>
</tr>
<tr>
<td>Dictionary name</td>
<td>Name for the typo handling dictionary. This field is automatically set based on the initial <code>Label</code> field value.</td>
</tr>
<tr>
<td>Type</td>
<td>Dictionary type. This field is automatically set to Spell Check.</td>
</tr>
<tr>
<td>State</td>
<td>Current state of the dictionary.</td>
</tr>
<tr>
<td></td>
<td>• <strong>New</strong>: The dictionary has never been published.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Draft</strong>: The dictionary is saved with unpublished changes.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Published</strong>: The dictionary is saved with all changes published.</td>
</tr>
<tr>
<td></td>
<td>This field is automatically set.</td>
</tr>
<tr>

<td>Option to enable case sensitivity for all auto-correction terms in the dictionary. For more details on case sensitivity, see Typo handling.</td>
</tr>
<tr>
<td>Punctuation sensitive</td>
<td>Option to enable punctuation sensitivity for all auto-correction terms in the dictionary. For more details on punctuation sensitivity, see Typo handling.</td>
</tr>
</tbody>
</table>
## Field | Description
--- | ---
**Derived** | Option to derive dictionary entries from indexed content. This field is automatically set.

**Derive Settings**

| **Indexed sources** | List of indexed sources. The dictionary derives auto-correction terms from content indexed for these sources. For more information on indexed sources, see Indexed sources. |

| **Auto refresh** | Interval, in hours, after which derived typo handling entries automatically refresh. The minimum value is 24 hours. |

**Blocked Fields**

| | Comma-separated list of fields. The dictionary excludes terms found in these fields when deriving typo handling auto-correction terms from indexed source records. You can specify fields using the following formats: |
| | • * (asterisk): Exclude terms found in all fields. This value disables derivation of typo-handling auto-corrections for the dictionary. |
| | • `fieldname`: Exclude terms found in the specified AI Search index field, such as `title` or `text`. For details on AI Search index fields, see AI Search index fields. |
| | • `tablename.fieldname`: Exclude terms found in the specified field on the specified Now Platform table. |
| | • `tablename.*`: Exclude terms found in all fields in the specified Now Platform table. |

---

5. **Click Update.**

To make updated settings for a typo handling dictionary take effect, publish the search profile linked to the dictionary. For details on publishing a search profile, see Publish a search profile.

**Exclude a term from a typo handling dictionary**

Prevent AI Search from auto-correcting a term in user search queries by excluding the term from a typo handling dictionary.

You must have already defined a search profile with one or more linked search sources.

Role required: ais_admin

1. Navigate to **AI Search > Search Experience > Search Profiles.**
2. Edit the search profile that you want to exclude a typo handling term for.
3. In the Typo Handling related list, edit the typo handling dictionary.
4. In the AI Search Dictionary Terms related list, click **New.**
5. On the form, fill in the fields.

### Dictionary Term form

<table>
<thead>
<tr>
<th><strong>Field</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Dictionary</strong></td>
<td>Typo handling dictionary that the term exclusion applies to. This field is automatically set.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Term</td>
<td>Term that you want auto-correction to ignore in user search queries.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope for the term exclusion. This field is automatically set.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate the term exclusion for the typo handling dictionary.</td>
</tr>
<tr>
<td>Marked for Deletion</td>
<td>Option indicating that AI Search will delete the term exclusion the next time you publish the search profile linked to the typo handling dictionary. This field is automatically set.</td>
</tr>
</tbody>
</table>

6. Click **Submit**.

The new term appears in the AI Search Dictionary Terms related list with the **State** set to **New**.

7. Optional: Repeat the preceding steps for each additional term that you want to exclude.

8. Click **Publish**.

The typo handling dictionary appears in the Typo Handling related list with the **State** set to **Published**.

To make updated typo handling settings take effect, publish the search profile that you edited. For details on publishing a search profile, see **Publish a search profile**.

**Genius Results**

Optionally display the best answers for a search query as actionable Genius Result cards included with search results.

**Note:** Genius Results are not enabled in the base system. To use Genius Results, you must manually enable them. For instructions on enabling Genius Results in your instance, see **Train and publish the NLU model for default Genius Result configurations** and **Enable Genius Results**.

A Genius Result configuration includes a trigger condition and logic for creating answers. The trigger condition determines whether the Genius Result configuration activates for a search query. When a configuration activates, its answer logic populates one or more Genius Result cards with information and actions. These Genius Result cards are displayed with the list of results for the search query, giving the user immediate access to answers and actions.

**Genius Result trigger conditions**

You can select any one of the following trigger conditions for a Genius Result configuration:

- **Always**: The Genius Result configuration activates for all search queries.
- **NLU**: The Genius Result configuration activates when the search query’s detected intent matches a specified NLU model intent. For more information on NLU models and intents, see **Natural Language Understanding**.
- **Term**: The Genius Result configuration activates when the search query consists of a single specified term or phrase.

**Genius Result answer types**

A Genius Result configuration can include either of the following answer types:

- **Search**: When triggered, displays Genius Result cards for up to three results from a search query defined by a server-side script in the Genius Result configuration. Each search result displays as a separate Genius Result card. If the search query returns no results, no Genius Result card is displayed.
• **Script**: When triggered, displays a Genius Result card containing key-value pairs from an object defined by a server-side script in the Genius Result configuration. The script can use methods from any Now Platform public API to construct this object.

### Language support

In the Quebec release, Genius Results only support English search queries.

### NLU model row limit for Genius Results

By default, Genius Result configurations with NLU trigger conditions only consider a maximum of 100,000 randomly selected records from their target table. As a result, they may not display all matches from large target tables.

You can override this default limit by modifying the value of the **Maximum number of records in a Table vocabulary source** NLU Workbench system property (glide.platform_ml.api.max_nlu_lookupsource_records).

**Warning**: Be careful when increasing this limit beyond the default value, as higher values may affect performance of search queries and other functions that rely on NLU matching.

For more information on NLU Workbench system properties, see NLU Workbench properties.

### Interaction with other features

The following table describes interactions between Genius Results and other features that modify search queries or results.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Interaction with Genius Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lemma and Unicode normalization</td>
<td>Search query terms added by lemma or Unicode normalization cannot trigger Genius Result configurations with Term trigger conditions.</td>
</tr>
<tr>
<td>Stop words</td>
<td>If a search query term that matches a Genius Result configuration’s Term trigger is defined as a stop word, evaluates the trigger before removing the stop word from the search query.</td>
</tr>
<tr>
<td>Synonyms</td>
<td>Synonym expansion terms cannot trigger Genius Result configurations with Term trigger conditions.</td>
</tr>
<tr>
<td>Typo handling</td>
<td>Auto-corrected search query terms cannot trigger Genius Result configurations with Term trigger conditions.</td>
</tr>
</tbody>
</table>

Train and publish the NLU model for default Genius Result configurations

Train and publish the NLU model used by default Genius Result configurations with NLU triggers.

Role required: admin or nlu_admin

Some of the default Genius Result configurations have NLU triggers. These configurations rely on intents defined in an AI Search NLU model. To make this model available for use in Genius Result configurations, sync its vocabulary sources, then train and publish it.

1. Navigate to NLU Workbench > Vocabulary Sources.
2. In the **ServiceNow Tables** tab, for each vocabulary source used in the Default AI Search Genius Results Model, point to the empty last column and click **Sync**.

**Vocabulary sources**

<table>
<thead>
<tr>
<th>Vocabulary handle</th>
<th>Source table</th>
<th>Source field</th>
<th>Used in</th>
<th>Last refresh</th>
<th>Current status</th>
<th>Refresh</th>
</tr>
</thead>
<tbody>
<tr>
<td>#CatalogItem</td>
<td>Catalog Item</td>
<td>Name</td>
<td>Default AI Search Genius Results Model</td>

<td>Never synced</td>
<td>Every 7 days</td>
</tr>
<tr>
<td>RightLocation</td>
<td>Location</td>
<td>City</td>
<td>Default AI Search Genius Results Model</td>
<td>-</td>
<td>Never synced</td>
<td>Every 7 days</td>
</tr>
</tbody>
</table>

The current status of each vocabulary source changes to **Syncing**. When sync is complete, it changes to **Synced**.

![Sync button](image)

**Note:** The system may take a few hours to complete initial sync for a vocabulary source. Later sync operations for the vocabulary source complete faster, in minutes or seconds.

3. Navigate to **NLU Workbench > Models**.
4. Edit the record for the Default AI Search Genius Results Model.
5. Click **Train**.
   The **Test model** and **Train and publish** tabs appear in a new pane.
6. In the **Train and publish** tab, click **Train**.

**Note:** Depending on the amount of data in your instance, the system may take some time to train the NLU model.

An informational message indicates that training completed successfully.

7. In the **Train and publish** tab, click **Publish**.
   The **Publish UI Model** dialog box appears.
8. In the **Publish UI Model** dialog box, click **Publish**.

**Note:** Depending on the amount of data in your instance, the system may take some time to publish the NLU model.

An informational message indicates that publishing completed successfully.

Genius Result configurations can use the Default AI Search Genius Results Model. The system retrains and republishes this NLU model every seven days.

Publish any search profiles that include Genius Results, then follow the steps in **Enable Genius Results** to activate Genius Results for your search queries.

Enable Genius Results
Genius Results are not enabled in the base system. To use Genius Results, you must manually enable them.

If you intend to use Genius Results configurations with NLU triggers, follow the steps from **Train and publish the NLU model for default Genius Result configurations** before performing this task.

Role required: admin
To enable Genius Results in your instance, set the value of the glide.ais.genius_result.enabled system property to true.

1. In the filter navigator, enter sys_properties.list and press Enter.
2. Edit the glide.ais.genius_result.enabled system property.
3. Change the system property’s value to true.
4. Click Update.

Train and publish the NLU model for default Genius Result configurations

Train and publish the NLU model used by default Genius Result configurations with NLU triggers.

Role required: admin or nlu_admin

Some of the default Genius Result configurations have NLU triggers. These configurations rely on intents defined in an AI Search NLU model. To make this model available for use in Genius Result configurations, sync its vocabulary sources, then train and publish it.

1. Navigate to NLU Workbench > Vocabulary Sources.
2. In the ServiceNow Tables tab, for each vocabulary source used in the Default AI Search Genius Results Model, point to the empty last column and click Sync.

Vocabulary sources

<table>
<thead>
<tr>
<th>Vocabulary handle</th>
<th>Source table</th>
<th>Source field</th>
<th>Used In</th>
<th>Last refresh</th>
<th>Current status</th>
<th>Refresh</th>
</tr>
</thead>
<tbody>
<tr>
<td>@ActionItem</td>

<tr>
<td>@ActionLocation</td>
<td>Location</td>
<td>City</td>
<td>Default AI Search Genius Results Model</td>
<td>Never synced</td>
<td>Every 7 days</td>
<td></td>
</tr>
</tbody>
</table>

The current status of each vocabulary source changes to Syncing. When sync is complete, it changes to Synced.

Note: The system may take a few hours to complete initial sync for a vocabulary source. Later sync operations for the vocabulary source complete faster, in minutes or seconds.

4. Edit the record for the Default AI Search Genius Results Model.
5. Click Train.

The Test model and Train and publish tabs appear in a new pane.

6. In the Train and publish tab, click Train.

Note: Depending on the amount of data in your instance, the system may take some time to train the NLU model.

An informational message indicates that training completed successfully.

7. In the Train and publish tab, click Publish.

The Publish UI Model dialog box appears.
8. In the Publish UI Model dialog box, click Publish.

Note: Depending on the amount of data in your instance, the system may take some time to publish the NLU model.

An informational message indicates that publishing completed successfully.

Genius Result configurations can use the Default AI Search Genius Results Model. The system retrain and republishes this NLU model every seven days.

Publish any search profiles that include Genius Results, then follow the steps in Enable Genius Results to activate Genius Results for your search queries.

Default Genius Result configurations

Pre-configured AI Search Genius Result configurations display actionable top results for People, Catalog Item, and Q&A search queries.

You can link these default Genius Result configurations to your own search profiles. You cannot modify the default Genius Result configurations, but you can clone them and modify the cloned configurations.

Catalog Item - EN

The Catalog Item - EN Genius Result configuration displays top search results from the Catalog Item [sc_cat_item] table. Each answer card shows a single CI record.

Sample Catalog Item - EN answer card

Click the answer card's Request Item action link to create a new request for the specified CI.

People - EN

The People - EN Genius Result configuration displays top search results from the User [sys_user] table. Each answer card shows a single user record.
Sample People - EN answer card

Click the answer card’s View profile action link to see the user’s profile, or click the View org chart action link to view the user’s organization chart.

Q&A

The Q&A Genius Result configuration displays top search results extracted from HTML fields of records on the Knowledge [kb_knowledge] table and tables that extend it. Each answer card shows a topic and answer pair extracted from a single Knowledge article.

Sample Q&A answer card

Click the answer card’s View Article action link to view the full Knowledge article.

Topic and answer extraction for Q&A Genius Results

By default, AI Search automatically determines which elements of a Knowledge article’s HTML field values to extract as the Q&A topic and answer. You cannot configure the criteria for this extraction behavior.

Topic and answer extraction behavior varies depending on the table that contains the Knowledge article:
Knowledge article source | Q&A heuristic extraction
---|---
FAQ [kb_template_faq] table | AI Search heuristically extracts the Q&A topic from the Knowledge article record's Question HTML field. It extracts the Q&A answer from the record's Answer HTML field.

**Note:** This table is enabled when you activate the Knowledge Management Advanced plugin (com.snc.knowledge_advanced). For more information, see Activate the Knowledge Management Advanced plugin.

Knowledge [kb_knowledge] table and all other tables that extend it | AI Search heuristically extracts the Q&A topic and answer from the Knowledge article record's HTML fields.

You can override the extraction heuristics for a Knowledge article by manually designating a topic and an answer in that article's HTML fields. To do so, set the HTML classes described in the following table on elements in the article's HTML fields.

<table>
<thead>
<tr>
<th>HTML Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>class=&quot;sn_snippet_topic&quot;</td>
<td>Set this class on the HTML field element that contains text you want to designate as the Q&amp;A Genius Result topic for the Knowledge article.</td>
</tr>
<tr>
<td>class=&quot;sn_snippet_answer&quot;</td>
<td>Set this class on the HTML element that contains text that you want to designate as the Q&amp;A Genius Result answer for the Knowledge article.</td>
</tr>
</tbody>
</table>

**Note:** Answer text should be from 250 to 300 characters in length. Longer answers may be cut off when displayed on the Q&A Genius Results card.

Link a Genius Result configuration to a search profile

Link a Genius Result configuration to one or more search profiles.

Role required: ais_admin

You can link a single Genius Result configuration to multiple search profiles.

1. Navigate to **AI Search > Search Experience > Search Profiles**.
2. Edit the search profile that you want to link the Genius Result configuration to.
3. In the Genius Results related list, click **Link Existing**.
4. On the form, fill in the fields.

**Search Profile - Genius Result Mapping form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Profile</td>
<td>The search profile to link the Genius Result configuration to. This field is automatically set to the profile that you edited.</td>
</tr>
<tr>
<td>Genius Result Configuration</td>
<td>The Genius Result configuration to link to the specified search profile.</td>
</tr>
<tr>
<td>Order</td>
<td>Order of evaluation for the Genius Result configuration in the context of the search profile.</td>
</tr>
</tbody>
</table>
Create a Genius Result configuration

Role required: ais_admin

1. Navigate to **AI Search > Search Experience > Search Profiles**.
2. Edit the search profile that you want to link the new Genius Result configuration to.
3. In the Genius Results related list, click **Create and Link**.
4. On the form, fill in the fields.

**AI Search Genius Result Configuration form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name for the Genius Result configuration.</td>
</tr>
</tbody>
</table>

5. Click **Submit**.

The new Genius Result configuration appears in the Genius Results related list.

---

The new Genius Result configuration appears in the Genius Results related list.

Create a Genius Result configuration

Create a Genius Result configuration, set its trigger condition, and configure the results displayed on its answer card.

Role required: ais_admin

1. Navigate to **AI Search > Search Experience > Search Profiles**.
2. Edit the search profile that you want to link the new Genius Result configuration to.
3. In the Genius Results related list, click **Create and Link**.
4. On the form, fill in the fields.

**AI Search Genius Result Configuration form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name for the Genius Result configuration.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Trigger condition</td>
<td>Condition that triggers evaluation of the Genius Result configuration. Supported values:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Always</strong>: The Genius Result configuration triggers for every search query.</td>
</tr>
<tr>
<td></td>
<td>• <strong>NLU</strong>: The Genius Result configuration triggers when the search query’s detected intent matches an NLU model intent. To use this trigger condition, you must link the NLU model and one or more of its intents to your Genius Result configuration. For instructions, see Link an NLU model and intents to a Genius Result configuration.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> For an NLU trigger condition to function, the NLU model must be published. You can verify NLU model status by navigating to <strong>AI Search &gt; Search Query Settings &gt; Search Intents</strong>.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Term</strong>: The Genius Result configuration triggers when the search query exactly matches a specified set of query terms.  <strong>Note:</strong> Exact matching means that the search query must contain only the specified terms in the specified order. For example, if you define <code>conference room</code> as the trigger term, a search for <code>conference room</code> triggers the Genius Result condition but searches for <code>hotel conference room</code> or <code>room conference</code> do not trigger it.</td>
</tr>
<tr>
<td>Term</td>
<td>Term that triggers the Genius Result configuration when it exactly matches the search query. This field appears only when you select <strong>Term</strong> from the <strong>Trigger condition</strong> field.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope for the Genius Result configuration. This field is automatically set.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to enable the Genius Result configuration. Inactive Genius Result configurations never trigger.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Genius result answer type</td>
<td>Type of answer the Genius Result configuration should return when triggered by a search query. Supported values:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Search</strong>: Displays Genius Result cards for up to three results from a search query. You define this search query in an answer object using server-side script logic in the Genius result logic field. Each search result is displayed as a separate Genius Result card. If the search query returns no results, no Genius Result card is displayed.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Script</strong>: Displays a Genius Result card containing arbitrary field names and values (key-value pairs). You add these fields to an answer object using server-side script logic in the Genius result logic field. The script can use methods from any Now Platform public API to construct this object.</td>
</tr>
<tr>
<td>Genius result logic</td>
<td>Server-side script function that takes a query context object as its parameter. This script returns a GeniusResultAnswer object used to populate Genius Result answer cards. The required structure for the answer object varies by Genius Result answer type:</td>
</tr>
<tr>
<td></td>
<td>• For the <strong>Search</strong> answer type, the GeniusResultAnswer object must define a search query using the GeniusResultAnswer.setTable(), GeniusResultAnswer.addSearchPhrases(), and GeniusResultAnswer setSearchPhrase() API methods. Each result from the search query is displayed as a separate Genius Result answer card, to a maximum of three results.</td>
</tr>
<tr>
<td></td>
<td>• For the <strong>Script</strong> answer type, the GeniusResultAnswer object must define a map of key-value pairs using the GeniusResultAnswer.addDataMap() API method. Each key-value pair represents a field name and value that you want the Genius Result answer card to display.</td>
</tr>
<tr>
<td></td>
<td>For descriptions of API methods usable in this script function, see the GeniusResultAnswer and GeniusResultContext scoped JavaScript API descriptions.</td>
</tr>
</tbody>
</table>
Return fields

Comma-separated list of fields to display on the Genius Result answer card. Behavior varies by Genius Result answer type:

- For the **Search** answer type, the answer card automatically displays the common AI Search index fields:
  - ai_search_parent_title
  - ai_search_teaser_text
  - ai_search_teaser_title
  - record_class_name
  - sys_id
  - table

Use this field to specify any additional AI Search index fields that you want to display for search results on the Genius Result answer cards.

To view the list of AI Search index fields, see [AI Search index fields](#).

- For the **Script** answer type, use this field to specify the names of fields defined in the GeniusResultAnswer object that you want to display on the Genius Result answer card.

5. Click **Submit**.
   The new Genius Result configuration appears in the Genius Results related list.

6. Optional: Edit the **Order** for the new Genius Result configuration to control its display order for the search profile.

Changes to Genius Result configurations take effect in search as soon as you save them. You do not need to publish the linked search profile to make the new configuration take effect.

If you selected an **NLU** trigger condition, you must link an NLU model and its intents to your Genius Result configuration. For instructions, see [Link an NLU model and intents to a Genius Result configuration](#).

Link an NLU model and intents to a Genius Result configuration
Specify the NLU model and intents to use for a Genius Result configuration with an NLU trigger condition.

Role required: ais_admin

1. Navigate to **AI Search > Search Query Settings > Genius Results**.
2. Edit the Genius Result configuration that you want to link an NLU model to.
3. In the NLU Model related list, click **Link Existing**.
4. On the form, fill in the fields.

**NLU Model form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Genius Result Configuration</td>
<td>The Genius Result configuration to link the NLU model to. This field is automatically set to the selected Genius Result configuration.</td>
</tr>
<tr>
<td>NLU Model</td>
<td>Existing NLU model to use for the Genius Result configuration's NLU trigger condition.</td>
</tr>
</tbody>
</table>
## ServiceNow DocVersion Now Platform administration

### Field | Description
--- | ---
Intents | List of intents from the NLU model that can trigger the Genius Result configuration when detected in the search query.
Order | Order of evaluation for the NLU model in the context of the Genius Result configuration.
Application | Application scope for the NLU model link. This field is automatically set.

5. Click **Submit**.

The NLU model and its selected intents appear in the NLU Models related list.

For an NLU trigger condition to function, the NLU model must be published. You can verify NLU model status by navigating to **AI Search > Search Query Settings > Search Intents**.

### Result improvement rules

Define rules with configurable trigger conditions to boost, block, or promote search results for specific searches. You can also boost search results for documents matching elements of the user context, such as a user's location or device.

Result improvement rules with boost actions override the default search result order produced by the AI Search machine learning relevancy feature. Rules with block or promote actions override the default result set for a search query.

### Rule structure

A result improvement rule consists of these parts:

- A set of conditions that determine when the rule activates.
- A set of boost, block, or promote actions that determine how the rule modifies the search query's results when activated. The rule can only include actions of a single type, but can include multiple actions of that type.

Rule conditions include the following:

- A date range bounded by start and end dates. The rule can only activate during the specified date range.
- A language. The rule can only activate if this language matches the search query's language.
- Optionally, a set of one or more trigger conditions. Triggers can act on the search query, its intent, or elements of the user context. The rule can only activate if all of its trigger conditions are met.

Rule actions include the following types:

- **Boost**: Increase the relevancy scores for search result records that include specific field values. You can use either of the following options:
  - Boost search result records that include field values matching a dynamically populated value from the user context.
  - Boost search result records that include field values matching a static value that you specify.

- **Block**: Exclude specific records from the search query's results.

- **Promote**: Display specific records at the start of the search query's results.

Each result improvement rule can only perform actions of a single type when activated. You can define multiple actions of the same type for a rule.

Block actions take precedence over promote actions. If two rules block and promote the same record, AI Search excludes the record from the search query's results.
Language dependence

Result improvement rule activation is language-dependent. You specify a language for each result improvement rule. AI Search supports result improvement rules for English, French Canada, French, German, Japanese, and Spanish.

Interaction with other features

The following table describes interactions between result improvement rules with Query triggers and other features that modify the user's search query or its results.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Interaction with result improvement rules</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lemma and Unicode normalization</td>
<td>A search query term added by lemma or Unicode normalization can trigger a result improvement rule if it matches the rule's Query trigger.</td>
</tr>
<tr>
<td>Stop words</td>
<td>If a search query term that matches a result improvement rule's Query trigger is defined as a stop word, evaluates the rule trigger before removing the stop word from the search query.</td>
</tr>
<tr>
<td>Synonyms</td>
<td>By default, a synonym expansion term can activate a result improvement rule if it matches the rule's Query trigger. You can prevent synonym expansion terms from activating a rule with a Query trigger by clearing the Expand Synonyms For Query Conditions option that appears when you define the Query trigger.</td>
</tr>
<tr>
<td>Typo handling</td>
<td>An auto-corrected search query term can trigger a result improvement rule if it matches the rule's Query trigger.</td>
</tr>
</tbody>
</table>

Create a result improvement rule

Create a rule to boost, block, or promote search results. Specify the conditions that activate your rule and choose the action it performs when activated.

Role required: ais_admin

This topic lists the steps required to configure activation conditions and triggers for a result improvement rule. Additional topics cover steps for configuring boost, block, or promote actions for your rule.

**Note:** Each result improvement rule can only perform actions of a single type when activated. You can define multiple actions of the same type for a rule.

1. Navigate to **AI Search > Search Experience > Search Profiles**.
2. Edit the search profile that you want to add the result improvement rule to.
3. In the Result Improvement Rules related list, click **Create**.
4. On the form, fill in the fields.

**AI Search Result Improvement Rule form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Label</td>
<td>Unique label for the result improvement rule.</td>
</tr>

</tr>
<tr>
<td></td>
<td>• Published: The rule is saved with all changes published.</td>
</tr>
<tr>
<td></td>
<td>• Expired: The rule cannot activate because its End Date is in the past. Publishing a search profile does not publish expired rules.</td>
</tr>
<tr>
<td>Marked for Deletion</td>
<td>Option indicating that AI Search will delete the result improvement rule the next time you publish the search profile.</td>
</tr>
<tr>
<td>Triggers</td>
<td>Option for enabling synonym expansion for Query condition arguments.</td>
</tr>
<tr>
<td></td>
<td>When expanding Query conditions, AI Search only considers active synonyms that are defined in the same search profile and that have the same language as the result improvement rule.</td>
</tr>
<tr>
<td>Triggers</td>
<td>List of conditions that must be met for the result improvement rule to activate. This field disappears if you select Activate on all queries.</td>
</tr>
</tbody>
</table>

5. Click **Submit**.
   The Actions related list appears.

6. Choose the action that you want the result improvement rule to perform when activated. See the appropriate task topic to configure that action.
   - To increase the relevancy scores of search result records that include specific field values, see **Boost search results using a result improvement rule**.
   - To prevent specific records from appearing in the search results, see **Block search results using a result improvement rule**.
   - To make specific records appear first in the search results, see **Promote search results using a result improvement rule**.
To make new or updated result improvement rule settings take effect, publish the search profile that you edited. For details on publishing a search profile, see Publish a search profile.

Boost search results using a result improvement rule

Configure a result improvement rule to increase the relevancy scores of search results that satisfy a custom condition.

Create your result improvement rule first to define your trigger conditions, then follow these steps to define the action taken when the rule activates. For steps to create a result improvement rule, see Create a result improvement rule.

Role required: ais_admin

1. In the Actions related list, click **Create Boost Action**.
2. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Label</td>
<td>Unique label for the boost action.</td>

<tr>
<td>Indexed Source</td>
<td>Reference to an indexed source. The boost action only applies to records from this indexed source.</td>
</tr>
<tr>
<td>Boost Weight</td>
<td>Numeric value to add to relevancy scores for boosted search results. Positive weights increase result relevancy; negative weights decrease it.</td>
</tr>
</tbody>
</table>

**Note:** Typical boost weights are in the order of 100, 200, 300, and so on.

<table>
<thead>
<tr>
<th>When</th>
<th>Name of a field from the selected search source. This field appears only when you select <strong>Boost by User Context (dynamic)</strong> or <strong>Boost by Field Match (static)</strong> from the <strong>Boost Type</strong> field.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Matches the Searcher's</td>
<td>Dynamically populated value from user context to compare with search result field value. This field appears only when you select <strong>Boost by User Context (dynamic)</strong> from the <strong>Boost Type</strong> field.</td>
</tr>
<tr>
<td>Contains</td>
<td>Static value to compare with search result field value. This field appears only when you select <strong>Boost by Field Match (static)</strong> from the <strong>Boost Type</strong> field.</td>
</tr>
</tbody>
</table>

3. Click **Submit**.

To make new or updated result improvement rule settings take effect, publish the search profile you edited. For details on publishing a search profile, see Publish a search profile.

List of result improvement rule boost types
This list describes the types of search result relevancy boost that you can apply using a result improvement rule.

**Boost action types**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boost All Documents in Search Source</td>
<td>Applies boost to every search result from the selected search source.</td>
</tr>
<tr>
<td>Boost by User Context (dynamic)</td>
<td>Applies boost to search results from the selected search source if they include a value for the selected field that matches a specified element from the dynamically populated user context.</td>
</tr>
<tr>
<td>Boost by Field Match (static)</td>
<td>Applies boost to search results from the selected search source if they include a value for the selected field that matches a specified static value.</td>
</tr>
</tbody>
</table>

Block search results using a result improvement rule
Configure a result improvement rule to prevent specific documents from appearing in results for a search.

Create your result improvement rule first to define your trigger conditions, then follow these steps to define the action taken when the rule activates. For steps to create a result improvement rule, see Create a result improvement rule.

Role required: ais_admin

1. In the Actions related list, click **Block Documents**.
2. In the Select Documents To Block dialog box, search for results that you want to block.
3. To add a search result to the selected results pane, click the plus sign next to it.
4. After selecting all the results that you want to block, click **Add Documents and Close**.

To make new or updated result improvement rule settings take effect, publish the search profile that you edited. For details on publishing a search profile, see Publish a search profile.

Promote search results using a result improvement rule
Configure a result improvement rule to make specific records appear first in results for a search.

Create your result improvement rule first to define your trigger conditions, then follow these steps to define the action taken when the rule activates. For steps to create a result improvement rule, see Create a result improvement rule.

Role required: ais_admin

1. In the Actions related list, click **Promote Documents**.
2. In the Select Documents To Promote dialog box, search for the results that you want to promote.
3. To add a search result to the selected results pane, click the plus sign next to it.
4. After selecting all the results that you want to promote, click **Add Documents and Close**.

To make new or updated result improvement rule settings take effect, publish the search profile that you edited. For details on publishing a search profile, see Publish a search profile.

**Search application configurations**
Define search application configurations that specify AI Search as the search engine for supported Now Platform applications. Select a search experience for the application and configure its search result display and refinement settings.

AI Search includes default search application configurations for use in the following Now Platform applications:

- Employee Service Center (ESC) Portal
- Service Portal
Virtual Agent

You can modify these default configurations, or create and configure your own search application configurations with AI Search specified as the search engine.

For details on enabling AI Search and specifying search application configurations in supported applications, see Enabling and configuring AI Search in Now Platform applications.

Create a search application configuration for AI Search
Create a search application configuration to specify AI Search as the search engine for a Now Platform application. Select a search profile for the application to use. Configure the application's settings for refinement and display of search results.

Role required: search_application_admin

1. Navigate to AI Search > Search Experience > Search Applications.
2. Click New.
3. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name for the search application configuration.</td>
</tr>
<tr>
<td>Search Engine</td>
<td>Search engine to use in the Now Platform search application that links to the search application configuration. Supported values:</td>
</tr>
<tr>
<td></td>
<td>• <strong>AI Search</strong>: Use AI Search as the search engine for the application. Select this engine if your search application has the Enable AI Search option enabled.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Zing</strong>: Use the Zing text indexing and search engine as the search engine for the application. Select this engine if your search application has the Enable AI Search option disabled, or if it lacks this option.</td>
</tr>
<tr>
<td>Search Profile</td>
<td>Search profile to use for searches in the application. This field appears only when you select AI Search from the Search Engine field.</td>
</tr>
<tr>
<td>Search Results Limit</td>
<td>Maximum number of search results the application should display on each search results page. This limit also specifies the minimum number of search results each query should return. When a search query returns less than this number of results, AI Search attempts to broaden the result set by automatically resubmitting the query with modified parameters. For more details on query resubmission, see Automatic search query resubmission.</td>
</tr>
</tbody>
</table>
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Genius Results Limit</td>
<td>Maximum number of Genius Result answer cards the application should display on the search results page. This field appears only when you select AI Search from the Search Engine field.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Genius Results return a maximum of 3 answer cards per search query. If you set this limit to 4 or more, AI Search still displays a maximum of 3 answer cards.</td>
</tr>
<tr>
<td>Enable Typo Handling</td>
<td>Option to auto-correct search query terms to match terms found in the search profile’s typo handling dictionary. This field appears only when you select AI Search from the Search Engine field.</td>
</tr>
<tr>
<td></td>
<td>For more details on typo handling auto-correction configuration and behavior, see Typo handling.</td>
</tr>
</tbody>
</table>

4. Click Submit.

The new search application configuration record appears in the Search Application Configurations list.

To use your new search application configuration, select it in the configuration for a Now Platform application that supports AI Search. For more information on these Now Platform applications, see Enabling and configuring AI Search in Now Platform applications.

Enable or disable hit-highlighting for an AI Search application

Specify whether your search application should highlight matching search terms when displaying search query results.

Role required: search_application_admin

1. Navigate to AI Search > Search Experience > Search Applications.
2. Edit the search application configuration that you want to change the hit-highlighting setting for.
   
   **Note:** The search application configuration must have AI Search selected as its search engine. Hit-highlighting is only available when using AI Search.

3. On the Search Application Configuration form, if the Enable Hit-Highlighting field is not displayed, follow these steps to add it:
   a) Click the form context menu icon
      
      ![Form Context Menu Icon](image)
      
      and select Configure > Form Layout.
   b) Move Enable Hit-Highlighting to the Selected list.
   c) Click Save.

4. Select or deselect the Enable Hit-Highlighting option.
5. Click Update.
Create a facet in an AI Search application configuration
Create facets to help your users refine their searches using categories dynamically generated from the current search results.

Role required: search_application_admin

1. Navigate to **AI Search > Search Experience > Search Applications**.
2. Edit the search application configuration that you want to configure a facet for.
3. In the Facets related list, click **New**.
4. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Unique name for the facet.</td>
</tr>
<tr>
<td>Label</td>
<td>Label to display for the facet in the search application.</td>
</tr>
<tr>
<td>Facet Field</td>
<td>Qualified name of the AI Search index field that the facet uses to categorize search results for refinement. Specify this field name in <code>[table_name].[field_name]</code> format.</td>
</tr>
<tr>
<td>Facet Value Limit</td>
<td>Maximum number of distinct field values to display for the facet.</td>
</tr>
<tr>
<td>Order</td>
<td>Order of appearance for the facet in the context of the search application configuration.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate the facet for the application.</td>
</tr>
</tbody>
</table>

5. Click **Submit**.

The new facet appears in the Facets related list.

Configure navigation tabs in an AI Search application configuration
Define settings for navigation tabs in a search application configuration. Users of the application can select navigation tabs to refine their search query results by search source.

Role required: search_application_admin

AI Search automatically defines navigation tabs for search application configurations. Each tab is tied to a search source linked to the search application configuration's search profile. You cannot create or delete these navigation tabs.

Follow these steps to configure display settings for navigation tabs in your search application configuration.

1. Navigate to **AI Search > Search Experience > Search Applications**.
2. Edit the search application configuration that you want to configure navigation tabs for.
3. In the Navigation Tabs related list, edit the navigation tab that you want to configure.
4. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name for the navigation tab. This field is set by default to the name of the originating search source. Changing the name does not affect the navigation tab's filtering behavior.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to enable the navigation tab. Inactive navigation tabs are not displayed.</td>
</tr>
<tr>
<td>Order</td>
<td>Order of appearance for the navigation tab in the context of the search application configuration.</td>
</tr>
<tr>
<td>Label</td>
<td>Label to display for the navigation tab in the search application.</td>
</tr>
<tr>
<td>Search Context Config</td>
<td>Search application configuration for the navigation tab.</td>
</tr>
</tbody>
</table>

5. Click Update.

The navigation tab appears with updated settings in the Navigation Tabs related list.

Auto-complete suggestions in AI Search applications

Automatically display intelligent suggestions in your search application's input field, helping users formulate their searches or jump directly to relevant results. Suggestions include popular queries, recent queries from the user's personal history, and popular search results.

When you create a new search application configuration, AI Search automatically populates it with auto-complete suggestion types. The settings for these suggestion types control the appearance of auto-complete suggestions when users interact with its input field.

Each auto-complete suggestion type includes default settings that you can configure to suit your application's needs.

You can remove an unwanted suggestion type from your search application configuration. If you need to restore a removed suggestion type, you can relink it to your search application configuration. You can only link one auto-complete suggestion source of each type to any given search application configuration.

Auto-complete suggestions are generated by the Search Suggestions application. For full details on configuration and use of the Search Suggestions application, see Search Suggestions.

List of auto-complete suggestion types for AI Search

AI Search provides auto-complete suggestions derived from popular and recent search queries and frequently selected search results.

Auto-complete displays the following types of suggestions in the search application's input field:

**Popular Searches**
Displays search queries commonly submitted by all users of the search application as suggestions.

**Recent Searches**
Displays search queries drawn from the user's recent personal search history for the search application as suggestions.

**Suggested Queries**
Displays a mixture of recent and popular search queries as suggestions.

**Suggested Results**
Displays search results that the user has selected from previous search queries as suggestions.
Configure an auto-complete suggestion type in an AI Search application configuration
Modify default settings for display of auto-complete suggestions of a selected type in your search application's input field.

Role required: search_application_admin

When you define a new search application configuration, AI Search automatically populates it with auto-complete suggestion types. You can alter the default settings for these auto-complete suggestion types.

1. Navigate to **AI Search > Search Experience > Search Applications**.
2. Edit the search application configuration that contains the auto-complete suggestion type that you want to modify.
3. In the Autocomplete Suggestions related list, edit the auto-complete suggestion type that you want to modify settings for.
4. On the form, fill in the fields.

**Suggestion Reader Group form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Suggestion Type</td>
<td>Application-specific name for the auto-complete suggestion type. This field is automatically set.</td>
</tr>
<tr>
<td>Section Header</td>
<td>Header displayed in the application search field for auto-complete suggestions of this type.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope for the auto-complete suggestion type. This field is automatically set.</td>
</tr>
<tr>
<td>Order</td>
<td>Order of appearance in the application search field for the section containing auto-complete suggestions of this type.</td>
</tr>
<tr>
<td>Suggestion Limit</td>
<td>Maximum number of auto-complete suggestions of this type that the application should display in the search field.</td>
</tr>
<tr>
<td>Click-in Mode</td>
<td>Option to control the display of the section containing auto-complete suggestions of this type.</td>
</tr>
<tr>
<td></td>
<td>• If selected, auto-complete suggestions of this type are displayed when the user first clicks in the empty application search field.</td>
</tr>
<tr>
<td></td>
<td>• If deselected, auto-complete suggestions of this type are displayed as the user enters search query terms into the application search field.</td>
</tr>
</tbody>
</table>

5. Click **Update**.

The updated settings for the auto-complete suggestion type appear in the search application configuration's Autocomplete Suggestions related list.

Remove an auto-complete suggestion type from an AI Search application configuration
Disable the display of auto-complete suggestions of a selected type in your search application's input field.

Role required: search_application_admin

When you define a search application configuration, AI Search automatically populates it with auto-complete suggestion types. You can remove unwanted auto-complete suggestion types from the search application configuration.

1. Navigate to **AI Search > Search Experience > Search Applications**.
2. Edit the search application configuration that contains the auto-complete suggestion type you want to remove.
3. In the Autocomplete Suggestions related list, edit the auto-complete suggestion type that you want to remove.

4. On the Suggestion Reader Group form, click Remove from Search Application.

The selected auto-complete suggestion type no longer appears in the search application configuration's Autocomplete Suggestions related list.

Relink an auto-complete suggestion type to an AI Search application configuration

Re-enable the display of auto-complete suggestions of a selected type in your search application's input field.

Role required: search_application_admin

When you define a search application configuration, AI Search automatically populates it with auto-complete suggestion types. If you removed one of these auto-complete suggestion types from the search application configuration, you can relink it.

**Note:** You can only link one auto-complete suggestion source of each type to any given search application configuration.

1. Navigate to AI Search > Search Experience > Search Applications.
2. Edit the search application configuration that you want to relink the auto-complete suggestion type to.
3. In the Autocomplete Suggestions related list, click Add Existing.
4. In the Suggestion Reader Groups list, edit the auto-complete suggestion type that you want to relink to your search application configuration.
5. On the Suggestion Reader Group form, enter or look up the search application configuration name in the Search Application field.
6. Click Update.

The selected auto-complete suggestion type appears in the search application configuration's Autocomplete Suggestions related list.

**Using search scripted post-processors in AI Search application configurations**

Use scripted post-processors to modify search result records for display in a search application.

For example, a search scripted post-processor can modify search result date or currency field values to display in the user's regional formats.

Create a search scripted post-processor

Define a script to post-process AI Search search results before displaying them to the user.

Role required: search_application_admin

1. In the filter navigator, enter sys_search_scripted_processor.list and press Enter.
2. In the Search Scripted Post-processors table, click New.
3. On the form, fill in the fields.

**Search Scripted Post-processor form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active</td>
<td>Option to activate the search script post-processor.</td>
</tr>
<tr>
<td>Name</td>
<td>Name for the search script post-processor.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope for the search script post-processor.</td>
</tr>
<tr>
<td></td>
<td>This field is automatically set.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| Type                     | Type of record the search script post-processor operates on.  
                            | Valid values:  
                            | • Genius Result: Script operates on a Genius Result answer record.  
                            | • Search Result: Script operates on a search result record.                                                                     |
| Post processing script   | Server-side script function that takes a record object as its parameter. When the search scripted post-processor is linked to a search application configuration, search results reflect changes made to the record object in this function. |

**Note:** The UI displays an overview of API methods usable in the post-processing script function.

4. Click **Submit**.

The new search scripted post-processor appears in the Search Scripted Post-processors table.

To make your new search scripted post-processor take effect, link it to the search application configuration for the application whose results you want to post-process.

**Link a search scripted post-processor to an AI Search application configuration**

Link a search scripted post-processor to an AI Search application configuration. The search application executes the linked script for each search result before displaying it to the user.

Role required: search_application_admin

You must have already created the search script post-processor that you want to link to the search application configuration.

1. Navigate to **AI Search > Search Experience > Search Applications.**
2. Edit the search application configuration that you want to link a search scripted post-processor to.
3. In the Search Scripted Post-processors related list, click **New.**
4. On the Search Scripted Post-processors form, click the reference lookup icon (🔍) for the **Search scripted processor** field and select the search scripted post-processor that you want to link to the search application configuration.

5. Click **Submit**.

The new search scripted post-processor appears in the Search Scripted Post-processors related list.

**Enabling and configuring AI Search in Now Platform applications**

Configure and use the AI Search engine in the , , and  applications.

For each supported Now Platform application that you want to use AI Search in, define a search application configuration and specify AI Search as the search engine. To learn more about search application configurations, see **Search application configurations.**

Some applications support additional configuration for AI Search, as described in the following sections.
Service Portal

**Service Portal** is a portal framework that enables administrators to build a mobile-friendly self-service experience for users. It interacts with parts of the Now Platform, so users can access specific platform features using Service Portal.

For details on enabling and using AI Search as the Service Portal search engine, see Enable and configure AI Search in Service Portal.

Now Mobile

Enable your users to submit incidents and requests, manage tasks, and access company resources from anywhere using the **Now Mobile** app.

For details on configuring and using AI Search as the Now Mobile search engine, see AI Search in mobile.

Virtual Agent

**Virtual Agent** is a platform for providing user assistance through conversations within a messaging interface. Use Virtual Agent to design and build automated conversations that help your users quickly obtain information, make decisions, and perform common work tasks.

For information on how Virtual Agent uses AI Search, see Virtual Agent integration with AI Search.

Domain separation and AI Search

Domain separation is unsupported for the AI Search application tables, but user search queries respect domain restrictions from indexed Now Platform table records. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

**Note:** Refer to the Overview and following sections for details on how AI Search search queries respect domain settings from indexed records.

Support level: No support

- The domain field may exist on data tables but there is no business logic to manage the data.
- This level is not considered domain-separated.

For more information, see Application support for domain separation.

Overview

AI Search enables users to index and search content from records in Now Platform tables. The AI Search application tables and properties do not support domain separation, but user search queries respect domain settings from indexed content as described in the following sections.

Domain separation in indexed content and search queries

When indexing searchable content from a Now Platform table, AI Search stores the `sys_domain` field values for records on the source table and referenced tables.
If domain separation is enabled, AI Search applies a filter for the current session domain to every search query. This filter excludes records that are not visible in the session domain. Only records visible in the session domain appear as search query results.

For child tables that have the domain_master attribute set, both indexing and search use the appropriate reference field to derive the child record domain from a referenced parent record.

Restrictions apply to referenced records in search queries, as summarized in the following table.

<table>
<thead>
<tr>
<th>Condition</th>
<th>Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>Referenced record is not visible in current session domain</td>
<td>• Search queries do not match content from the referenced record</td>
</tr>
<tr>
<td></td>
<td>• Filtering on the reference field has no effect on search results</td>
</tr>
<tr>
<td></td>
<td>• Faceting on the reference field has no effect</td>
</tr>
<tr>
<td>Referenced record domain differs from parent record domain</td>
<td>Search result records do not display the reference field</td>
</tr>
</tbody>
</table>

### Indexing changes to record domains

AI Search automatically updates indexed domains for records in tables configured as indexed sources.

AI Search does not automatically update indexed domains for referenced tables. You can update the indexed domain for a referenced table in either of the following ways.

<table>
<thead>
<tr>
<th>Use case</th>
<th>Action</th>
</tr>
</thead>
</table>
| Perform a one-time update of domain field values for a referenced table | Perform a full table reindex for the indexed source that includes the affected table.  
For details on this procedure, see [Perform a full table index or reindex for a single indexed source](#). |
| Enable automatic updating of domain field values for a referenced table | Create a dot_walk_fields field setting for the reference field, specifying the sys_domain,sys_domain_path domain fields as the attribute value.  
For full steps for this task, see [Enable automatic domain updates for a referenced table](#). |

**Enable automatic domain updates for a referenced table**

Configure a field setting to automatically index domain field value updates for records from a referenced table.

Role required: ais_admin

This topic provides steps for configuring a dot_walk_fields field setting to enable automatic indexing of domain field values for records in referenced tables. For more general instructions on defining field settings, see [Create a field setting for an indexed source](#).

1. Navigate to **AI Search > AI Search Index > Indexed Sources**.
2. Edit the indexed source that you want to define a field setting for.
3. In the Field Settings & Mapping related list, click **New**.
4. On the Field Setting form, enter the following field values.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attribute</td>
<td>dot_walk_fields</td>
</tr>
<tr>
<td>Field</td>
<td>&lt;reference field&gt;</td>
</tr>
<tr>
<td>Value</td>
<td>sys_domain.sys_domain_path</td>
</tr>
</tbody>
</table>

5. Click Submit.

The new **dot_walk_fields** field setting appears in the Field Settings & Mapping related list.

To make the new **dot_walk_fields** attribute take effect, perform a full table reindex for the indexed source. For details on this procedure, see Perform a full table index or reindex for a single indexed source.

**Indexing and searching external content in AI Search**

Make content from external data sources searchable in Now Platform applications that support AI Search.

To enable indexing of content from external data sources, you must purchase a subscription for the External Content plugin (com.glide.ais.external_content) and activate it.

Next, you must create and configure an external content schema table. This table does not store data in the database. Instead, its columns serve as a map of AI Search index fields to populate when you index content from the external data source.

Finally, you must create an indexed source for the content schema table and derive search sources from it. Link these search sources to search profiles normally.

After defining the indexed source, you can use the External Content Ingestion REST API to index searchable content for the external data source's documents:

- Feed external data source documents to the AI Search index using the `ingestDocuments` API endpoint.
- Upload external data source document binary content to AI Search using the `storeContent` API endpoint. You can link this uploaded binary content stream to a document fed via the `ingestDocuments` endpoint.
- Delete external data source documents from the AI Search index using the `deleteDocument` and `deleteByQuery` API endpoints.

Once documents from the external data source are indexed, your users can search for them just as they would for records indexed from Now Platform tables.

**Using an external content schema table for multiple external data sources**

You can use the same external content schema table for multiple external data sources. To avoid data loss, the external data sources must satisfy these conditions.

- All documents in the external data sources must include the same fields, matching the columns defined in the content schema table.
- Every document in the external data sources must have a unique identifier so that documents do not overwrite one another in the AI Search index.

If the external data sources cannot satisfy these conditions, create a separate external content schema table for each data source.
Content security for external content

In the release, does not index security settings for external content. As a result, all users can view all indexed external records as search results.

For more information on AI Search content security, see Content security in AI Search.

Activate the External Content for AI Search plugin

The External Content for plugin (com.glide.ais.external_content) provides support for indexing searchable content from records in external data sources.

You must purchase a paid subscription before activating the plugin. For details on purchasing a paid subscription for a plugin, see ServiceNow plugins.

Role required: admin

1. Navigate to System Applications > All Available Applications > All.
2. Find the plugin using the filter criteria and search bar.
   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel. For more information, see Request a plugin.
3. Click Install, and then in the Activate Plugin dialog box, click Activate.

   Note: When domain separation and delegated admin are enabled in an instance, the administrative user must be in the global domain. Otherwise, the following error appears: Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.

Create an external content schema table

Define a schema table with columns corresponding to fields on records from an external data source. AI Search uses the schema when indexing content from the external data source.

Role required: ais_admin

1. Navigate to AI Search > External Content > Create Schema.
2. Enter a name for your new external source schema table.
3. Click Submit.
   The new external content schema table opens in list view.
4. Optional: If you need to define additional field mappings for records from the external data source, add a new column for each field by following these steps.
   a) In the Columns related list, click New.
   b) On the Dictionary Entry form, fill in the fields. For descriptions of these fields, see Dictionary entry form.

      Note: When filling in the Type field, select String, Date, Date/Time, or Integer. AI Search only supports these column types on external content schema tables.

   c) Click Submit.
5. If you modified the default column set, click Update to save your changes.

Record the new schema table’s name. When you index or delete records associated with this content schema using endpoints from the External Content Ingestion REST API, you must specify the schema table name as a path parameter.
Components installed with External Content for AI Search
When you activate the External Content for plugin (com.glide.ais.external_content), the system creates a new virtual table.

Tables installed

<table>
<thead>
<tr>
<th>Table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AI Search External Search Content [v_ais_external_search_content]</td>
<td>Stores the base set of field mapping columns for inclusion in external content schema tables.</td>
</tr>
</tbody>
</table>

Note: All user-created external content schema tables extend this table.

Integrating AI Search into your instance or application
You can create and configure search profiles to use with AI Search Assist.

AI Search Assist integration
AI Search Assist uses AI Search to:
- Create a search profile that can link to a portal
- Add Knowledge Base articles or Catalog items

Search components in UI Builder
You can add search components to a custom-built application in UI Builder. These components include:
- Search facets
- Search input
- Search results
- Tab filter

EVAM integration
Entity View Action Mapper (EVAM) is an application that standardizes how different data sources display in cards and lists.
EVAM enables you to show information as a card grid view or as a list view. Users can page through large data sets of search results and see different views based on filtering.
AI Search Assist

AI Search Assist uses AI Search functionality to fetch the most relevant set of search results for users. AI Search Assist displays related results within a record producer and can be used instead of Contextual Search.

Overview

AI Search Assist can help a user find the most relevant items in a search on your portal. For example:

- A user, creating an Incident via the Service Portal, can see related catalog items that the user can order. The user can also view related Knowledge articles to assist them to resolve the issue on their own without involving the service desk.

AI Search Assist helps with incident deflection for the following areas:

- Incident record producers: Deflecting incidents by helping end users resolve issues before they raise an incident.

AI Search Assist supports ServiceNow mobile.

Activation information

The AI Search Assist plugin (com.snc.ai_search_assist) is a Now Platform application that is activated by default when AI Search is active.

Configure AI Search Assist for a record producer

You can configure different components of AI Search Assist.

Role required: admin or aisa_admin

AI Search Assist is a Service Portal widget used with a record producer configuration.

Note: If both AI Search Assist and Contextual Search are configured for the same record producer, see the Results at the end of this task for how to control which one is displayed.

1. Navigate to AI Search > AI Search Assist > Record Producer Configuration.
2. Click New and fill in the form to create a configuration for search results.

Record Producer Configuration form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Title</td>
<td>Title of the record producer configuration. For example, Search Results.</td>
</tr>
<tr>
<td>Results per page</td>
<td>Number of search results to display per page.</td>
</tr>
<tr>
<td>Allow expand/collapse</td>
<td>Option to allow users to expand or collapse search results in this record producer configuration.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to make this record producer configuration active for your instance.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope for this record producer configuration.</td>
</tr>
</tbody>
</table>
3. On the **Search application information** tab, select a Search application configuration. You can choose from a list of pre-defined configurations for specific features. For example, **[AI Search Assist] - Incident Deflection**.

4. On the **Record producer information** tab, select a Record producer and Search variable. For example, **Service Category Request** as a record producer can have a search variable of **Category name**.

5. Optional: To adjust the visibility of your card or detail view, click **Show UI Actions** under the new Record Producer Configuration record’s related links. **AI Search Assist UI actions** can hide from view using a simple condition or advanced condition via a script.
6. Click **Submit**.

AI Search Assist is active. If Contextual Search has been configured for the same record producer, and is showing results instead of AI Search Assist, check the following conditions:

- The **Enable AI Search** flag on the Portal (sp_portal) is active
- The AI Search Assist record configuration is active
- The AI Search Profile is active and published
- The record producer variable for AI Search Assist is created for the associated record producer and the variable is active

If these conditions are not all met, then Contextual Search is the fallback for the same record producer to make sure you see related search results.

**AI Search Assist admin role**

Grant users the AI Search Assist admin role [aisa_admin] so they can configure and manage AI Search Assist settings.

### AI Search Assist admin role

<table>
<thead>
<tr>
<th>Roles</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AI Search Assistant administrator [aisa_admin]</td>
<td>Users with the aisa_admin role can do the following:</td>
</tr>
<tr>
<td></td>
<td>• Manage AI Search Assist on record producers, including the associated UI actions</td>
</tr>
<tr>
<td></td>
<td>• Add a variable to a record producer</td>
</tr>
<tr>
<td></td>
<td>• Administer AI Search capability</td>
</tr>
</tbody>
</table>

**AI Search Assist properties**

The AI Search Assist properties determine when searching begins based on characters entered and the time that has elapsed. These properties reduce the impact of searches for systems with many Catalog Items or Knowledge articles.

### AI Search Assist properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.snc.ai_search_assist.min_length</td>
<td>The minimum number of characters entered before a search initiates. The default is 3.</td>
</tr>
</tbody>
</table>
| com.snc.ai_search_assist.wait_time     | The time elapsed after the user finishes entering characters in the search field before the search begins. | 💡 **Note:** If you set the time to `-1`, the search begins when the user leaves the search field. This behavior is known as 'Search on tab'.

**Domain separation and AI Search Assist**

Domain separation is supported for AI Search Assist. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.
Overview

The goal of AI Search Assist is to give a Service Portal record producer AI Search capabilities, which improve search results over time. Domain separation is enabled in AI Search Assist.

How domain separation works in AI Search Assist

Domain separation for AI Search Assist is set in the record producer configuration. A related link for each record producer configuration enables you to expand or collapse the domain scope. If you expand the domain scope, any child domain record producer configurations can override a global or parent domain record configuration.

Using AI Search

See how AI Search displays search results, refinement filter options, and Genius Result answers. Learn how to search using the AI Search query language. Understand when and how AI Search automatically resubmits queries.

Viewing search results

Learn about the components that AI Search uses to display results for search queries.

Search result page elements

The layout and appearance of AI Search UI elements varies from application to application. This example shows the elements as they might appear on a Service Portal search results page.
Sample search result screen
## Search result screen elements

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Search input field</td>
<td>Displays the search query that produced the listed search results. You can modify this search query and search again to view different results.</td>
</tr>
<tr>
<td>2. Navigation tab filters</td>
<td>Displays static filter options for refining search results by source. To view only search results from a single source, click the source name. Click <strong>All</strong> to remove the navigation tab filter.</td>
</tr>
<tr>
<td>3. Facet filters</td>
<td>Displays dynamic filter options for refining search results by field value. To expand or collapse a facet, click the + (plus) or - (minus) symbol by its name. To view only search results that contain a specific field value, select the field value in the facet. Deselect the field value to remove the facet filter.</td>
</tr>
<tr>
<td>4. Genius Result answer cards</td>
<td>Display the best answers for the search query along with actions you can take directly from each card. <strong>Note:</strong> Genius Result answer cards may not appear for all search queries.</td>
</tr>
<tr>
<td>5. Search results</td>
<td>Displays the icon, summary field values, title, and text snippet for each search result. Click a result to view its source record in full. <strong>Note:</strong> When hit-highlighting is enabled for the search application, AI Search highlights search query terms found in search result titles and text snippets.</td>
</tr>
</tbody>
</table>

## Auto-correction message

When AI Search auto-corrects a misspelled search query term, a **Showing results for <corrected_term>** message appears above the search results list.
**Auto-correction message elements**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6. Typo handling auto-correction message and link</td>
<td>Displays the auto-corrected query term used for the search. To repeat the search using your original search query term, click the <strong>Search instead for &lt;original_term&gt;</strong> link that appears below the message.</td>
</tr>
</tbody>
</table>

**AI Search query language**

Learn how to construct search queries using terms, phrases, and AI Search query operators.

**Search query terms and phrases**

Specify terms and quoted phrases in the search query to find records that contain the same words or phrases.

<table>
<thead>
<tr>
<th>Search query terms</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>conference room</td>
<td>Conjunctive multi-term search. Finds records that contain both conference and room (an intersection of sets). The search terms can appear in any order or proximity in the record and may appear in different fields.</td>
</tr>
</tbody>
</table>

**Note:** If you set the **Boolean search operator to use when a search query includes multiple terms** (glide.ais.query.search_operator) system property to **OR query**, this search finds records that contain either conference or room (a union of sets).

| "conference room" | Quoted phrase search. Finds records that contain conference followed immediately by room. The search terms must appear in this order and in the same field. |

**Note:** Quoting a phrase does not disable linguistic features (such as normalization, synonym expansion, and stop word removal) or wildcard operators. For example, a search for the quoted phrase "email acc*" expands the wildcard operator normally to find records that contain email account and email access.

Search ignores letter case for search query terms and phrases. For example, searching for PIN finds records containing PIN and pin.
### Boolean search operators

Separate query terms and phrases with Boolean operators to override the default matching logic for the search query.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OR</td>
<td>Boolean disjunction operator. Finds records that contain any of the terms or phrases separated by OR. For example, searching for &quot;conference room&quot; OR suite finds records that contain the phrase conference room and records that contain the term suite.</td>
</tr>
<tr>
<td>hyphen (−)</td>
<td>Boolean negation operator. Excludes records containing the term or phrase that immediately follows the hyphen. For example, searching for email -&quot;email signature&quot; finds records that contain the term email but do not contain the phrase email signature.</td>
</tr>
</tbody>
</table>

**Note:** If you set the **Boolean search operator to use when a search query includes multiple terms** (glide.ais.query.search_operator) system property to **OR query**, this operator has no effect because search already treats all query terms and phrases as though separated by the OR operator.

### Wildcard matching operators

Use wildcard operators to find records that contain indexed terms matching a wildcard pattern.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>%</td>
<td>Single-character wildcard operator. Include % in a search query term to match any one character in an indexed term. For example, searching for the%e finds records containing theme, there, or these.</td>
</tr>
</tbody>
</table>

**Note:** The % operator must follow a string of three or more non-wildcard characters. Without this prefix, the search query finds no records.
ServiceNow    DocVersion    Now Platform administration

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>String wildcard operator. Include * in a search query term to match any string of zero or more characters in an indexed term. For example, searching for acc* finds records containing access, account, accrue, accumulate, accuracy, and so on.</td>
</tr>
<tr>
<td>***</td>
<td>Universal wildcard operator. Specify *** as a search query term to find all indexed terms and thus all records.</td>
</tr>
</tbody>
</table>

**Automatic search query resubmission**

When a search query returns too few results, AI Search automatically modifies and resubmits it with the goal of returning at least the desired number of results.

Search administrators configure the minimum number of desired results per search query using the **Search Results Limit** field in search application configurations. For more details, see Create a search application configuration for AI Search.

**AND-to-OR search query resubmission**

When a search query with conjunctive terms or phrases returns insufficient results, AI Search resubmits it with the default Boolean operator changed from AND to OR and displays results for the modified query.

For example, if a query for hotel "conference room" suite matches no results, AI Search resubmits it as hotel OR "conference room" OR suite. This less-restrictive query may match more results than the original query.

**Note:** If you set the **Boolean search operator to use when a search query includes multiple terms** (glide.ais.query.search_operator) system property to **OR query**, AI Search does not resubmit search queries in this way because the initial search already treats all query terms and phrases as though separated by the OR operator.

When automatically resubmitting a search query in this way, AI Search adds a minimum match count restriction to the OR expression. The modified query only returns results that match at least half (rounded up) of the terms separated by OR operators. This restriction improves query performance and provides more relevant results.

For example, suppose a search query for laptop can't access wi-fi network returns no results. AI Search automatically resubmits the query as laptop OR can't OR access OR wi-fi OR network. Only records that match at least three of the five query terms appear as results for the resubmitted search.

**Conditions for automatic search query resubmission**

Automatic search query resubmission ignores search queries that meet any of the following conditions.

- The original search query only includes a single term.
- The original search query includes 8 or more terms and returns at least one search result.
Administering AI Search

Learn how AI Search features and behavior affect indexing and search. Gain insight into AI Search behavior by reviewing log messages, ingestion history for indexed sources, and session debugging messages.

AI Search and performance testing

Understand how the AI Search topology affects performance testing on instances created with System Clone.

**Warning:**

Be careful when testing AI Search performance in cloned non-production instances. The same dedicated AI Search nodes handle search query traffic from all of your instances. As a result, search queries on non-production instances may impact search query performance in your production instance.

Lemma and Unicode normalization

AI Search normalizes inflected words and Unicode glyphs during indexing and at search query time. Normalization improves search recall and enables users to find content with variant forms of their search query terms.

Normalization features are automatically enabled and are not configurable.

Lemma normalization

Many languages include inflected forms of terms, such as plural nouns or verb tenses. AI Search normalizes inflected terms found in indexed content and search queries. Normalization enables matching based on a root form, such as the singular for a plural noun or the base form for a conjugated verb. This root form is called a lemma, and this process is referred to as lemma normalization.

For example, when a source record includes the conjugated verb *selling*, AI Search expands the indexed term to include the lemma form *sell* in addition to *selling*. When a user searches for the past-tense conjugated form *sold*, AI Search expands the search query term to include the lemma form *sell* as well as *sold*. Because the indexed term and the search query term include matching forms, the user's search returns the *selling* record as a result.

AI Search supports language-specific lemma normalization for English, French Canada, French, German, Japanese, and Spanish.

As part of lemma normalization for German, AI Search splits compound words into their components. For example, when indexing a record that contains the compound word *Humanressourcen*, AI Search indexes the component terms *Human* and *ressourcen* in addition to the compound term.

Unicode normalization

AI Search performs Unicode normalization on indexed terms and search query terms. This normalization makes alphabetical Unicode glyphs searchable using their nearest equivalent characters.

For example, when indexing a record containing the term *resumé*, AI Search expands the term to also include the non-accented form *resume*. This record appears as a search result when users search for either *resume* or *resumé*.

Unicode normalization includes NFKD (compatibility decomposition) and NFKC (compatibility composition) stages. For more information on these normalization forms, see the Unicode Standard Annex #15, https://www.unicode.org/reports/tr15/.
Interaction with other features

The following table describes interactions between normalization and other features that modify search queries or results.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Interaction with lemma and Unicode normalization</th>
</tr>
</thead>
<tbody>
<tr>
<td>Genius Results</td>
<td>Search query terms added by lemma or Unicode normalization cannot trigger Genius Result configurations with Term trigger conditions.</td>
</tr>
<tr>
<td>Result improvement rules</td>
<td>A search query term added by lemma or Unicode normalization can trigger a result improvement rule if it matches the rule's Query trigger.</td>
</tr>
<tr>
<td>Stop words</td>
<td>If a search query term is defined as a stop word, removes the term without normalizing it.</td>
</tr>
<tr>
<td>Synonyms</td>
<td>If a search query term is defined as a synonym, does not normalize it.</td>
</tr>
<tr>
<td>Typo handling</td>
<td>Performs lemma and Unicode normalization on auto-corrected search query terms.</td>
</tr>
</tbody>
</table>

Internationalization support for AI Search

AI Search supports search in all languages offered by the Now Platform. Search query linguistic features support English, French Canada, French, German, Japanese, and Spanish.

Internationalization support is automatically enabled and is not configurable.

Indexing and search query behavior in supported languages

When indexing searchable content, AI Search preserves the language specified for the source table record. If a record has no specified language, AI Search uses heuristics to detect its language.

At query time, AI Search inherits the language from the Now Platform language context. Only records with this language are returned as search results.

These language settings determine how AI Search tokenizes the text of indexed content or search query terms. When the language for the indexed content matches the search language context, the tokenization settings match and search returns results.

Search query linguistic features

The following search query linguistic features are language-dependent and supported only for the listed languages.
# Search feature language dependence

<table>
<thead>
<tr>
<th>Feature</th>
<th>Language dependence and supported languages</th>
</tr>
</thead>
<tbody>
<tr>
<td>Genius Results</td>
<td>AI Search only evaluates Genius Results with NLU triggers if the linked NLU model has the same language as the search query. Supported languages: English.</td>
</tr>
<tr>
<td>Lemma and Unicode normalization</td>
<td>AI Search performs language-specific lemma normalization for search query terms from supported languages. Supported languages: English, French Canada, French, German, Japanese, and Spanish. For German, AI Search performs term decompounding as part of lemma normalization. AI Search performs Unicode normalization for all search query terms.</td>
</tr>
<tr>
<td>Result improvement rules</td>
<td>AI Search only evaluates result improvement rules that have the same language as the search query and rules that have no language specified. Supported languages: English, French Canada, French, German, Japanese, and Spanish.</td>
</tr>
<tr>
<td>Stop words</td>
<td>AI Search only considers stop words from dictionaries that have the same language as the search query. Supported languages: English, French Canada, French, German, Japanese, and Spanish.</td>
</tr>
<tr>
<td>Synonyms</td>
<td>AI Search only considers synonyms from dictionaries that have the same language as the search query. Supported languages: English, French Canada, French, German, Japanese, and Spanish.</td>
</tr>
<tr>
<td>Typo handling</td>
<td>AI Search derives a separate list of auto-correction terms for each supported language found in search source indexed content. Auto-correction only replaces search query terms with terms from the list that has the same language as the search query. Supported languages: English, French Canada, French, German, and Spanish. Japanese is not supported.</td>
</tr>
</tbody>
</table>

## Machine learning relevancy in AI Search

AI Search displays the most relevant search results for a query first. Machine learning automatically tunes search result relevancy scoring for search experiences based on aggregated user interactions.

Machine learning relevancy is automatically enabled and is not configurable.
Relevancy models and scoring

AI Search uses a relevancy model to compute a relevancy score for each result returned by a search. Documents with higher relevancy scores appear first in the result set. A result’s relevancy score is specific to the particular document, search terms, and user associated with the query.

Each search profile includes its own relevancy model. You cannot view, modify, or delete this relevancy model.

Search signals and machine learning relevancy tuning

AI Search UX components record signals associated with user searches. These search signals include data on how search users interact with the search input field, auto-complete suggestions, facet and navigation tab filters, Genius Result answer cards, and search results.

Machine learning relevancy uses data from these search signals to intelligently tune relevancy models on a continual basis. Every 30 days, AI Search computes a new version of each relevancy model, iteratively modifying its parameters and regression testing it against aggregated search signal data.

When this tuning process is complete, AI Search compares the existing and new relevancy models to see which one produces better matches for user search behavior as recorded in signal data. It selects the better-performing relevancy model, which remains in use until the next tuning cycle begins.

These relevancy model tuning processes occur separately for each search profile. Changes made to the relevancy model in one search profile do not affect relevancy models in other search profiles.

Content security in AI Search

AI Search filters search query results and displays only records that the currently logged in user can access.

Content security is automatically enabled and is not configurable.

Indexed security features

When indexing records from Now Platform tables, AI Search preserves the following access control settings:

- Scripted and non-scripted access control list rules (ACLs)
- User criteria
- Before Query business rules
- Domain separation

Early and late binding security implementations for search queries

At query time, AI Search filters search results by evaluating user access to indexed tables and records. The filtering implementation used depends on the security features present on tables and records that match the search query.
<table>
<thead>
<tr>
<th>Content security implementation</th>
<th>Description</th>
</tr>
</thead>
</table>
| Early binding                   | Default content security implementation that incorporates security filters into the search query. The system adds relevant security filters for the user to each search query. To appear in the search results, records must match the search query and pass all security filters. Early binding security supports non-scripted ACLs, user criteria, Before Query business rules, and domain separation. If a search matches records that have scripted ACLs, the search query automatically falls back to use late binding security.  

**Note:** If an early binding filter produces an error, the search query automatically falls back to use late binding security. |
| Late binding                    | More computationally expensive alternate content security implementation that post-filters search query results. The system applies security filters to the search query just as early binding security does. After retrieving records that match the filtered query, it invokes the GlideRecord.canRead() method for each record. To appear in the search results, records must match the search query, pass all security filters, and return true for the API method. Late binding security supports all indexed security features. By default, late binding security serves as a fallback mechanism for early binding security. Setting the **Force AI Search to use late binding for ACL evaluation** (glide.ais.security.force_late_binding) system property to true forces AI Search to use late binding security for all search queries. |

**Content security for external content**

In the release, does not index security settings for external content. As a result, all users can view all indexed external records as search results.

For more details on using AI Search with external data sources, see Indexing and searching external content in AI Search.

**Encrypted fields in AI Search**

AI Search excludes source record fields encrypted with Encryption Support or Edge Encryption. When dealing with an encrypted source record field, AI Search has the following limitations:

- Content indexing excludes the encrypted field. This exclusion means that search query terms will not match terms from the encrypted field’s content.
- You cannot create a facet using the encrypted field.
• If a search query attempts to filter on the encrypted field, such as when applying an access control list (ACL) filter, the search query fails. An "Encrypted Field is not supported" error message is logged.

For detailed descriptions of the encryption options available for source records, see Encryption.

AI Search logging and debugging

Review AI Search logs and history to analyze performance and diagnose issues. View log messages and ingestion history, or use session debugging to capture detailed messages for a user session.

View AI Search ingestion log messages
Review AI Search ingestion and indexing events by viewing log messages.

Role required: admin

1. Navigate to AI Search > AI Search Logs > Ingestion Warnings & Errors.
   The Log [syslog] table appears with a [Source] [starts with] [AIS-Datasource] filter condition applied.
2. Use the list search, sort, filter, and group functions to locate messages of interest.

View all AI Search log messages
Review AI Search events by viewing log messages.

Role required: admin

1. Navigate to AI Search > AI Search Logs > All.
   The Log [syslog] table appears with a [Message] [contains] [ais] filter condition applied.
2. Use the list search, sort, filter, and group functions to locate messages of interest.

Review ingestion history for an indexed source
View processing results and performance statistics associated with an ingestion event for an indexed source.

Role required: ais_admin

The AI Search Indexed Source History [ais_ingest_datasource_stats] table contains records for indexed source ingestion events. Each record includes performance statistics and processing results for the ingestion event. You can review the ingestion event history record to analyze ingestion performance and diagnose issues.

1. Navigate to AI Search > AI Search Index > Indexed Sources.
2. Edit the indexed source whose indexing history you want to review.
3. In the Indexing History related list, edit the ingestion event record that you want to review.
4. On the Indexed Source History form, review the fields for the selected ingestion event.

**Indexed Source History form fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Indexed Source</td>
<td>Reference to the indexed source from which AI Search ingested records for indexing.</td>
</tr>
<tr>
<td>Ingestion Event ID</td>
<td>Sys_id of the ingestion event.</td>
</tr>
<tr>
<td>Partial Ingestion</td>
<td>Option indicating whether AI Search ingested all parent and child tables defined in the indexed source. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• false: AI Search ingested records from the indexed source table and all child tables configured for indexing.</td>
</tr>
<tr>
<td></td>
<td>• true: AI Search only ingested records from a subset of the indexed source tables configured for indexing.</td>
</tr>
</tbody>
</table>
### Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of Errors</td>
<td>Count of error messages logged for the ingestion event.</td>
</tr>
<tr>
<td>Number of Minor Errors</td>
<td>Count of minor error messages logged for the ingestion event.</td>
</tr>
<tr>
<td>Number of Warnings</td>
<td>Count of warning messages logged for the ingestion event.</td>
</tr>
<tr>
<td>Ingestion State</td>
<td>State for the ingestion event. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• <strong>cancelled</strong>: Ingestion and indexing did not complete successfully.</td>
</tr>
<tr>
<td></td>
<td>• <strong>indexed</strong>: Ingestion and indexing completed successfully.</td>
</tr>
<tr>
<td></td>
<td>• <strong>indexing</strong>: Ingestion and indexing are ongoing.</td>
</tr>
<tr>
<td></td>
<td>• <strong>not started</strong>: Ingestion and indexing are pending.</td>
</tr>
<tr>
<td>Start Time</td>
<td>System time at which the ingestion event began.</td>
</tr>
<tr>
<td>End Time</td>
<td>System time at which the ingestion event completed.</td>
</tr>
<tr>
<td>Content Preparation Duration</td>
<td>Total time that the Now Platform spent retrieving source records for the ingestion event.</td>
</tr>
<tr>
<td>Indexing Duration</td>
<td>Total time that AI Search spent indexing source records for the ingestion event.</td>
</tr>
<tr>
<td>Records Processed</td>
<td>Count of source records processed for the ingestion event.</td>
</tr>
<tr>
<td>Attachments Processed</td>
<td>Count of source record attachments processed for the ingestion event.</td>
</tr>
<tr>
<td>Documents Processed per Second (DPS)</td>
<td>Average number of source records and attachments processed per second for the ingestion event.</td>
</tr>
</tbody>
</table>

### Enable session debugging for AI Search

Capture and review detailed AI Search log messages for a user session.

Role required: admin

Debugging messages create a log of AI Search events as they occur. Review these messages to diagnose issues or configure optimal performance settings.

When enabled, session debugging is active during the user session or until disabled. For more information on session debugging, see [Session debug](#).

1. To enable debugging, navigate to **System Diagnostics > Session Debug > Debug AI Search**. A message reports completion of the Debug AI Search session debug script.
2. To review debug logs, navigate to **System Diagnostics > Session Debug > Debug Log**. The **Session Log** window opens and displays debug log messages.
3. To disable debugging, navigate to **System Diagnostics > Session Debug > Disable All**. A message reports completion of the Disable All session debug script.
AI Search reference

These reference topics provide additional information about AI Search installed components, system properties, and features.

Plugins installed with AI Search

AI Search adds the following plugin.

AI Search plugins

<table>
<thead>
<tr>
<th>Plugin</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>plugin (com.glide.ais)</td>
<td>Enables core functionality for AI Search. Installed in the base system.</td>
</tr>
</tbody>
</table>

Components installed with AI Search

Several types of components are installed with activation of the AI Search plugin, including user roles, scheduled jobs, and tables.

Note: The Application Files table lists the components that are installed with this application. For instructions on how to access this table, see Find components installed with an application.
## Roles installed

<table>
<thead>
<tr>
<th>Role title [name]</th>
<th>Description</th>
<th>Contains roles</th>
</tr>
</thead>
<tbody>
<tr>
<td>administrator [ais_admin]</td>
<td>Manages configuration settings for the application, including the following: • Creates, reads, updates, and deletes indexed sources • Creates, reads, updates, and deletes search sources • Creates and deletes mappings between search sources and search profiles • Creates, reads, updates, and deletes search profiles • Creates, reads, updates, and deletes synonym and stop word dictionaries • Creates and deletes mappings between dictionaries and search profiles • Reads and updates typo handling auto-correction dictionaries linked to search profiles • Creates, reads, updates, and deletes Genius Result configurations • Creates and deletes mappings between Genius Result configurations and search profiles • Creates, reads, updates, and deletes result improvement rules • Creates and deletes mappings between result improvement rules and search profiles This role is included in the Search application administrator [search_application_admin] role.</td>
<td>• None</td>
</tr>
</tbody>
</table>

## Scheduled jobs installed

<table>
<thead>
<tr>
<th>Scheduled job</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aggregate Health Data for AIS Partition</td>
<td>Collects health check data for AI Search query nodes connected to your instance.</td>
</tr>

**Now Platform tables excluded from AI Search indexing**

AI Search excludes the following Now Platform tables when indexing content. You cannot configure these tables, or tables derived from them, as AI Search indexed sources.

- Base Configuration Item [cmdb]
- Email [sys_email]
- Event [sysevent]
- Import Set Row [sys_import_set_row]
- Log [syslog]
- Queue [ecc_queue]
- Replicated Operation [sys_replication_queue]
- Sys Audit [sys_audit]
- Task [task]

**AI Search index fields**

List of fields available on records in the AI Search index. Data from fields on source records maps to these fields during indexing.
## AI Search index fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ai_search_parent_title</td>
<td>This field is automatically generated by AI Search.</td>
</tr>
<tr>
<td>ai_search_teaser_text</td>
<td>This field is automatically generated by AI Search.</td>
</tr>
<tr>
<td>ai_search_teaser_title</td>
<td>This field is automatically generated by AI Search.</td>
</tr>
<tr>
<td>datasource_id</td>
<td>Name of the indexed data source that added the record to the AI Search index.</td>
</tr>
<tr>
<td>ext_record_id</td>
<td>Unique identifier for the external data source record that corresponds to the indexed record. Only populated for records from external data sources.</td>
</tr>
<tr>
<td>index_event_id</td>
<td>Sys_id of the indexing event that added the record to the AI Search index.</td>
</tr>
<tr>
<td>language</td>
<td>Language configured for the source record in its Now Platform table.</td>
</tr>
<tr>
<td>record_class_name</td>
<td>The hierarchical class used to render the source record.</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id for the source record.</td>
</tr>
<tr>
<td>table</td>
<td>For records from Now Platform tables, this index field indicates the name of the source table. For records from external data sources, this index field indicates the name of the content schema table specified during document ingestion.</td>
</tr>
<tr>
<td>text</td>
<td>Searchable text for the indexed record. Displayed in search results.</td>
</tr>
<tr>
<td>title</td>
<td>Title for the indexed record. Displayed in search results.</td>
</tr>
</tbody>
</table>

### Common index fields

The following AI Search index fields appear on all records indexed from Now Platform source tables:

- ai_search_parent_title
- ai_search_teaser_text
- ai_search_teaser_title
- record_class_name
- sys_id
- table
Extending AI Search with ServiceNow Store applications

Install applications from the ServiceNow® Store to extend AI Search functionality and gain insight into search usage and behavior.

Analytics and Reporting Solution for Advanced Management Tools

ServiceNow® Analytics and Reporting Solutions contain prepackaged Performance Analytics and Reporting content for use with other Now Platform products. This Analytics and Reporting Solution helps AI Search administrators analyze search query traffic trends, review indexed record and configuration settings, and preview search query results.

Required roles

The following roles are associated with this solution:

- Now Platform administrator (admin): Install and activate this Analytics and Reporting Solution and make any necessary changes to system properties.
- AI Search administrator (ais_admin): Review the AI Search dashboards. Share the dashboards with appropriate stakeholders. Test search queries using the Search Preview UI module.
- User Experience Analytics administrator (analytics_admin), User Experience Analytics viewer (analytics_viewer), User Portal Analytics administrator (portal_analytics_admin), Portal Analytics viewer(portal_analytics_viewer), Web Analytics administrator (web_analytics_admin), or Web Analytics viewer(web_analytics_viewer): View the Search Analytics dashboard metrics and reports.
- Impersonator (impersonator): View NLU intents detected in queries, enable debugging, or search as another user in the Search Preview UI module.

Activate the Analytics and Reporting Solution for Advanced Management Tools

Activate the content pack ServiceNow® Store application for the Analytics and Reporting Solution.

The User Experience Analytics API application from the ServiceNow Store must be activated in your instance.

Role required: admin

1. Navigate to System Applications > All Available Applications > Available To Obtain From Store.
2. Browse for Advanced Management Tools and verify that you have the necessary valid entitlements.
   You need a Now Support account and permission to request applications for the instances under consideration. The Now Support account and the instance must be part of the same company. For more information, see Install a ServiceNow Product on the ServiceNow Store.
4. Install the application.

The following application menus and modules appear in the application navigator:

<table>
<thead>
<tr>
<th>Application</th>
<th>Application navigator path</th>
</tr>
</thead>
<tbody>
<tr>
<td>AI Search Profile dashboard</td>
<td>AI Search &gt; AI Search Analytics &gt; Search Profile Analytics</td>
</tr>
<tr>
<td>AI Search dashboard</td>
<td>AI Search &gt; AI Search Analytics &gt; Search Index Analytics</td>
</tr>
<tr>
<td>Search preview UI</td>
<td>AI Search &gt; Preview &gt; Search Preview</td>
</tr>
</tbody>
</table>
Populate data tables for the Search Analytics dashboard

Execute the scheduled job that populates data tables used by metrics, trends, and reports on the Search Analytics dashboard.

Role required: admin

The Advanced Management Tools application includes a `AISearchAnalyticsGlobalScheduledJobUtils` scheduled job. Execute this scheduled job to begin populating tables needed for data visualizations on the Search Analytics dashboard. Until the first job run completes, some elements on the Search Analytics dashboard display no data.

1. In the navigation filter, enter `sys_trigger.list`.
2. Edit the `AISearchAnalyticsGlobalScheduledJobUtils` scheduled job.
3. Click Execute Now.

The `AISearchAnalyticsGlobalScheduledJobUtils` scheduled job populates the data tables needed by the Search Analytics dashboard. To keep the tables current, the system runs this scheduled job again every day around midnight. You do not need to run this job again.

Note: The exact run time for the scheduled job may vary by a few hours depending on server resource availability.

If you uninstall the Advanced Management Tools application, disable the scheduled job by following the steps in Disable population of data tables for the Search Analytics dashboard.

Disable population of data tables for the Search Analytics dashboard

Delete the scheduled job that populates data tables used by metrics, trends, and reports on the Search Analytics dashboard.

Only perform this task if you uninstall the Advanced Management Tools application after enabling the `AISearchAnalyticsGlobalScheduledJobUtils` scheduled job. For the steps to enable this scheduled job, see Populate data tables for the Search Analytics dashboard.

Role required: admin

After uninstalling the Advanced Management Tools application, delete the scheduled job that populates the Search Analytics dashboard with search user data.

1. In the navigation filter, enter `sys_trigger.list`.
2. Edit the `AISearchAnalyticsGlobalScheduledJobUtils` scheduled job.
3. Click Delete.

The `AISearchAnalyticsGlobalScheduledJobUtils` scheduled job no longer runs and populates the data tables needed for the Search Analytics dashboard.
**AI Search Profile dashboard**

The AI Search Profile dashboard summarizes indexed record counts and search query traffic associated with a search profile defined in AI Search. Interactive filters enable users to choose a search profile and select the time frame for analysis of search query traffic.
To access the dashboard, navigate to **AI Search > AI Search Analytics > Search Profile Analytics.**

**Note:** If the dashboard displays a Read operation on table '<name>' from scope 'Advanced AI Search Management Tools' was denied informational message, ask your administrator to perform the steps described in Create a cross-scope access privilege for the AI Search dashboards for the listed table.

**Required Now Platform roles**

- The ais_admin role is required to view or edit the dashboard

**Use cases**

For examples of how different people in your organization would use this dashboard, see these use cases.

<table>
<thead>
<tr>
<th>User</th>
<th>Dashboard use</th>

Create a cross-scope access privilege for the AI Search dashboards
Enable the AI Search dashboards to read records from tables that cannot be accessed from the Advanced Management Tools application scope.

Role required: admin

The AI Search Profile and AI Search dashboards belong to the Advanced Management Tools application scope. If an indexed source or search source table cannot be accessed from this scope, the dashboards display the following informational message:

Read operation on table '<name>' from scope 'Advanced AI Search Management Tools' was denied. The application 'Advanced AI Search Management Tools' must declare a cross scope access privilege. Please contact the application author to update their privilege requests.

To resolve this issue, define a cross-scope table access privilege for the Advanced Management Tools application.

For more information on cross-scope privileges, see Cross-scope privilege record.

1. Set your current application scope context to Advanced Management Tools using the application picker.
3. Click New.
4. On the Cross scope privilege form, enter the following field values.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target Scope</td>
<td>&lt;table scope&gt;</td>
</tr>
<tr>
<td>Target Name</td>
<td>&lt;table name&gt;</td>
</tr>
<tr>
<td>Target Type</td>
<td>Table</td>
</tr>
<tr>
<td>Operation</td>
<td>Read</td>
</tr>
<tr>
<td>Status</td>
<td>Allowed</td>
</tr>
</tbody>
</table>

5. Click Submit.

The new cross-scope privilege appears in the Cross scope privilege table.
Search Analytics dashboard
The Search Analytics dashboard displays key performance metrics, trends, and reports for AI Search usage. Interactive filters enable analysts to view performance analytics for individual search applications and to select the time frame to analyze.
To access the Search Analytics dashboard, navigate to **User Experience Analytics > Dashboard** and click the AI Search Analytics icon ( ) or link in the modules menu. To learn more about the User Experience Analytics dashboard, see **Overview of the dashboard**.

### Required Now Platform roles

To view the Search Analytics dashboard, you must have one of the following roles:

- analytics_admin
- analytics_viewer
- portal_analytics_admin
- portal_analytics_viewer
- web_analytics_admin
- web_analytics_viewer

### Use cases

For examples of how different people in your organization would use this dashboard, see these use cases.

<table>
<thead>
<tr>
<th>User</th>
<th>Dashboard use</th>
</tr>
</thead>
</table>
| Any of the following:  
  - Portal Analytics administrator or viewer  
  - User Experience Analytics administrator or viewer  
  - Web Analytics administrator or viewer |  
  - View and monitor search usage and search performance for a specified search application and date range  
  - Review search trends to better understand the needs of search application end users  
  - Gain insights on how to improve search experience and knowledge coverage |

### Interactive filters

**Search Preview UI for AI Search**

The Search Preview UI enables you to test AI Search queries using settings from a selected search profile. Administrator tools help you review search query performance data and feedback, debug queries, and override default query settings for testing purposes.

Access the Search Preview UI by navigating to **AI Search > Preview > Search Preview.**
Required Now Platform roles

- The ais_admin role is required to view and use the Search Preview UI
- The impersonator role is required for some AI Search administrator tools
Search Preview UI components

1. Service Portal Option, Search Profile
2. Delete email
3. Table
4. Genius Results for delete email
5. Showing results 1 - 10 for delete email
6. Process Data

Query Rules Triggered: 0
Intents Matched: 1
catalogFind
Total time: 3051ms
Pre-processing time: 34ms
Search query time: 205ms
GeniusResult computation: 2792ms
Security processing time: 56ms
## Search Preview UI components

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Search profile list</td>
<td>Select the search profile to apply when previewing search queries.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> The list only includes published search profiles that have one or more linked search sources.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> If a search profile has unpublished changes, the list displays a warning icon (⚠️) and shows [DRAFT] after the profile's name. Publish the search profile to see these changes reflected in the search query preview.</td>
</tr>
<tr>
<td>2. Search input field</td>
<td>Enter search query terms and operators in this field. To preview the query's results using settings from the selected search profile, click <strong>Search</strong>.</td>
</tr>
<tr>
<td>3. Table facet filter</td>
<td>View the distribution of search query results by source table. To filter the query results by table, click a table's name. To remove the table facet filter, select <strong>All</strong>.</td>
</tr>
<tr>
<td>4. Genius Result answers</td>
<td>Review the key-value pairs for each Genius Result answer the search query produces when executed with the selected search profile.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Genius Result answers may not appear for all search queries.</td>
</tr>
<tr>
<td>5. Search query results</td>
<td>Review the results the search query produces when executed with the selected search profile. To page through results, click <strong>Next</strong> or <strong>Previous</strong>.</td>
</tr>
</tbody>
</table>
6. AI Search administrator tools

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6. AI Search administrator tools</td>
<td>Click the icon for the administrator tool that you want to use:</td>
</tr>
<tr>
<td></td>
<td>• Process data tool icon ( ? ) <strong>Process data</strong>: View summary information on the search query's triggered result improvement rules, matched NLU model intents, and processing time.</td>
</tr>
<tr>
<td></td>
<td>• Alerts tool icon ( ! ) <strong>Alerts</strong>: Review alert feedback messages produced during processing of the search query.</td>
</tr>
<tr>
<td></td>
<td>• Dictionary and query feedback tool icon ( ) <strong>Dictionary and query feedback</strong>: Review dictionary and query feedback messages and NLU model intent data for the search query. Enable debugging.</td>
</tr>
<tr>
<td></td>
<td>• Context settings tool icon ( ) <strong>Context settings</strong>: Specify user context values for the search query to trigger result improvement rules.</td>
</tr>
<tr>
<td></td>
<td>• User impersonation tool icon ( ) <strong>User impersonation</strong>: Change the search query's user or locale to test access settings and view translated documents.</td>
</tr>
</tbody>
</table>

For more detailed descriptions of each administrator tool's output, controls, and fields, see the following reference section.

**Search preview admin tools**

Understand the output, controls, and fields provided by admin tools in the search preview UI.

**Process data tool**

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Query Rules Triggered</td>
<td>Count of result improvement rules triggered by the search query.</td>
</tr>
<tr>
<td>Intents Matched</td>
<td>Count and names of NLU model intents detected in the search query.</td>
</tr>
<tr>
<td>Total time</td>
<td>Total time spent processing the search query. Includes pre-processing, search query, Genius Result computation, and security processing times.</td>
</tr>
<tr>
<td>Pre-processing time</td>
<td>Time spent preparing the search query for execution. Includes time spent looking up the user's access permissions for content security.</td>
</tr>
<tr>
<td>Entry</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Search query time</td>
<td>Time spent retrieving records that match the search query and generating the result set.</td>
</tr>
<tr>
<td>Genius Result computation</td>
<td>Time spent computing Genius Result answers for the search query.</td>
</tr>
<tr>
<td>Security processing time</td>
<td>Time spent filtering inaccessible records out of the search query's result set based on the user's access permissions.</td>
</tr>
</tbody>
</table>

**Alerts tool**

This tool displays a list of alert feedback messages produced while processing the search query.

If the search query produced no alert feedback messages, the tool instead displays **No Alert Feedback**.

**Dictionary and query feedback tool**

This tool displays separate panes for dictionary feedback entries and query feedback controls.

**Dictionary feedback**

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stop words</td>
<td>List of feedback messages relating to stop word removal for the search query.</td>
</tr>
<tr>
<td>Spellcheck</td>
<td>List of feedback messages relating to typo handling autocorrection for the search query.</td>
</tr>
<tr>
<td>Synonyms</td>
<td>List of feedback messages relating to synonym expansion for the search query.</td>
</tr>
</tbody>
</table>

**Query feedback**

<table>
<thead>
<tr>
<th>Control</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Show all feedback</td>
<td>Display a JSON array of feedback messages produced for the search query.</td>
</tr>
<tr>
<td>Show all intent data</td>
<td>Display a JSON array of NLU model intents detected in the search query.</td>
</tr>
<tr>
<td>Debug</td>
<td>Enable this option to set <code>sysparm_debug</code> to <code>true</code> when submitting search preview queries.</td>
</tr>
</tbody>
</table>

**Note:** To use this tool, you must have the impersonator role.
Context settings tool

With these tools, you can specify user context values to test user context triggers for result improvement rules.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Domain</td>
<td>To set a domain in the user context for search preview, enter the name of a group from the Group [sys_user_group] table.</td>
</tr>
<tr>
<td>User Company</td>
<td>To set a company in the user context for search preview, enter the name of a company from the Company [core_company] table.</td>
</tr>
<tr>
<td>User Office</td>
<td>To set an office in the user context for search preview, enter the name of a building from the Building [cmn_building] table.</td>
</tr>
<tr>
<td>User Department</td>
<td>To set a department in the user context for search preview, enter the name of a department from the Department [cmn_department] table.</td>
</tr>
<tr>
<td>User Title</td>
<td>To set a title in the user context for search preview, select it from the list. This list includes all Title values found in the User [sys_user] table.</td>
</tr>
<tr>
<td>User Location</td>
<td>To set a location in the user context for search preview, enter the name of a location from the Location [cmn_location] table.</td>
</tr>
<tr>
<td>User Role</td>
<td>To set a role in the user context for search preview, enter the name of a role from the Role [sys_user_role] table.</td>
</tr>
<tr>
<td>User Country</td>
<td>To set a country in the user context for search preview, select it from the list. This list includes all countries found in user locations from the User [sys_user] table.</td>
</tr>
<tr>
<td>User Language</td>
<td>To set a language in the user context for search preview, select it from the list of supported languages.</td>
</tr>
<tr>
<td>User Office Country</td>
<td>To set an office country in the user context for search preview, select it from the list. This list includes all countries found in user locations from the User [sys_user] table.</td>
</tr>
<tr>
<td>User Office City</td>
<td>To set an office city in the user context for search preview, enter it in this field. You can enable session debugging for AI Search to review values submitted for this user context field in user queries.</td>
</tr>
<tr>
<td>User Office State</td>
<td>To set an office state in the user context for search preview, enter it in this field. You can enable session debugging for AI Search to review values submitted for this user context field in user queries.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>User OS</td>
<td>To set an operating system in the user context for search preview, enter its name in this field. You can enable session debugging for AI Search to review values submitted for this user context field in user queries.</td>
</tr>
<tr>
<td>User Device Type</td>
<td>To set a user device type in the user context for search preview, enter it in this field. You can enable session debugging for AI Search to review values submitted for this user context field in user queries.</td>
</tr>
<tr>
<td>User OS Version Type</td>
<td>To set an operating system version type in the user context for search preview, enter it in this field. You can enable session debugging for AI Search to review values submitted for this user context field in user queries.</td>
</tr>
<tr>
<td>User Browser Agent</td>
<td>To set a browser agent string in the user context for search preview, enter it in this field. You can enable session debugging for AI Search to review values submitted for this user context field in user queries.</td>
</tr>
<tr>
<td>User Browser</td>
<td>To set a browser name in the user context for search preview, enter it in this field. You can enable session debugging for AI Search to review values submitted for this user context field in user queries.</td>
</tr>
<tr>
<td>User Device Form</td>
<td>To set a device form in the user context for search preview, enter it in this field. You can enable session debugging for AI Search to review values submitted for this user context field in user queries.</td>
</tr>
</tbody>
</table>

**User impersonation tool**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Search as</td>
<td>To submit search preview queries as another user, enter the user's name from the User [sys_users] table. You must have the impersonator role. Use this control to see how content security affects search query results for specific user accounts.</td>
</tr>
</tbody>
</table>

**Note:** Searches performed while impersonating another user do not affect the Search users metric, trend, and report on the Search Analytics dashboard.

| Query Locale | To submit search preview queries using a specific supported language, select the language from the list. Use this control to observe differences in search query results for different languages. |
**Contextual search**

Contextual search is a search technology that focuses on the context of the query as well as the intent of the user in order to fetch the most relevant set of results. Contextual search displays related results within a form or record producer based on the text you enter in a field.

Example use cases for Incident:

- An agent, working on an Incident record, can use contextual search to find and attach knowledge articles, order a catalog item on behalf of the caller, or search for an article and link it to a related incident or problem.
- A user, creating an Incident via the Service Portal, can see related catalog items that the user can order. The user can also view related knowledge articles to help them resolve the issue on their own without involving the service desk operators.

Contextual search helps with incident deflection for the following areas:

- Incident record producers: deflecting incidents by helping end users resolve issues before they raise an incident.
- Incident forms: helping service desk staff resolve incidents quickly by providing relevant knowledge.
- Incident email notifications: helping end users resolve their incidents themselves without requiring manual intervention from service desk staff.

**Contextual search plugin**

Contextual search plugin is activated in the base system.

**Contextual search plugin**

The Contextual Search plugin (com.snc.contextual_search) is activated by default in the base system. This plugin activates related plugins if they are not already active.

If the related plugins are not activated, Contextual Search activates the plugins.

<table>
<thead>
<tr>
<th><strong>Plugins for Contextual Search</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Contextual Search — Internal [com.snc.contextual_search.internal]</td>
<td>An internal plugin component for Contextual Search.</td>
</tr>
<tr>
<td>GraphQL Schema for Contextual Search [com.snc.contextual_search.graphql]</td>
<td>Provides GraphQL schema for contextual search services.</td>
</tr>
</tbody>
</table>

1. Navigate to System Applications > All Available Applications > All.
2. Find the plugin using the filter criteria and search bar.
   
   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel. For more information, see Request a plugin.
3. Click Install, and then in the Activate Plugin dialog box, click Activate.

**Note:** When domain separation and delegated admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: Application...
Components installed with Contextual Search
Several types of components are installed with the activation of the Contextual Search plugin (com.snc.contextual_search), including tables and user roles.

Note: The Application Files table lists the components that are installed with this application. For instructions on how to access this table, see Find components installed with an application.

Tables installed

<table>
<thead>

<td></td>
</tr>
</tbody>
</table>
### Contextual search concepts

Contextual search concepts help you to understand different contextual search components that are used in the documentation, configuration, and user interface. Understanding of the concepts makes it easier for you to comprehend the interconnection between the components.

Contextual search uses terms and concepts that can differ from industry norms due to the unique nature of the ServiceNow platform. Contextual search includes the following concepts and components:

**Search resource**

Resource that can be searched such as Catalog or Knowledge Articles. As the resources are scripted and contain JavaScript, they can combine results from more than one table.

**Note:**

- ServiceNow provides pre-defined scripted search resources. You cannot create, update, or delete search resources.
- A search resource uses the Zing search engine to search a table.

**Searcher**

A single search resource or a group of search resources that can be searched. For example, the Knowledge and catalog searcher contains Knowledge Articles, Questions and Catalog Items as its search resources.

**Note:** ServiceNow provides pre-defined searchers. You cannot create, update, or delete searchers.

**Additional resources**

An additional resource is a single table source with query conditions that you can search. Additional resource are not scripted as you search from a single table. For example, Resolved Incidents (within the last six months).

**Note:**

<table>
<thead>
<tr>
<th>Table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Search Resource Context Property</td>
<td>Property values for search resource context configuration.</td>
</tr>
<tr>
<td>[cxs_res_context_config_prop]</td>
<td></td>
</tr>
<tr>
<td>Search Resource Property</td>
<td>Property values for search resource searcher configuration.</td>
</tr>
<tr>
<td>[cxs_search_res_config_prop]</td>
<td></td>
</tr>
<tr>
<td>Searcher Configuration</td>
<td>Details of available search configurations.</td>
</tr>
<tr>
<td>[cxs_searcher_config]</td>
<td></td>
</tr>
<tr>
<td>Table Configuration</td>
<td>Lists the tables configured for table configurations.</td>
</tr>
<tr>
<td>[cxs_table_config]</td>
<td></td>
</tr>
<tr>
<td>Wizard Configuration</td>
<td>Lists the tables configured for wizard configurations.</td>
</tr>
<tr>
<td>[cxs_wizard_config]</td>
<td></td>
</tr>
<tr>
<td>Base UI Configuration</td>
<td>Common elements for the record producer, table, and wizard configurations.</td>
</tr>
<tr>
<td>[cxs_ui_config_base]</td>
<td></td>
</tr>
</tbody>
</table>
• ServiceNow provides pre-defined additional resources. You cannot create or delete additional resources, but can update additional resources to better match your organization requirements. For example, you can update the condition and description for Resolved Incidents (Last 6 months) to change it to Resolved Incidents (Last 3 months).
• An additional resource performs the search based on the type of the source:
  • Table: The Zing search engine to used to search a table.
  • Predictive Intelligence Similarity: Search is based on similarity and not on the Zing search engine.

Search result display fields

Defines the fields whose values are displayed with the search result of an additional resource. The fields can include Assigned to, Opened by, and State. The search result display fields appear at the bottom of a search result record.

**Note:** ServiceNow provides pre-defined search result display fields. You cannot create or delete additional resources, but you can update search result display fields to better match your organization requirements. For example, change which field to use as a title or the description or which fields to show at the bottom of a search result record.

Search context

Brings together a searcher and additional resources (if any) that can be searched.

**Note:** ServiceNow provides pre-defined search contexts. You can also create search contexts.

Searcher text

Defined in a search context, a searcher text specifies a user-friendly group name for the searcher. When a searcher contains more than one search resource, a group name is used to represent that group of search resources. For example, the Incident Deflection search context uses a searcher that searches Knowledge Articles, Questions and Catalog Items. The user-friendly searcher group name that represents all of them is Knowledge & Catalog.

Search on tab

Defined in the search context, Search on tab specifies when a contextual search should start the search. The different scenarios when search is performed are:

- If you select the Search on tab check box, the search only runs when you update and leave the search field (recommended).
- If you clear the Search on tab check box, the search runs when you pause typing.

Search actions

Specifies the actions for each such results. For example, for catalog items, the search action is Order and for knowledge articles it is Attach. All sources have the This helped action.
Contextual search components diagram

The contextual search components diagram helps you to understand how contextual search concepts work together to perform a search and from which module you can configure the components.
You can configure the search header text and the form using the Contextual search > Table configuration module. For more information, refer Configure table for a contextual search.

You can configure the searcher text and the searcher using the Contextual search > Search Contexts module. For more information, see Define a search context.
Components

<table>

</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>You can configure the card title, card description field, and card additional fields using the Contextual search &gt; Search Result Display Configurations module. For more information, see Edit search resource display field record.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Search Action Configurations</th>
<th>Navigation</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>You can configure the search actions using the Contextual search &gt; Table Configuration &gt; Search Action Configurations module. For more information, see Modify or disable search actions available for contextual search.</td>
</tr>
</tbody>
</table>

Configuring contextual search

You can configure different components of contextual search.

Contextual search properties

Contextual search properties are used to control the fields that you can search from and the number of results displayed per page.

The contextual search properties are available at Contextual Search > Properties.

Properties for contextual search

<table>
<thead>
<tr>
<th>Property label</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default value for maximum number of search results returned for table and record producer configurations</td>
<td>Default value for the maximum number of search results returned when you create a new table or record producer configuration. By default, the value is 10.</td>
</tr>
<tr>
<td>[com.snc.contextual_search.result.default.limit]</td>
<td></td>
</tr>
</tbody>
</table>

| Number of characters that a configured field needs before triggering a search | Number of characters that contextual search requires before triggering a search based on the typed text in the search field. By default, the value is set to 3 characters. |
| [com.snc.contextual_search.min_length] | |

| Number of milliseconds that a configured field will wait before triggering a search | Number of milliseconds that contextual search waits before triggering a search based on the typed text in the search field. By default, the value is set to 1,000 milliseconds (one second). |
| [com.snc.contextual_search.wait_time] | |

<p>| Records returned above this threshold will log warnings | Triggers a warning message within the system log whenever more than this number of results are returned in a search. This logging helps if you are experiencing performance issues because of large searches. By default, the value is set to 10,000 results. |
| [com.snc.contextual_search.result.threshold] | |</p>
<table>
<thead>
<tr>
<th>Property label</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>When a Form configuration is created a search field with a name matching this property will be automatically created</td>
<td>The default field that is used for searching when you create a new table configuration. By default, the value is set to short_description.</td>
</tr>
<tr>
<td>[com.snc.contextual_search.widget.form.default_field]</td>
<td></td>
</tr>
<tr>
<td>Collapse the search results widget when creating a new record in a form</td>
<td>When the value is set to false and you create a new record, the search results widget is collapsed to save space. By default, the value is set to false.</td>
</tr>
<tr>
<td>[com.snc.contextual_search.widget.form.open_collapsed_new_records]</td>
<td></td>
</tr>
<tr>
<td>Collapse the search results widget when opening an existing record in a form</td>
<td>When the value is set to true and you open an existing record, the search results widget is collapsed to save space. By default, the value is set to true.</td>
</tr>
<tr>
<td>[com.snc.contextual_search.widget.form.open_collapsed_existing_records]</td>
<td></td>
</tr>
<tr>
<td>Auto expand the search results widget when search field updates in a form</td>
<td>When the value is set to true and the search results widget stays collapsed until you click the search results widget to expand it manually. By default, the value is set to true.</td>
</tr>
<tr>
<td>[com.snc.contextual_search.widget.form.expand_on_search_field_update]</td>
<td></td>
</tr>
<tr>
<td>Show meta data on form contextual search results</td>
<td>When the value is set to true, each search result includes additional meta data below each result record. By default, the property is set to true.</td>
</tr>
<tr>
<td>[com.snc.contextual_search.widget.form.show_meta_data]</td>
<td></td>
</tr>
</tbody>
</table>

**Define a search context**

Define a search context to configure relevant resources based on your business needs. For example, you can show different resources for an agent working on an Incident and different resources for a problem co-ordinator working on a Problem. The search resources can be pre-defined resources as well as additional resources.

Role required: admin

1. Navigate to Contextual Search > Search Contexts.
2. Click New.
3. On the form, fill in the fields.

![Search Context form](image)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Unique name of the search context.</td>
</tr>
<tr>
<td>Short description</td>
<td>Brief summary of the context.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Searcher</td>
<td>Lookup icon to select a searcher for this context. The searcher determines the information source to search.</td>
</tr>
<tr>
<td></td>
<td>• Catalog only: Provides search results from service catalog items.</td>
</tr>
<tr>
<td></td>
<td>• Knowledge and catalog: Provides search results from knowledge articles and service catalog items.</td>
</tr>
<tr>
<td></td>
<td>• Knowledge only: Provides search results from knowledge articles.</td>
</tr>
<tr>
<td></td>
<td>• Knowledge, Discussions and pinned: Provides search results from knowledge articles, pinned knowledge articles and Now Community.</td>
</tr>
<tr>
<td></td>
<td>• Knowledge, pinned knowledge and catalog: Provides search results from knowledge articles, pinned knowledge articles and service catalog items.</td>
</tr>
<tr>
<td></td>
<td>• Knowledge and pinned knowledge: Searches knowledge articles and pinned knowledge articles.</td>
</tr>
<tr>
<td></td>
<td>• Knowledge, Pinned, Catalog: Provides search results from Knowledge, Pinned Knowledge, and Catalog items.</td>
</tr>
<tr>
<td></td>
<td>• Knowledge and pinned: Provides search results from knowledge articles and pinned knowledge articles.</td>
</tr>
<tr>
<td></td>
<td>• Pinned Knowledge only: Provides search results from pinned knowledge articles.</td>
</tr>
</tbody>
</table>

**Note:** The **Searcher** field is optional. You can decide whether to show or hide sources from an agent.

<table>
<thead>
<tr>
<th>Searcher text</th>
<th>Unique label for the searcher group that is used when there is more than one resource in the searcher.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active</td>
<td>Check box to activate the search context form.</td>
</tr>
<tr>
<td>Enable wildcard searches</td>
<td>Check box to enable wildcard characters, such as * and %, for searches.</td>
</tr>
<tr>
<td>Search on tab</td>
<td>Check box to determine when to perform the search. If you select this option, the search runs only when you enter text in a field and then leave the field. If you clear the check box, the search runs after you stop typing even though the cursor is still in the same field.</td>
</tr>
</tbody>
</table>

**Note:** Ensure you select the check box to see additional resources in the source selector on Platform.

4. Right-click the form header and click **Save**.
Configure table for a contextual search

Configure the search that is performed and the actions that you can take on the search result for the table.

Role required: admin

1. Navigate to Contextual Search > Table Configuration and click New.
2. On the form, fill in the fields.
### Table Configuration fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>Name and label of the table associated with the form. For example, Incident [incident].</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>UI type</td>
<td>User interface differs depending on whether you use the table configuration for Platform or Workspace.</td>
</tr>
</tbody>
</table>

**Note:** The *When to display* section appears only when you select **Platform** from **UI type**.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Show searcher first</td>
<td>Option to display searcher resources before additional resources in the search context. This field appears only when you select <strong>Workspace</strong> from <strong>UI type</strong>.</td>
</tr>
<tr>
<td>Search context</td>
<td>Lookup icon</td>
</tr>
<tr>
<td></td>
<td>to select a search context for which you are configuring the table.</td>
</tr>
<tr>
<td>Results header text</td>
<td>Unique name that appears as a header for the search results area that appears in the form. For example, if you enter <strong>Knowledge results</strong> as the value in this field, the related search area displays <strong>Knowledge results</strong> as the name.</td>
</tr>
<tr>
<td>Enable related search box</td>
<td>Option to show the related search box in the form.</td>
</tr>
<tr>
<td>Enable source selector</td>
<td>Option to show the list of search sources that you can search from.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope of the table configuration. The configuration is available for all applications or for scoped applications.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate the table configuration.</td>
</tr>
<tr>
<td>Limit</td>
<td>Maximum number of search results returned.</td>
</tr>
<tr>
<td>Results per page</td>
<td>Number of results to display per page.</td>
</tr>
<tr>
<td>Allow expand/collapse</td>
<td>Option to enable a user to collapse the search results in the form.</td>
</tr>
<tr>
<td>Enable preview buttons</td>
<td>Option to show a preview button (platform only) for each search result. The user can then use the preview button or the search result title to preview the result record.</td>
</tr>
</tbody>
</table>

**Note:** This field appears only when you select **Enable related search box**.

**Note:** The option is available from the London release. Clear the option to provide a more compact display for each search result.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allow search with empty search text</td>
<td>Option to specify whether the search runs when there is no search text.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>There is no search text when there is no search field specified or when there is a search field whose value is empty.</td>
</tr>
<tr>
<td>When to display</td>
<td></td>
</tr>
<tr>
<td>Required roles</td>
<td>List of roles that grant access to the related search results widget from the table. Users must have one of these roles to see the widget when viewing the table.</td>
</tr>
<tr>
<td>Condition</td>
<td>Conditions that records must satisfy to appear as related search results. For example, set <strong>[Active] [is] [true]</strong> to only enable the active records as related search results.</td>
</tr>
<tr>
<td>Search as</td>
<td></td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Enable search as</td>
<td>Option to enable searching as a different user. The message box describes the settings available when you select this.</td>
</tr>
</tbody>
</table>
3. Click **Submit**.
   The Search Fields, Filter Configurations, Email Configurations, and Search Action Configurations related lists appear. By default, the **Short description** field is added to the Search Fields related list.

**Filter configuration for contextual search**

Define filter configurations to map fields from the form to provide a more targeted search result set. 

*Create a filter configuration using mapping*

Create filter conditions using mapping that you can associate with a table configuration. The search result displays result that meets the filter conditions.

Role required: admin

1. Navigate to **Contextual Search > Table Configuration**.
2. Open a table configuration record on which to create the filter.
3. In the Filter Configurations related list, click **New**.
4. On the form, fill in the fields.

**Filter Configuration form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| Resource configuration | Lookup icon  
|                   | to select a resource such as Knowledge Articles.                           |
| Table configuration | [Read-only field]. Table for which you are applying the filter configuration. |
| Scripted filter   | Check box to select if you want to enter scripts in the **Script** field.    |
| Note: Clear the check box as you want to create a filter configuration using mapping. |
| Active            | Check box to activate the filter configuration.                             |

5. Click **Submit**.
   The Table Configurations form appears.

6. In the Filter Configuration related list, click the filter that you have created.
7. In the Filter Conditions related list, click **New**.

![FilterConditions.png](image)

8. In the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Short description</td>
<td>Brief summary of the filter condition.</td>
</tr>
<tr>
<td>Query table</td>
<td>[Read-only] Table from which the filter condition is queried.</td>
</tr>
<tr>
<td>Current form</td>
<td>[Read-only] Form for which you created the filter conditions.</td>
</tr>
<tr>
<td>Field to compare</td>
<td>Value of the field is compared with the value of the <strong>Compare to</strong> field.</td>
</tr>
<tr>
<td>Operator</td>
<td>Operation that should be performed on the <strong>Field to compare</strong> and <strong>Compare to</strong> field.</td>
</tr>
<tr>
<td>Compare to</td>
<td>Value of the field is compared against the value of <strong>Field to compare</strong>.</td>
</tr>
<tr>
<td>Compare</td>
<td>Comparison of the field can be based on the actual value stored on the database or the value that is displayed on the interface. The available values are: <strong>Value</strong> and <strong>Display Value</strong>.</td>
</tr>
<tr>
<td>Include if blank</td>
<td>Check box to include a condition when the value of the <strong>Compare to</strong> field is blank.</td>
</tr>
<tr>
<td>Active</td>
<td>Check box to activate the filter configuration.</td>
</tr>
</tbody>
</table>

9. Click **Submit**.

*Create a filter configuration using scripts*

Create filter conditions using script that you can associate with a table configuration. The search result displays results that meet the filter conditions.

Role required: admin

1. Navigate to **Contextual Search > Table Configuration**.
2. Open a table configuration record on which to create the filter.
3. In the Filter Configurations related list, click **New**.
4. On the form, fill in the fields.

**Filter Configuration form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resource configuration</td>
<td>Lookup icon to select a resource such as Knowledge Articles.</td>
</tr>
<tr>
<td>Table configuration</td>
<td>[Read-only field]. Table for which you want to apply the filter configuration.</td>
</tr>
<tr>
<td>Scripted filter</td>
<td>Check box to select if you want to enter scripts in the Script field.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope for your filter configuration.</td>
</tr>
<tr>
<td>Active</td>
<td>Check box to activate the filter configuration.</td>
</tr>
</tbody>
</table>

5. Enter a script corresponding to the resource configuration.

**Note:**

Use one of these dynamic filter scripts to set up your dynamic filter.

6. Click Submit.

**Configure search resource context properties**

Configure the properties to limit the search to a specific catalog or knowledge base. For example, if you want to limit the knowledge search to an IT knowledge base or a service catalog search to software service catalog, you can configure the properties.

Role required: admin

The following procedure uses Incident Deflection as an example.

1. Navigate to **Contextual Search > Search Contexts**.
2. Open the Incident Deflection record.
3. Click the Resource Configurations related list.

In the Resource Configurations related list, click a resource configuration record to know the properties of the search resource.

The **knowledge** record displays the following knowledge resource configuration properties:

<table>
<thead>
<tr>
<th><strong>Property</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Condition</td>
<td>Conditions to specify one or more knowledge bases to search.</td>
</tr>
<tr>
<td>Exclude pinned articles</td>
<td>Pinned article is a knowledge article. This property helps to decide whether to exclude pinned articles from knowledge base search or not.</td>
</tr>
</tbody>
</table>

The **catalog** record displays the following catalog resource configuration properties:

<table>
<thead>
<tr>
<th><strong>Property</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Catalog name</td>
<td>A catalog name to search the catalog items.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| Search operator  | Value of the operator is used in the Zing search engine to instruct how to combine the AND and OR conditions when parsing the search string. The integration of the search strings helps to score the displayed results. The value can only be one of the following values:  
  - **IR_AND_OR_QUERY** (the default): Display results with exact matches of all terms if the number of results is greater than the value of the `glide.ts.query.and_or_limit` property (default 0) or the (overriding) value of the table custom attribute `text_search_and_or_limit` (when added). Otherwise display results with any matches of any terms.  
  - **IR_AND_QUERY**: Display results with exact matches of all terms only.  
  - **IR_OR_QUERY**: Display results with any matches of any terms.                                                                                                    |

4. To edit the value of any property, click the property name and in the Search Resource Context Property form, update the **Value** field to **true** or **false**.

5. Click **Update**.

**Managing contextual search**

Contextual search provides a way to display results that can be relevant to the issue for which you are creating an incident or requesting a service.

The section covers topics that help you to:

- Understand the actions that are taken on the search results.
• Use contextual search results in a record producer within the Service Portal or as an agent in a form.

Set a search context as default

If you use the contextual search REST API and do not specify which search context to use, the API uses the search context that you have set as default. The search context that you use in the API takes preference over the one marked as default.

Role required: admin

1. Navigate to **Contextual Search > Search Contexts.**
2. Open the search context record that you want to set as default.
3. Click **Set As Default**.
Set default source for search context

You can decide if you want an additional resource to be the default source or the searcher.

Role required: admin

- If you set an additional resource as default that is considered as the default source.
- If you do not mark any additional resource as default, then the searcher is considered as the default source.
- If you do not have a searcher and you have not marked any additional resource as default, the default is the additional resource with the lowest value in the `Order` field.

1. Navigate to **Contextual Search > Search Contexts.**
2. Open the search context record to change its default source.
3. Click the Additional Resource Configuration related list.

4. Click the preview information icon to the left of the search resource configuration record and click **Open Record.**
5. Click **Set As Default.**

**Note:** If you want to remove the default value, click **Clear Default.**
**View a searcher**

View the details of a searcher to know which search resources are searched.

Role required: admin

ServiceNow provides pre-defined searchers. You cannot create, update, or delete searchers.

1. Navigate to **Contextual Search > Searchers**.
2. Open a searcher record.

![Searcher configuration](image)

3. Optional: In the Search Resources related list, view which search resources are searched.
4. Optional: In the Search Contexts related list, view all the search contexts that use this specific searcher.

**Show related search box in a form**

Show the related search box when you want the agent to search for different text without having to modify the text in the **Short description** field.
Role required: admin

From the London release, the related search box is available in the forms by default for the new customers. In case you do not find the related search box for any form, you can always configure the table for the same.

1. Navigate to **Contextual Search > Table Configuration**.
2. Open the table record for which you want to show the related search box.
3. Select the **Enable related search box** check box.
   The **Enable source selector** check box appears.
4. Right-click the header form and select **Save**.

### Add multiple search fields for contextual search

Add multiple search fields if you want to search from a field other than the short description without using the related search box.

Role required: admin

Search results for the default search field appear automatically when you open a record. You can configure contextual search to search for results even when there is no text in the search field. Search results in other associated fields only appear when you have updated content in those fields. For example, in the base system the **Short description** field is the default search field for the Incident form, so search results based on the field are displayed automatically. If there are multiple fields, the search is conducted based on the last updated field.

1. Navigate to **Contextual Search > Table Configuration**.
2. Open the table record for which you want to add multiple search fields.
3. In the Search fields related list, click **New**.
4. On the form, fill in the fields.

![Search Field form](image)

**Search Field form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Field</td>
<td>The search field to be added in the search fields list.</td>
</tr>
</tbody>
</table>

**Note**: You can only select a text field.
5. Click **Submit**.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application</td>
<td>Application scope of the table configuration. The configuration is available for all applications or for scoped applications.</td>
</tr>
<tr>
<td>Order</td>
<td>Order in which the field appears in the search fields list. If there are multiple search fields, this field indicates which searched field is executed first.</td>
</tr>
</tbody>
</table>

Use the **Default** column to set any field as the default one.

**Add additional resources to the source selector of a form**

Add additional resources when you want the user to search beyond knowledge and service catalog search resources. For example, add additional resources for **Open Incidents**, **Resolved Incidents** or **Similar Open Incidents**.

Role required: admin

Additional resources are pre-defined. An additional resource is a single source table with query conditions that can be searched or they can reference a Predictive Intelligence Similarity solution definition.

You can view the Predictive Intelligence sources only if you are licensed for Predictive Intelligence and have activated **Predictive Intelligence for Contextual Search**

1. Navigate to **Contextual Search > Search Contexts**.
2. Open the search context record for which you want to see the additional resources.
3. In the Additional Resource Configurations related list, click **Edit**.
4. From the Collection field, move the required additional resources to the Additional Resource Configurations List field.

For example, if you want to move additional resources whose type is Predictive Intelligence Similarity, then move Similar Incidents, Similar Knowledge Articles, Similar Open Incidents, and Similar Resolved Incidents from the Collection field to the Additional Resource Configurations List field.

Note: You can view the Predictive Intelligence sources only if you have license for Predictive Intelligence.
5. Click **Save**.

The search resources appear under **Additional Resource Configurations**.

![Additional Resource Configurations Table]

---

**Edit search resource display field record**

Use the search result display fields to provide title, description, and additional information about the search result.

Role required: admin

ServiceNow provides pre-defined additional resource or search sources to the user. You cannot create or delete search result display configurations. Each table referred by an additional resource has a search result display configuration record. You can edit the values in the **Card title field**, **Card description field**, and the **Card additional fields**.
Note: Ensure that you select the contextual search property **Shows meta data on form contextual search results** to view **Card additional fields** in the search result.

1. Navigate to **Contextual Search > Search Result Display Configurations**.
2. Open the search result display configuration record that you want to modify.
3. In the form, edit the fields.

### Search Result Fields form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UI type</td>
<td>[Read-only] Interface where the values of the search result display fields should appear. It can appear in platform or workspace.</td>
</tr>
<tr>
<td>Table</td>
<td>[Read-only] Name of the table in which the values of the search result display fields should appear. For example, if you mention Incident [incident] as the table, then the additional resource field values appear in the search result for the Incident [incident] table.</td>
</tr>
<tr>
<td>Application</td>
<td>[Read-only] Application scope of the record. The record is available for all applications or for scoped applications.</td>
</tr>
<tr>
<td>Card View</td>
<td></td>
</tr>
<tr>
<td>Card icon</td>
<td>[Workspace] Icon name displayed on the search result card view.</td>
</tr>
<tr>
<td>Card label</td>
<td>[Workspace] Label displayed on the search result card view.</td>
</tr>
<tr>
<td>Card title field</td>
<td>[Platform or Workspace] Field whose value is shown as title in the search result title.</td>
</tr>
<tr>
<td>Card additional fields</td>
<td>[Platform or Workspace] List of field names displayed on the search result to provide more context to the search result. The card additional fields appear at the bottom of a search result record.</td>
</tr>
<tr>
<td>Card description field</td>
<td>[Platform or Workspace] Name of the field whose value is shown as the search result description.</td>
</tr>
<tr>
<td>Card display updated date</td>
<td>[Workspace] Check box to display the latest date on the search result card view.</td>
</tr>
<tr>
<td>Details View (only when the UI type is Workspace)</td>
<td></td>
</tr>
<tr>
<td>Detail title field</td>
<td>Field whose value is shown as title in the search result detail view.</td>
</tr>
<tr>
<td>Detail link field</td>
<td>Field used as clickable link on the search result detail view.</td>
</tr>
<tr>
<td>Detail additional fields</td>
<td>List of field names displayed on the search result detail view.</td>
</tr>
<tr>
<td>Detail show last work note</td>
<td>Check box to display the latest work note on the search result detail view.</td>
</tr>
</tbody>
</table>

4. Click **Update**.

### Specify fields for the Cxs_popup view

Edit the Cxs_popup view to specify the fields to be shown for addition resources in the preview window of a task record. The preview helps you with the summary of the record.

Role required: admin
If a Cxs_popup view is not defined for the additional resource table, the sys_popup view is used. If the sys_popup view is also not defined, the default view is considered.

1. Navigate to **Incident > All**.
2. Open the incident record whose view you want to change to Cxs_popup.
3. Click the additional actions icon ( ) and in the View option, click **Cxs_popup**.

The view of the incident record changes to **Cxs_popup** view.
4. Click the additional actions icon ( ), and in the Configure option, select Form Layout.

5. From the Available list of fields, select the fields that you want to be available in the Cxs_popup view and move them under Selected.

6. Click Save.

Modify or disable search actions available for contextual search

Modify or disable search actions to restrict the actions that a user can perform on a search result.

Role required: admin

The Search Action Configurations related list contains all the available Search actions available for the selected Search context. Search actions can be modified and disabled but not deleted and new actions cannot be created.

1. Navigate to Contextual Search > Table Configuration.

2. Open a record.
3. In the Search Action Configurations related list, view the list of search actions available for the contextual search.

<table>
<thead>
<tr>
<th>Action label</th>
<th>Attachment type</th>
<th>Show on new record</th>
<th>Active</th>
</tr>
</thead>
<tbody>
<tr>
<td>Order</td>
<td>ServiceCreateSearchResource</td>
<td>true</td>
<td>false</td>
</tr>
<tr>
<td>This helped</td>
<td>Helpful</td>
<td>true</td>
<td>true</td>
</tr>
<tr>
<td>This helped</td>
<td>HelpdeskSearchSearchResource</td>
<td>true</td>
<td>true</td>
</tr>
<tr>
<td>This helped</td>
<td>HelpdeskSearchSearchResource</td>
<td>true</td>
<td>true</td>
</tr>
<tr>
<td>Attach</td>
<td>Embedded link to article</td>
<td>true</td>
<td>true</td>
</tr>
<tr>
<td>This helped</td>
<td>ServiceCreateSearchResource</td>
<td>true</td>
<td>false</td>
</tr>
<tr>
<td>Link to incident</td>
<td>HelpdeskSearchSearchResource</td>
<td>true</td>
<td>true</td>
</tr>
<tr>
<td>Link to incident</td>
<td>HelpdeskSearchSearchResource</td>
<td>true</td>
<td>true</td>
</tr>
<tr>
<td>Link to incident</td>
<td>HelpdeskSearchSearchResource</td>
<td>true</td>
<td>true</td>
</tr>
</tbody>
</table>

To disable a search action, set the value of **Active** to **false**.

**Note:** You cannot disable the **This helped** action.

The search actions that you can modify are as follows:

- **Action label**: Label on the action button on the preview window. For example, **This helped** or **Attached To Incident**.
- **Attachment type**: Method to attach a knowledge article with the record. You can embed a link (recommended) to the article or embed a copy of the article.
- **Show on new record**: Enables the **Attach** button to appear when you are creating a record. Prior to the London release, the user had to fill out and save the form, then re-expand the related search results to access the **Attach** button.
Note: This option only applies to tables with the Platform UI type. It defaults to false to provide a consistent user experience between Platform and Workspace tables.
Getting Around in Windows

Windows 8.x

Windows 8.x is designed for using touch, mouse, and keyboard together, on hardware ranging from touch-enabled tablets and laptops to PCs and all-in-one computers, including those without touch capability.

Start screen and Desktop

- 8.1: Microsoft updated the Windows 8.1 interface by returning the Start button, providing ease of access along with the option of the Metro interface. The intent is to provide a seamless experience on desktops, laptops, tablets, and phone devices.
  
  By default, the Start screen is displayed. Move your mouse pointer to the bottom left corner of the screen to make the Start button appear.
  
  Click it to display the desktop; click it again to display the Start screen.

- 8: The Start screen has a default application display you can customize:

  1. Right-click any app and the Application bar will appear at the bottom, with options for the application you selected.
  
  2. To add an app to the Start screen, click Pin to Start.

  If an application is already on the Start screen, you’ll see Unpin from Start instead.
Enable viewing of search results for the current and another selected user

Enable the search as functionality when you want the user to be able to view the search result based on what is common for both the user as well as another user.

Role required: admin

For example, an HR administrator may have some confidential information. A user might have partial access to the information. The Search as functionality applies security access to display results that are common to both the logged in or current user and the user referenced in the Search as field. The search result for the other user may have fewer entries than what that current user can actually view.

Note: No search result is displayed for the Predictive Intelligence Similarity additional resource. Record producers only support searching for the current user.

1. Navigate to Contextual Search > Table Configuration.
2. Open a table configuration record.
3. In the Search as section, fill in the fields.
When enabled, Search As displays the search results that appear for the user defined in the Search As field.

Results appear in a separate tab next to the search results the current user sees.

Use Condition and Script to restrict when the other user's results appear. Results appear if both checks evaluate to true:

- Condition in the Condition field evaluates to true, or the condition is empty.
- The script in the Script field evaluates to true, or sets the variable "answer" to true, or is empty.

Enable search as

Search as field

### Search as configuration fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable search as</td>
<td>Option to enable the Search as functionality.</td>
</tr>
<tr>
<td>Search as field</td>
<td>Field defining the other user to search as. This field appears only when you select <strong>Enable search as</strong>.</td>
</tr>
<tr>
<td>Results message</td>
<td>Message to display with search results when searching as a different user. This field appears only when you select <strong>Enable search as</strong>.</td>
</tr>
<tr>
<td>Condition</td>
<td>Condition restricting when the search result of the user mentioned in the <strong>Search as field</strong> should appear. This field appears only when you select <strong>Enable search as</strong>.</td>
</tr>
<tr>
<td>Script</td>
<td>A condition script, enabling administrators to implement more powerful conditions. For example, to restrict access to users that are members of a group, use <code>gs.getUser().isMemberOf(&quot;&lt;group name&gt;&quot;)</code>. This field appears only when you select <strong>Enable search as</strong>.</td>
</tr>
</tbody>
</table>

**Note:** Both **Condition** and **Script** must evaluate to **true** for search results to appear. An empty condition or script also evaluates to **true**.

The **My Results** tab displays the search result for the current user. The **<User name>’s results** tab displays the search result for the user referenced in the **Search as field**.

### Define contextual search for record producer

Define a record producer to trigger a search based on the text that you enter in a variable field. Search results appear at the bottom of the record producer form.

**Role required:** admin

The base system **Create New Incident** record producer is configured to use contextual search. If you have customized this record producer, you can configure contextual search to link to a specific field on your record producer.

**Note:** Only one variable within a record producer can use contextual search.

1. Navigate to **Contextual Search > Record Producer Configuration** and click **New**.
2. In the form, fill in the fields.

![Record Producer Configuration Form](image)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Record producer</td>
<td>Unique name of the record producer where you want to add the contextual search.</td>
</tr>
<tr>
<td>Search context</td>
<td>Name of the search context to use.</td>
</tr>
<tr>
<td>Search variable</td>
<td>Variable within the selected record producer that uses the contextual search.</td>
</tr>
<tr>
<td>Results header text</td>
<td>Unique name that appears as a header for the search results area that appears in the form.</td>
</tr>
<tr>
<td>Active</td>
<td>Check box to activate the record producer configuration.</td>
</tr>
<tr>
<td>Limit</td>
<td>Maximum number of search results returned.</td>
</tr>
<tr>
<td>Results per page</td>
<td>Number of results to display per page.</td>
</tr>
<tr>
<td>Allow expand/collapse</td>
<td>Check box to expand or collapse the search results in the form.</td>
</tr>
</tbody>
</table>

3. Click **Submit**.
Define email configuration for contextual search

Define email configurations to allow the system to include search results with an email notifications.

Role required: admin

When knowledge articles are associated with a record, those search results can be included in email notifications. For example, email notifications sent when an incident is created can include knowledge search results. An article in the search results may help the user, who raised the incident, to resolve the issue independently.

1. Navigate to **Contextual Search > Table Configuration**.
2. In the Email Configurations related list, click **New**.
3. In the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email notification</td>
<td>Lookup icon to select an email notification to attach the search results. You can select only from the notifications that are on the same table as the table configuration record.</td>
</tr>
<tr>
<td>User field</td>
<td>A reference field that helps to narrow down on the search results. For example, if you select <strong>Opened by</strong>, the search results include only the articles that the <strong>Opened by</strong> user can access based on user criteria.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope of the email configuration. The configuration is available for all applications or for scoped applications.</td>
</tr>
<tr>
<td>Limit</td>
<td>Maximum number of search results returned.</td>
</tr>
</tbody>
</table>

4. Click **Submit**.

Provide knowledge in incident email notification

Contextual search results are included in email notifications that are sent to users who create a new incident.

Role required: admin

The email notification provides links to knowledge articles that may help users resolve their issues faster. For example, if a user raises an incident when the service desk staff is not available, the email notification provides knowledge links that may help the user.

By default, contextual search results are based on the short description in the incident. Within the automated email response, contextual search adds links to relevant knowledge articles.

1. A customer sends an email to IT support with the subject **My laptop keeps crashing**.
2. An incident is created based on this email.
3. The email subject is inserted into the **Short description** field of the new incident.
4. The automated email notification sent to the user includes search results based on **My laptop keeps crashing**.

By default, notifications provide three article links.
5. The customer may then be able to use the search results to resolve the incident.

**Note:** The knowledge links provided are filtered to ensure that the articles are accessible to the user who submitted the email.

You can configure notification options, such as changing the number of links provided with notifications. You can also configure contextual search functionality to match the email notifications of your organization or you can use contextual search with notifications for other records.

**Edit an email notification for the search results**

Edit the email notification that is sent to include search results.

Role required: admin

1. Navigate to **System Notification > Email > Notifications**.
2. Open the email template that you want to edit.
3. Click **What it will contain**.
4. In the **Message HTML** field, add the following script:

   `_${mail_script.cxs_EmailSearchResults}_`

5. Right-click on the header form and click **Save**.
Attach a knowledge article

Attach a knowledge article to an incident to solve issues quickly by going through the in-depth troubleshooting steps and other detailed information in the article.

1. Navigate to Incident > All.
2. Open an active incident record.

In the Related Search Results, search results appear.
3. Click **Attach** for the knowledge article that you want to attach with the incident record. A note about the knowledge article is copied or appended to the **Additional comments (Customer visible)** field. If you want to change the field, refer to **Specify field for attached knowledge article links**.

4. Click **Post** or right-click the header of the form and click **Save** to add the note to the activity stream.

**Specify field for attached knowledge article links**

Specify which field to add a note to when you attach a knowledge article to a record. By default, a link of the knowledge article is added to the **Additional comments (Customer visible)** field. You can specify the field based on the table. For example, a Problem record does not have **Additional comments (Customer visible)** field on the form. The **Attach** action is configured to add the note to the **Work notes** field.

Role required: admin

You can specify the field either globally or locally. The local field for a table overrides the global default field value.

To specify the global field, navigate to **Knowledge > Administration > Properties > Other Knowledge Properties** and specify the name of the field in the **glide.knowman.attach.fields** property.

You can specify the local field using the following procedure.

1. Navigate to **Contextual Search > Table Configuration**.
2. Edit the table configuration that you want to change attachment fields for.
3. Click the Search Action Configurations related list.
4. For each search action that you want to change the default field for, perform the following steps:
   a) Edit the search action.
   b) Select the **Use custom field for attach note** option, if not already selected.
   c) In the **Attach note field**, enter the name of the field that you want the copy the article into, such as `comments` or `work_notes`.
   d) Click **Update**.

**Note:**
- If you do not want to add a note to any field, leave the **Attach note field** blank.
- If the field you have specified in the **Attach note field** is not found on the form, then the note is not added to any field.

Clear the system cache to make sure the changed field specification applies. You can clear the system cache by appending `cache.do` to the instance URL. For example, `https://<instance name>.service-now.com/cache.do`.

**Warning:**
Clearing the system cache can affect overall performance and degrade system response times. Do not run cache flushes during business hours, and do not trigger cache flushes automatically.

**Feedback information on contextual search**

When a user clicks any of the action buttons such as **This helped**, **Order**, or **Attached**, the feedback information is stored in specific tables. The information helps you to understand the effectiveness of the searches. You can also create custom reports by querying these tables.

<table>
<thead>
<tr>
<th>Table [name]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Relevant Document Detail [cxs_rel_doc_detail]</td>
<td>The list of individual recorded actions. For example, Preview, This helped, Attach, or Order. The key fields in the Relevant Document Detail table are as follows:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Original search terms</strong>: The original search terms. This field is used only when the fulfiller has overridden the original search terms using the related search box.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Relevance type</strong>: The recorded action.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Relevant document</strong>: The reference to the search session group in the Relevant Document table.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Created by</strong>: The user who performed the action.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Position</strong>: The position of the recorded action in the result list.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Search Resource</strong>: The reference to the search resource for that particular result. Used only for an Predictive Intelligence Similarity result.</td>
</tr>
</tbody>
</table>
Run a report on contextual search usage

Run a report on usage such as how many times a knowledge article is attached to a record to know the effectiveness of the contextual search results.

Role required: admin

A service desk manager can generate a report on user issues that were resolved without an incident being raised. The information can help to create targeted knowledge based on trends. You can analyze commonly raised incidents and then create knowledge articles around those incidents which can help resolve or deflect similar incidents in future.

1. Navigate to Reports > View/Run.
2. Click Create a report.
3. Under Data, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Report name</td>
<td>Unique name for the report.</td>
</tr>
<tr>
<td>Source type</td>
<td>Source from which the data is populated. The default value is Table.</td>
</tr>
<tr>
<td>Table</td>
<td>Select the Relevant Document Detail table [cxs_rel_doc_detail].</td>
</tr>
</tbody>
</table>

4. Under Type, click Next.
5. Under Configure, click Next.
6. Click **Choose columns** and move the required fields from the **Available** box to the **Selected** box.
7. Click **OK** and then click **Run**.
<table>
<thead>

</table>
**Note:** When users select the **Search on tab** check box in Table Configuration and then modify and leave the search field, an action gets logged in the Relevant Document Detail table [cxs_rel_doc_detail]. The information in the table can help you find the instances where users ran a search but did not take any action. In those cases, the value of the **Position** column is `-1`.

---

**Domain separation and Contextual Search**

Domain separation is supported in Contextual Search. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

**Support level: Standard**

- Includes **Basic** level support.
- Business logic: The service provider (SP) creates or modifies processes per customer. The use cases reflect proper use of the application by multiple SP customers in a single instance.
- The instance owner must configure the minimum viable product (MVP) business logic and data parameters per tenant as expected for the specific application.

Use case: An admin must be able to make comments required when a record closes for one tenant, but not for another.

To learn more, see Application support for domain separation.

**How domain separation works in Contextual Search**

By default, Contextual Search Suggestions results that appear use the domain of the currently logged-in user.

**Search as a different user**

In addition to being able to search for results using the domain of the logged-in user, the administrator can also configure Contextual Search to **Search as a different user**.

When **Search as** is configured, two tabs appear in the search results:

1. **My Results** tab searches using the currently logged-in user domain.
2. The **Search as** user tab searches using the domain of the User Reference field selected by the administrator. For example: The domain of the user who made the request (**Opened by** or **Caller** fields).

**Note:**

- The search as user results apply security access to display results that are common to both the logged in user and the search as user. Hence, the search result view for that user may have fewer entries than what that user can actually view.
- Record producers only support searching as the currently logged in user.

Example: The Incident's short description displaying My Results (the currently logged-in user).
Example: The Incident's short description displaying the caller results (reference field).
CMDB Search

Query on CMDB CIs and relationships by entering a search text with configurable synonyms and stop words, which CMDB Search converts into a properly formulated query.

CMDB Search is integrated into global text search, providing enhanced capabilities for searching the CMDB. CMDB Search is designed to search within CMDB tables and relationships, allowing for queries that are more complex than basic text search. For example, you can query for all Tomcat instances that are running on Linux, or for all applications of a specific version that are running on Linux.

CMDB Search parses the search text that you enter, to formulate a properly formatted query that runs on the CMDB. Your search text can include plain words which are then parsed to identify any CMDB table, column, or relationship names. CMDB Search also uses synonyms and stop words to replace any plain text strings within your search text.
Localization is not supported for CMDB Search. In a localized instance, query words such as CI, relationship, or server, must be in English.

**Stop Words**

A collection of words that are ignored when CMDB Search parses your search text. When CMDB Search finds a stop word in your search text, that word is ignored. CMDB Search provides default stop words such as 'if', 'me', and 'have'. You can delete or add stop words.

To view stop words, navigate to Configuration > CMDB Search > Stop Words.

**Relation Synonyms**

A collection of synonyms for relationships. CMDB Search searches your search text for strings that match any relationship synonym. For any such string that is found, CMDB Search replaces that string with the relationship type specified in the relation synonym. CMDB Search provides relationship synonyms for common words that stand for any relationship between two tables. For example, the strings "connect", "in", and "on" in your search text, are all treated as a general reference to a relationship, without specifying any relationship in particular. You can modify, delete, or add relationship synonyms.

To view relationship synonyms, navigate to Configuration > CMDB Search > Relation Synonyms.

**CI Class Synonyms**

A collection of synonyms for CI classes. CMDB Search searches your search text for strings that match any CI class synonym. For any such string that is found, CMDB Search replaces that string with the CI class name specified in the CI class synonym. CMDB Search provides at least one default CI class synonym for each CMDB table. Most default CI class synonyms are the class label. You can modify, delete, or add CI class synonyms.

To view CI class synonyms, navigate to Configuration > CMDB Search > CI Class Synonyms.

**Column Synonyms**

A collection of synonyms for table columns. CMDB Search searches your search text for strings that match any column synonym. For any such string that is found, CMDB Search replaces that string with the column name specified in the column synonym. CMDB Search provides at least one default column synonym for each table column in the CMDB. Most default column synonyms are similar to the column name itself. You can modify, delete, or add column synonyms.

To view column synonyms, navigate to Configuration > CMDB Search > Column Synonyms.

CMDB Search supports domain separation, searching CIs according to the user domain.

**Plugin**

To use CMDB Search, activate the CMDB Search (com.snc.cmdb_search) plugin. Activating CMDB Search triggers Zing text search indexing of all CMDB tables, since the Zing search engine is required for some CMDB Searches.

**Search text format and examples**

The format of the search text is:

```
(<CI class name> (<attribute> "value")* (<relationship>))*)
```

Consisting of a table name, followed by pairs of `<column> "<value>">`, without any separating commas, and with values surrounded by quotation marks. For column, table, and relationship names, you can search by actual names, labels, or synonyms, and column names can be omitted.

Examples:

- application runs on ci name "ciname"
• application name "JBoss Server13" version "1.0.0.0" on tomcat name "Tomcat10" version "2.1"
• tomcat on linux
• tomcat name “My Tomcat” version “2.0” running on linux server name “Linux8”
• tomcat “My Tomcat”
• tomcat name “My Tomcat”
• tomcat name related to Linux server “my server”
• tomcat name related to Linux server ip 1.1.1.1
• services related to tomcat “my tomcat”
• CI impacted by service “EmailService”

Sometimes the search text contains a name, such as Port, which is both a class and a column name. In this situation, the CMDB Search strategy is to first search for a class with the specified name, and then search for a column with the specified name. If this strategy does not yield the expected results, then use the actual class or column name to prevent ambiguity.

**Results**

Up to 10 query results appear after running the query. To view any additional results, click **View all <record> matches**. The total number of results that you can view depends on the value of the `cmdb.search.rows.limit` system property, which is set to 100 by default. You can increase this property value, or you can change the query to return a smaller number of results. Increasing the number of query results might impact performance.

**Events**

Events are special records the system uses to log when certain conditions occur and to take some kind of action in response to the conditions.

The system uses business rules to monitor for system conditions and to generate event records in the Event [sysevent] table, which is also known as the event log or event queue.

Event-generating business rules typically use this script logic:

If [some condition is true for the current record], then [add a specific event to the queue].

For example, here are some of the conditions in the **incident event** business rule:

• If a user adds a comment to an incident record, add an **incident.commented** event.
• If a user adds an incident record, add an **incident.inserted** event.
• If a user updates an incident record, add an **incident.updated** event.

Event-generating business rules use the GlideSystem `eventQueue` method to insert event records, which typically contain this information:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Unique name of event. Baseline event names include the record affected and the triggering action, such as <strong>incident.commented</strong>.</td>
</tr>
<tr>
<td>Parm1</td>
<td>Event-specific parameter the system uses to pass record information to other parts of the system, such as a record Sys ID or a field value.</td>
</tr>
</tbody>
</table>
Scheduled jobs periodically read the event queue and forward them to the appropriate handler for processing. The handler uses information from event records to take some kind of action such as:

- Run a script action
- Schedule a job
- Send a notification
- Trigger a workflow activity
- Trigger an inactivity monitor

By default, the system provides events covering a broad view of application activity. If existing events do not meet your needs, you can create your own events to watch for specific changes to records.

For developer training, see Scheduled Script Executions and Events Objectives on the ServiceNow® Developer Site.

### Event registry

The events registry lists the events the system recognizes. Use registered events to automate other activities, such as script actions or notifications.

After you create a new event and a business rule that uses the event, you must register it.

Registration lets other parts of the system, such as Email Notifications and Script Actions, see the event in their list of available events and react to the event when it occurs.

### Event states

The event state describes where in the life cycle the event is.

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ready</td>
<td>The system created the event and it is in the queue waiting to be processed.</td>
</tr>
<tr>
<td>Processed</td>
<td>The event successfully ran. An event does not necessarily trigger any further action when processed. Additional functionality must make use of the event.</td>
</tr>
<tr>
<td>Error</td>
<td>The event encountered an error during processing. This state is often caused by invalid event parameters. Reprocessing the event may resolve the error.</td>
</tr>
</tbody>
</table>
### Event logs

The event log records all system events that occur within the Now Platform.

This log provides the following information for all events that occur:

#### Event log

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created</td>
<td>Date and time of the event for the locale of the machine running the instance.</td>
</tr>
<tr>
<td>Name</td>
<td>Name of the event as listed in the Event Registry.</td>
</tr>
<tr>
<td>URI</td>
<td>HTTP query that generated the event.</td>
</tr>
<tr>
<td>Parm1</td>
<td>Event-specific value that depends on the event and the recipient.</td>
</tr>
<tr>
<td>Parm2</td>
<td>Event-specific value that depends on the event and the recipient.</td>
</tr>
<tr>
<td>Table</td>
<td>Database table acted on for this event.</td>
</tr>
<tr>
<td>Processed</td>
<td>Date and time the event was processed This time reflects the locale of the machine running the instance.</td>
</tr>
<tr>
<td>Processing time</td>
<td>Time taken to process this event, in milliseconds.</td>
</tr>
<tr>
<td>Queue</td>
<td>Processor queue name.</td>
</tr>
</tbody>
</table>
The incident events business rule

The incident events business rule comes with the system and defines a number of events that can be triggered by different actions in the Incident table.

Incident events business rule

This business rule defines several events, three of which are triggered after a record in the Incident table is inserted or updated. The first script is:

```java
if (current.operation() != 'insert' && current.comments.changes()) {
    gs.eventQueue("incident.commented", current, gs.getUserID(), gs.getUserName());
}
```

The condition in this script requires that a change be made to the Comments field in an existing (not inserted) incident record. If this condition is true, then the platform adds the incident.commented event to the event queue.
The second condition requires that a record be inserted before the event is added to the queue.

```java
if (current.operation() == 'insert') {
    // Code here
}
```

The third condition is true whenever the incident record is updated (including updates to the **Comments** field, as specified by the first script).

```java
if (current.operation() == 'update') {
    // Code here
}
```

The then part of each script, the `gs.eventQueue` function, adds the event to the event queue. This statement uses the following syntax, set off with braces:

```java
gs.eventQueue("incident.updated", current, gs.getUserID(),
             gs.getUserName());
```

The `gs.eventQueue` function takes the following parameters:

<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name of the event triggered, set in quotation marks</td>
</tr>
<tr>
<td>Record</td>
<td>The record referenced when the condition in the script evaluates to <code>true</code>. Usually this is expressed as <code>current</code>, meaning the current record the business rule is working on. If the business rule is being triggered as part of a scheduled job, use a GlideRecord argument in its place.</td>
</tr>
<tr>
<td>Parm 1</td>
<td>An optional parameter you can use to pass system or record information with the event. For example, the GlideSystem API call <code>gs.getUserID()</code> passes the Sys ID of the user who acted on the current record as a string value. Other scripts can reference this string value as <code>parm1</code> using the format <code>${event.parm1}</code>.</td>
</tr>
<tr>
<td>Parm 2</td>
<td>An optional parameter you can use to pass system or record information with the event. For example, the GlideSystem API call <code>gs.getUserName()</code> passes the user name of the user who acted on the current record. Other scripts can reference this string values as <code>parm2</code> using the format <code>${event.parm2}</code>.</td>
</tr>
</tbody>
</table>

**Note:** The `gs.EventQueue` function works directly with the backend and therefore business rules that are called by `gs.EventQueue()` are not invoked.

### Sample scripts from the change events business rule

Several scripts are found in the baseline change events business rule.

This business rule defines events that fire after a change request is inserted or updated.

```java
if (current.operation() == 'insert') {
    gs.eventQueue("change.inserted", current, gs.getUserID(),
                 gs.getUserName());
}
```

```java
if (current.operation() == 'update') {
    gs.eventQueue("change.updated", current, gs.getUserID(), gs.getUserName());
}
```
if (!current.assigned_to.nil() && current.assigned_to.changes()) {
    gs.eventQueue("change.assigned", current,
    current.assigned_to.getDisplayValue(),
    previous.assigned_to.getDisplayValue());
}

if (current.priority.changes() && current.priority == 1) {
    gs.eventQueue("change.priority.1", current, current.priority,
    previous.priority);
}

if (current.risk.changes() && current.risk == 1) {
    gs.eventQueue("change.risk.1", current, current.risk, previous.risk);
}

if (current.start_date.changes() || current.end_date.changes() ||
    current.assigned_to.changes()) {
    if (!current.start_date.nil() && !current.end_date.nil() && !
    current.assigned_to.nil()) {
        gs.eventQueue("change.calendar.notify", current, current.assigned_to,
        previous.assigned_to);
    }
}

// Remove from previous assigned to, due to assigned_to changing
if (!previous.assigned_to.nil()) {
    if (!previous.assigned_to.nil() && current.assigned_to.changes() &&
        !previous.start_date.nil() && !previous.end_date.nil()) {
        gs.eventQueue("change.calendar.notify.remove", current,
        current.assigned_to, previous.assigned_to);
    }
}

// Remove old calendar from current assigned to, due to date changing
else if (!current.assigned_to.nil()) {
    if ((current.start_date.changes() && !previous.start_date.nil()) ||
        (current.end_date.changes() && !previous.end_date.nil())) {
        gs.eventQueue("change.calendar.notify.remove", current,
        current.assigned_to, "current.assigned_to");
    }
}

Script actions

You can use script actions to create server-side scripts that perform a variety of tasks, such as modifying a
collection item (CI), or managing failed login attempts. Script actions are triggered by events only.

Configuration

To create a new script action, navigate to System Policy > Events > Script Actions and click New.

<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Type a unique name for your script action.</td>
</tr>
<tr>
<td>Event Name</td>
<td>Select the event to use for this script. If you do not find an event for your script action that suits your purpose, you can create a new one.</td>
</tr>
<tr>
<td>Field</td>
<td>Input Value</td>
</tr>
<tr>
<td>------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Application</td>
<td>The application that contains this script.</td>
</tr>
<tr>
<td>Order</td>
<td>The order in which the script will be executed.</td>
</tr>
<tr>
<td>Active</td>
<td>Select the check box (true) to enable this script action.</td>
</tr>
<tr>
<td>Condition Script</td>
<td>Create a statement for a condition under which this script should execute. The system only parses the <strong>Script</strong> field if the condition evaluates to true. If you decide to include the condition statement in the script, leave this field blank.</td>
</tr>
<tr>
<td>Script</td>
<td>Create a script that runs when the condition you define evaluates to true. Two additional objects are available in this script: [ \begin{itemize} \item event: a GlideRecord - the sysevent that caused this to be invoked. If you wanted so get this first parameter on the event, you would use event.parm1 or event.parm2 for the second parameter. For the date/time of the event, use event.sys_created_on. To get the user ID that created the event (if there was a user associated), use event.user_id. \item current: a GlideRecord - the event scheduled on behalf of (incident for example). \end{itemize} ]</td>
</tr>
</tbody>
</table>

This is a sample of a script action that creates an email notification for Workflow activity:
```javascript
function sendWorkflowNotification() {
  // get the activity that defines the information about the event
  var activity = new GlideRecord('wf_activity');
  if (activity.get(parts)) return 0;

  // The EmailAction does not know how to handle \${workflow...} constructs so we need to handle those for it
  var context = new GlideRecord('wf_context');
  if (parts.length == 1) context.put(parts[0]);

  GlideController.putGlobal('context', context);
  var workflow = new Workflow(workflow, new WorkflowProxy());
  GlideController.putGlobal('workflow', workflow);

  var subject = new GlideEmailAction('subject', workflowactivity vars subject);
  var email = new GlideEmailAction('email', workflowactivity vars email);
  var email = new GlideEmailAction('email', workflowactivity vars email);
  var email = new GlideEmailAction('email', workflowactivity vars email);
  var email = new GlideEmailAction('email', workflowactivity vars email);
```
Global events

Your instance has a global function called `global_events()` that triggers from a business rule when certain conditions occur.

This function triggers when your instance is:

- Inserting new records
- Updating existing records
- Adding comments to an existing record
- Assigning a record to a user
- Exceeding a record's inactive timer

For example, if you add the script `global.events(current)` to a business rule on the `change_request` table, the instance automatically configures the following events:

- `change_request.inserted`
- `change_request.updated`
- `change_request.commented`
- `change_request.assigned`
- `change_request.inactive`

The business rule for global events on the `change_request` table looks like this:

![Business Rule](image)

Change request tasks global business rule
Create an event

If you do not find a suitable existing event, you can create your own.

Role required: admin

The gs.EventQueue function works directly with the backend and therefore business rules that are called by gs.EventQueue() are not invoked.

1. Navigate to System Policy > Events > Registry.
2. Click New and fill in the form.
3. Click the Business Rules related link.
4. If you are creating an event for a base system table, select the existing event business rule for the table. For example, select the sc request events business rule to create a custom Request event.
5. If you are updating an existing event business rule, add a new condition to the Script. The following sample script adds a request commented event with the user's Sys ID as parm1 and the user's user name for parm2.

   ```javascript
   if (current.operation() != 'insert' && current.comments.changes()) {
     gs.eventQueue('request.commented', current, gs.getUserID(),
     gs.getUserName());
   }
   ```

6. If you are creating an event for a custom table, create a new business rule that runs after database operations. For example, this business rule defines several events for a custom application called Marketing Events.

   **Sample event business rule**

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Attendee Events</td>
</tr>
<tr>
<td>Table</td>
<td>Attendee [x_snc_marketing_ev_attendee]</td>
</tr>
<tr>
<td>Application</td>
<td>Marketing Events</td>
</tr>
<tr>
<td>Advanced</td>
<td>Selected</td>
</tr>
<tr>
<td>When</td>
<td>after</td>
</tr>
<tr>
<td>Insert</td>
<td>Selected</td>
</tr>
<tr>
<td>Update</td>
<td>Selected</td>
</tr>
<tr>
<td>Delete</td>
<td>Selected</td>
</tr>
<tr>
<td>Script</td>
<td>Add custom script that:</td>
</tr>
<tr>
<td></td>
<td>• Checks for one or more conditions on the current record.</td>
</tr>
<tr>
<td></td>
<td>• Calls the gs.eventQueue() method and specifies an event name.</td>
</tr>
<tr>
<td></td>
<td>See code sample.</td>
</tr>
</tbody>
</table>

**Note:** If you add Filter Conditions, Role conditions, or a Condition value, verify it runs the business rule when expected.
//This function will be automatically called when this rule is processed.
//Add event when attendee inserted
if (current.operation() == 'insert' &&
current.marketing_event.changes()) {
  gs.eventQueue('x_snc_marketing_ev.attendee.added',
  current,
  current.marketing_event, current.email);
}
//Add event when marketing event changes
if (current.operation() == 'update' &&
current.marketing_event.changes()) {
  gs.eventQueue('x_snc_marketing_ev.attendee.deleted',
  previous,
  previous.marketing_event, previous.email);
  gs.eventQueue('x_snc_marketing_ev.attendee.added',
  current,
  current.marketing_event, current.email);
}
//Add event when attendee deleted
if (current.operation() == 'delete') {
  gs.eventQueue('x_snc_marketing_ev.attendee.deleted',
  current,
  current.marketing_event, current.email);
}
})(current, previous);

7. Register the event.

Create a script action or notification to process the event.

Register an event

You can register an event for a specific table and a business rule that fires the event.

1. To register an event, browse to System Policy > Events > Registry, and then click New.
2. On the form fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of your new event.</td>
</tr>
<tr>
<td>Table</td>
<td>Database table for this event.</td>
</tr>
<tr>
<td>Description</td>
<td>Short description of the purpose of the event.</td>
</tr>
<tr>
<td>Fired by</td>
<td>Name of the business rule that runs the event. This field is for reference only and is not used by any process. Make sure that there is enough information to locate your event again.</td>
</tr>
<tr>
<td>Queue</td>
<td>Name of the queue that the event is placed into when triggered.</td>
</tr>
</tbody>
</table>

Note: Only tables and database views that are in the same scope as the event appear on the listing.
Reprocess an event

You can fire the event again for testing or diagnostic purposes.

Role required: admin

1. Navigate to System Logs > Events.
2. Open an event.
   The event returns to the event queue.

Pass event parameters from a workflow to a notification

You can pass two event parameters that send information about a record or related records from a workflow to a notification.

Role required: admin

1. Navigate to System Policy > Events > Registry and define a new event to call.
2. Create the activity step that calls the event from your workflow and assign the two possible parameters.
   These parameters can be references or fields on the record that triggered the workflow, such as current.number for the request item number. You can also dot-walk to records in other tables. The event then sends the parameters information to the notification that it triggers.
3. Retrieve the parameters in the notification with email scripts by using event.parm1 and event.parm2.
   For example:

   ```javascript
   var string = event.parm1.toString();
   template.print(string);
   ```

   Another example using Sys IDs gives you access to anything in the record that triggered the workflow. Use a script like this to send information about a change or request to support personnel, for example.

   ```javascript
   var id = event.parm1.toString();
   var now_GR = new GlideRecord('sc_req_item');
   gr.get('sys_id', id);
   if (gr.next()){
     // Do something.
   }
   ```

Data management

Data is stored and managed in your instance according to a principled structure that administrators can view and configure. Data management functions include importing, exporting, and archiving database data and configuring fields and tables.

Database structure

All of the information in the instances is stored in tables, which consist of a series of records. The record in turn holds a series of fields that hold the individual bits of data and can be viewed either as a list or a form.
Tables can be related to each other in the following ways:

**Extensions**

A table can extend another table. The table doing the extending (child class) includes all of the fields of the other table (parent class) and adds its own fields. For instance, the Incident [incident] table has all of the Task [task] table fields (because an incident is a special form of task) and has its own incident-specific tasks.

**One-to-Many**

Within a table, a field can hold a reference to a record on another table. There are three types of one-to-many relationship fields:

- **Reference Field**: allow a user to select a record on a table defined by the reference field. For instance, the **Caller** field on the Incident table allows the user to select any record on the User table.
- **Glide List**: allows a user to select multiple records on a table defined by the glide list. For instance, the **Watch list** field on the Incident table allows the user to select records on the User table.
- **Document ID Field**: allows a user to select a record on any table in the instance. These fields are much less common, but one example is the **Document** field on the Translated Text [sys_translated_text] table.

**Many-to-Many**

Two tables can have a bi-directional relationship, so that the related records are visible from both tables in a related list.

**Database Views**

Two tables can be joined virtually with Database Views to enable reporting on data that might be stored over more than one table.

**Data management tools**

There are a number of tools that can help manage data within the instance.

**Schema map**

The Schema Map displays the relationships between tables visually, helping to navigate through the database structure.

The Schema Map provides an interface for viewing the relationships between tables. The inter-table relationships it captures include many-to-many relationships, tables that extend other tables, and tables that reference other tables through reference fields.

**Data dictionary tables**

Data dictionary tables holds information that defines the database and can be accessed for information on the database schema.

These tables hold important information on the database and its structure:

- **Tables [sys_db_object]**: contains a record for each table.
- **Dictionary Entries [sys_dictionary]**: contains additional details for each table and the definition for every column on each table. Each row represents either a column on a table or a table.
- **Field Labels [sys_documentation]**: contains the human-readable labels and language information.

**Table cleaner**

Table cleaner automatically deletes records on certain tables to prevent data growing exponentially. Records are automatically deleted from specific tables after a specific time to deletion. Deleting these records automatically prevents the tables from growing to an unmanageable size.
The time before a record is deleted begins on the date and time value in the tracked field. The Table Cleaner scheduled job runs the table cleaner every hour. To view the list of tables that are auto-cleaned, in the Navigator filter, type: sys_auto_flush_list.do. All records with \[\text{MatchField} < (\text{current_time} - \text{Age in seconds})\] are deleted.

- The \text{MatchField} field represents a Date/Time column in the table that you are trying to clean up.
- The \text{Age in seconds} field represents a value in seconds.

You can set up multiple table cleaner entries for a particular table. Performance depends on the size of the table and the conditions used. For example, if you use a custom column in a very large table that has no index on, performance is severely degraded. Performance also depends on the number of rows to be deleted.

\[\text{Note: TableCleaner does not call DBDelete.setWorkflow()}. \text{This means DBDelete objects run with workflow=false (false is the default value for a Java boolean), hence Delete business rules and workflows are not triggered.}\]

### Cleaned tables

</tr>
<tr>
<td>Many to Many task relations</td>
<td>Provides the ability to define many-to-many relationships between task tables.</td>
</tr>
</tbody>
</table>

## Unique record identifier (sys_id)

A unique 32-character GUID (Globally Unique ID), called a Sys ID (sys_id) identifies each record in an instance. There are various ways a record is assigned a sys_id.

When created within the application, sys_id values are unique. The Now Platform and database should manage all operations on sys_id values. The same sys_id value is never generated twice, which ensures that every record created in every table in every instance in the world has a unique identifier. If two records have the same sys_id value, it occurs as a result of the following situations:

- If a record with the sys_id was copied to the other at the database level outside of the Now Platform.
- If a record with the sys_id was copied using an Update Set or via XML, its sys_id is the same.

### Note:

A new record has a sys_id of -1, and once inserted, it is assigned a new sys_id. The sys_id is not meant to show as a field on a form or as a column in a list. To learn more, see the Users are unable to add the sys_id field to a form or list view [KB0690876] article in the Now Support Knowledge Base.

## Get the sys_id from the header bar

Users can locate the sys_id of a record using the header bar.

1. **Navigate to the record.**
2. **Right click the header bar and select Copy URL.**

   The sys_id is inside of the URL, after the parameter sys_id=. For example, the following is a URL for an Incident:

   ```
   https://<instance name>.service-now.com/nav_to.do?uri=incident.do?sys_id=9d385017c611228701d22104cc95c371
   ```

   Therefore the sys_id is 9d385017c611228701d22104cc95c371.

## Get the sys_id from a script

Users can locate the sys_id of a record using a script.

- The sys_id value of a record can be found in a business rule (or any other server-side JavaScript) by dot-walking from the GlideRecord.

   ```
   var id = current.sys_id;
   ```
• The sys_id of a record can be found in client-side JavaScript using g_form.getUniqueValue() as shown in the following example.

```javascript
function onLoad() {
    var incSysid = g_form.getUniqueValue();
    alert(incSysid);
}
```

**Get the sys_id from the URL**

Users can locate the sys_id of a record by viewing the URL.

Since the sys_id of a record is always part of the URL for a link to that record, it is possible to retrieve the sys_id by viewing the URL.

• View the sys_id in the information bar of the browser by hovering over a link to the record.
  
  For example, an Incident with the following URL: https://<instance name>.service-now.com/nav_to.do?uri=incident.do?sys_id=23dc968f0a0a3c1900534f399927740e, has this sys_id: 23dc968f0a0a3c1900534f399927740e.

**Data archiving**

Data archiving involves managing table size growth and archiving old data. It moves data that is no longer needed every day from primary tables to a set of archive tables.

The longer an instance runs, the more likely it is to accumulate data that is no longer relevant. For example, task records from two years ago are typically less relevant than currently active tasks. Old data may eventually cause performance issues by consuming system resources and slowing down queries and reports.

If you cannot delete this data because you need it for auditing or for historical purposes:

1. Set up an archive rule that archives the data and removes it from immediate access to free up system resources.
2. Set up a destroy rule to delete the data after a specified period.
3. Configure the archive and destroy rule properties that control batch processing of the archive and destroy rules.
Sample Benefits of Archiving Data

Data archiving supports Domain separation for service providers. For example, incidents that belong to a domain keep their domain designation even after they are archived.

**Note:** If you want to archive emails, activate the Email retention plugin and use the archive and destruction rules that come with the plugin. Do not use the archive feature to create your own archiving rules on the email table.

Tables and modules created by an archive rule

The first time you activate an archive rule, it performs the following actions:

- Creates the archive table in the database. The archive table has the same name as the primary table with an "ar_" prefix. For example, if you archive the Incident [incident] table, then the archive table is [ar_incident].
• Stores an xml version of each archived record in the sys_archive_log table. This archive log is the same table for all archive rules, and you cannot alter this behavior. It is also the only place where the sys_id is stored together with the display value for reference fields.

For example, for ar_incident \texttt{<assigned_to>Fred Luddy</assigned_to>}, the sys_archive_log record is as follows:

\begin{verbatim}
<assigned_to display_value="Fred Luddy">5137153cc611227c000bbd1bd8cd2005</assigned_to>
\end{verbatim}

• Converts multiple joined tables into a single flat-file archive table. The archive table no longer consists of a base and extended tables.
• Converts reference field values (values set by references to records in other tables) into string values. The archive record contains the display value of the reference field at the time of the archive.
• Adds a module to the Archive Tables list in the System Archiving application. The module name is a combination of the word “Archive” plus the display name for the archived table. For example, the archive module for the Attachment \texttt{[sys_attachments]} table is Archive Attachment. Click the module name to view records in the archive table.
• Creates a list of the archive table using the default list view.
• Creates a form for the archive table using the default form view. The form excludes any dot-walking fields such as Caller ID.Email.
Conversion of Multiple Joined Tables into a Flat Archive Table

Query archived data

Archived tables are not optimized for ad hoc queries. They only contain index entries for the display value, creation date, and the primary key of sys_id.

For this reason, do not make on-demand queries against an archived table, such as searching for all priority 1 archived incidents. Instead, only search against the indexed fields. For example, search for incident INC100001 or incidents created on a specific date.
Archive tables and ACLs

By default, archive tables use the ACLs for the unarchived table of the same name. For example, the archived Incident [ar_incident] table uses the ACLs defined for the unarchived Incident [incident] table.

You can manage access to archive tables explicitly by creating ACLs for specific archive tables and setting the `glide.security.enable_archive_table_acls` property to `true`. The system then follows one of two paths:

1. If one or more active ACLs are defined for an archive table, those ACLs control access to the archive table.
2. If no ACLs are defined for an archive table, the system reverts to default behavior and uses the ACLs for the unarchived version of the table.

**Note:** The two paths are mutually exclusive: If archive table ACLs deny access, the system doesn't attempt to revert to the default behavior.

The read operation read is the only operation evaluated, and other operations are prevented.

The Execution Plan UI is aware of this logic and presents information accordingly. For example, adding the first ACL to an archive table shows that the archive table ACL is "masking" ACLs on the unarchived (original data) table.

If you have existing ACLs on archived tables, they are ignored unless you set the `glide.security.enable_archive_table_acls` property to `true`. Those newly activated ACLs may possibly cause access issues. To prevent this occurrence, the system sets the `glide.security.enable_archive_table_acls` property as follows:

- Instances without the `glide.security.enable_archive_table_acls` property use the default value of `false`.
- Upgraded instances don't install the property. The property must be added manually and set to `true` to enable the archive table ACL behavior.
- Zbooted instances install the property and set it to `true`.

Create an archive rule

The System Archiving application includes several sample archive rules that illustrate the archive features. Related records can be added to an archive rule, and you can view an estimate of the number of records the rule affects.

Role required: admin

The sample archive rules are inactive by default.

**Note:** If you want to archive emails, activate the Email retention plugin and use the archive and destruction rules that come with the plugin. Do not use the archive feature to create your own archiving rules on the email table.

1. Navigate to System Archiving > Archive Rules.
2. Click New.
<table>
<thead>
<tr>
<th><strong>Name</strong></th>
<th>Inactive and closed over 9 months</th>
<th><strong>Parent</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Table</strong></td>
<td>Change Request</td>
<td></td>
</tr>
<tr>
<td><strong>Active</strong></td>
<td>False</td>
<td></td>
</tr>
</tbody>
</table>

**Description**
Archive Change Requests (and related change tasks/change phases) that are no longer active and their close date is older than 9 months

**Conditions**

**All of these conditions must be met**

<table>
<thead>
<tr>
<th>Active ▼</th>
<th>is ▼</th>
<th>false ▼</th>
<th>AND ▼</th>
<th>OR ▼</th>
<th>X ▼</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Closed ▼</th>
<th>before ▼</th>
<th>Last 9 months ▼</th>
<th>AND ▼</th>
<th>OR ▼</th>
<th>X ▼</th>
</tr>
</thead>
</table>

**Auto archive**

**Auto archive duration**

<table>
<thead>
<tr>
<th>Days</th>
<th>01</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Hours</th>
<th>00</th>
<th>00</th>
<th>00</th>
</tr>
</thead>
</table>
3. Fill in the fields as appropriate.

**Archive Rule form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Required. Enter a unique name that identifies the rule. Since this name is the display field for archive rules, references to archive rules display the name you enter here.</td>
</tr>
<tr>
<td>Table</td>
<td>Required. Select the table containing records to archive. There can only be one archive rule per table (even if the rule is inactive). If there is an existing archive rule for a table, the table no longer appears as an option on the archive rule table list.</td>
</tr>
<tr>
<td>Active</td>
<td>Select this check box to enable the archive rule. Clear the check box to disable the rule. Leave your archive rules inactive until you calculate an estimate of the number of records the rule affects and verify that rule behaves as expected.</td>
</tr>
<tr>
<td>Description</td>
<td>Enter a description of the archive rule.</td>
</tr>
<tr>
<td>Parent</td>
<td>Select an existing archive rule on which this rule depends on to run. This archive rule only runs when the parent rule also runs.</td>
</tr>
<tr>
<td>Conditions</td>
<td>Select the fields and values that must be true in order for the archive rule to run. Typically, you would archive inactive records older than a certain date.</td>
</tr>
<tr>
<td>Auto Rearchive</td>
<td>If a record is restored, this enables the record to be automatically rearchived after a set period of time.</td>
</tr>
<tr>
<td>Auto Rearchive Duration</td>
<td>If you set the Auto Rearchive option, you must set a time interval before the restored record is automatically archived.</td>
</tr>
</tbody>
</table>

4. Click **Submit**.

After verifying that the archive rule is selecting records as expected, activate the archive rule.

If you do not want to wait for the scheduled job to run the archive rule, you can manually start the archive rule by clicking **Run Archive Now**.

**Archive related records**

Use the **Archive Related Records** related list to add related records to the archive rule.

Role required: admin

1. Navigate to **System Archiving > Archive Rules**.
2. Select the appropriate archive rule.
3. From the **Archive Related Records** related list, click **New**.
4. Fill in the Archive Related Records form.

**Archive Related Records form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Archive map</td>
<td>Displays the archive rule to which the related records apply.</td>
</tr>
<tr>
<td>Action</td>
<td>Select the action you want the archive rule to take on related records.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Archive</strong>: archive records that reference the archived record.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Clear</strong>: remove the reference to the archived record. The record no</td>
</tr>
<tr>
<td></td>
<td>longer references the archived record and does not appear as a related</td>
</tr>
<tr>
<td></td>
<td>record in future archives.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Delete</strong>: delete records that reference the archived record.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Reference</td>
<td>Select the relationship of the records you want to apply an action to. The <strong>Reference</strong> field lists all relations that currently exist for the table being referenced. There are two types of possible relations.</td>
</tr>
<tr>
<td></td>
<td>• Another table has a reference field calling the archived table. For example, if you are archiving problem records, there is a <strong>Problem ID</strong> field in the Incident table that references the related problem records.</td>
</tr>
<tr>
<td></td>
<td>• The <strong>Archive</strong> action archives the related record in addition to the primary record. For example, if you select the <strong>Problem in Incident</strong> reference, the related record rule also archives any incident record that references an archived problem.</td>
</tr>
<tr>
<td></td>
<td>• The <strong>Clear</strong> action removes the reference to the primary record. For example, if you select the <strong>Problem in Incident</strong> reference, the related record rule updates any incident record with a reference to the archived problem record by clearing the reference. If the reference is a many-to-many relationship, the related record rule deletes the reference instead of clearing the reference.</td>
</tr>
<tr>
<td></td>
<td>• The <strong>Delete</strong> action deletes any record that references the primary record. For example, if you select the <strong>Problem in Incident</strong> reference, the related record rule deletes any incident record that references the archived problem record.</td>
</tr>
<tr>
<td></td>
<td>• Another table has a <strong>Document ID</strong> field which might point to the archived table. For example, if you are archiving problem records, there is a <strong>sys ID</strong> field in the Attachments table that may reference the problem record. The list indicates document ID relationships by displaying an asterisk (*) character at the end of the selection name.</td>
</tr>
<tr>
<td></td>
<td>• The <strong>Archive</strong> action updates the <strong>Document ID</strong> of the related record to point to the archived table. For example, if you select the <strong>Table sys ID Attachment(sys_attachment)</strong> reference, the related record rule updates the attachment record to change the <strong>Document ID</strong> to refer to the archived table record.</td>
</tr>
<tr>
<td></td>
<td>• The <strong>Clear</strong> action removes the <strong>Document ID</strong> reference to the archived record. The record no longer references the archived record and does not appear as a related record in future archives.</td>
</tr>
<tr>
<td></td>
<td>• The <strong>Delete</strong> action deletes any record that references the primary record. For example, if you select the <strong>Table sys ID Attachment(sys_attachment)</strong> reference, the related record rule deletes any attachment record that references the archived primary.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Reference table</td>
<td>Displays the table where the rule looks for related records.</td>
</tr>
<tr>
<td>Reference element</td>
<td>Displays the reference field or <strong>Document ID</strong> the rule queries for.</td>
</tr>
<tr>
<td>Reference table rule</td>
<td>Select an existing archive rule that applies to the related records you are archiving. For example, if you already have an archive rule for the Incident table, you can select the existing Incident table rule when archiving records related to incidents records.</td>
</tr>
</tbody>
</table>

5. Click **Submit**.

**Verify the number of records affected**

Each archive rule provides an estimate of the number of records the rule affects.

Role required: admin

This estimate only includes primary records and excludes any related records added to the archive rule. The estimate helps you determine if the archive rule affects the number of records you expect it to. If the estimate is too high or low, change the archive rule conditions and then click the **Recalculate Estimate** related link.

1. Navigate to **System Archiving > Archive Rules**.
2. Select the archive rule you want to estimate records for.
3. Click the **Recalculate Estimate** related link.

**Setting the language of archived strings**

On internationalized instances, the archive process uses the language of the **SYSTEM** user to select the display value strings.

If there is no **SYSTEM** user, the instance uses the default language setting to select the display value strings. You can either create a **SYSTEM** user with a specific language setting or set the system default language to **select the language of archived strings**.

**Create a destroy rule**

Create a destroy rule to delete archived records and related records after a specified amount of time.

Role required: admin

If you need to amend the destroy rule properties running against your archived data, see **Archive rule and destroy rule properties**.

1. Navigate to **System Archiving > Archive Destroy Rules**.
2. Click **New**.
3. Fill out the form fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Provide a descriptive name.</td>
</tr>
<tr>
<td>Table</td>
<td>Select the archive table that the system created when you archived records.</td>
</tr>
<tr>
<td>Description</td>
<td>Provide a description.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Destroy Related Records</td>
<td>Automatically destroy related records associated with the archived records.</td>
</tr>
<tr>
<td>Archive Duration</td>
<td>Specify the amount of time that records stay in the archive table before the system deletes them.</td>
</tr>
</tbody>
</table>

4. Click **Submit**.

5. You can check the archive destroy log at any time

**Archive rule and destroy rule properties**

Rules to prevent the archive process from consuming too many system resources have been automated.

In prior releases, you could set archive rules and deletion rules properties. This process has been automated, so that it is no longer necessary to adjust these parameters.

**Manage archived data**

You can view archived data, change an archive schedule, restore archived data, and archive a restored record.

Role required: admin
Use the following procedure to view archived data in the archive tables.

1. Navigate to **System Archiving > Archive Tables**.
2. Click the module name for the archived table you want to view. For example, **Archive Incidents**.

<table>
<thead>
<tr>

Change an archive schedule

All active archive rules are executed by a system-scheduled job set to run every 60 minutes. You can modify the job if you need to change the interval.

Role required: admin

1. Navigate to System Scheduler > Scheduled Jobs.
2. Open the Archive record.
3. Modify the repeat value.

Restore archived records and related records

When you restore a record, the instance inserts it back into the primary table and flags the record as having been restored in the log. You can also restore the record along with related records.

Role required: admin

1. Navigate to System Archiving > Archive Log.
2. Select the archived record to restore.

Data archive table size limits

There are constraints to the size of the table you use to archive your instance data.

Limits on data archive tables

There is a limit on the size of an archive table you can create to store data. If you receive an error that an archive table could not be created, it might be related to this size limitation.

<table>
<thead>
<tr>
<th>Archive table size limits</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Table Attribute</strong></td>
</tr>
<tr>
<td>Single table static size limit</td>
</tr>
<tr>
<td>Rowsize limit</td>
</tr>
</tbody>
</table>

You can follow KB0689595 to reduce the size of a table you need to archive by identifying unused columns and converting large varchar fields into mediumtext fields, but you might then encounter a rowsize limitation. You can address a rowsize limitation in the TPP hierarchy by migrating fields to another partition table. However, you are attempting to create a single archive table which has all the fields for the table spread over two or more partition tables. Creating this single archive table can result in a table which still exceeds the overall table size limit.

If you cannot create an archive table after reducing the size to meet the table limits, please contact Customer Service and Support.

Data migration process for archiving table data from non-reference fields to reference fields

The data migration process moves data from an existing archive table, including descendent and related tables. There are special scripts and notes to understand when completing this process.

Data migration job (RefCopyJob)

For each table that goes through the migration process, the **RefCopyJob** identifies the sys_id of the reference fields and updates the display value to be the correct sys_id. The job configures 10k records at a time unless there are more than 10k records with the same timestamp. The migration progress relies on the archived timestamp. The script determines the tables to migrate:

```javascript
var tables = GlideDBObjectManager.get().getAllExtensions(current.table);
for (i = 0; i < tables.size(); i++) {
  var gr = new GlideRecord('sys_archive_ref_migration');
  gr.addQuery('table', 'ar_' + tables.get(i));
  gr.query();
  if (!gr.next()) {
    if (GlideTableDescriptor.isValid('ar_' + tables.get(i))) {
      var gr2 = new GlideRecord("sys_archive_ref_migration");
      gr2.initialize();
      gr2.setValue('rule', current.sys_id);
      gr2.setValue('table', 'ar_' + tables.get(i));
      gr2.setValue('reference_migration_progress', 'waiting');
      gr2.insert();
    }
  }
}
//Also get insert related records tables as well
```
var map = new GlideRecord('sys_archive');
map.addQuery('table', current.table);
map.query();
if (map.next()) {
    var id = map.getValue('sys_id');
    if (!(id === undefined)) {
        var related = new GlideRecord('sys_archive_related');
        related.addQuery('archive_map', id);
        related.addQuery('action', 'archive');
        related.query();
        while (related.next()) {
            if (!GlideTableDescriptor.isValid('ar_' +
                related.getValue('table'))) {
                gs.log('Related Record table: ' +
                    related.getValue('table') + ' not created yet');
                continue;
            }
            var gr3 = new GlideRecord("sys_archive_ref_migration");
            gr3.initialize();
            gr3.setValue('rule', current.sys_id);
            gr3.setValue('table', 'ar_' + related.getValue('table'));
            gr3.setValue('reference_migration_progress', 'waiting');
            gr3.insert();
        }
    }
}

Change the sys_dictionary types of migrated tables job (ArchiveRefJob)

After the tables associated with an archive rule completely migrate, the ArchiveRefJob job executes. This job changes
the sys_dictionary types of the archive table from String to Reference.

Fixing node failures for RefCopyJob and ArchiveRefJob

If node failure occurs while these jobs are running, it leaves the status of the data migration in an improper state. If
the RefCopyJob fails, it can leave a table in a migrating status. You can verify this condition by checking if rows in
the sys_archive_ref_migration are stuck in migrating status for an extraordinary amount of time (quantify?). Update
the specific row status from migrating to waiting and the RefCopyJob continues the data migration on the table
when the job runs again.

The node can also fail when the ArchiveRefJob terminates prematurely. Check if tables have fields that are
reference fields and some that are still string type fields. The job might have died in the middle of changing the field
types. You can resolve this condition by setting up a trigger job to execute in a background script which starts the
process over again:

GlideRecord trigger = new GlideRecord(SYS_TRIGGER);
trigger.initialize();
trigger.setValue('state', 0);
trigger.setValue('trigger_type', 0);
trigger.setValue('next_action', new GlideDateTime());
trigger.setValue('job_context', 'fcRuleId=' + ruleId);
trigger.setValue('name', 'Job Reference Migration' + ' Node - ' + new
    GlideClusterSynchronizer().getSystemID());
trigger.setValue('trigger_class',
    com.glide.db.auxiliary.job.ArchiveRefJob);
trigger.insert();
Export and import XML files

To occasionally migrate data from one instance to another, you can export XML data from one instance and import it to another.

This method ensures that all fields and values are transferred exactly. Migrating data in an XML file saves time for unscheduled data imports because there is no need to build an import set or a transform map.

Exporting and importing data in XML files is commonly used for records created in a development instance that must be migrated with the update sets as part of a migration procedure. Examples of these records include lookup tables, unit test records, and other information required to support production. Typically, this information is only migrated once and the overhead of an import set is not justified.

Note: Image field data is not preserved when exporting to XML.

Exporting data

There are a variety of ways for administrators and users to export data.

Form export
Export an individual record from the user interface. Choose PDF or XML format directly from a form.

List export
Export multiple records from the user interface. Choose CSV, Excel, PDF, or XML format directly from a list.

URL export
Export multiple records from a table using the CSV, Excel, PDF, or XML processor. Specify the table form or list you want to export in the URL.

Web services
Export multiple records from a table when an external client makes a web services request. Create an external application or process to automate the retrieval of data from an instance via web services such as REST or SOAP.

Export sets
Create a file called an export set that contains all the data you want to export.
## Export formats

### Available export formats

<table>
<thead>
<tr>
<th>Export format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CSV</td>
<td>Export table records as a comma-separated value text file. Use this option to export the currently displayed fields in the list or form as a text file. Configure the list or form to add or remove fields from the export. When exported to CSV, dot-walked fields appear using their full field name, such as u_assignment_group.parent.</td>
</tr>
</tbody>
</table>

**Note:** By default, ServiceNow exports all CSV files in Windows-1252 encoding. If you need to export translated data, set the `glide.export.csv.charset` system property to UTF-8.

| Excel         | Export table records as a Microsoft Excel spreadsheet. Use this option to export the currently displayed fields in the list or form as an Excel spreadsheet. Configure the list or form to add or remove fields from the export. |

| XML           | Export table records as an XML document. Use this option to export all data from a table or all data for a particular record. The XML file has an XML element for each column in the table. |

**Note:** Image field data is not preserved when exporting to XML.

| PDF           | Export table records as a Portable Document Format file. Use this option to export the currently displayed fields in the list or form as a PDF file. Configure the list or form to add or remove fields from the export. |

**Note:** The PDF export processor prints data from left-to-right, which can produce rendering errors when displaying right-to-left language data.

| JSON          | Export the table records as a JSON string. The JSON file has an element for each column in the table. |

### Column headers

The file type you export to, such as CSV or PDF determines how column headers are exported. In general, formats meant for human consumption such as PDF display the column label, whereas formats meant for machine use such as CSV use the database field_name.
## Header format by file type

<table>
<thead>
<tr>
<th>File type</th>
<th>Column header format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Excel</td>
<td>Label</td>
</tr>
<tr>
<td>PDF</td>
<td>Label</td>
</tr>
<tr>
<td>CSV</td>
<td>field_name</td>
</tr>
<tr>
<td>XML</td>
<td>field_name</td>
</tr>
<tr>
<td>JSON</td>
<td>field_name</td>
</tr>
</tbody>
</table>

## Export limits

The platform provides a default upper limit for data exports.

The purpose of the upper limit is to avoid creating performance issues when a table is excessively large. If you need to export more records than the threshold permits, Break up a large export into separate manageable chunks.

## Export limit properties

You can set the number of records to return during an export using the `sysparm_record_count` URL parameter. However, the system analyzes the following settings to determine whether an export limit should be applied.

1. First, the platform checks the property that defines the format-specific export limit (see table below). Each format can have a different limit. Although this property can be set to any value, exceeding the default export limit can impact system performance. You may want to set the property at or below the default limit and have users Break up a large export to export large amounts of data.

2. If the format-specific property is not set, the system checks the property for the general export limit (see table below). This property can also be set to any value, but exceeding the default export limit can impact system performance.

3. If neither the format-specific export limit nor the general export limit property is set, the system enforces the default export limit (see table below).

### Important: To set these properties, navigate to System Properties > Import Export.

## Default export limit

<table>
<thead>
<tr>
<th>Format</th>
<th>Format-specific export limit</th>
<th>General export limit</th>
<th>Default export limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>XML</td>
<td>glide.xml.export.limit</td>
<td>glide.ui.export.limit</td>
<td>10,000</td>
</tr>
<tr>
<td>CSV</td>
<td>glide.csv.export.limit</td>
<td>glide.ui.export.limit</td>
<td>10,000</td>
</tr>
<tr>
<td>EXCEL (XLSX)</td>
<td>glide.xlsx.export.limit</td>
<td>glide.ui.export.limit</td>
<td>10,000</td>
</tr>
<tr>
<td>EXCEL (XLS)</td>
<td>glide.excel.export.limit</td>
<td>glide.ui.export.limit</td>
<td>10,000</td>
</tr>
<tr>
<td>EXCEL (XLSX)</td>
<td>glide.xlsx.max_cells</td>
<td>N/A</td>
<td>500,000</td>
</tr>
<tr>
<td>EXCEL (XLS)</td>
<td>glide.excel.max_cells</td>
<td>N/A</td>
<td>500,000</td>
</tr>
</tbody>
</table>
### Export limit examples

<table>
<thead>
<tr>
<th>Example</th>
<th>Property</th>
<th>Table</th>
<th>Note</th>
</tr>
</thead>
</table>
| Exporting to CSV | • glide.csv.export.limit = 20,000  
• glide.ui.export.limit = 10,000  
• com.glide.processors.XMLProcessor.max_record_count = 20,000  
• Default export limit for CSV = 10,000 | ![Table](#) | In the second export, the number of records returned from the database is limited because the number of records specified for export exceeds the value set in the glide.csv.export.limit property. |

---

**Note:**
- The number of rows can be set from 0 to 5,000. If no value is specified, the default is 1,000. If a value greater than 5,000 is specified, the default value of 1,000 is used.
- Although the number of columns can be set higher than 25, this is not advisable, since only 25 header labels fit on a page.
### Excel export threshold

Excel exports are intended for relatively small exports, fewer than 500,000 cells, while CSV can handle larger exports.

Whenever you export to Excel and the resultant spreadsheet has more than 500,000 cells (by default), the export process stops and you are given the Excel file at that point. In the bottom row, there will be the following message: Export stopped due to excessive size. Use CSV for a complete export:

```
    1       A          B          C          D
      1  Table Column name Text index Calculated Reason
16848  16848 cmdb_tcp_half sys_mod_count   FALSE       FALSE
16849  16849 cmdb_tcp_half sys_created_on  FALSE       FALSE
16850  16850 cmdb_tcp_half sys_created_by  FALSE       FALSE
16851  16851 cmdb_tcp_half sys_modified   FALSE       FALSE
16852  16852 Export stopped due to excessive size. Use CSV for a complete export.
16853
```

### Excel export threshold

The Excel export cell threshold is customizable using the `glide.xlsx.max_cells` integer property (or `glide.excel.max_cells` if using XLS).
**Note:** Increasing this threshold may cause a memory issue in your instance. The threshold is set at an appropriate level to prevent resource issues.

The export will put the information into the Excel document with 32,000 rows per spreadsheet.

**Form export**

Any user role can export form data in a variety of formats.

Export formats include:

- PDF (Portrait)
- PDF (Landscape)
- XML (This Record)

Export an individual record from a form by right-clicking a form header bar and selecting the export type.

Export from form

**Note:** When exporting PDF data from a form, any field that is disabled by UI scripts (UI policies, UI actions, client scripts) and any fields that are visible from the current view, are exported. However, when
exporting XML data, all of the fields are exported, regardless of the view. You cannot export records to CSV or Excel from a form.

When exporting to XML, a dialog box may prompt you to save the file, or the browser may automatically save the XML file to the downloads folder specified in the browser preferences.

**List export**

You can export a list of records in a variety of formats.

The Export option is available in the column heading context menu in List v2. In List v3, it is available in the list title menu.
Note: To export records in an embedded list, export the record containing the list.

Export formats include:

- Excel
- CSV
- XML
- JSON
- PDF (Portrait)
- PDF (Landscape)
- PDF (Detailed Portrait): Exports the list and the associated form for each record.
- PDF (Detailed Landscape): Exports the list and the associated form for each record.

Note: You can control how line breaks appear in exported CSV data using the glide.csv.export.line_break system property.

Note: To remove unwanted HTML tags from list data, see the blog Rendering HTML in Exported Lists by a ServiceNow employee in the Now Community.

When exporting to XML, a dialog box may prompt you to save the file, or the browser may automatically save the XML file to the downloads folder specified in the browser preferences.

Determining which list fields are exported

By default, exporting data from a list exports only the fields that are visible from the current view.

By default, exporting data from a list exports only the fields that are visible from the current view. If you want to export fields from another list view, you can switch views from the UI. Alternatively, you can add the sysparm_view parameter to the URL request. For example, to export fields visible from the Self Service (ess) view:

https://instance_name.service-now.com/incident.do?CSV&sysparm_view=ess

If you are exporting CSV or Excel data and do not specify a view, the export uses the default list view. You can export all fields by setting the sysparm_default_export_fields parameter to all. If you are exporting XML data, the export returns all fields unless you specify a particular view. The sysparm_default_export_fields parameter has no effect on XML exports.

Use a URL query to filter a list result

Use URL queries to programmatically generate filtered lists before exporting them.

URL queries are useful for scripts that generate a list of records and where no user will manually add the filter from the UI. You must be familiar with the table's column names and values to create a query.

1. Specify the instance URL. For example, https://demo.service-now.com/.
2. Specify the list URL for the table you want to export. For example, incident_list.do.
3. Specify the export format processor for the export. For example, ?XML.
4. Specify the query as the value of the sysparm_query parameter. For example, ?sysparm_query=priority=1.
5. Optional: Specify the result sort order with the sysparm_orderby= parameter. For example, CSV&sysparm_orderby=assigned_to.

Note: All queries use a column name, an operator, and a value. See Condition Builder for a list of available operators.

For example, to export a list of all priority 1 incidents as an XML file, use the following URL: https://<instance_name>.service-now.com/incident_list.do?XML&sysparm_query=priority=1&sysparm_orderby=assigned_to
Export controls

Control the column value and header value in export files using query parameters, export set properties, and system properties.

Depending on the output formats you prefer, you can use export controls to do the following:

- Export column values as either display values (for example, `Assignment group = Network`) or raw values (for example, `Assignment Group = 287ebd7da9fe198100f92cc8d1d2154e`).
- Export table headings as either heading labels (for example, `Assignment Group`) or heading names (for example, `assignment_group`).

Query parameters for display value and header

Use query parameters to export the display value or raw value of fields and the field label or field name for headers.

Query parameters control the output for CSV, Excel, JSON, XLSX, and XML file formats. Query parameters, if present, override system properties.

The following table describes each of the query parameters that control display values and headers.

<table>
<thead>
<tr>
<th>Query parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_display_value</td>
<td>Exports the display value (true) or raw value (false) for the CSV, Excel, XLSX, and XML file formats. See Field types affected by export controls for more information.</td>
</tr>
<tr>
<td>displayvalue</td>
<td>Exports the display value (true), raw value (false), or both (All) for the JSON file format. See Field types affected by export controls for more information.</td>
</tr>
<tr>
<td>sysparm_export_column_header_label</td>
<td>Exports the CSV, Excel, and XLSX file formats with the field label (true) or field name (false).</td>
</tr>
</tbody>
</table>

**sysparm\_display\_value**

**Example:**

```
sysparm\_display\_value = true
```

<table>
<thead>

displayvalue = true
Example:

sysparm_export_column_header_label = false

Export Set fields for display value and header

Use Export Set fields to export the display value or raw value of fields and the field label or field name for headers.

Export Set fields control the output for the CSV, Excel, JSON, XLSX, and XML file formats. Export Set fields, if present, override system properties.

The following table describes each of the Export Set fields that control display values and headers.

<table>
<thead>
<tr>
<th>Export Set Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Column headers</strong></td>
<td>Exports the CSV, Excel, and XLSX file formats with the field label (Use field label) or field name (Use field name).</td>
</tr>
</tbody>
</table>
| **Column values**        | Exports the display value (Use display value) or raw value (Use raw value) for the CSV, Excel, JSON, XLSX, and XML file formats.  
                           | See Field types affected by export controls for more information.             |

Column headers

Example:

Use field label

Example:
Use field name

System properties for display value and header

Use system properties to export the display value or raw value of fields and the field label or field name for headers.

System properties control the output for the CSV, Excel, JSON, and XLSX file formats. System properties define default behavior if overrides such as query parameters are not specified. System properties apply to exported files downloaded with URL parameters, exported from list view, or generated by export sets.

The following table describes each of the system properties that control display values and headers.

<table>
<thead>
<tr>
<th>Format</th>
<th>Property</th>
<th>Default Value</th>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>CSV</td>
<td>glide.export.csv.raw.value</td>
<td>false</td>
<td>Setting the property as false also crops the value's string to 32000 characters.</td>
</tr>
<tr>
<td></td>
<td>glide.export.csv.column_header_label</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Format</td>
<td>Property</td>
<td>Default Value</td>
<td></td>
</tr>
<tr>
<td>--------</td>
<td>----------------------------------------------</td>
<td>---------------</td>
<td></td>
</tr>
<tr>
<td>Excel</td>
<td>glide.export.excel.display_value</td>
<td>true</td>
<td></td>
</tr>
<tr>
<td></td>
<td>glide.export.excel.column_header_label</td>
<td></td>
<td></td>
</tr>
<tr>
<td>JSON</td>
<td>glide.json.return_displayValue</td>
<td>false</td>
<td></td>
</tr>
<tr>
<td>XLSX</td>
<td>glide.export.xlsx.display_value</td>
<td>true</td>
<td></td>
</tr>
<tr>
<td></td>
<td>glide.export.xlsx.column_header_label</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**CSV**

Example:

```plaintext
glide.export.csv.raw.value = false  (default)
glide.export.csv.column_header_label = false  (default)
```

<table>

```
Example:

```plaintext
glide.export.xlsx.display_value = false  
glide.export.xlsx.column_header_label = false
```

Field types affected by export controls

Different field types are affected differently by export controls.

The following table describes how different field types are affected by export controls.

<table>
<thead>
<tr>
<th>Field type</th>
<th>Display value</th>
<th>Raw value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Date/Time</td>
<td>CSV: User timezone date/time with user format.</td>
<td>CSV: UTC timezone date/time with system format.</td>
</tr>
<tr>
<td></td>
<td>Excel/XLSX: User timezone date/time with user format if <code>glide.excel.use_user_date_format</code> set, otherwise system format.</td>
<td>Excel/XLSX: UTC timezone date/time with user format if <code>glide.excel.use_user_date_format</code> set, otherwise system format.</td>
</tr>
<tr>
<td>Date</td>
<td>Date with user format.</td>
<td>Date with system format.</td>
</tr>
<tr>
<td></td>
<td>Excel/XLSX: Date with user format if <code>glide.excel.use_user_date_format</code> set, otherwise system format.</td>
<td>Excel/XLSX: Date with user format if <code>glide.excel.use_user_date_format</code> set, otherwise system format.</td>
</tr>
<tr>
<td>Time</td>
<td>CSV: Time with user format.</td>
<td>CSV: UTC time, assuming 1970-01-01 as the date with system format.</td>
</tr>
<tr>
<td></td>
<td>Excel/XLSX: User timezone time with user format if <code>glide.excel.use_user_date_format</code> set, otherwise system format.</td>
<td>Excel/XLSX: UTC time, assuming 1970-01-01 as the date with user format if <code>glide.excel.use_user_date_format</code> set, otherwise system format.</td>
</tr>
<tr>
<td>References</td>
<td>Display value of the referenced record.</td>
<td>Sys_id of the referenced record.</td>
</tr>
<tr>
<td>Choice</td>
<td>Label of the selected choice.</td>
<td>Value of the selected choice.</td>
</tr>
<tr>
<td>Currency</td>
<td>Value with the currency symbol.</td>
<td>USD value without the currency symbol.</td>
</tr>
<tr>
<td>Field type</td>
<td>Display value</td>
<td>Raw value</td>
</tr>
<tr>
<td>--------------------</td>
<td>--------------------------------------</td>
<td>------------------------------------------------</td>
</tr>
<tr>
<td>Price (calculated)</td>
<td>Value with the currency symbol.</td>
<td>USD value without the currency symbol.</td>
</tr>
<tr>
<td>Price (fixed)</td>
<td>Value with the currency symbol.</td>
<td>USD value without the currency symbol.</td>
</tr>
</tbody>
</table>

**Default values for column headers and column values**

Default values are used for column headers and column values, unless overridden by query parameters, Export Set fields, or system properties.

The following table describes the default values used if you do not use query parameters, Export Set fields, or system properties to control output format.

<table>
<thead>
<tr>
<th>Output format</th>
<th>Column headers</th>
<th>Column values</th>
</tr>
</thead>
<tbody>
<tr>
<td>CSV</td>
<td>Use field name</td>
<td>Use raw value if glide.export.csv.raw.value set, otherwise Use display value.</td>
</tr>
<tr>
<td>Excel</td>
<td>Use field label</td>
<td>Use display label</td>
</tr>
<tr>
<td>JSON</td>
<td>N/A</td>
<td>Use raw value</td>
</tr>
<tr>
<td>XLSX</td>
<td>Use field label</td>
<td>Use display value</td>
</tr>
<tr>
<td>XML</td>
<td>N/A</td>
<td>Use raw value</td>
</tr>
</tbody>
</table>

**Exporting currency fields to Excel**

Exporting currency fields to Excel applies Account formatting and can be configured to convert all values to US dollars or to export values in the user's session currency.

When exporting currency fields to Microsoft Excel, the cells containing currency data use Accounting formatting. This formatting allows you to perform numeric operations on those values as well as view the currency symbol, such as $ or €.

When exporting currency fields the type of currency, such as $ or €, is preserved by default. The conversion rates for non-USD currencies are stored on the Exchange Rates [fx_rate] table.

You can choose to export all currency values either in US dollars or in the user's session currency.

- To export all currency values in US dollars, set the property `glide.excel.fixed_currency_usd` to `true`.
- To export all currency values in the user's session currency, set the property `glide.excel.convert_to_user_currency` to `true`.

If both `glide.excel.fixed_currency_usd` and `glide.excel.convert_to_user_currency` are set to `true`, `glide.excel.fixed_currency_usd` overrides `glide.excel.convert_to_user_currency`.

**Currency export behavior and symbols**

The behavior of the currency field in Excel depends on the Symbol of the currency.

- When the currency symbol is $, the Excel cell type is set as Currency.
- When the currency symbol is 1 character (such as ¥ or €) or more than 1 character (such as KR), the Excel cell type is set to Custom.
Export directly from a URL

You may want to export data from the URL if you need to dynamically export data from a script or web service.

You must be familiar with the ServiceNow table and column names to export data directly from the URL. See Navigate to a record or a module using a URL for more information about navigating to forms and lists.

Query parameters are available for you to use in the instance URL so you can display a specific list of records in a specific order:

<table>
<thead>
<tr>
<th>URL Parameter</th>
<th>URL Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_query</td>
<td>sysparm_query=[column name] [operator][value]</td>
<td>Displays a list of records that match the query. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>https://&lt;instance name&gt;.service-now.com/incident_list.do?XML&amp;sysparm_query=priority=1</td>
</tr>
<tr>
<td>sysparm_orderby</td>
<td>sysparm_orderby=[column name]</td>
<td>Sorts a list of records by the column name provided. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>https://&lt;instance name&gt;.service-now.com/incident_list.do?XML&amp;sysparm_query=priority=1&amp;sysparm_orderby=assigned_to</td>
</tr>
<tr>
<td></td>
<td></td>
<td>You can sort by only one column using sysparm_orderby. To sort by multiple columns, use sysparm_query=ORDERBY[column name]^ORDERBY[column name]. For example: sysparm_query=ORDERBYassigned_to^ORDERBYpriority.</td>
</tr>
</tbody>
</table>

To export data directly from the URL, create a URL containing the following parts:

1. Specify the instance URL. For example, https://<instance name>.service-now.com/.
2. Specify the table form or list to export. For example, incident_list.do.
3. Specify the export format processor to use for the export. For example, ?CSV.
4. Optional: Specify a query and sort order with URL parameters. For example, &sysparm_query=sys_id%3E%3Db4aedb520a0a0b1001af10e278657d27.

The final URL should look like one of these sample URLs:

<table>
<thead>
<tr>
<th>URL</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>https://&lt;instance name&gt;.service-now.com/incident_list.do?CSV&amp;sysparm_query=sys_id%3E%3Db4aedb520a0a0b1001af10e278657d27</td>
<td>Export a particular incident to a comma-separated value text file.</td>
</tr>
<tr>
<td>URL</td>
<td>Description</td>
</tr>
<tr>
<td>-----</td>
<td>-------------</td>
</tr>
<tr>
<td><code>https://&lt;instance name&gt;.service-now.com/incident_list.do?CSV&amp;sysparm_orderby=sys_id</code></td>
<td>Export all incidents to a comma-separated value text file and sort the list by sys_id.</td>
</tr>
</tbody>
</table>

**Note:** ServiceNow enforces basic authentication for direct URL access. The data extracted from the URL contains only the fields to which the currently authenticated user has read access.
Call URL export programmatically
You can dynamically export data from a script or web service by calling a URL export from any programming language.

The following procedure includes code samples that demonstrate calling a URL export in C# for a .Net framework call:

1. Add the following Imports:

   ```csharp
   using System.Net;
   using System.IO;
   ```

2. Call the Download method:

   ```csharp
   static void Main(string[] args)
   {
       // Call to DownloadFile method supplying the URL and location to
       // save CSV file locally
       int read = DownloadFile("https://
       <instance>.service-now.com/incident_list.do?
       CSV&sysparm_query=priority=1&sysparm_orderby=assigned_to",
       "c:\\test\\incident.csv");
   }
   ```

3. Create a Download method as follows:

   ```csharp
   public static int DownloadFile(String url,
       String localFilename)
   {
       // Function will return the number of bytes processed
       // to the caller. Initialize to 0 here.
       int bytesProcessed = 0;
       // Assign values to these objects here so that they can
       // be referenced in the finally block
       Stream remoteStream = null;
       Stream localStream = null;
       WebResponse response = null;
       // Use a try/catch/finally block as both the WebRequest and
       Stream
       // classes throw exceptions upon error
       try
       {
           // Create a request for the specified remote file name
           WebRequest request = WebRequest.Create(url);
           // Create the credentials required for Basic Authentication
           System.Net.ICredentials cred = new
           System.Net.NetworkCredential("user_name", "password");
           // Add the credentials to the request
           request.Credentials = cred;
           if (request != null)
           {
               // Send the request to the server and retrieve the
               // WebResponse object
               response = request.GetResponse();
               if (response != null)
               {
                   // Once the WebResponse object has been retrieved,
                   // get the stream object associated with the
                   response's data
                   remoteStream = response.GetResponseStream();
                   // Create the local file
                   localStream = File.Create(localFilename);
               }
           }
       }
   }
   ```
// Allocate a 1k buffer
byte[] buffer = new byte[1024];
int bytesRead;
// Simple do/while loop to read from stream until
// no bytes are returned
do {
   // Read data (up to 1k) from the stream
   bytesRead = remoteStream.Read(buffer, 0, buffer.Length);
   // Write the data to the local file
   localStream.Write(buffer, 0, bytesRead);
   // Increment total bytes processed
   bytesProcessed += bytesRead;
} while (bytesRead > 0);
}
}
catch (Exception e)
{
    Console.WriteLine(e.Message);
}
finally
{
   // Close the response and streams objects here
   // to make sure they're closed even if an exception
   // is thrown at some point
   if (response != null) response.Close();
   if (remoteStream != null) remoteStream.Close();
   if (localStream != null) localStream.Close();
}
// Return total bytes processed to caller.
return bytesProcessed;

Break up a large export

If the number of records to be exported exceeds the actual export limit, you may want to break the export into smaller increments that do not place a significant performance load on the platform.

1. Filter the list to display the records you want to export.
2. Write down the number of records returned.
3. If the record number is higher than the defined threshold, issue a sysparm query for the first 10,000 records using the following syntax:

   https://<instance name>.service-now.com/syslog_list.do?
   XML&sysparm_orderby=sys_id&sysparm_record_count=10000

   This exports the first 10,000 records in order, sorted by the sys_id number.

4. Find the next record in order, such as 10,001.
5. Right-click the row and copy the sys_id of the next record you want to export.
6. Access the next series of records with a **greater than or equal to** query run against the **sys_id** of record 10,001.

The following example shows a query that uses a sys_id of b4aeb520a0a0b1001af10e278657d27. Use the syntax shown in this query to export the next set of records.

```xml
https://<instance name>.service-now.com/syslog_list.do?XML&sysparm_query=sys_id%3E%3Db4aeb520a0a0b1001af10e278657d27&sysparm_orderby=sys_id&sysparm_record_count=10000
```

**Note:** URL queries use typical percent encoding. In this example, the greater than sign (> ) is encoded as %3E and the equal sign (=) is encoded as %3D.

7. Continue issuing this query, using the starting sys_id for the next set of records until you have exported all the necessary records.

**Enable export debug logging**

When the property **glide.export.debug** is true, the instance logs export processing including database query time and the time taken to write data to the file.

When the property **glide.export.debug** is **true**, the instance logs export processing including database query time and the time taken to write data to the file. Debug logs are indicated by the text **Export API**. Prolonged use of this property can affect performance, so it is best to use it while debugging export processing, and then set the property back to **false**.

```
**Import an XML file**

After you have successfully exported data from the source instance, you can import the XML file directly to the target instance.

Role required: admin

Importing XML does not trigger business rules or update the instance cache.

1. Sign in to the target instance (the instance that should receive the data).
2. In the banner frame, click the Elevate privileges icon (𝐸) beside the user name.
3. In the Activate an Elevated Privilege dialog box, select the **security_admin** check box and click OK.
4. Navigate to any list in the system.
   Any list can be used because the XML file contains the destination table name for the records.
5. Perform the appropriate action for the list version.

<table>
<thead>
<tr>
<th>Version</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>List v2</td>
<td>Open any column context menu and select <strong>Import XML</strong>.</td>
</tr>
<tr>
<td>List v3</td>
<td>Open the list title menu and select <strong>Import XML</strong>.</td>
</tr>
</tbody>
</table>
6. In the import screen, click **Choose File** and select the previously exported XML file.

![Importing records from an XML file will not run Business Rules](Image)

(1) Choose file to upload:

| Choose File | No file chosen |

(2) Upload the file

![Upload](Image)

7. Click **Upload**.

![Note: If the data does not import, navigate to System Definition > Tables & Columns and verify that the table from which the data was exported also exists in the instance importing the data. If the table does not exist in that instance, you can move it using an update set.](Image)

**Export sets**

Export sets allow you to push data from an instance to an external file.

You can export data to a remote system using a MID Server.

![Note: You must use a MID Server from the Geneva release or later. Earlier MID Server releases do not support export sets. Export sets are not supported on MID Servers in a cluster.](Image)

**Create an export set**

Create an export set to export records from your instance to a file on a MID Server.

Role required: export_set_admin

![Note: Export sets do not export attachments to records. To download an attachment, either use the REST Attachment API (HTTP request originates from a third-party HTTP client), or use the outbound REST Message module to send the attachment from the instance (HTTP request originates from the instance).](Image)

1. Navigate to **System Export Sets > Create Export Set**.
2. Enter a descriptive **Name** for the export set.
3. In the **What to export** section, define what data to export in one of these ways.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select Yes and select an Export Definition record.</td>
<td>Use this configuration if you have already created an export definition record specifying what data to export.</td>
</tr>
</tbody>
</table>
4. In the **Where to export to** section, define where you want to export data to in one of these ways.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select Yes and select an Export Target record.</td>
<td>Use this configuration if you have already created an export target record specifying where to export data to.</td>
</tr>
<tr>
<td>Select No and select a MID Server, and specify a path on the MID Server to save the exported data to.</td>
<td>Use this configuration if you have not created an export target record. A new export target record is created automatically for the selected MID Server and file path. You can modify the export target record as needed after creating the export set.</td>
</tr>
</tbody>
</table>

5. Click **Submit**.

After creating the export set, the Export Set form appears. You can configure advanced options from the form such as specifying a data format or scheduling recurring exports.

**Export Set form fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a descriptive name for this export set.</td>
</tr>
<tr>
<td>File name</td>
<td>Enter a name for the target file.</td>
</tr>
<tr>
<td>Format</td>
<td>Select the format of the target file, such as CSV.</td>
</tr>
<tr>
<td>Append timestamp</td>
<td>Select this check box to append the current date and time to the name of the exported file.</td>
</tr>
<tr>
<td>Export definition</td>
<td>Select the export definition that specifies the data to export.</td>
</tr>
<tr>
<td>Export target</td>
<td>Select the export target that specifies the location you want to export to.</td>
</tr>
</tbody>
</table>

**Create an export set from a list**

You can quickly create an export set from a list.

Role required: export_set_admin

1. Navigate to a list of records.
2. Perform the appropriate action for the list version.

<table>
<thead>
<tr>
<th>Version</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>List v2</td>
<td>Right-click the list header and select Export &gt; Export Set.</td>
</tr>
<tr>
<td>List v3</td>
<td>Open the list title menu and click Export, and then click Export Set.</td>
</tr>
</tbody>
</table>

The Export Set form appears. An export definition is created automatically based on the list.

3. Configure the export set as needed.
4. Click **Submit**.
Create an export definition

Create an export definition to define what data to export in an export set.

Role required: export_set_admin

An export definition specifies the data to be exported in an export set. This data includes a table, one or more fields, and optionally a filter to limit the included records.

1. Navigate to System Export Sets > Export Definition.
2. Click New.
3. Enter a descriptive Name for the export definition.
4. Select the Table to export data from.
5. Select one or more Fields from the selected table to export data from.
6. Optional: Specify a Filter to export only certain records from the selected table.

Specifying a filter condition on the Created (sys_created_on) or Updated (sys_updated_on) fields may prevent scheduled data exports from using delta exports functionality. Do not specify filter conditions on these fields if you intend to use scheduled delta exports.

Create an export target

Define where to export data to by creating an export target.

Role required: export_set_admin

You must use a MID server as the export destination.

Navigate to System Export Sets > Export Targets and create a new record (see table for field descriptions).

Export target fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a descriptive name for the export target.</td>
</tr>
<tr>
<td>MID Server</td>
<td>Select the MID Server to export to. The MID Server must have a Validated value of Yes and a Status value of Up.</td>
</tr>
</tbody>
</table>

**Note:** You must use a MID Server from the Geneva release or later. Earlier MID Server releases do not support export sets. Export sets are not supported on MID Servers in a cluster.

File Path | Specify a path relative to the MID Server directory to save the exported data to. The user account used to run the MID Server must have permission to write to this location.
Export set supported file types

Export sets support multiple file types for exporting and pushing data.

File types

You can export to these formats:

- CSV
- XML
- Excel
- JSON

Schedule an export

You can schedule an export to regularly push data from an export set to a remote destination. By setting up a recurring, scheduled export you are able to regularly push data to an external location, such as for reporting or for preserving a snapshot of the data.

Role required: export_set_scheduler or export_set_admin

You can configure scheduled export sets to export only new or changed records using delta exports.

1. Navigate to **System Export Sets > Scheduled Exports**.
2. Click **New**.
3. Fill in the following fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a descriptive name for this scheduled export.</td>
</tr>
<tr>
<td>Export set</td>
<td>Select the export set to schedule.</td>
</tr>
<tr>
<td>Run as</td>
<td>Select the user to run the scheduled export as. Ensure the user has any roles needed to view the data to export.</td>
</tr>
<tr>
<td>Run</td>
<td>Select the frequency for scheduled export.</td>
</tr>
<tr>
<td>Day</td>
<td>Select which day of the week or month to run this scheduled export.</td>
</tr>
<tr>
<td>Repeat interval</td>
<td>Enter the number of days and hours to wait before repeating this scheduled export.</td>
</tr>
<tr>
<td>Time</td>
<td>Enter the time of day to run the scheduled export.</td>
</tr>
<tr>
<td>Delta Exports</td>
<td>Select this check box to enable delta functionality for this scheduled export. When selected, only new or changed records are exported.</td>
</tr>
</tbody>
</table>
Field | Description
--- | ---
Delta on or after | Select **Updated** to export all records that changed since the last export, including new records. Select **Created** to export only new records created after the last export.

**Note:** If the export definition already includes a filter condition on the sys_updated_on or sys_created_on fields, enabling delta exports will prevent you from saving the scheduled data export record. An error appears at the top of the form in this event.

Last export scheduled run | Leave this field blank to export all records from the export definition. When using delta exports, this field is set automatically each time the scheduled export runs. Records updated or created after this date and time are included in the export delta, depending on the Delta on or after value.

Scripts

Conditional | Select this check box to run the schedule only when a condition is met.
Condition | Write the script to be used to evaluate whether the export should run. This field is visible if you select the Conditional check box.

Execute pre-export script | Select this check box to run a script before the export begins.
Pre script | Write the script you want to run before the data is exported. This field is visible if you selected the Execute pre-export script check box.

Execute post-export script | Select this check box to run a script after the export finishes.
Post script | Write the script you want to run after the export finishes. This field is visible if you selected the Execute post-export script check box.

4. Click **Submit**.

You can click the **Execute Now** button to run the export immediately and confirm the data is exported as expected.

**Scheduled export set delta exports**

Delta exports include only the records that changed since the last scheduled export.

You can use delta export for regular tables only, such as the task and problem tables.

**Important:** You cannot use delta export for a database view table, which is a virtual table that joins physical tables.

A database view does not include system fields such as sys_created_on, sys_created_by and sys_updated_on. Because the system date fields are not included in the database view, you cannot use delta exports with database views since there is no way to know when the table was last updated.
Scheduled export set scripting options

When scheduling an export set, you can access certain JavaScript objects. Use these objects in scheduled export set scripts, such as the **Pre-script** and **Post-script** fields.

**cancel**

Set this object to `true` to stop the export action. Any child export sets are also cancelled if the parent is cancelled. This object is available only in the **Pre-script** field.

**Example:** Use the **Pre-script** field to evaluate the conditions of the export and determine whether to cancel the export process. To cancel the export process, use the following call:

```javascript
cancel = true;
```

**export_set**

Get the GlideRecord object for the new export set. This variable allows you to query the following columns from the `sys_export_set` table:

- name
- `sys_id`
- state
- `table_name`

This object is available in both the **Pre-script** and **Post-script** fields.

**Example:** If you want to use information from the export set, you can specify one of the properties of the `export_set` variable.

```javascript
var x = export_set.sys_id;
```

Export set history

An export set history record is automatically created whenever an export set runs, either scheduled or manually started by a user. Export set history records allow you to monitor and troubleshoot the progress of export sets.

Fields on the Export History form display the current status of the export set. The **Export Log** related list shows a detailed list of changes to the export set status.

**Export History form fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Export set</td>
<td>The export set that was run.</td>
</tr>
<tr>
<td>Started</td>
<td>The date and time the export started.</td>
</tr>
<tr>
<td>Completed</td>
<td>The date and time the export completed.</td>
</tr>
<tr>
<td>Export time</td>
<td>The amount of time it took to export the data, excluding the</td>
</tr>
<tr>
<td></td>
<td>time it took to transfer the data to the target.</td>
</tr>
<tr>
<td>Run time</td>
<td>The amount of time it took to export the data, including the</td>
</tr>
<tr>
<td></td>
<td>time it took to transfer the data to the target.</td>
</tr>
<tr>
<td>State</td>
<td>The current state of the export.</td>
</tr>
</tbody>
</table>
### ServiceNow, DocVersion, Now Platform administration

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delta export</td>
<td>The export used delta export functionality if this check box is selected.</td>
</tr>
<tr>
<td>ECC queue</td>
<td>The ECC Queue record associated with this export set run. This field is visible only to users with the admin role.</td>
</tr>
<tr>
<td>MID Server Attachment</td>
<td>A MID Server attachment record containing a copy of the exported file. The exported file is attached to this record in addition to being saved on the MID Server.</td>
</tr>
</tbody>
</table>

The **State** field may have the following values.

#### States

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exporting</td>
<td>The export set is creating a file with the data to export.</td>
</tr>
<tr>
<td>MID Server Processing</td>
<td>The export set successfully created a file with the data to export. The file is being processed by the MID Server.</td>
</tr>
<tr>
<td>Completed</td>
<td>The export set successfully ran and sent the exported file to the target.</td>
</tr>
<tr>
<td>Completed wth errors</td>
<td>The export set ran, but encountered one or more errors.</td>
</tr>
<tr>
<td>Cancel requested</td>
<td>A user requested that the export set be cancelled.</td>
</tr>
<tr>
<td>Cancelled</td>
<td>The export set was cancelled.</td>
</tr>
</tbody>
</table>

### Cancel an export set

You can cancel a running export set to stop the data from being sent to a MID server.

Role required: export_set_admin

You can cancel only exports that have not yet been sent to a MID server. You cannot cancel an export after it reaches the **MID Server Processing** state.

1. Navigate to **System Export Sets > Export Sets**.
2. Select an export set.
3. In the **Export Histories** related list, select a record with the **State** value of **Exporting**.
4. Click **Cancel Export Set**.

### Export Set properties

These properties control the behavior of export sets.

#### Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.scheduled_export.stop_on_parent_error</td>
<td>When true, if a parent scheduled export set encounters an error, scheduled child export sets do not run. This property is false by default.</td>
</tr>
</tbody>
</table>
Import sets

Import sets allow administrators to import data from various data sources, and then map that data into ServiceNow tables.

Import sets key concepts

Learn about Import Sets before importing data to your instance.

The Import Sets table acts as a staging area for records imported from a data source.

Note: You should not import data in extremely large chunks. Creating an extremely large import set can cause delays and system outages.

A transform map determines the relationships between fields displaying in an Import Set table and fields in an existing ServiceNow table, such as the Incidents or Users table.

Importing sets skip records when the data in the instance matches the data being imported.

Note: Import Sets run as user System and therefore cannot add data to encrypted fields.

Terminology

Key terms

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Import Set table</td>
<td>A table that acts as a staging location for records imported from a data source before transforming those records. Fields on these tables are generated automatically based on imported data and should not be modified manually.</td>
</tr>
</tbody>
</table>
## Term

<table>
<thead>
<tr>
<th>Data source</th>
<th>A record that defines where to get the data to import. A data source may point to a file, a JDBC-compatible database, or an LDAP organizational unit.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transformation</td>
<td>The conversion of data from an import set table to another table according to the rules defined in a transform map.</td>
</tr>
<tr>
<td>Transform map</td>
<td>A set of field maps that define the relationships between fields in an import set and fields on a table, such as Incident. During transformation, data is copied from the Import Set table to the destination table based on the transform map. A single import set field may be mapped to multiple fields on other tables.</td>
</tr>
<tr>
<td>Robust import set transformer</td>
<td></td>
</tr>
<tr>
<td>Foreign record insert</td>
<td>A foreign record insert occurs when an import makes a change to a table that is not the target table for that import. This happens when updating a reference field on a table. For example, when updating a value for the caller on an incident, the import is actually updating the sys_user table.</td>
</tr>
<tr>
<td>Coalesce</td>
<td>Lets you update existing target table records when transforming import data. You can specify whether a <strong>Target field</strong> should be used to coalesce on when import set records are transformed. If the field map <strong>Coalesce</strong> check box is selected, when the import set row is transformed, the instance checks for an existing record in the target table that has the same value in the <strong>Target field</strong> as the import set row <strong>Source field</strong>. If an existing record with a matching value in the target table is found, that record is updated. If no matching record is found, then a new record is created in the target table.</td>
</tr>
</tbody>
</table>

## Supported import formats

You can import data from several different file formats or external data sources.

### File formats

<table>
<thead>
<tr>
<th>Format</th>
<th>Limitations</th>
</tr>
</thead>
<tbody>
<tr>
<td>CSV</td>
<td>CSV files must comply with the proposed CSV standard in <a href="https://tools.ietf.org/html/rfc4180">RFC4180</a>. In particular, this means that double quotes may not appear inside fields. The first row of data in an imported CSV file becomes the header row and defines the columns for that import set.</td>
</tr>
<tr>
<td>Excel</td>
<td>Excel files must have the XLS or XLSX extension.</td>
</tr>
<tr>
<td>XML</td>
<td>XML files must have a consistent XPath for each data row.</td>
</tr>
</tbody>
</table>
ServiceNow can import data from the following external data sources.

### External data sources

<table>
<thead>
<tr>
<th>Data Source</th>
<th>Limitations</th>
</tr>
</thead>
<tbody>
<tr>
<td>JDBC</td>
<td>JDBC imports require a valid transform map. Some network configurations may require a MID Server.</td>
</tr>
<tr>
<td>LDAP</td>
<td>LDAP imports require a valid transform map.</td>
</tr>
<tr>
<td>OIDC</td>
<td>OIDC imports require a valid transform map.</td>
</tr>
<tr>
<td>REST (IntegrationHub)</td>
<td>REST imports require a valid transform map.</td>
</tr>
<tr>
<td>Custom (Load by Script)</td>
<td>Custom imports require a valid transform map.</td>
</tr>
</tbody>
</table>

### Transform maps versus robust import set transformers

Both transform maps and robust import set transformers convert data. Transform maps convert data from the staging table to the destination file. Robust import set transformers convert data from a source table to a message listener. If a data source has both a transform map and a robust import set transformer, the system uses the robust import set transformer instead of the transform map.

### Import set scheduled cleanup

The Import Set Deleter scheduled job cleans up old import set data every day at midnight. By default, the job deletes all import sets that are older than 7 days, as well as the associated import set table records. If this scheduled job is not active on your instance, activate it to mitigate the growing import set tables you may have, especially when using recurring imports.

**Note:** If scheduled cleanup is not currently active on your system, you must ensure that your import set tables are not too big (> 5 million records total across all tables) before enabling this cleanup. If the tables are too big, manually delete the records first before proceeding. Please contact Customer Service and Support to coordinate the deletion of this data.
For procedures, see Delete import sets.

**Import set table deleter**

You can manually delete any or all of the following import set tables:

- Computer
- User
- Notification
- Location

You can also delete the related transform maps, or you can delete data only and preserve the table structure.

For procedures, see Delete import set tables.
Concurrent imports

Split incoming data into multiple import sets and transform the import sets concurrently to reduce processing time.

Running a concurrent import can be helpful when order does not matter and imports take a long time due to large data sets with time-consuming scripts. If order matters, you can split the import into multiple partitions to ensure that each partition is processed in order.

**Note:** Concurrent imports add processing and monitoring overhead. Use them only with large data sets.

Enable concurrent imports only after fine-tuning all other parameters, such as database indexes and transformations.

Scheduling concurrent imports

You enable concurrent imports by selecting **Concurrent Import** on the Scheduled Data Import form. For instructions, see Schedule a data import.

When the schedule runs a concurrent import, the system pulls the data from databases, Excel spreadsheets, CSV files, or other sources to a temporary staging table, and then transforms the data from the staging table to the target table.

When you run a concurrent import, the system creates multiple import sets, up to the value of the `glide.scheduled_import.max.concurrent.import_sets` system property (default = 10). For example, a two-node cluster produces four import sets, and a ten-node cluster produces ten import sets.

Import Set Transformer job

Each active node runs two Import Set Transformer jobs every minute, and those jobs poll the Concurrent Import Sets Jobs queue, pick import sets from the queue, and transform those import sets. All jobs run concurrently, depending on the availability of worker threads.

Concurrent Import Set record

Each concurrent import creates a Concurrent Import Set record. The form view shows all related import sets, concurrent import set jobs, and transform histories.

You can resume or reprocess any import set. For more information, see Monitor concurrent import sets.

Concurrent Import Sets Jobs queue

After loading data, the system adds the import sets to the Concurrent Import Sets Jobs table. The Concurrent Import Sets Jobs table indicates the job type and status of each concurrent import set job.

For more information, see Monitor concurrent import set jobs.

Partitioning concurrent imports

You can partition import sets to maintain the processing order within each partition.

By default, the system allocates records to import sets in a round robin fashion. However, you can write a custom script to define a custom `partition key` that identifies the target import set. Every row with the same partition key adds to the same import set, and the data in that import set is processed in sequential order.
Hierarchical imports

You can create a scheduled import set hierarchy by scheduling an import to run after another import set completes. One parent scheduled import can have many child scheduled imports, and each child scheduled import executes in the order specified. For concurrent scheduled imports, child scheduled imports can be started only after all Import Set Transformer jobs complete.

The last Import Set Transformer job starts the next import in the hierarchy.

The system generates an execution plan at the beginning of parent import process. Each import process uses the execution plan to fetch the next process to invoke. For concurrent imports, the last Import Set Transformer job fetches the next import and executes it.

Synchronized inserts

Coalesce fields help define uniqueness among records. The transformation process checks for an existing record with the coalesce values and updates the existing record, if it exists, or inserts a new record if none exists. For more information, see Updating records using coalesce.

By default, concurrent imports allow each running import set to insert new records. When an import set inserts a record, it establishes a write lock on the target table to prevent other import sets from inserting the same record.

Tables for concurrent imports

<table>
<thead>
<tr>
<th>Table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Concurrent Import Set (sys_concurrent_import_set)</td>
<td>Stores details of each concurrent import set in import set records.</td>
</tr>
<tr>
<td>Concurrent Import Set Jobs (sys_concurrent_import_set_job)</td>
<td>Lists the import sets to be processed.</td>
</tr>
<tr>
<td>Execution Context for Scheduled import (sys_execution_context)</td>
<td>Specifies the execution context for each scheduled import. The execution context specifies the next scheduled import to use when processing a hierarchical scheduled import.</td>
</tr>
<tr>
<td>Hierarchical scheduled import execution plan (sys_execution_plan)</td>
<td>Stores the execution plan for hierarchical imports. The execution plan is a tree structure that identifies which scheduled import runs after the preceding scheduled input.</td>
</tr>
</tbody>
</table>

Domain Separation with concurrent imports

You can add the sys_domain field to a scheduled import table to enable domain separation for the import set. Both import set loading and transform jobs run in the domain specified in the scheduled import set job.
Data sources

Data sources are used to create an import set so that data can be processed, if necessary, prior to being mapped onto a production table.

### Data Source Types

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>File</td>
<td>Data is in a recognized file format, accessible locally or remotely through several file retrieval methods.</td>
</tr>
<tr>
<td>JDBC</td>
<td>Data is in a database, accessible using JDBC. Customer Service and Support supports Oracle, MySQL, Sybase, DB2 Universal, and MS SQL Server drivers.</td>
</tr>
<tr>
<td>LDAP</td>
<td>Data is in an LDAP server, accessible through the LDAP or LDAPS ports, 389 and 636 respectively.</td>
</tr>
<tr>
<td>OIDC</td>
<td>Data is accessible via OIDC.</td>
</tr>
<tr>
<td>REST (IntegrationHub)</td>
<td>Data is in a REST API, accessible through IntegrationHub.</td>
</tr>
<tr>
<td>Data Stream IntegrationHub</td>
<td>Data is loaded from a Data Stream Action, accessible through IntegrationHub.</td>
</tr>
<tr>
<td>Custom (Load by Script)</td>
<td>Data is obtained using a custom script.</td>
</tr>
</tbody>
</table>

### File type data sources

Import a file from a local source, a remote network server, or another instance by providing a path and authentication information.

For file type import sets, you can select from a list of file retrieval methods: SFTP, FTP, FTPS, HTTP, HTTPS, and SCP.

**Note:** FTPS is not recommended because it is no longer supported by some firewall vendors. Consider using SFTP as an alternative.

### File retrieval methods

The following file retrieval methods are available to copy the file from where it resides to ServiceNow to be loaded into an import set.

After defining the files that are compatible for importing, define how the files can be imported.

**Note:** For the import to succeed, your FTP server and client must be set up for the same authentication mechanism that you select here.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attachment</td>
<td>Attach a file to the record and import that file in an import set.</td>
</tr>
<tr>
<td>SFTP</td>
<td>Retrieve a file using SFTP. Fields are provided for the server name and login credentials.</td>
</tr>
<tr>
<td>Method</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>FTP</td>
<td>Retrieve a file from an FTP server in your network. Fields are provided for the server name and login credentials. <strong>Note:</strong> FTP transfers are sent as clear text and cannot be encrypted. Use SCP or SFTP instead whenever possible.</td>
</tr>
<tr>
<td>FTPS (Auth SSL) [not recommended]</td>
<td>Not recommended because FTPS is no longer supported by some firewall vendors. Consider using SFTP as an alternative. An FTP Secure authentication command issued through the Secure Socket Layer (SSL) protocol. This method is also known as explicit FTP over SSL.</td>
</tr>
<tr>
<td>FTPS (Auth TLS) [not recommended]</td>
<td>Not recommended because FTPS is no longer supported by some firewall vendors. Consider using SFTP as an alternative. An FTP Secure authentication command issued through the Transport Layer Security (TLS) protocol. This method is also known as explicit FTP over TLS.</td>
</tr>
<tr>
<td>FTPS (Implicit SSL) [not recommended]</td>
<td>Not recommended because FTPS is no longer supported by some firewall vendors. Consider using SFTP as an alternative. In implicit security, the FTPS server defines a specific port for the client (990) to use for secure connections. Implicit security automatically begins with an SSL connection the moment an FTPS client connects to an FTPS server.</td>
</tr>
<tr>
<td>FTPS (Implicit TLS) [not recommended]</td>
<td>Not recommended because FTPS is no longer supported by some firewall vendors. Consider using SFTP as an alternative. In implicit security, the FTPS server defines a specific port for the client (990) to use for secure connections. Implicit security automatically begins with a TLS connection the moment an FTP client connects to an FTP server.</td>
</tr>
<tr>
<td>HTTP</td>
<td>Retrieve a file using HTTP. Fields are provided for the server name and login credentials. <strong>Important:</strong> For HTTP and HTTPS protocols, the file path is automatically URL encoded. Do not specify a URL-encoded file path when using either of these protocols.</td>
</tr>
<tr>
<td>HTTPS</td>
<td>Retrieve a file using HTTPS. Fields are provided for the server name and login credentials. Use this method to transfer data between ServiceNow instances.</td>
</tr>
</tbody>
</table>
### File data source examples

These examples describe how to import various file types as data sources.

#### Excel data source file

You can import using both the XLSX format and the legacy XLS format. XLS is the default format for spreadsheets created in Excel for versions 2003 and older. XLSX is the default format for Excel 2007 or later. Use XLSX instead of legacy XLS whenever possible for optimal performance.

**Note:** All .xls files must use the 1900 date system as opposed to the 1904 date system. The 1904 date system causes your dates to be imported with a year that is four years earlier than what appears in your spreadsheet. Refer to MS Support for additional information about date systems.

---

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCP</td>
<td>The Secure Copy protocol (SCP) securely transfers files between a local and a remote host or between two remote hosts, using the Secure Shell (SSH) protocol.</td>
</tr>
</tbody>
</table>
XML data source file

XPath for each row

XML data source definitions have an extra field to specify the XPath for each row. This field is an XPath expression to select the elements whose children are converted to rows in the import set table. Each selected element causes a row to be created in the import set table. The children of the selected element are converted into columns in the row. For example, to import the asset information from the sample XML file below, the XPath expression should be specified as /export/asset. This expression matches the three <asset> elements in the file, so three rows are created. Although you could also specify //asset, this expression is much less efficient for large files. Use the absolute location path form for XPath expressions when using the XML loader. In other words, avoid expressions containing // unless strictly necessary.

Be careful not to specify an insufficiently restrictive XPath expression with a large XML file. For example, the expression /export would be wrong for the following sample file, since it matches the document (root) element. In general, you should never specify an XPath expression which matches the root element unless you want everything in the document to be made into a single row. Specifying an insufficiently restrictive XPath expression when attempting to load large XML files could result in lengthy processing times and incorrect output. For this reason, it is best to test and debug XML data source specifications with small XML files containing only a few rows worth of data. Once the specification has been tested, you can run it again with the full file.

(userInfo) elements

Note that the <userInfo> elements contained within <asset> contain child elements. This type of nesting creates a column called userInfo that contains XML for the <userInfo> element. If Expand child nodes is checked, individual columns are also created for userInfo/lastName and userInfo/firstName. If Expand child nodes is not checked, only the userInfo XML column is created.

<?xml version= "1.0" encoding= "utf-8"?><export><asset><assetTag>AT-01939</assetTag><type>Desktop</type><os>Windows 7 Professional</os><lastlogondate>12-07-2010 12:31:24</lastlogondate><userInfo><lastName>Loo</lastName><firstName>David</firstName></userInfo><isenabled>true</isenabled></asset><asset><assetTag>AT-53480</assetTag><type>Desktop</type><os>Windows 7 Professional</os><lastlogondate>09-07-2010 13:25:53</lastlogondate><userInfo><lastName>Merritt</lastName><firstName>Norris</firstName></userInfo><isenabled>true</isenabled></asset><asset><assetTag>AT-55782</assetTag><type>Desktop</type><os>Unknown</os><lastlogondate>01-01-1900 00:00:00</lastlogondate><userInfo><lastName>Currie</lastName><firstName>Mike</firstName></userInfo><isenabled>true</isenabled></asset></export>

Loading data from an XML file

When loading data from an XML file, ServiceNow samples the first 10 records to determine what fields are required to hold the data. If none of the first 10 records specify a value for a field, ServiceNow does not add that field to the table that holds the imported data. Ensure that at least one of the first 10 records specifies a value for any fields being imported.

If the XML file used for an XML data source does not contain a field in the first 10 nodes, the field is ignored. To import the field and ensure it is not ignored, you can add the glide.db.impex.XMLLoader.max.scan_nodes system property with a value greater than or equal to the position of the node where the field is first encountered. This property applies to all XML data sources. glide.db.impex.XMLLoader.max.scan_nodes defaults to 10, but you can enter a value from 1 to 2147483647 to specify how many nodes should be scanned to determine the values to be used for the import. You can specify -1 to scan all nodes in the XML files.
Important: If you specify -1 or increase the value of glide.db.impex.XMLLoader.max.scan_nodes beyond the default of 10, all XML import processing may incur a significant increase in overall load time.

CSV data source file

CSV files are used as a cross-compatible file format for transferring files across platforms. A CSV file is a text file that defines a grid, where commas define columns and line breaks define rows. To define precise spacing for importing strings, you can optionally wrap text in quotes.

When using CSV files, you can specify the encoding charset using the Properties field on the Data Source form. You may need to configure the Data Source form to see this field. For example, to use utf-8 encoding, enter charset=utf-8.

Data in single column

For the JSON and XML formats, this feature lets you store a full record in a single column.

The column name used to store the full record is data.

If you create a JSON format data source to save data in a single column, selecting the Data in single column check box updates the following options:

- **Discard Array** becomes unselected and is removed from the form.
- **Expand node children** becomes selected and is removed from the form.
If you create an XML format data source to save data in a single column and you select the **Data in single column** check box, **Expand node children** becomes selected and is removed from the form.

### Custom (Parse by Script) format

When you select a **Type** of *File* and a **Format** of *Custom (Parse by Script)*, a Javascript editor called **Parsing script** appears. You can use the parsing script to create customized Javascript to parse input lines into the list of maps.

The Javascript has three predefined parameters:

- The **line** parameter is a string which contains line data from the source file.
- The **lineNumber** is the line number from the source file for this line data.
- The **result** parameter is used to pass back the parsed result from Javascript.
The **result** parameter is an instance of Java object ScopedScriptParseResult. When you type `result.`, four available methods appear as script auto-complete in the Javascript editor:

- `void setSkip(boolean skip);`
- `boolean getSkip();`
- `addRow(Map<String, String> map);`
- `List<Map<String, String>> getRows();`

The `setSkip()` and `getSkip()` set and retrieve the skip flag. When the skip flag is set to true, the entire parsing result from Javascript is ignored.

The `addRow()` adds one map of the parsing row result, which is inserted into the staging table.

The `getRows()` retrieves all rows of the current parsing result, which are inserted into the staging table.

One line of source data can contain one row or multiple rows. It is up to the script writer to decide how to process the line data. For example, for line data `name=john, computer=windows; name=joe, computer=linux; name=linda, computer=windows`, if you use a semicolon (`;`) as a row break, then this line contains three rows of data. Each row is a map with two keys: `name` and `computer`. The `name` and `computer` become the column names for the staging table schema. You could use the following sample of Javascript to parse this line data:

```javascript
(function(line, lineNumber, result) {
    var rowArr = line.split(";");
    var i;
    for(i in rowArr) {
        var map = {};
        var arr = rowArr[i].split","");
        var x;
        for(x in arr) {
            var items = arr[x].split("=");
            map[items[0]]=items[1];
        }
        result.addRow(map);
    }
})(line, lineNumber, result);
```

The script writer must add the result so that the result is inserted in the staging table.
Processing custom CSV files
You can process CSV files that are delimited by a character other than commas.

This is an advanced step to create a CSV import. Normally, you would upload the data and import it directly using System Import Sets, which will create this CSV data source for you automatically.

1. Create the data source record.
2. Attach the CSV file to the data source.
3. Customize the Data Source form and add the CSV Delimiter field.
4. Enter the character you want to use as the CSV file delimiter, such as the pipe symbol (|).
5. Test load the data source.

Importing JSON files
These examples demonstrate how to import various types of JSON data and the necessary path for each row. JSON files that you import should follow these guidelines.

• For JSON arrays, the path for each row must specify the array root element twice, such as /incidents/incidents.
• JSON files should follow RFC-4627. For example, a single comma should separate a value from the following name. Names within an object should be unique.
• Predicates such as @element, [index], or text(), as well as Axis such as children, siblings, or ancestors are not supported.

Simple array

• Path for each row: /incidents/incidents
• Result: 2 records

In this example, the path for each row includes the array root node /incidents twice. This is necessary when importing an array.

```json
{
    "source":"HI",
    "incidents": [
        {
            "number":"INC0000001",
            "short_description":"Can't read email"
        }
    ],
```
Array in 2nd level

- Path for each row: `/problems/data/data`
- Result: 4 records

In this example, the path for each row includes the array root node `/data` twice.

```json
{
  "problems":{
    "id":0,
    "data":[
      {
        "number":"PRBTEST001",
        "short_description":"testsd1"
      },
      {
        "number":"PRBTEST002",
        "short_description":"testsd2"
      },
      {
        "number":"PRBTEST003",
        "short_description":"testsd3"
      }
    ]
  }
}
```

Nested array

- Path for each row: `/problems/problems/data/data`
- Result: 3 records

In this example, the path for each row includes the root nodes for both arrays twice, `/problems` and `/data`.

```json
{
  "problems": [ 
    { 
      "id":0,
      "data": [ 
        { 
          "number":"PRBTEST001",
          "short_description":"testsd1"
        },
        { 
          "number":"PRBTEST002",
          "short_description":"testsd2"
        },
        { 
          "number":"PRBTEST003",
          "short_description":"testsd3"
        }
      ]
    }
  ]
}
```
Supporting child (nested) arrays

By default, import does not support child (nested) arrays. You can enable support by unchecking the **Discard Arrays** check box in the Data Source view. The following table describes different behaviors when enabling and disabling child array support.

```json
{
    "response":{
        "docs":[
            {
                "id":"id_val",
                "childrenArray":[1,2,3],
                "anotherArray":[{"key1":"value1"}, {"key1": "value2"}],
                "elementWithArray":{"childrenArray":[1,2,3]}
            }
        ]
    }
}
```

<table>
<thead>
<tr>
<th>Path</th>
<th>Discard Arrays Enabled</th>
<th>Discard Arrays Disabled</th>
</tr>
</thead>
<tbody>
<tr>
<td>/response/docs/docs</td>
<td>Creates one record with the following columns and values:</td>
<td>Creates one record with the following columns and values:</td>
</tr>
<tr>
<td></td>
<td>- Id : id_val</td>
<td>- Id : id_val</td>
</tr>
<tr>
<td></td>
<td>- elementWithArray : {}</td>
<td>- childrenArray : [1, 2, 3]</td>
</tr>
<tr>
<td></td>
<td>Any arrays found in a record, such as childrenArray or anotherArray, are not created as columns in the import table.</td>
<td>anotherArray : [{&quot;key1&quot;: &quot;value1&quot;}, {&quot;key1&quot;: &quot;value2&quot;}]</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- elementWithArray : {}</td>
</tr>
<tr>
<td>/response/docs/docs/anotherArray/anotherArray</td>
<td>Creates two records, each with one column: key1.</td>
<td>Creates two records, each with one column: key1.</td>
</tr>
<tr>
<td>/response/docs/docs/childrenArray/childrenArray</td>
<td>Does not work and returns a Path should always refer JSON Objects error because the values in the array are not in a key-value structure.</td>
<td>Does not work and returns a Path should always refer JSON Objects error because the values in the array are not in a key-value structure.</td>
</tr>
</tbody>
</table>
Orphan array

**Important:** This format is supported. A JSON array must always be inside an element. The JSON file must always start with `{` and end with `}`.

```
{
  "number":"PRBTEST001",
  "short_description":"tests1"
},
{
  "number":"PRBTEST002",
  "short_description":"tests2"
}
```

Multiple elements instead of an array

- Path for each row: `/problems/problem`
- Result: 3 records

**Important:** This format is not recommended. JSON files should follow RFC-4627, which states that names within an object should be unique. Use JSON arrays instead.

```
{
  "problems":{
    "title":"2 problems",
    "problem":{
      "number":"PRBTEST001",
      "short_description":"tests1"
    },
    "problem":{
      "number":"PRBTEST002",
      "short_description":"tests2"
    }
  },
  "problems":{
    "title":"1 problem",
    "problem":{
      "number":"PRBTEST005",
      "short_description":"tests5"
    }
  }
}
```

FTP data source extended properties

Certain properties are available for customizing your FTP data source.

To enter these properties, you must configure the Data Source form and add the **Properties** field. When specifying more than one property, use a comma to separate each property.
**Available FTP Properties**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>connection.timeout</td>
<td>Defines the number of milliseconds to wait before timing out the FTP connection attempt.</td>
</tr>
<tr>
<td></td>
<td>• Default value: 10000</td>
</tr>
<tr>
<td></td>
<td>• Example custom value: connection.timeout=12000</td>
</tr>
<tr>
<td></td>
<td>• Data source: FTP, FTPS</td>
</tr>
<tr>
<td>remove_file</td>
<td>Determines if the remote file is deleted after the import.</td>
</tr>
<tr>
<td></td>
<td>• Default value: true</td>
</tr>
<tr>
<td></td>
<td>• Example custom value: remove_file=false</td>
</tr>
<tr>
<td></td>
<td>• Data source: FTP, FTPS, SFTP</td>
</tr>
<tr>
<td>rename_file</td>
<td>Determines if the remote file is renamed after the import.</td>
</tr>
<tr>
<td></td>
<td>• Default value: false</td>
</tr>
<tr>
<td></td>
<td>• Example custom value: rename_file=true</td>
</tr>
<tr>
<td></td>
<td>• Data source: FTP, FTPS, SFTP</td>
</tr>
</tbody>
</table>

**JDBC type data source**

A JDBC data source retrieves its data via a JDBC driver, usually type 4 network.

The JDBC connection is available either directly from the ServiceNow instance (a VPN setup required), or via a dedicated MID Server installed inside your firewall that can access the database port.

**Note:** JDBC calls from the MID Server are never encrypted. Limit the rights available to the MID Server user whenever making JDBC calls from a MID server.

**JDBC data source supported database formats**

JDBC data sources support several database formats and ports.

**Supported database formats**

<table>
<thead>
<tr>
<th>SQL Server Type</th>
<th>Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL</td>
<td>3306</td>
</tr>
<tr>
<td>Microsoft SQL Server</td>
<td>1433</td>
</tr>
<tr>
<td>Oracle</td>
<td>1521</td>
</tr>
</tbody>
</table>

**Note:** Oracle DATE fields are loaded as ServiceNow Date/Time fields.
### JDBC data source SQL statement requirements

JDBC queries that run SQL statements must specify a column name.

For example, this query specifies the column name `ServerID`.

```sql
SELECT DISTINCT 'server_name:' + CONVERT ( VARCHAR , lg .ResourceID ) AS 'ServerID'
  ,LastHWScan
  ,Account0
  ,Category0
FROM v_GS_WORKSTATION_STATUS sInner 
  JOIN v_GS_LocalGroupMembers0lg
  ON s .ResourceID  = lg .ResourceID
WHERE Type0  = 'Local' AND Category0  = 'SystemAccount'
```

### SQL server integrated authentication for Windows

A JDBC data source can use the ID of for the Windows MID Server service user to authenticate with SQL Server.

The **Use integrated authentication** check box on the Data Source form determines if the JDBC data source uses the MID Server service user credentials. For this field to appear on the Data Source form, the integration must meet these criteria:

- The MID Server must be running on a Windows computer with SQL Server.
- The MID Server service must use the same credentials that SQL Server requires.
- The data source **Type** is JDBC.
- The data source **Use MID Server** check box is selected.
- The data source **Format** is SQLServer.

**Important:** If integrated authentication is chosen, and you are integrating with Microsoft System Center Configuration Manager, the account running the MID Server service must have read rights on the SCCM database.
Data Source form

**Note:** The Last run database field on the JDBC data source is case-sensitive for the SQL server.
Adding JDBC drivers for unsupported database formats

Use the following procedure to extend the data source to use a driver for a database that is not provided in the base system. JDBC connections are supported for the following default databases:

Add a new JDBC format choice

Extend the available JDBC driver options by creating a new choice list entry to specify the JDBC driver Java package name.

Role required: import_admin

Add a new choice list entry for the new database to the Format field in the sys_data_source table.

1. Navigate to System Import Sets > Administration > Data Sources.
2. Click New.
3. In the Data Sources form, right-click the Format field label, and select Show Choice List from the pop-up menu.

![Image of Data Source form with Format field expanded]
4. Click **New** in the list of choices.

5. Provide the following values to create the new database choice. Look at the existing drivers for examples.

   - **Table**: `sys_data_source`
   - **Label**: Database name that appears as an option in the **Format** choice list, for example: **Teradata**.
   - **Value**: Package name and class of the driver. For example, the value for TeraData is `com.ncr.teradata.TeraDriver`.

   **Note**: The driver package and class must be provided by the driver vendor. This information is often available in the vendor’s documentation, such as for MariaDB or Teradata.

   - **Dependent value**: JDBC

6. Click **Submit**.

The new data source now appears in the list of available JDBC formats.

**Add Sybase or DB2 JDBC format choices**

Extend the available JDBC driver options by activating the Sybase or DB2 choices.

Roles required: admin

**Important**: To use Sybase or DB2 JDBC drivers, you must manually install the driver JAR file on a MID server. Refer to KB0551236 for more information.

Activate the Sybase or DB2 JDBC drivers to connect with those database formats through a MID server. This procedure assumes you are using the following Sybase or DB2 drivers:

**Drivers**

<table>
<thead>
<tr>
<th>Format</th>
<th>Driver</th>
<th>Driver class</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sybase</td>
<td>jconnect-jdbc</td>
<td>com.sybase.jdbc3.jdbc.SybDriver</td>
</tr>
<tr>
<td>DB2</td>
<td>db2jcc</td>
<td>com.ibm.db2.jcc.DB2Driver</td>
</tr>
</tbody>
</table>
If you are using a different implementation of the Sybase or DB2 driver, you must modify the choice Value to use the driver class from your driver implementation.

1. Navigate to System Import Sets > Administration > Data Sources.
2. Click New.
3. In the Type field, select JDBC.
4. Right-click the Format field label, and select Configure Choices from the pop-up menu.
5. Move the Sybase or DB2 Universal choices from the Available column to the Selected column.
6. Click Save.

The new data source now appears in the list of available JDBC formats.

Install a driver on a MID Server
You can install a new JDBC driver JAR file to a MID server to access database formats that are not supported by default.

Role required: agent_admin

1. Navigate to MID Server > JAR Files.
2. Click New.
3. Complete the following fields:
   • Name: A unique and descriptive name for identifying the file in the instance.
   • Version: A version number for the file, if one is available.
   • Source: Location of the JAR file for reference purposes. Source information is not used by the system.
   • Description: Short description of the JAR file and its purpose in the instance.
4. Click the paper clip icon in the banner and attach the JAR file to the record.
5. Click Submit.
6. Restart the MID Server service.

The platform makes the JAR file available to any MID Server configured to communicate with the instance.

Create a new JDBC data source for an unsupported database format
Add a new JDBC data source by defining a data source record.

Role required: import_admin

1. Navigate to System Import Sets > Administration > Data Sources and click New.
2. In the Data Source form, select JDBC from the list in the Type field.
3. Select the new data source from the choice list in the **Format** field.

4. Configure the form and add the **Connection URL** field.
5. Provide the connection URL to the JDBC data source, and then click **Submit**.

No other connection information is required.
LDAP type data source

An LDAP data source is automatically created when you configure your instance to integrate with LDAP.

Processing a large LDAP request without paging

When an LDAP server does not support paging, a large request is automatically broken into multiple smaller requests. This process is known as "nibbling" the LDAP request. The large request is broken into multiple smaller requests based on the value of the Query field in the LDAP OU definition. This field should specify a unique value such as email address or user ID.

For example, the following LDAP query might return more than 1000 records.

```
(&(objectclass=user)(sn=*))
```

In this example, the LDAP server Query field is preferredIdentity. The instance then splits the large request into multiple smaller requests, grouping records based on the preferredIdentity value.

```
(&((&((preferredIdentity>=0)(preferredIdentity<=1))))(&(objectclass=user)(sn=*)))
(&((&((preferredIdentity>=1)(preferredIdentity<=2))))(&(objectclass=user)(sn=*)))
(&((&((preferredIdentity>=2)(preferredIdentity<=3))))(&(objectclass=user)(sn=*)))

...
(&((&((preferredIdentity>=9)(preferredIdentity<=a))))(&(objectclass=user)(sn=*)))
(&((&((preferredIdentity>=a)(preferredIdentity<=b))))(&(objectclass=user)(sn=*)))
(&((&((preferredIdentity>=b)(preferredIdentity<=c))))(&(objectclass=user)(sn=*)))
```

Data Stream (IntegrationHub) data source

Enable platform Data Sources to load data from IntegrationHub Data Stream actions.

A Data Stream is a stream of response data larger than 10 MB or data that returns paginated results. Successful execution of the Data Stream action returns a complex data output stream that the Data Source consumes. For more information, see Data Stream actions and pagination.
Complex data allows you to encode and store structured data in a machine-readable format. Based on Data Source configuration, complex objects can be either flattened into an import table or serialized completely as JSON data into a single column.

Complex data includes parent and child objects and nested objects, as shown in the following example:

For more information, see Complex data.

**Custom (Load by Script) type data source**

Write a custom script to store any type of incoming data in the import set table.

When you select a Type of **Custom (Load by Script)**, a Javascript field called **Data Loader** appears. You can use the data loader script to fetch data and insert it into the import set table using the **import_set_table** input parameter. Data may be obtained, for example, from a REST API or a file attachment.
The data loader script has one input parameter, `import_set_table`, and the following methods:

- **addColumn**: Adds a string type column to the import set table.
- **addJSONColumn**: Adds a JSON type column to the import set table.
- **addXMLColumn**: Adds an XML type column to the import set table.
- **insert**: Inserts a map (key = column name, value = column value) in the import set table.
- **getMaximumRows()**: Returns 20 when the user clicks **Test load 20 records**. In every other case, returns -1.

As you type the script, script auto-complete presents the choices available to you, as shown in this example:

---

**Create a data source**

Create a data source record to define what data an import set should import.

Depending on the type of data source you want to create, see the following topics for procedures.

*Create a File type data source*

Create a **File** type data source record to define what data an import set should import.

Role required: import_admin

For additional information, see [File type data sources](#).

1. Navigate to **System Import Sets > Administration > Data Sources**.
2. Click **New**.
3. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name for this data source.</td>
</tr>
<tr>
<td>Import set table label</td>
<td>A label for the import set staging table to use.</td>
</tr>
<tr>
<td>Import set table name</td>
<td>The label you entered to construct a unique table name. This prevents namespace collision with an already existing table.</td>
</tr>
<tr>
<td>Type</td>
<td><strong>File.</strong></td>
</tr>
<tr>
<td>Format</td>
<td>Only the default XML-based file format (.xlsx) is supported, unless saved as &quot;Strict Open XML Document.&quot;</td>
</tr>
<tr>
<td>Zipped</td>
<td>Selected if the import file is compressed.</td>
</tr>
<tr>
<td>Use Batch Import</td>
<td>If selected, specifies that loading data should be batched when you click <strong>Load data</strong> or <strong>Test load 20 records</strong>.</td>
</tr>
<tr>
<td>Batch Size</td>
<td>Specifies how big the batches should be. Appears only when the <strong>Use Batch Import</strong> field is selected.</td>
</tr>
<tr>
<td></td>
<td>The <strong>glide.import_set_load_usebatch</strong> and <strong>glide.import_set_load_batch_size</strong> properties affect these fields. The priority order for the properties and fields are as follows: If the property is set, use the property value. If not, use the field value. If neither property is set, use the default batch size of 1000.</td>
</tr>
<tr>
<td></td>
<td>• For example, if <strong>glide.import_set_load_usebatch</strong> = <strong>true</strong> and <strong>glide.import_set_load_batch_size</strong> = <strong>200</strong>, use 200 as the batch size, regardless of the field values.</td>
</tr>
<tr>
<td></td>
<td>• For example, if <strong>glide.import_set_load_usebatch</strong> = <strong>true</strong> and the <strong>glide.import_set_load_batch_size</strong> property is not set, use the default batch size of 1000.</td>
</tr>
<tr>
<td></td>
<td>• For example, if the <strong>glide.import_set_load_usebatch</strong> property is not set and the <strong>Use Batch Import</strong> field = <strong>true</strong>, use the <strong>Batch Size</strong> field value (or the default of 1000 if the <strong>Batch Size</strong> field value is not set)</td>
</tr>
<tr>
<td></td>
<td>• For example, if the <strong>glide.import_set_load_usebatch</strong> property = <strong>false</strong> and the <strong>Use Batch Import</strong> field = <strong>true</strong>, do not use batch import, since the property is set to false.</td>

<tr>
<td>Discard Arrays</td>
<td>Selected to discard JSON arrays as a value. Unselected to serialize JSON arrays as a value.</td>
</tr>
<tr>
<td>Expand node children</td>
<td>Selected if child elements of the XML node or JSON object should be converted into additional columns. Unselected if the parent column value should be an XML or JSON fragment. For JSON, note that selecting this option expands objects only, not arrays. For nested array support, see Importing JSON files.</td>
</tr>
<tr>
<td>Data in single column</td>
<td>Selected to store data in a single column.</td>
</tr>
<tr>
<td>Xpath for each row</td>
<td>XPath expression that selects the nodes which become rows in the import table. The children of the selected nodes will become the columns in the rows.</td>
</tr>
</tbody>
</table>
### Field | Description
--- | ---
SCP authentication method | Choice to authenticate with a username and password or with a public key.

**Note:** You cannot authenticate to data sources with a public-private key pair. Use a username and password authentication instead.

Server | Name of the server from which the tables will be imported.
Port | Port to use to connect to the specified server. This field appears if you select HTTP or HTTPS as the file retrieval method.
Username | User name for authentication on the JDBC server.
Password | Password for authentication on the JDBC server.
Private keyfile | Keyfile when using legacy SCP public-private keyfiles.

**Note:**
- You cannot authenticate to data sources with a public-private key pair. Use username and password authentication instead.
- Do not use this legacy option. Although it is available for use, it is not supported.

System keystore | Selected to validate the certificate from the FTPS server against all saved certificates. This certificate may be any type supported by the instance. If not selected, the instance uses the Java default certificate to validate the FTPS server. This field is available only for data sources with a **File retrieval method** value of **FTPS**. All FTPS file retrieval methods are supported, including Auth TLS, Auth SSL, Implicit SSL, and Implicit TLS.

4. Click **Submit**.

Define a transform map for the new data source and run an import.

*Create a JDBC type data source*

Create a **JDBC** type data source record to define what data an import set should import.

Role required: import_admin

For additional information, see **JDBC type data source**.

1. Navigate to **System Import Sets > Administration > Data Sources**.
2. Click **New**.
3. Complete the form.

<table>
<thead>
<tr>

</tbody>
</table>

4. Click Submit.

Define a transform map for the new data source and run an import.

Define action properties
Create and configure a Data Source request action in IntegrationHub. After the request action is published in IntegrationHub, you can choose it as a Request action in the Data Source record.

Role required: import_admin

1. Navigate to System Import Sets > Administration > Data Sources.
2. Select New.
3. Select a **Type** of **REST** *(IntegrationHub)*.
4. Click the link under **Request action**.
5. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the request action.</td>
</tr>
<tr>
<td>Accessible From</td>
<td>Scope from which the request action is accessible.</td>
</tr>
<tr>
<td>Category</td>
<td>Category of the request action.</td>
</tr>
<tr>
<td>Protection</td>
<td>Specifies whether the request action is read-only.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the request action.</td>
</tr>
<tr>
<td>Application</td>
<td>Scope of the application.</td>
</tr>
<tr>
<td>In-Flow Annotation</td>
<td>Text you want to appear under the <strong>Action</strong> title on the Data Source Request Action page.</td>
</tr>
</tbody>
</table>

6. Click **Submit**.
7. The Data Source Request Action page appears with the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limit</td>
<td>Limit set by the user in the REST <em>(IntegrationHub)</em> data source record. If the REST API supports pagination and <strong>Support pagination</strong> is selected in the Data Source record, you must supply this input to your REST step.</td>
</tr>
<tr>
<td>Offset</td>
<td>Offset set by user in the REST <em>(IntegrationHub)</em> data source record. If the REST API supports pagination and <strong>Support pagination</strong> is selected in the Data Source record, you must supply this input to your REST step.</td>
</tr>
<tr>
<td>Last Success Import Time</td>
<td>Last time data was successfully imported. A numeric value representing the number of milliseconds since January 1, 1970, 00:00:00 GMT. The data source populates this value. If the REST API supports queries based on time, you must supply this input to your REST step.</td>
</tr>
<tr>
<td>Import Start Time</td>
<td>Time the import is actually started. A numeric value representing the number of milliseconds since January 1, 1970, 00:00:00 GMT. The data source populates this value. If the REST API supports queries based on time, you must supply this input to your REST step.</td>
</tr>
</tbody>
</table>

8. If desired, you can add a Script step to validate or modify action inputs, set default values, or build request payloads before executing the REST step.
   a) Select **Data Source Request** from the Action Outline.
   b) Select **Enable Processing Script**.
   c) Select **Script step** from the Action Outline.
   d) Configure the Script step as described in **Script step**.

9. Select **REST step** from the Action Outline.
10. Configure the REST step as described in **REST step**.
11. Choose from the following:
   • Click **Properties** to return to the Action Properties window.
   • Click **Test** to test the request action before publishing it.
   • Click **Executions** to view the history of executions of the request action.
   • Click **Save** to save the request action.
   • Click **Publish** to publish the request action and make it available for use.

Create a Data Stream (IntegrationHub) type data source

Create a **Data Stream (IntegrationHub)** type data source record to define what complex data an import set should import from a Data Stream action.

Role required: import_admin and action_designer

1. Navigate to **System Import Sets > Administration > Data Sources**.
2. Click **New**.
3. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name for this data source.</td>
</tr>
<tr>
<td>Import set table label</td>
<td>A label for the import set staging table to use.</td>
</tr>
<tr>
<td>Import set table name</td>
<td>The uses the label you entered to construct a unique table name. This prevents namespace collision with an already existing table.</td>
</tr>
<tr>
<td>Type</td>
<td>Data Stream () type data source.</td>
</tr>
<tr>
<td>Data Stream action</td>
<td>• Selected to use an existing published Data Stream action from .</td>
</tr>
<tr>
<td></td>
<td>• Selected for one of the following reasons:</td>
</tr>
<tr>
<td>Data in single column</td>
<td>Selected to store data in a single column.</td>
</tr>
<tr>
<td>Use Batch Import</td>
<td>If selected, specifies that loading data should be batched when you click <strong>Load data</strong> or <strong>Test load 20 records</strong>.</td>
</tr>
</tbody>
</table>
### Field Description

**Batch Size**
- Specifies how big the batches should be. Appears only when the **Use Batch Import** field is selected.

The `glide.import_set.load.usebatch` and `glide.import_set.load.batch_size` properties affect these fields. The priority order for the properties and fields are as follows: If the property is set, use the property value. If not, use the field value. If neither property is set, use the default batch size of 1000.

- For example, if `glide.import_set.load.usebatch = true` and `glide.import_set.load.batch_size = 200`, use 200 as the batch size, regardless of the field values.
- For example, if `glide.import_set.load.usebatch = true` and the `glide.import_set.load.batch_size` property is not set, use the default batch size of 1000.
- For example, if the `glide.import_set.load.usebatch` property is not set and the **Use Batch Import** field = true, use the **Batch Size** field value (or the default of 1000 if the **Batch Size** field value is not set).
- For example, if the `glide.import_set.load.usebatch` property = false and the **Use Batch Import** field = true, do not use batch import, since the property is set to false.

---

**Data Stream action inputs**
- Additional fields may appear, based on the inputs defined in the **Data Stream action**.

### 4. Click **Submit**.

Define a transform map for the new data source and run an import.

*Create a Custom (Load by Script) type data source*

Create a **Custom (Load by Script)** type data source record to define what data an import set should import.

**Role required:** import_admin

For additional information, see **Custom (Load by Script) type data source**.

1. Navigate to **System Import Sets > Administration > Data Sources**.
2. Click **New**.
3. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name for this data source.</td>
</tr>
<tr>
<td>Import set table label</td>
<td>A label for the import set staging table to use.</td>
</tr>
<tr>
<td>Import set table name</td>
<td>The uses the label you entered to construct a unique table name. This prevents namespace collision with an already existing table.</td>
</tr>
<tr>
<td>Type</td>
<td><strong>Custom (Load by Script)</strong>.</td>
</tr>
</tbody>
</table>
### Field | Description
--- | ---
Use Batch Import | If selected, specifies that loading data should be batched when you click **Load data** or **Test load 20 records**.
Batch Size | Specifies how big the batches should be. Appears only when the **Use Batch Import** field is selected.

The `glide.import_set_load_usebatch` and `glide.import_set_load_batch_size` properties affect these fields. The priority order for the properties and fields are as follows: If the property is set, use the property value. If not, use the field value. If neither property is set, use the default batch size of 1000.

- For example, if `glide.import_set_load_usebatch = true` and `glide.import_set_load_batch_size = 200`, use 200 as the batch size, regardless of the field values.
- For example, if `glide.import_set_load_usebatch = true` and the `glide.import_set_load_batch_size` property is not set, use the default batch size of 1000.
- For example, if the `glide.import_set_load_usebatch` property is not set and the **Use Batch Import** field = true, use the **Batch Size** field value (or the default of 1000 if the **Batch Size** field value is not set)
- For example, if the `glide.import_set_load_usebatch` property = false and the **Use Batch Import** field = true, do not use batch import, since the property is set to false.

### Data Loader
Script used to load data. For more information, see [Custom (Load by Script) type data source](https:// servicenow.com).

4. Click **Submit**.

Define a transform map for the new data source and run an import.

### Data source fields
In addition to common fields, other fields appear on the data source form, depending on the value of the **Type** field.

### Common data source fields
These fields are common to all data sources.

<table>

**File type data source fields**

These additional fields appear on the data source form when the **Type** field value is **File**.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Format</td>
<td>Only the default XML-based file format (.xlsx) is supported, unless saved as “Strict Open XML Document.”</td>
</tr>
<tr>
<td>Zipped</td>
<td>Selected if the import file is compressed.</td>
</tr>
<tr>
<td>File retrieval method</td>
<td>The retrieval method for this file.</td>
</tr>
<tr>
<td>File path</td>
<td>The path to the file to import. You can include a system property value in this field using the format ${\text{system.property.name}}$. When the connection is made, the variable is replaced with the value of the specified property.</td>
</tr>
<tr>
<td></td>
<td>For example, you can specify the file path value <code>/countries.csv?key=${datasource.apikey}</code>. When the connection is made, the value of the <code>datasource.apikey</code> system property is passed as the value for the <code>key</code> parameter.</td>
</tr>
<tr>
<td>CSV delimiter</td>
<td>The delimiter character for the CSV file.</td>
</tr>
<tr>
<td>Parsing script</td>
<td>The script used to parse a single line of input. As you type the script, script auto-complete presents the choices available to you. For more information, see File type data sources.</td>
</tr>
<tr>
<td>Sheet number</td>
<td>The Excel sheet number to load data.</td>
</tr>
<tr>
<td>Header row</td>
<td>The Excel sheet number to load the column labels.</td>
</tr>
<tr>
<td>Path for each row</td>
<td>The path expression used to select JSON objects, which will become rows in the import set table. The path should be // for JSON objects.</td>
</tr>
<tr>
<td>Discard Arrays</td>
<td>Selected to discard JSON arrays as a value. Unselected to serialize JSON arrays as a value.</td>
</tr>
<tr>
<td>Expand node children</td>
<td>Selected if child elements of the XML node or JSON object should be converted into additional columns. Unselected if the parent column value should be an XML or JSON fragment. For JSON, note that selecting this option expands objects only, not arrays. For nested array support, see Importing JSON files.</td>
</tr>
<tr>
<td>Data in single column</td>
<td>Selected to store data in a single column.</td>
</tr>
<tr>
<td>Xpath for each row</td>
<td>XPath expression that selects the nodes which become rows in the import table. The children of the selected nodes will become the columns in the rows.</td>

</tbody>
</table>
| SCP authentication method   | Choice to authenticate with a username and password or with a public key.  
|                             | **Note:** You cannot authenticate to data sources with a public-private key pair. Use a username and password authentication instead.         |
| Server                      | Name of the server from which the tables will be imported.  
| Port                        | Port to use to connect to the specified server. This field appears if you select HTTP or HTTPS as the file retrieval method.                    |
| Username                    | User name for authentication on the JDBC server.                                                                                                                                                      |
| Password                    | Password for authentication on the JDBC server.                                                                                                                                                       |
| Private keyfile             | Keyfile when using legacy SCP public-private keyfiles.  
|                             | **Note:**  
|                             | • You cannot authenticate to data sources with a public-private key pair. Use username and password authentication instead.  
| System keystore             | Selected to validate the certificate from the FTPS server against all saved certificates. This certificate may be any type supported by the instance. If not selected, the instance uses the Java default certificate to validate the FTPS server. This field is available only for data sources with a File retrieval method value of FTPS. All FTPS file retrieval methods are supported, including Auth TLS, Auth SSL, Implicit SSL, and Implicit TLS. |

### JDBC type data source fields

These additional fields appear on the data source form when the **Type** field value is **JDBC**.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use MID Server</td>
<td>MID Server to use to connect to this data source.</td>
</tr>
<tr>
<td>Format</td>
<td>One of the following formats: MySQL, Oracle, or SQLServer.</td>
</tr>
<tr>
<td>Instance name</td>
<td>Used to support dynamic port connectivity with SQL Server. To ensure connectivity, provide the instance name for a SQL Server that receives a new port number dynamically after each reboot. This field only appears when SQLServer is selected as a data source format.</td>
</tr>
<tr>
<td>Database name</td>
<td>Name of the database instance.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Database port</td>
<td>Port number for the database. Leave this field empty when using dynamic port connectivity with SQL Server.</td>
</tr>
<tr>
<td>Use integrated</td>
<td>Selected to allow the JDBC connection to use the ID of the user configured for the Windows MID Server service for SQL Server authentication. For additional details, see JDBC type data source.</td>
</tr>
<tr>
<td>authentication</td>
<td></td>
</tr>
<tr>
<td>Username</td>
<td>User name for authentication on the JDBC server.</td>
</tr>
<tr>
<td>Password</td>
<td>Password for authentication on the JDBC server.</td>
</tr>
<tr>
<td>Server</td>
<td>Name of the server from which the tables will be imported.</td>
</tr>
<tr>
<td>Query</td>
<td>Type of query to run: <strong>All rows from Table</strong> or <strong>Specific SQL</strong>. If you select to run a SQL statement, the SQL statement field appears.</td>
</tr>
<tr>
<td>Query timeout</td>
<td>Number of seconds the JDBC driver will wait for a query (SELECT) to complete. Zero (0) means no timeout. If timeout is exceeded, the integration considers the JDBC result inaccessible and places it in an error state.</td>
</tr>
<tr>
<td>Connection timeout</td>
<td>Number of seconds before MID Server connection cache pool closes and removes it from the pool. Zero (0) means no timeout.</td>
</tr>
<tr>
<td>Table name</td>
<td>Name of the table from which the data is being exported.</td>
</tr>
<tr>
<td>SQL statement</td>
<td>SQL statement to extract the desired data from the database.</td>
</tr>
<tr>
<td>Use last run</td>
<td>Controls the amount of data that is retrieved from a database during an import run. If unselected, then all rows in the table specified are imported, every time. You might want to use this setting if this is a one-time import, or if all the data in the target table is new. If selected, two additional fields appear, enabling you to select a datetime value to limit imported data to delta values only.</td>
</tr>
<tr>
<td>datetime</td>
<td></td>
</tr>
<tr>
<td>Last run datetime</td>
<td>The datetime value in this field is automatically populated from the database field you select below and represents the latest value from the previous run. This value acts as a dynamic filter to restrict the number of records retrieved to those records that have changed since the data source's last runtime.</td>
</tr>
<tr>
<td>Last run database</td>
<td>Field name from the source table that will be used as the filter in the next run. This value may need to be case sensitive, depending on the target database type.</td>
</tr>
<tr>
<td>Additional Database</td>
<td>Optional parameters to add to the end of the URL generated for this data source. Semicolon-separated list of parameters. You may need to configure the form to view this field.</td>
</tr>
<tr>
<td>Parameters</td>
<td></td>
</tr>
</tbody>
</table>

**LDAP type data source field**

This additional field appears on the data source form when the **Type** field value is **LDAP**.
### OIDC type data source field

This additional field appears on the data source form when the Type field value is **OIDC**.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Format</td>
<td>Defaults to <strong>-- None --</strong> and can’t be changed.</td>
</tr>
</tbody>
</table>

### REST (IntegrationHub) type data source fields

These additional fields appear on the data source form when the Type field value is **REST (IntegrationHub)**.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Format</td>
<td>One of the following formats: Custom (Parse by Script), JSON, or XML.</td>
</tr>
<tr>
<td>Request action</td>
<td>Data source request action that will be invoked to get data. You can choose only published request actions. Click the link in the dialog box below to create/configure a new Data Source request action in . After the request action is published in , you can choose it as a Request action in the Data Source record. For more information, see Define action properties.</td>
</tr>
<tr>
<td>Support pagination</td>
<td>Selected to enable pagination for the request action. Pagination helps you reduce processing overhead by processing a specified number of records at a time, instead of processing all records at once.</td>
</tr>
<tr>
<td>Limit</td>
<td>Maximum number of records per page. For example, to process 50 records at a time, enter a Limit of 50.</td>
</tr>
<tr>
<td>Offset</td>
<td>The initial offset used for pagination. The offset is the starting record number. For example, to process 50 records at a time, starting with the first record, enter a Limit of 50 and an Offset of 0.</td>
</tr>
<tr>
<td>Parsing script</td>
<td>The script used to parse a single line of input. As you type the script, script auto-complete presents the choices available to you. For more information, see File type data sources.</td>
</tr>
<tr>
<td>Path for each row</td>
<td>The path expression used to select JSON objects, which will become rows in the import set table. The path should be / / for JSON objects.</td>
</tr>
<tr>
<td>Discard Arrays</td>
<td>Selected to discard JSON arrays as a value. Unselected to serialize JSON arrays as a value.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Expand node children</td>
<td>Selected if child elements of the XML node or JSON object should be converted into additional columns. Unselected if the parent column value should be an XML or JSON fragment. For JSON, note that selecting this option expands objects only, not arrays. For nested array support, see Importing JSON files.</td>
</tr>
<tr>
<td>Data in single column</td>
<td>Selected to store data in a single column.</td>
</tr>
<tr>
<td>Xpath for each row</td>
<td>XPath expression that selects the nodes which become rows in the import table. The children of the selected nodes will become the columns in the rows.</td>
</tr>
</tbody>
</table>

### Data Stream (IntegrationHub) type data source fields

These additional fields appear on the data source form when the **Type** field value is **Data Stream (IntegrationHub)**.

<table>
<thead>
<tr>

<td>Data Stream () type data source.</td>
</tr>
</tbody>
</table>
| Data Stream action  | • ![Search icon](image)  
Selected to use an existing published Data Stream action from .  
• ![Arrow icon](image)  
Selected for one of the following reasons:  
• If you select a published Data Stream action, click this button to open the Data Stream action in .  
• If you don't select a Data Stream action, click this button to create and publish a new Data Stream action in .  

**Note:** Data Stream actions require a subscription for production use.  

| Data in single column | Selected to store data in a single column.                                                                                                                                                                                                                                                                                                   |
| Data Stream action inputs | Additional fields may appear, based on the inputs defined in the Data Stream action.                                                                                                                                                                                                                                               |

### Custom (Load by Script) type data source field

This additional field appears on the data source form when the **Type** field value is **Custom (Load by Script)**.
### Transform maps

A transform map is a set of field maps that determine the relationships between fields in an import set and fields in an existing ServiceNow table, such as Incident [incident] or User [sys_user].

![Diagram of transform maps and data sources](image)

#### Import process transform

After creating a transform map, you can reuse it to map data from another import set to the same table. The Transform Maps module enables an administrator to define destinations for imported data on any tables. Transform mapping can be as simple as a drag and drop operation to specify linking between source fields on an import set table and destination fields on any table. Use transform mapping to map source and destination fields dynamically.
Transform considerations

**Auto-mapping**

Double-check that fields the system maps automatically are actually required. For example, encrypted passwords probably should not be mapped.

**Mapping reference fields**

If you are mapping reference field data and the sys_id does not exist, the sys_id could potentially appear in the target record as the DisplayValue, and this may be undesirable.

Field mapping a large number of reference fields incurs additional performance overhead because the system checks that the referenced sys_id actually exists before performing choice actions at the field level.

**Note:** You can bypass the performance overhead using transform scripts such as onBefore (on the assumption that there is no requirement to validate the import of reference fields). For example, `target.<field_name> = source.<field_name>.

Using multiple transform maps

Multiple transform maps can be applied to a single data source.

One import set row is created per transform map, which can cause a large number of temporary records to be generated.

**Note:** If you use multiple transform maps for the same import set, the transform creates multiple entries in the import set table.

Run multiple transforms off a single import set

Users can select multiple transform maps during data import.

The selected transform maps will be executed on the same import set in the order specified.
Multi-map transform

Transform map scripts

Transform Map scripts allow you to customize import operations using a robust programming interface to introduce advanced logic.

A transform map script executes as events occur while an import set is being transformed onto a ServiceNow table. Transform Map scripting is fully integrated into the ServiceNow scripting environment. There are two types of Transform Map scripts:

- Explicit Transform Map scripts, which explicitly define mapping relationships
- Transformation Event scripts, which modify the processing of events at different stages of a transformation

Transformation script variables

Multiple variables can be used to define explicit mapping relationships in a transform map script.

Variable name: source

Type: GlideRecord object

Description: Contains the import source record currently being transformed. Specify a specific field from the source record as an object property.

Example:

```javascript
var x = source.incident_state;
```
**Variable name: target**

**Type:** GlideRecord object

**Description:** Contains the import target record currently being inserted. Specify a specific field from the target record as an object property.

**Example:**

```java
target.incident_state = "active";
```

**Variable name: map**

**Type:** GlideRecord object

**Description:** Contains the transformation map record currently being used for the transformation process. Specify a specific field from the transform map record with one of these properties.

- `name`
- `sys_id`
- `source_table`
- `target_table`
- `order`

**Example:**

```java
var x = map.order;
```

**Variable name: log**

**Type:** Function

**Description:** Log information about the current import process. Each log level has its own method.

**Example:**

```java
log.info("This is an information message");
log.warn("This is a warning message");
log.error("This is an error message");
```

**Variable name: action**

**Type:** Function

**Description:** Specify the transformation action occurring on the target record. This value can be either “insert” or “update”.

**Example:**

```java
if(action == "insert"){
    ignore = true;
}
```

**Variable name: ignore**

**Type:** Boolean

**Description:** When set to true, skips or aborts the current import action. In onStart scripts, this variable aborts the entire transformation process. In onBefore scripts, this variable only skips the current row being transformed.
Example:

```java
if(source.u_user_name.nil()){
    ignore = true;
}
```

**Variable name: error**

**Type:** Boolean

**Description:** When set to true, aborts the current import action and logs an error message in the Import Set Log.

**Example:**

```java
if(source.name=="no_trantform"){
    error = true;
}
```

**Variable name: error_message**

**Type:** String (output message)

**Description:** When an error occurs, adds the specified error message to SOAP response.

**Example:**

```java
if(source.name=="no_trantform"){
    error = true;
    error_message = "Source is not intended for transformation";
}
```

**Variable name: status_message**

**Type:** String (output message)

**Description:** Adds the specified status message to SOAP response.

**Example:**

```java
if(action =="insert"){
    status_message = "Inserting record";
}
```

**Map with explicit transform map scripts**

Explicitly define mapping relationships in the Transform Map record itself.

An explicit Transform Map script explicitly defines mapping relationships in the Transform Map record itself. It runs after the source field values have been copied over to the target record, and before they are written to the database.

**CMDB software import facilitated by explicit mapping script**

An example demonstrating how explicit map scripting can be used to facilitate an import of software instances to the CMDB where it is necessary to have the count in the software packages table reflect the number of instances.

In the CMDB there exist tables for software packages and software instances. A software package refers to a one individual software title, such as Mozilla Firefox. A software instance refers to an individual instance of a software title such as Mozilla Firefox on Jared_T60_Laptop.
In more technical terms a software instance is a many-to-many relationship with a software package and a configuration item. This script imports software instances. In doing so it checks to see if a software package for the instance exists. If the software package doesn't exist then it is created and the sys_id for the newly created package is associated with the instance via the instance record's Software field.

```javascript
//First we will initialize some temporary variables, referencing values from the Import Set table source that will be used to reference software package records and create them if necessary.

var name= source.u_name;
var version = source.u_version;
var sid ="";

//Next we will perform a glide query on the software package table (Note: The target table for the import is software instances)
var sgr =new GlideRecord("cmdb_ci_spkg");

//Here we are building our query to search for software packages where the name and version of the package matches the name and version of the instance being imported
sgr.addQuery("name",name);
sgr.addQuery("version", version);
sgr.query();

//Now if a software package with the correct name and version are found then we record the sys_id of the package record otherwise we create the package and then record the sys_id
if(sgr.next()){
    sid = sgr.sys_id;}
else {// create it
    sgr.initialize();
    sgr.newRecord();
    sgr.name=name;
    sgr.version= version;
    sid = sgr.insert();

//Here we make an entry in System Import Set Log saying that we had to create a software package
log.info("Created new spkg: "+name+ " - "+ version);}

//Finally we set the reference field on our software instance record to the sys_id we have recorded for the software package. In doing so we are also relating the software package with the instance and so the count, which keeps track of the number of instances associated with a package, will automatically be incremented.
target.software= sid;
```

**Populating child tables by setting class names in an import to the CMDB**

An example demonstrating how to import servers into the configuration management database.

The destination table for the import is the cmdb_ci_servers table.

```javascript
var operating_system = source.u_operating_system.toString();

//This if statement uses JavaScript regular expressions to search the operating system
```

User import data sanitation

An example script demonstrating how to sanitize user data before import.

```javascript
//Note: The field names referenced from an import set are
//prefixed with an "u_", also note that it is necessary to use the java
//method
//toString() to so that we can use JavaScript functions to
//manipulate the data.
var name= source.u_name.toString();

//Use native JavaScript function split to create an array for each word in
//the name "splitting" it
//anywhere that there is a space
var split_names =name.split(" ");

//Find the number of of names (i.e., first and last name only, or first
//middle and last name, etc.)
var num_names = split_names.length;

// If there is only one name then map it to the last name field in the user
//table
if(num_names ==1){
target.last_name= split_names[0];}

//if there are two names then map the first one to first name and the last
//one to last name
if(num_names ==2){
target.first_name= split_names[0];
target.last_name= split_names[1];}

//if there are more than 3 names then all middle names get combined into one
//middle name this is done
//by shifting off the first name (array element 0 ) and mapping to first
//name and popping off the last
// name and returning it to the last name field
if(num_names >=3){
target.first_name= split_names.shift();
target.last_name= split_names.pop();
target.middle_name= split_names.join(" ");}
```

Map with transformation event scripts

Transformation events occur during the process of transforming an import set table onto a table.

These events modify the transformation behavior from any type of mapping specification. Transformation Event
scripts modify the processing of the events at various stages of the transformation.

For example, the processing of a mapping operation defined using the Mapping Assist Utility can be manipulated
using the event scripts. There are a number of import set JavaScript objects that are accessible during these events.
These objects represent tables or portions of tables. It is important to note that what these objects refer to varies
depending on the context of the event in which they are referenced.

The following is a table of all of the transform events and their contextual variables:
transform events and their contextual variables

<table>
<thead>
<tr>
<th>Event name</th>
<th>Event Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>onStart</td>
<td>When: The onStart event script is processed at the start of an import run, before any data rows are read.</td>
</tr>
</tbody>
</table>

**Import Set JS objects available to be referenced and their context in the onStart event**

<table>
<thead>
<tr>
<th>Import Set JS object</th>
<th>Type</th>
<th>Context in the onStart import set event</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>GlideRecord</td>
<td>The first row of the source table, there is no data yet since the row has not been read.</td>
</tr>
<tr>
<td>import_set</td>
<td>GlideRecord</td>
<td>The import set that is currently being transformed.</td>
</tr>
<tr>
<td>map</td>
<td>GlideTransformMap</td>
<td>Read-only information about the current transform map record.</td>
</tr>
<tr>
<td>log</td>
<td>Function</td>
<td>The log object for the current import run. For example, log.info(...), log.warn(...), log.error(...).</td>
</tr>
<tr>
<td>ignore</td>
<td>Boolean</td>
<td>When set to true, the entire transformation will be stopped and no further processing will occur.</td>
</tr>
<tr>
<td>error</td>
<td>Boolean</td>
<td>When set to true, has the same effect as the ignore flag of stopping the entire transformation, with an error message.</td>
</tr>
</tbody>
</table>

Example:

```javascript
var info = "Starting Import Set Transformation Mapping operation using Data source, " + map.table_source + " and Transform Map " + map.name + " on import set " + import_set.number;
log.info(info);
```
Event name | Event Parameters
---|---
oneComplete

When: The onComplete event script is processed at the end of an import run, after all data rows are read and transformed.

**Import Set JS objects available to be referenced and their context in the onComplete event**

<table>
<thead>
<tr>
<th>Import Set JS object</th>
<th>Type</th>
<th>Context in the onComplete import set event</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>GlideRecord</td>
<td>The last row of the source import set table.</td>
</tr>
<tr>
<td>target</td>
<td>GlideRecord</td>
<td>The last row of target table.</td>
</tr>
<tr>
<td>import_set</td>
<td>GlideRecord</td>
<td>The import set that is currently being transformed.</td>
</tr>
<tr>
<td>map</td>
<td>GlideTransformMap</td>
<td>Read-only information about the current transform map record.</td>
</tr>
<tr>
<td>log</td>
<td>Function</td>
<td>The log object for the current import run. For example, log.info(...), log.warn(...), log.error(...).</td>
</tr>
<tr>
<td>error</td>
<td>Boolean</td>
<td>When set to true, will mark the current import set status to error after it completes.</td>
</tr>
</tbody>
</table>

Example:

```javascript
// Create a myimport_completed event that can be reacted by an email notification or script action
// (there is already an import.finished event that the system will create at the end of an import)
var e = new GlideEvent("myimport_completed", import_set.sys_id, map.sys_id, "");
e.insert();
```
<table>
<thead>
<tr>
<th>Event name</th>
<th>Event Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>onBefore</td>
<td>When: The onBefore event script is processed at the start of a row transformation, before the source row is transformed into the target row.</td>
</tr>
</tbody>
</table>

**Import Set JS objects available to be referenced and their context in the onBefore event**

<table>
<thead>
<tr>
<th>Import Set JS object</th>
<th>Type</th>
<th>Context in the onBefore import set event</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>GlideRecord</td>
<td>The row of the source table that is currently being processed.</td>
</tr>
<tr>
<td>target</td>
<td>GlideRecord</td>
<td>The row of the target table that is currently being processed.</td>
</tr>
<tr>
<td>import_set</td>
<td>GlideRecord</td>
<td>The import set that is currently being transformed.</td>
</tr>
<tr>
<td>map</td>
<td>GlideTransformMap</td>
<td>Read-only information about the current transform map record.</td>
</tr>
<tr>
<td>log</td>
<td>Function</td>
<td>The log object for the current import run. For example, log.info(...), log.warn(...), log.error(...).</td>
</tr>
<tr>
<td>action</td>
<td>String</td>
<td>Action returns a value of either “insert” or “update” indicating whether the current target row is about to be created or updated.</td>
</tr>
<tr>
<td>ignore</td>
<td>Boolean</td>
<td>When set to true, the current row transformation will be skipped and the remaining rows will be processed.</td>
</tr>
<tr>
<td>Event name</td>
<td>Event Parameters</td>
<td></td>
</tr>
<tr>
<td>------------</td>
<td>------------------</td>
<td></td>
</tr>
<tr>
<td>onAfter</td>
<td>When: The onAfter event script is processed at the end of a row transformation, after the source row has been transformed into the target row and saved.</td>
<td></td>
</tr>
</tbody>
</table>

**Import Set JS objects available to be referenced and their context in the onAfter event**

<table>
<thead>
<tr>
<th>Import Set JS object</th>
<th>Type</th>
<th>Context in the onAfter import set event</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>GlideRecord</td>
<td>The row of the source table that is currently being processed.</td>
</tr>
<tr>
<td>target</td>
<td>GlideRecord</td>
<td>The row of the target table that is currently being processed.</td>
</tr>
<tr>
<td>import_set</td>
<td>GlideRecord</td>
<td>The import set that is currently being transformed.</td>
</tr>
<tr>
<td>map</td>
<td>GlideTransformMap</td>
<td>Read-only information about the current transform map record.</td>
</tr>
<tr>
<td>log</td>
<td>Function</td>
<td>The log object for the current import run. For example, log.info(...), log.warn(...), log.error(...).</td>
</tr>
<tr>
<td>action</td>
<td>String</td>
<td>Action returns a value of either &quot;insert&quot; or &quot;update&quot; indicating whether the current target row was created or updated.</td>
</tr>
<tr>
<td>status_message</td>
<td>String</td>
<td>Defines a custom message to be sent in the &lt;status_message&gt; XML response.</td>
</tr>
<tr>
<td>error</td>
<td>Boolean</td>
<td>When set to true, will halt the entire import process.</td>
</tr>
</tbody>
</table>
**Event name** | **Event Parameters**
--- | ---
onForeignInsert | When: The onForeignInsert event script is processed at the start of the creation of a related, referenced record, before the record is created.

*Import Set JS objects available to be referenced and their context in the onForeignInsert event*

<table>
<thead>
<tr>
<th>Import Set JS object</th>
<th>Type</th>
<th>Context in the onForeignInsert import set event</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>GlideRecord</td>
<td>The row of the source table that is currently being processed.</td>
</tr>
<tr>
<td>target</td>
<td>GlideRecord</td>
<td>The row of the target table that is currently being processed.</td>
</tr>
<tr>
<td>map</td>
<td>GlideTransformMap</td>
<td>Read-only information about the current transform map record.</td>
</tr>
<tr>
<td>log</td>
<td>Function</td>
<td>The log object for the current import run. For example, log.info(...), log.warn(...), log.error(...).</td>
</tr>
<tr>
<td>action</td>
<td>String</td>
<td>Action returns a value of either “insert” or “update” indicating whether the current target row is about to be created or updated.</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>Evaluates to the field name of the target record for which a foreign record that is about to be created.</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>Evaluates to the display value from the source record.</td>
</tr>
<tr>
<td>Event name</td>
<td>Event Parameters</td>
<td></td>
</tr>
<tr>
<td>----------------</td>
<td>------------------</td>
<td></td>
</tr>
<tr>
<td>onChoiceCreate</td>
<td>When: The onChoiceCreate event script is processed at the start of a choice value creation, before the new choice value is created.</td>
<td></td>
</tr>
</tbody>
</table>

**Import Set JS objects available to be referenced and their context in the onChoiceCreate event**

<table>
<thead>
<tr>
<th>Import Set JS object</th>
<th>Type</th>
<th>Context in the onChoiceCreate import set event</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>GlideRecord</td>
<td>The row of the source table that is currently being processed.</td>
</tr>
<tr>
<td>target</td>
<td>GlideRecord</td>
<td>The row of the target table that is currently being processed.</td>
</tr>
<tr>
<td>map</td>
<td>GlideTransformMap</td>
<td>Read-only information about the current transform map record.</td>
</tr>
<tr>
<td>log</td>
<td>Function</td>
<td>The log object for the current import run. For example, log.info(...), log.warn(...), log.error(...).</td>
</tr>
<tr>
<td>action</td>
<td>String</td>
<td>Action returns a value of either &quot;insert&quot; or &quot;update&quot; indicating whether the current target row is about to be created or updated.</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>Evaluates to the field name of the target record for which a choice value is about to be created.</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>Evaluates to the display value from the source record for which a choice value is about to be created.</td>
</tr>
<tr>
<td>ignore</td>
<td>Boolean</td>
<td>When set to true, ignores the creation of a choice value.</td>
</tr>
<tr>
<td>error</td>
<td>Boolean</td>
<td>When set to true, rejects the entire transformation row, no data is saved for this row.</td>
</tr>
</tbody>
</table>

Example:

```
//Create an event
var e = new GlideEvent("myimport_ChoiceCreate", action, value, 
"");
```
### Event name

onReject

### Event Parameters

When: The onReject event script is processed during the occurrence of a foreign record or choice creation, and the foreign record or choice is rejected, the entire transformation row is not saved.

**Import Set JS objects available to be referenced and their context in the onError event**

<table>
<thead>
<tr>
<th>Import Set JS object</th>
<th>Type</th>
<th>Context in the onError import set event</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>GlideRecord</td>
<td>The row of the source table that is currently being processed.</td>
</tr>
<tr>
<td>target</td>
<td>GlideRecord</td>
<td>The row of the target table that is currently being processed.</td>
</tr>
<tr>
<td>map</td>
<td>GlideTransformMap</td>
<td>Read-only information about the current transform map record.</td>
</tr>
<tr>
<td>action</td>
<td>String</td>
<td>Action returns a value of either &quot;insert&quot; or &quot;update&quot; indicating whether the current target row is about to be created or updated.</td>
</tr>
<tr>
<td>log</td>
<td>Function</td>
<td>The log object for the current import run. For example, log.info(...), log.warn(...), log.error(...).</td>
</tr>
</tbody>
</table>

**Example:**

```javascript
//Create an event
var e = new GlideEvent("myimport_onReject", action, ",", ");
e.insert();
```
Robust Import Set Transformers

Use robust import set transformers instead of transform maps if you want to extract, transform, and load data to one or more target tables.

Robust import set transformers versus transform maps

Transform maps define the mapping from imported data stored in a staging table to a single target table in the Now Platform. Transform maps also insert data into target tables, performing both transform and processing functions. You can define multiple table mappings with multiple transform maps.

The Robust Transform Engine (RTE) and the robust import set transformer separate the transform and processing functions, providing a more flexible alternative to transform maps. The robust import set transformer allows you to extract data from a source table into an intermediary data structure. You can transform the data as desired and then load that data to one or more target tables. Records are processed as batches to enhance performance.

With transform maps, if you want data from the source table to go to three different target tables, you must create three separate transform maps. Each transform map parses the data separately, which results in three separate read operations. By contrast, the robust import set transformer requires only a single read operation to prepare the data for three target tables. The robust import set transformer is more efficient, especially when dealing with multiple target tables.

Extract Transform Load (ETL)

When you use the robust import set transformer, Extract Transform Load (ETL) functionality transfers imported data to target tables. You define how the data is extracted, transformed, and loaded to one or more target tables. You can use ETL definitions to do the following:

- Define entities (an abstraction similar to tables).
- Define entity fields (an abstraction similar to table fields).
- Define mapping between entities, and optionally designate whether a specific mapping should be ignored during data integration.
- Define entity field mappings.
- Define entity operations.

For procedures, see Create Extract Transform Load (ETL) definitions.

As of the Paris release, ETL definitions also support nested data structures such as the following when the Data source has JSON/XML payloads in a single column.

```json
{
  "records": [
    {
      "network": {
        "location": "San Diego",
        "computers": [
          {
            "id": "C100",
            "os": "Mac",
            "disks": [
              {
                "size": "200GB",
                "type": "SSD"
              },
              {
                "size": "1TB",
                "type": "Magnetic"
              }
            ]
          }
        ]
      }
    }
  ]
}
```
Create a robust import set transformer

Define how information is sent from the source table to target tables via a Robust Transform Engine (RTE).

Role required: importTransformer

1. Navigate to System Import Sets > Administration > Robust Import Set Transformers.
2. Click New.
3. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name of the robust import set transformer.</td>
</tr>
<tr>
<td>Source table</td>
<td>The source table for the robust import set transformer.</td>
</tr>
<tr>
<td>Robust transform engine</td>
<td>Enables you to select an ETL definition or CMDB definition. For procedures to define an RTE, see Create robust transform definitions.</td>
</tr>
<tr>
<td>Description</td>
<td>A description of the robust import set transformer.</td>
</tr>
<tr>
<td>Properties</td>
<td>Custom properties which can be used in processing the data.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope for this record.</td>
</tr>
<tr>
<td>Active</td>
<td>Selected if the robust import set transformer is currently active. Deselected if the robust import set transformer is not currently active.</td>
</tr>
<tr>
<td>Batch size</td>
<td>The number of items in each batch being transformed.</td>
</tr>
<tr>
<td>Verbose</td>
<td>Enables some transform logs that show how transform operations are applied to records.</td>
</tr>
</tbody>
</table>

4. Click Submit.

Create robust transform definitions

Specify your own Robust Transform Engine (RTE) to transfer data from a source table to a target table.
Role required: import_transformer

1. Navigate to System Import Sets > Administration > Robust Import Set Transformers.
2. Select an existing robust import set transformer, or click New to create a new robust import set transformer. For procedures, see Create a robust import set transformer.
3. At the Transformer Definition field, click the search icon.
4. On the Robust Transform Definitions window, click New.
5. On the Robust Transformer Definition pop-up, select ETL Definition.
6. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active</td>
<td>Selected if the robust transform engine is active. Deselected if the robust transform engine is not active.</td>
</tr>
<tr>
<td>Description</td>
<td>A description of the robust transform engine.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope for this record.</td>
</tr>
<tr>
<td>Name</td>
<td>The name of the robust transform engine.</td>
</tr>
</tbody>
</table>

7. Click Submit.

Create Extract Transform Load (ETL) definitions

Create ETL definitions to extract data from a source table, transform the data as desired, and load the data into a target table. ETL definitions also support nested data structures.

Role required: import_transformer

1. Navigate to System Import Sets > Administration > ETL Definitions.
2. Click New.
3. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the ETL definition.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the ETL definition.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope for this record.</td>
</tr>
<tr>
<td>Active</td>
<td>Selected if the ETL definition is active. Unselected if the ETL definition isn't active.</td>
</tr>
</tbody>
</table>

4. Click Submit.

Define ETL entities

Define the Extract Transform Load (ETL) entities used by the Robust Transform Engine.

Role required: import_transformer

1. Navigate to System Import Sets > Administration > ETL Definitions.
2. Select an ETL definition.
3. On the ETL Entities tab, click New.
4. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the ETL entity.</td>
</tr>
<tr>
<td>Table</td>
<td>Target table for the ETL entity.</td>
</tr>
</tbody>
</table>
Define ETL entity mappings
Map the source entity to a target entity.

Role required: import_transformer

You can optionally set the Ignore check box to exclude the entity mapping when performing data integrations using Robust Import Set Transformation (RTE).

1. Navigate to System Import Sets > Administration > ETL Definitions.
2. Select an ETL definition.
4. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the mapping.</td>
</tr>
<tr>
<td>Source Entity</td>
<td>Source entity for the mapping.</td>
</tr>
<tr>
<td>Target Entity</td>
<td>Target entity for the mapping.</td>
</tr>
<tr>
<td>Order</td>
<td>Order in which the mapping should be processed.</td>
</tr>
<tr>
<td>Is Conditional</td>
<td>Check box that designates that the mapping is conditional. Select the check box if the mapping is conditional and clear it if it is not.</td>
</tr>
<tr>
<td>Condition Script</td>
<td>Script that defines the conditions that must be met for the mapping.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope for this record.</td>
</tr>
<tr>
<td>Definition</td>
<td>Selected ETL entity that this mapping belongs to.</td>
</tr>
</tbody>
</table>
Create ETL entity field definitions
Define the entity fields mapped for Extract Transform Load (ETL) operations.

Role required: import_transformer

1. Navigate to **System Import Sets > Administration > ETL Definitions**.
2. Select an ETL definition.
3. On the ETL Entities tab, select an ETL entity.
4. On the ETL Entity fields tab, click **New**.
5. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the ETL Entity field definition.</td>
</tr>
<tr>
<td>Field/Path</td>
<td>Column name when the entity is Import or Target table, or a path when the field has nested structures.</td>
</tr>
<tr>
<td>Coercion action</td>
<td>What the system should do if a reference or choice could not be found. Available options are create, ignore, and reject.</td>
</tr>
<tr>
<td>Coalesce</td>
<td>Use this field to query the existing records.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope for this record.</td>
</tr>
<tr>
<td>Entity</td>
<td>Name of the robust transform engine entity.</td>
</tr>
<tr>
<td>Definition</td>
<td>Selected ETL entity that this field definition belongs to.</td>
</tr>
</tbody>
</table>

6. Click **Submit**.

Define Robust Transform Engine operations
Define the operations the Robust Transform Engine (RTE) should perform.

Role required: import_transformer
You should always perform operations on only one entry. Select all source and target fields from the same entity.

1. Navigate to **System Import Sets > Administration > ETL Definitions**.
2. Select an ETL definition.
3. On the ETL Entities tab, select an ETL entity.
4. On the RTE Entity Operations tab, click **New**.
5. Select the kind of operation you want to create.
6. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the operation.</td>
</tr>
<tr>
<td>Source Field</td>
<td>Input ETL field for the operation if the operation takes a single input.</td>
</tr>
<tr>
<td>Target Field</td>
<td>Output ETL field for the operation if the operation takes a single output.</td>
</tr>
<tr>
<td>Source Fields</td>
<td>Input ETL fields for the operation if the operation takes multiple inputs.</td>
</tr>
<tr>
<td>Target Fields</td>
<td>Output ETL fields for the operation if the operation takes multiple outputs.</td>
</tr>
<tr>
<td>Operation Group</td>
<td>Optional name to group related operations.</td>
</tr>
<tr>
<td>Overwrite Existing Value</td>
<td>If true, overwrites an existing non-empty value in the target fields.</td>
</tr>
<tr>
<td>Optional Joining String</td>
<td>Optional string to join values on.</td>
</tr>
<tr>
<td>Decimal Places</td>
<td>Optional number of decimal places to force output value to.</td>
</tr>
<tr>
<td>Remainder Target Field</td>
<td>Optional second target field to write the trimmed remainder of the source string after the first numeric value is removed.</td>
</tr>
<tr>
<td>Glide Matching Fields</td>
<td>Comma-delimited list of column names to use for lookup in the target table.</td>
</tr>
<tr>
<td>Target Table</td>
<td>Table to perform a lookup on.</td>
</tr>
<tr>
<td>Glide Target Fields</td>
<td>Comma-delimited list of columns to return from the target table.</td>
</tr>
<tr>
<td>Match Regular Expression</td>
<td>Matching regular expression for replace operations.</td>
</tr>
<tr>
<td>Replacement Regular Expression</td>
<td>Replacement string.</td>
</tr>
<tr>
<td>Use Unique Input Sets</td>
<td>If true, the operation processes only the unique set of inputs to the operation. Otherwise, the operation processes every record individually.</td>
</tr>
<tr>
<td>Literal Set Value</td>
<td>String value to set to target.</td>
</tr>
<tr>
<td>Splitting String</td>
<td>String to split the input value on.</td>
</tr>
<tr>
<td>Date Format</td>
<td>Date/time format expressed in simple Java format.</td>
</tr>
<tr>
<td>Order</td>
<td>Order in which the operation runs on the entity.</td>
</tr>
<tr>
<td>Script</td>
<td>Script that runs as part of the operation.</td>
</tr>
<tr>
<td>Is Conditional</td>
<td>Specifies whether to apply the operation if the specified conditions are met.</td>
</tr>
<tr>
<td>Conditional Fields</td>
<td>Fields to use in the condition.</td>
</tr>
</tbody>
</table>
Field | Description
--- | ---
Conditional Script | Condition specified as a string.
Application | Application scope for this record.
Operation Type | Operation type for this operation.
Entity | Entity this operation applies to.
Definition | Selected ETL entity definition that this entity and operation belong to.

7. Click **Submit**.

### Updating records using coalesce

The coalesce option allows you to update existing target table records when transforming import data.

The coalesce option on a field map allows you to specify if the selected **Target field** should be used to coalesce on when import set records are transformed. If the field map **Coalesce** checkbox is selected, when the import set row is transformed the instance checks for an existing record in the target table that has the same value in the **Target field** as the import set row **Source field**.

If an existing record with a matching value in the target table is found, that record is updated. If no matching record is found, then a new record is created in the target table.

**Note:** Choose fields in the target table to coalesce on only if those fields will have unique values. If more than one record in the target table matches the specified coalesce options, only the first matching record in the target table is updated.

### Coalesce options

There are several possible configurations you can use to coalesce data in import sets.

**No coalesce**

If no coalesce is defined, all imported rows are treated as new records. No existing records are updated.

**Single-field coalesce**

You can coalesce on a single field to update an existing record.

If a target table record exists with the same value in the coalesce field as the staging table record, the target table record is updated using the import set record values.

**Multiple-field coalesce**

You can coalesce on multiple fields to update an existing record.

If a target table record exists with the same values in all coalesce fields as the staging table record, the target table record is updated using the staging table record values. All coalesce field values between the target and staging tables must match to coalesce with multiple fields.
Conditional coalesce

You can use a script to determine if a staging table row should coalesce to a target record. Most conditional coalesce scripts are defined in the **Source script** field of a field map for the sys_id field. To update a target record using the staging table record values, the script must return the sys_id of the target table record.

**Example conditional coalesce scripts**

Review examples of conditional coalesce scripts.

**Updates only**

To only update records where a match is found, and skip records where a match is not found, specify a coalesce field and add the following script as an **onBefore** script to the transform map.

```javascript
if (action == 'insert')
    ignore = true;
```

**Conditional coalesce using dot-walking**

You can use dot-walked fields in a conditional coalesce script, such as to match the email address of a user when importing incident data.

In this example, this script is defined in the **Source script** of a field map for the Incident target table sys_id field.

```javascript
var now_GR = new GlideRecord('incident');
gr.addQuery('caller_id.email', source.u_email); //check if the incident caller's email matches the import row email value
gr.query();
if(gr.next())
{
    answer = gr.sys_id; //if a match exists, return the sys_id of the matching Incident record
}
else
{
    answer= -1;
}
```

**Conditional coalesce with an OR condition**

You can use a conditional coalesce script to match source and target records based on multiple field values. Unlike multiple-field coalesce where all coalesce fields must match, you can specify a script to only require one of the fields to match.

In this example, this script is defined in the **Source script** of a field map for the User target table sys_id field.

```javascript
var now_GR = new GlideRecord('sys_user');
var qc = gr.addQuery('email', source.u_email); //first check if the user's email matches
qc.addOrCondition('user_name', source.u_name); //alternatively, check if the username matches
```
```java
gr.query();
if(gr.next())
{
    answer = gr.sys_id; //if a match exists, return the sys_id of the matching User record
}
else
{
    answer = -1;
}
```

**Case-sensitive coalesce field values**

You can control if an import set will coalesce on matching values with different cases.

The field map **Coalesce case sensitive** field enables you to coalesce field values by case sensitivity.

By default, fields marked as **Coalesce** in the field map are used in a case insensitive lookup for existing records. If the **Coalesce case sensitive** check box is selected, the instance attempts to match coalesce field values by case. The target table record is updated only if the value in the target record and the import set staging record have the same value and case. Otherwise, a new record is created.

**Coalesce on empty fields**

You can control if an import set will coalesce on fields with no value.

The field map **Coalesce empty fields** field allows you to coalesce on fields with no value.

By default, fields marked as **Coalesce** in the field map cause the import set to check for a target record with a field value that matches the value from the import set staging record. When **Coalesce empty fields** is selected for that field map, an empty value in the target record and import set staging record counts as a match for the purpose of coalescing.

For example, the User transform map coalesces on the email field. With the **Coalesce empty fields** option selected, a source record containing an empty email address coalesces to a target record containing an empty email address.

**Standard import set tables**

Several Import Set tables are available by default.

**Notification**

A standard object for describing an external interface for a notification in the system, eg. alarms and alerts from monitoring systems. The default transform map for this object will create or update an incident record. The incoming notifications are coalesced into incidents based on the UUID field.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>uuid</td>
<td>The universally unique identification number or string that uniquely identifies this notification. It is marked as the coalescing value in the default transform map for the corresponding Incident and is mapped to the correlation_id field of Incident.</td>
<td>Character (40)</td>
</tr>
<tr>
<td>corrective_message</td>
<td>A free form string value that indicates the corrective or followup steps to be taken to address the issue identified in this notification. This field is not mapped by default.</td>
<td>Character (40)</td>
</tr>
<tr>
<td>duration</td>
<td>A string value representing the time value duration affecting the issue reported in this notification. Out of box, the duration field is not mapped. The format of the time is up to the calling program and must be mapped accordingly in the default map to be used.</td>
<td>Character (40)</td>
</tr>
<tr>
<td>expires_on</td>
<td>A string value representing the datetime value that the issue reported in this notification will expire. Out of box, the expires_on field is not mapped. The format of the time is up to the calling program and must be mapped accordingly in the default map to be used.</td>
<td>Character (40)</td>
</tr>
<tr>
<td>message</td>
<td>A string value describing the nature of the issue related to this notification. It should be a concise description and is mapped to the short_description field of the Incident.</td>
<td>Character (80)</td>
</tr>
<tr>
<td>comments</td>
<td>A string value containing additional comments related to this notification. The value is mapped to the comments field of the Incident.</td>
<td>Character (4000)</td>
</tr>
<tr>
<td>category</td>
<td>A string value categorising the nature of this notification. The value is mapped to the category field of the Incident, and therefore should be one of its valid values. If an existing value does not exist, the default behavior is to create a new category.</td>
<td>Character (40)</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
<td>Data type</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------</td>
</tr>
<tr>
<td>assignment_group</td>
<td>A string value of the assignment group for this notification. The value is mapped to the assignment_group field of the Incident, and therefore should be one of its valid values. If an existing value does not exist, the default behavior is to create a new assignment group and set it for the resulting incident.</td>
<td>Character (40)</td>
</tr>
</tbody>
</table>
| severity      | A string representation of a numeric value that indicates the severity of the issue being reported in this notification. This field is mapped to the severity field on Incident. The out of box numeric values and their meanings are:  
  • 1 - High  
  • 2 - Medium  
  • 3 - Low | Character (40) |
| state         | A string that indicates the state of the issue being reported in this notification. This field is mapped to the incident_state field on Incident. The out of box values are:  
  • New  
  • Active  
  • Resolved  
  • Closed | Character (40) |
<p>| source        | A string value to indicate the source of the issue or the configuration item (by unique identifier eg IP address, host name etc) related to the issue in this notification. It’s mapped to the cmdb_ci field of Incident. | Character (40) |
| timestamp     | A string value representing the datetime value that marks the beginning of the issue reported in this notification. Out of box, the timestamp field is not mapped. The format of the time is up to the calling program and must be mapped accordingly in the default map to be used. | Character (40) |</p>
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>A string value categorizing the type of issue related to this notification. Out of box, this field is not mapped to any field on Incident. Integrations using this Notification message may use this field to identify its source and trigger additional scripts.</td>
<td>Character (40)</td>
</tr>
</tbody>
</table>

**Computer**

A standard object for describing an external interface for a computer in the system. The default transform map will create/update a Computer (cmdb_ci_computer) or Server (cmdb_ci_server, cmdb_ci_win_server, cmdb_aix_server etc ..) based on the operating_system field value. The incoming computers are coalesced based on the serial_number field. Additionally, the transform script of the map will map to various extensions of the Computer (cmdb_ci_computer) based on the operating_system value being entered.

- UNIX Server (cmdb_ci_unix_server)
  - AIX
  - HP/UX
  - Solaris
  - AIX

- Windows Server (cmdb_ci_win_server)
  - Windows 2000 Server
  - Windows 2003 Server
  - Windows NT 4.0

- Server (cmdb_ci_server)
  - Any operating system that contains the word "Linux"

**imp_computer**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>serial_number</td>
<td>The unique identifier for this computer. It is marked as the coalescing value in the default transform map for the corresponding Computer and is mapped to the serial_number field of Computer (cmdb_ci_computer).</td>
<td>Character (40)</td>
</tr>
<tr>
<td>cpu_count</td>
<td>The number of CPUs that this computer has. It is mapped to the cpu_count field of the Computer (cmdb_ci_computer) table.</td>
<td>Character (40)</td>
</tr>
<tr>
<td>cpu_speed</td>
<td>The clock speed of the CPU in MHz. This field is mapped to the cpu_speed field of Computer (cmdb_ci_computer)</td>
<td>Character (40)</td>
</tr>
<tr>

<tr>
<td></td>
<td>• Windows 2003 Enterprise</td>
<td></td>
</tr>
<tr>
<td>ram</td>
<td>A numeric value for the total number of memory installed on this computer in MB. This value is mapped to the ram field of Computer (cmdb_ci_computer)</td>
<td>Character (40)</td>
</tr>
</tbody>
</table>
User

A standard object for describing an external interface for a user in the system. The default transform map script sets the user_name field value to first_name.last_name if the web service's user_id field value is not supplied, otherwise, the user_id value is mapped directly to the user_name field in the User (sys_user) table.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>email</td>
<td>A string value containing the user's email address. This value is mapped to the email field in User (sys_user) and is set as the coalesce value for the transform.</td>
<td>Character (40)</td>
</tr>
<tr>
<td>department</td>
<td>The department the user is in. This field is mapped to the department field in User (sys_user) which is a reference to the Department (cmn_department) table.</td>
<td>Character (40)</td>
</tr>
<tr>
<td>first_name</td>
<td>The first name of the user, mapped to the first_name field of the User (sys_user) table.</td>
<td>Character (40)</td>
</tr>
<tr>
<td>last_name</td>
<td>The last name of the user, mapped to the last_name field of the User (sys_user) table.</td>
<td>Character (40)</td>
</tr>
<tr>
<td>location</td>
<td>The location the user is in, mapped to the location field of the User (sys_user) table which is a reference field to Location (cmn_location)</td>
<td>Character (40)</td>
</tr>
<tr>
<td>phone</td>
<td>The phone number of the user, mapped to the phone (Business Phone) field of the User (sys_user) table.</td>
<td>Character (40)</td>
</tr>
<tr>
<td>user_id</td>
<td>This is the user identification, usually a login name, that maps to the user_name (User ID) field of the User (sys_user) table.</td>
<td>Character (40)</td>
</tr>
</tbody>
</table>

Location

A standard object for describing an external interface for a location in the system. The web service will create or modify records in the Location (cmn_location) table.
imp_location

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the location, for example &quot;Headquarters&quot;, &quot;Sales office&quot; etc. This field is mapped to the name field of Location (cmn_location) and is part of the coalesce to search for an existing location.</td>
<td>Character (40)</td>
</tr>
<tr>
<td>street</td>
<td>The street address of the location, for example &quot;1234 ServiceNow way&quot; etc. This field is mapped to the street field of Location (cmn_location) and is part of the coalesce to search for an existing location.</td>
<td>Character (40)</td>
</tr>
<tr>
<td>city</td>
<td>The city of the location, for example &quot;San Diego&quot;, &quot;Madrid&quot; etc. This field is mapped to the city field of Location (cmn_location) and is part of the coalesce to search for an existing location.</td>
<td>Character (40)</td>
</tr>
<tr>
<td>state</td>
<td>The state of the location, for example &quot;California&quot;, &quot;Connecticut&quot; etc. This field is mapped to the city field of Location (cmn_location) and is part of the coalesce to search for an existing location.</td>
<td>Character (40)</td>
</tr>
<tr>
<td>zip</td>
<td>The zip code for the location, for example &quot;92130&quot;, &quot;10001&quot; etc. This field is mapped to the zip field of Location (cmn_location) and is part of the coalesce to search for an existing location.</td>
<td>Character (40)</td>
</tr>
<tr>
<td>country</td>
<td>The country for the location, for example &quot;USA&quot;, &quot;United Kingdom&quot; etc. This field is mapped to the country field of Location (cmn_location).</td>
<td>Character (40)</td>
</tr>
</tbody>
</table>

**Import sets maximum row size**

Rows imported using import sets must not exceed the maximum row size.

A single row in a database may not contain more than 8126 bytes of data. The size of each row is determined by the amount of content in all fields, as well as the character set for text fields. For example, a row with 10 text fields each containing 1000 characters using a French character set takes 15360 bytes.

Attempting to import more data to a single row than the maximum size causes the import to skip that row. Any rows that were skipped for this reason are listed in the import log.
**Importing data using import sets**

To import data define a data source and transform map, and run or schedule an import.

---

**Creating a data source**

Create a data source record to define what data an import set should import.

Depending on the type of data source you want to create, see the following topics for procedures.

*Create a File type data source*

Create a File type data source record to define what data an import set should import.

Role required: import_admin

For additional information, see [File type data sources](#).

1. Navigate to **System Import Sets > Administration > Data Sources**.
2. Click **New**.
3. Complete the form.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name for this data source.</td>
</tr>
<tr>
<td>Import set table label</td>
<td>A label for the import set staging table to use.</td>
</tr>
<tr>
<td>Import set table name</td>
<td>The uses the label you entered to construct a unique table name. This prevents namespace collision with an already existing table.</td>
</tr>
<tr>
<td>Type</td>
<td>File.</td>
</tr>
<tr>
<td>Format</td>
<td>Only the default XML-based file format (.xlsx) is supported, unless saved as &quot;Strict Open XML Document.&quot;</td>
</tr>
<tr>
<td>Zipped</td>
<td>Selected if the import file is compressed.</td>
</tr>
<tr>
<td>Use Batch Import</td>
<td>If selected, specifies that loading data should be batched when you click Load data or Test load 20 records.</td>
</tr>
<tr>
<td>Batch Size</td>
<td>Specifies how big the batches should be. Appears only when the Use Batch Import field is selected.</td>
</tr>
<tr>
<td>File retrieval method</td>
<td>The retrieval method for this file.</td>
</tr>
</tbody>
</table>

The glide.import_set_load_usebatch and glide.import_set_load_batch_size properties affect these fields. The priority order for the properties and fields are as follows: If the property is set, use the property value. If not, use the field value. If neither property is set, use the default batch size of 1000.

- For example, if `glide.import_set_load_usebatch = true` and `glide.import_set_load_batch_size = 200`, use 200 as the batch size, regardless of the field values.
- For example, if `glide.import_set_load_usebatch = true` and the `glide.import_set_load_batch_size` property is not set, use the default batch size of 1000.
- For example, if the `glide.import_set_load_usebatch` property is not set and the Use Batch Import field = true, use the Batch Size field value (or the default of 1000 if the Batch Size field value is not set)
- For example, if the `glide.import_set_load_usebatch` property = false and the Use Batch Import field = true, do not use batch import, since the property is set to false.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>File path</td>
<td>The path to the file to import. You can include a system property value in this field using the format <code>${system.property.name}</code>. When the connection is made, the variable is replaced with the value of the specified property.</td>
</tr>
<tr>
<td><strong>Note:</strong> For files retrieved using HTTP or HTTPS, the <code>glide.ds.file.http.variable_replacement</code> property must be true to use system property expansion.</td>
<td></td>
</tr>
<tr>
<td>For example, you can specify the file <em>path</em> value <code>/countries.csv?key=${datasource.apikey}</code>. When the connection is made, the value of the <code>datasource.apikey</code> system property is passed as the value for the <strong>key</strong> parameter.</td>
<td></td>
</tr>
<tr>
<td><strong>Note:</strong> For HTTP and HTTPS protocols, the file path is automatically URL encoded. Do not specify a URL-encoded file path when using either of these protocols.</td>
<td></td>
</tr>
<tr>
<td>CSV delimiter</td>
<td>The delimiter character for the CSV file.</td>
</tr>
<tr>
<td>Parsing script</td>
<td>The script used to parse a single line of input. As you type the script, script auto-complete presents the choices available to you. For more information, see File type data sources.</td>
</tr>
<tr>
<td>Sheet number</td>
<td>The Excel sheet number to load data.</td>
</tr>
<tr>
<td>Header row</td>
<td>The Excel sheet number to load the column labels.</td>
</tr>
<tr>
<td>Path for each row</td>
<td>The path expression used to select JSON objects, which will become rows in the import set table. The path should be <code>/</code> for JSON objects.</td>
</tr>
<tr>
<td>Discard Arrays</td>
<td>Selected to discard JSON arrays as a value. Unselected to serialize JSON arrays as a value.</td>
</tr>
<tr>
<td>Expand node children</td>
<td>Selected if child elements of the XML node or JSON object should be converted into additional columns. Unselected if the parent column value should be an XML or JSON fragment. For JSON, note that selecting this option expands objects only, not arrays. For nested array support, see Importing JSON files.</td>
</tr>
<tr>
<td>Data in single column</td>
<td>Selected to store data in a single column.</td>
</tr>
<tr>
<td>Xpath for each row</td>
<td>XPath expression that selects the nodes which become rows in the import table. The children of the selected nodes will become the columns in the rows.</td>

<tr>
<td>Use last run datetime</td>
<td>Controls the amount of data that is retrieved from a database during an import run. If unselected, then all rows in the table specified are imported, every time. You might want to use this setting if this is a one-time import, or if all the data in the target table is new. If selected, two additional fields appear, enabling you to select a datetime value to limit imported data to delta values only.</td>
</tr>
<tr>
<td>Last run datetime</td>
<td>The datetime value in this field is automatically populated from the database field you select below and represents the latest value from the previous run. This value acts as a dynamic filter to restrict the number of records retrieved to those records that have changed since the data source's last runtime.</td>
</tr>
<tr>
<td>Last run database field</td>
<td>Field name from the source table that will be used as the filter in the next run. This value may need to be case sensitive, depending on the target database type.</td>
</tr>
<tr>
<td>Additional Database Parameters</td>
<td>Optional parameters to add to the end of the URL generated for this data source. Semicolon-separated list of parameters. You may need to configure the form to view this field.</td>
</tr>
</tbody>
</table>

4. Click **Submit**.

Define a transform map for the new data source and run an import.

Create an **LDAP type data source**

Create an **LDAP** type data source record to define what data an import set should import.

Role required: **import_admin**
For additional information, see LDAP type data source.

1. Navigate to **System Import Sets > Administration > Data Sources.**
2. Click **New.**
3. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name for this data source.</td>
</tr>
<tr>
<td>Import set table label</td>
<td>A label for the import set staging table to use.</td>
</tr>
<tr>
<td>Import set table name</td>
<td>The uses the label you entered to construct a unique table name. This prevents namespace collision with an already existing table.</td>
</tr>
<tr>
<td>Type</td>
<td>LDAP.</td>
</tr>
<tr>
<td>LDAP target</td>
<td>Target selected from the list of your LDAP OU definitions.</td>
</tr>
<tr>
<td>Use Batch Import</td>
<td>If selected, specifies that loading data should be batched when you click <strong>Load data</strong> or <strong>Test load 20 records</strong>.</td>
</tr>
<tr>
<td>Batch Size</td>
<td>Specifies how big the batches should be. Appears only when the <strong>Use Batch Import</strong> field is selected.</td>
</tr>
</tbody>
</table>

The `glide.import_set_load_usebatch` and `glide.import_set_load_batch_size` properties affect these fields. The priority order for the properties and fields are as follows: If the property is set, use the property value. If not, use the field value. If neither property is set, use the default batch size of 1000.

- For example, if `glide.import_set_load_usebatch = true` and `glide.import_set_load_batch_size = 200`, use 200 as the batch size, regardless of the field values.
- For example, if `glide.import_set_load_usebatch = true` and the `glide.import_set_load_batch_size` property is not set, use the default batch size of 1000.
- For example, if the `glide.import_set_load_usebatch` property is not set and the **Use Batch Import** field = `true`, use the **Batch Size** field value (or the default of 1000 if the **Batch Size** field value is not set)
- For example, if the `glide.import_set_load_usebatch` property = false and the **Use Batch Import** field = `true`, do not use batch import, since the property is set to false.

4. Click **Submit.**

Define a transform map for the new data source and run an import.
Create an OIDC type data source

Create an **OIDC** type data source record to define what data an import set should import.

Role required: import_admin

1. Navigate to **System Import Sets > Administration > Data Sources**.
2. Click **New**.
3. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name for this data source.</td>

<tr>
<td>Batch Size</td>
<td>Specifies how big the batches should be. Appears only when the <strong>Use Batch Import</strong> field is selected.</td>
</tr>
</tbody>
</table>

The **glide.import_set_load_usebatch** and **glide.import_set_load_batch_size** properties affect these fields. The priority order for the properties and fields are as follows: If the property is set, use the property value. If not, use the field value. If neither property is set, use the default batch size of 1000.

- For example, if
  - **glide.import_set_load_usebatch = true** and
  - **glide.import_set_load_batch_size = 200**,
  - use 200 as the batch size, regardless of the field values.

- For example, if
  - **glide.import_set_load_usebatch = true** and
  - the **glide.import_set_load_batch_size** property is not set,
  - use the default batch size of 1000.

- For example, if the **glide.import_set_load_usebatch** property is not set and the **Use Batch Import** field = **true**,
  - use the **Batch Size** field value (or the default of 1000 if the **Batch Size** field value is not set)

- For example, if the **glide.import_set_load_usebatch** property = **false** and the **Use Batch Import** field = **true**,
  - do not use batch import, since the property is set to false.

| Format | Defaults to **None** and can't be changed. |

4. Click **Submit**.

Define a transform map for the new data source and run an import.
Create a REST (IntegrationHub) type data source
Create a REST (IntegrationHub) type data source record to define what data an import set should import from a REST API.

Roles required: import_admin and action_designer

1. Navigate to System Import Sets > Administration > Data Sources.
2. Click New.
3. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>

</tbody>
</table>

4. Click **Submit**.

Define a transform map for the new data source and run an import.

Define action properties

Create and configure a Data Source request action in IntegrationHub. After the request action is published in IntegrationHub, you can choose it as a **Request action** in the Data Source record.

Role required: import_admin

1. Navigate to **System Import Sets > Administration > Data Sources**.
2. Select **New**.
3. Select a Type of REST (IntegrationHub).
4. Click the link under Request action.
5. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the request action.</td>
</tr>
<tr>
<td>Accessible From</td>
<td>Scope from which the request action is accessible.</td>
</tr>
<tr>
<td>Category</td>
<td>Category of the request action.</td>
</tr>
<tr>
<td>Protection</td>
<td>Specifies whether the request action is read-only.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the request action.</td>
</tr>
<tr>
<td>Application</td>
<td>Scope of the application.</td>
</tr>
<tr>
<td>In-Flow Annotation</td>
<td>Text you want to appear under the Action title on the Data Source Request Action page.</td>
</tr>
</tbody>
</table>

6. Click Submit.
7. The Data Source Request Action page appears with the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limit</td>
<td>Limit set by the user in the REST (IntegrationHub) data source record. If the REST API supports pagination and Support pagination is selected in the Data Source record, you must supply this input to your REST step.</td>
</tr>
<tr>
<td>Offset</td>
<td>Offset set by user in the REST (IntegrationHub) data source record. If the REST API supports pagination and Support pagination is selected in the Data Source record, you must supply this input to your REST step.</td>
</tr>
<tr>
<td>Last Success Import Time</td>
<td>Last time data was successfully imported. A numeric value representing the number of milliseconds since January 1, 1970, 00:00:00 GMT. The data source populates this value. If the REST API supports queries based on time, you must supply this input to your REST step.</td>
</tr>
<tr>
<td>Import Start Time</td>
<td>Time the import is actually started. A numeric value representing the number of milliseconds since January 1, 1970, 00:00:00 GMT. The data source populates this value. If the REST API supports queries based on time, you must supply this input to your REST step.</td>
</tr>
</tbody>
</table>

8. If desired, you can add a Script step to validate or modify action inputs, set default values, or build request payloads before executing the REST step.
   a) Select Data Source Request from the Action Outline.
   b) Select Enable Processing Script.
   c) Select Script step from the Action Outline.
   d) Configure the Script step as described in Script step.

10. Configure the REST step as described in REST step.
11. Choose from the following:
   • Click **Properties** to return to the Action Properties window.
   • Click **Test** to test the request action before publishing it.
   • Click **Executions** to view the history of executions of the request action.
   • Click **Save** to save the request action.
   • Click **Publish** to publish the request action and make it available for use.

Create a Custom (Load by Script) type data source

Create a **Custom (Load by Script)** type data source record to define what data an import set should import.

Role required: import_admin

For additional information, see **Custom (Load by Script) type data source**.

1. Navigate to **System Import Sets > Administration > Data Sources**.
2. Click **New**.
3. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name for this data source.</td>
</tr>
<tr>
<td>Import set table label</td>
<td>A label for the import set staging table to use.</td>
</tr>
<tr>
<td>Import set table name</td>
<td>The label you entered to construct a unique table name. This prevents namespace collision with an already existing table.</td>
</tr>
<tr>
<td>Type</td>
<td><strong>Custom (Load by Script)</strong>.</td>
</tr>
<tr>
<td>Use Batch Import</td>
<td>If selected, specifies that loading data should be batched when you click <strong>Load data</strong> or <strong>Test load 20 records</strong>.</td>
</tr>
</tbody>
</table>
### Field Description

**Batch Size**

Specifies how big the batches should be. Appears only when the **Use Batch Import** field is selected.

The `glide.import_set_load_usebatch` and `glide.import_set_load_batch_size` properties affect these fields. The priority order for the properties and fields are as follows: If the property is set, use the property value. If not, use the field value. If neither property is set, use the default batch size of 1000.

- For example, if `glide.import_set_load_usebatch = true` and `glide.import_set_load_batch_size = 200`, use 200 as the batch size, regardless of the field values.
- For example, if `glide.import_set_load_usebatch = true` and the `glide.import_set_load_batch_size` property is not set, use the default batch size of 1000.
- For example, if the `glide.import_set_load_usebatch` property is not set and the **Use Batch Import** field = true, use the **Batch Size** field value (or the default of 1000 if the **Batch Size** field value is not set).
- For example, if the `glide.import_set_load_usebatch` property = false and the **Use Batch Import** field = true, do not use batch import, since the property is set to false.

### Data Loader

Script used to load data. For more information, see Custom (Load by Script) type data source.

4. Click **Submit**.

Define a transform map for the new data source and run an import.

**Data source fields**

In addition to common fields, other fields appear on the data source form, depending on the value of the **Type** field.

**Common data source fields**

These fields are common to all data sources.

<td>Application scope for this record.</td>
</tr>
</tbody>
</table>

**File type data source fields**

These additional fields appear on the data source form when the **Type** field value is **File**.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Format</td>
<td>Only the default XML-based file format (.xlsx) is supported, unless saved as &quot;Strict Open XML Document.&quot;</td>
</tr>
<tr>
<td>Zipped</td>
<td>Selected if the import file is compressed.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>File retrieval method</td>
<td>The retrieval method for this file.</td>
</tr>
<tr>
<td>File path</td>
<td>The path to the file to import. You can include a system property value in this field using the format <code>${system.property.name}</code>. When the connection is made, the variable is replaced with the value of the specified property.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> For files retrieved using HTTP or HTTPS, the glide.ds.file.http.variable_replacement property must be true to use system property expansion.</td>
</tr>
<tr>
<td></td>
<td>For example, you can specify the file path value /countries.csv?key=${datasource.apikey}. When the connection is made, the value of the datasource.apikey system property is passed as the value for the key parameter.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> For HTTP and HTTPS protocols, the file path is automatically URL encoded. Do not specify a URL-encoded file path when using either of these protocols.</td>
</tr>
<tr>
<td>CSV delimiter</td>
<td>The delimiter character for the CSV file.</td>
</tr>
<tr>
<td>Parsing script</td>
<td>The script used to parse a single line of input. As you type the script, script auto-complete presents the choices available to you. For more information, see File type data sources.</td>
</tr>
<tr>
<td>Sheet number</td>
<td>The Excel sheet number to load data.</td>
</tr>
<tr>
<td>Header row</td>
<td>The Excel sheet number to load the column labels.</td>
</tr>
<tr>
<td>Path for each row</td>
<td>The path expression used to select JSON objects, which will become rows in the import set table. The path should be / / for JSON objects.</td>

| Port                  | Port to use to connect to the specified server. This field appears if you select HTTP or HTTPS as the file retrieval method.                                                                                                                                                                                                                                                                                     |
| Username              | User name for authentication on the JDBC server.                                                                                                                                                                                                                                                                                                                                                                  |
| Password              | Password for authentication on the JDBC server.                                                                                                                                                                                                                                                                                                                                                                   |
| Private keyfile       | Keyfile when using legacy SCP public-private keyfiles.  

**Note:**  
- You cannot authenticate to data sources with a public-private key pair. Use username and password authentication instead.  
- Do not use this legacy option. Although it is available for use, it is not supported.                                                                                                                                                                                                                                                                     |
| System keystore       | Selected to validate the certificate from the FTPS server against all saved certificates. This certificate may be any type supported by the instance. If not selected, the instance uses the Java default certificate to validate the FTPS server. This field is available only for data sources with a **File retrieval method** value of FTPS. All FTPS file retrieval methods are supported, including Auth TLS, Auth SSL, Implicit SSL, and Implicit TLS.                                                                               |

**JDBC type data source fields**

These additional fields appear on the data source form when the **Type** field value is **JDBC**.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use MID Server</td>
<td>MID Server to use to connect to this data source.</td>
</tr>
<tr>
<td>Format</td>
<td>One of the following formats: MySQL, Oracle, or SQLServer.</td>
</tr>
<tr>
<td>Instance name</td>
<td>Used to support dynamic port connectivity with SQL Server. To ensure connectivity, provide the instance name for a SQL Server that receives a new port number dynamically after each reboot. This field only appears when <strong>SQLServer</strong> is selected as a data source format.</td>
</tr>
<tr>
<td>Database name</td>
<td>Name of the database instance.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Database port</td>
<td>Port number for the database. Leave this field empty when using dynamic port connectivity with SQL Server.</td>
</tr>
<tr>
<td>Use integrated authentication</td>
<td>Selected to allow the JDBC connection to use the ID of the user configured for the Windows MID Server service for SQL Server authentication. For additional details, see JDBC type data source.</td>
</tr>
<tr>
<td>Username</td>
<td>User name for authentication on the JDBC server.</td>
</tr>
<tr>
<td>Password</td>
<td>Password for authentication on the JDBC server.</td>
</tr>
<tr>
<td>Server</td>
<td>Name of the server from which the tables will be imported.</td>
</tr>
<tr>
<td>Query</td>
<td>Type of query to run: <strong>All rows from Table</strong> or <strong>Specific SQL</strong> If you select to run a SQL statement, the SQL statement field appears.</td>
</tr>
<tr>
<td>Query timeout</td>
<td>Number of seconds the JDBC driver will wait for a query (SELECT) to complete. Zero (0) means no timeout. If timeout is exceeded, the integration considers the JDBC result inaccessible and places it in an error state.</td>
</tr>
<tr>
<td>Connection timeout</td>
<td>Number of seconds before MID Server connection cache pool closes and removes it from the pool. Zero (0) means no timeout.</td>
</tr>
<tr>
<td>Table name</td>
<td>Name of the table from which the data is being exported.</td>
</tr>
<tr>
<td>SQL statement</td>
<td>SQL statement to extract the desired data from the database.</td>
</tr>
<tr>
<td>Use last run datetime</td>
<td>Controls the amount of data that is retrieved from a database during an import run. If unselected, then all rows in the table specified are imported, every time. You might want to use this setting if this is a one-time import, or if all the data in the target table is new. If selected, two additional fields appear, enabling you to select a datetime value to limit imported data to delta values only.</td>
</tr>
<tr>
<td>Last run datetime</td>
<td>The datetime value in this field is automatically populated from the database field you select below and represents the latest value from the previous run. This value acts as a dynamic filter to restrict the number of records retrieved to those records that have changed since the data source’s last runtime.</td>
</tr>
<tr>
<td>Last run database field</td>
<td>Field name from the source table that will be used as the filter in the next run. This value may need to be case sensitive, depending on the target database type.</td>
</tr>
<tr>
<td>Additional Database Parameters</td>
<td>Optional parameters to add to the end of the URL generated for this data source. Semicolon-separated list of parameters. You may need to configure the form to view this field.</td>
</tr>
</tbody>
</table>

**LDAP type data source field**

This additional field appears on the data source form when the **Type** field value is **LDAP**.
### LDAP target

Target selected from the list of your LDAP OU definitions.

### OIDC type data source field

This additional field appears on the data source form when the `Type` field value is **OIDC**.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Format</td>
<td>Defaults to <strong>None</strong> and can’t be changed.</td>
</tr>
</tbody>
</table>

### REST (IntegrationHub) type data source fields

These additional fields appear on the data source form when the `Type` field value is **REST (IntegrationHub)**.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Format</td>
<td>One of the following formats: Custom (Parse by Script), JSON, or XML.</td>
</tr>
<tr>
<td>Request action</td>
<td>Data source request action that will be invoked to get data. You can choose only published request actions. Click the link in the dialog box below to create/configure a new Data Source request action in . After the request action is published in , you can choose it as a <strong>Request action</strong> in the Data Source record. For more information, see Define action properties.</td>
</tr>
<tr>
<td>Support pagination</td>
<td>Selected to enable pagination for the request action. Pagination helps you reduce processing overhead by processing a specified number of records at a time, instead of processing all records at once.</td>
</tr>
<tr>
<td>Limit</td>
<td>Maximum number of records per page. For example, to process 50 records at a time, enter a <strong>Limit</strong> of 50.</td>
</tr>
<tr>
<td>Offset</td>
<td>The initial offset used for pagination. The offset is the starting record number. For example, to process 50 records at a time, starting with the first record, enter a <strong>Limit</strong> of 50 and an <strong>Offset</strong> of 0.</td>
</tr>
<tr>
<td>Parsing script</td>
<td>The script used to parse a single line of input. As you type the script, script auto-complete presents the choices available to you. For more information, see File type data sources.</td>
</tr>
<tr>
<td>Path for each row</td>
<td>The path expression used to select JSON objects, which will become rows in the import set table. The path should be <code>/</code> for JSON objects.</td>
</tr>
<tr>
<td>Discard Arrays</td>
<td>Selected to discard JSON arrays as a value. Unselected to serialize JSON arrays as a value.</td>
</tr>
</tbody>
</table>
### Field

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Expand node children</td>
<td>Selected if child elements of the XML node or JSON object should be converted into additional columns. Unselected if the parent column value should be an XML or JSON fragment. For JSON, note that selecting this option expands objects only, not arrays. For nested array support, see Importing JSON files.</td>
</tr>
<tr>
<td>Data in single column</td>
<td>Selected to store data in a single column.</td>
</tr>
<tr>
<td>Xpath for each row</td>
<td>XPath expression that selects the nodes which become rows in the import table. The children of the selected nodes will become the columns in the rows.</td>
</tr>
</tbody>
</table>

### Data Stream (IntegrationHub) type data source fields

These additional fields appear on the data source form when the Type field value is Data Stream (IntegrationHub).

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Data Stream () type data source.</td>
</tr>
<tr>
<td>Data Stream action</td>
<td>• Selected to use an existing published Data Stream action from .</td>
</tr>
<tr>
<td></td>
<td>• Selected for one of the following reasons:</td>
</tr>
<tr>
<td></td>
<td>• If you select a published Data Stream action, click this button to open the Data Stream action in .</td>
</tr>
<tr>
<td></td>
<td>• If you don't select a Data Stream action, click this button to create and publish a new Data Stream action in .</td>
</tr>
<tr>
<td>Note:</td>
<td>Data Stream actions require a subscription for production use.</td>
</tr>
<tr>
<td>Data in single column</td>
<td>Selected to store data in a single column.</td>
</tr>
<tr>
<td>Data Stream action inputs</td>
<td>Additional fields may appear, based on the inputs defined in the Data Stream action.</td>
</tr>
</tbody>
</table>

### Custom (Load by Script) type data source field

This additional field appears on the data source form when the Type field value is Custom (Load by Script).
Create a transform map

Every import operation to a production table requires at least one transform map associated with an import set.

Role required: import_transformer, import_admin, or admin

The transform map specifies the data relationships between the import set and the target table. For every transformation, you must either create a new transform map or select an existing one.

1. Navigate to System Import Sets > Create Transform Map.
2. Complete the form.

Table transform map fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>User-friendly label to identify the transform map.</td>
</tr>
<tr>
<td>Source table</td>
<td>Import table containing the raw import set data. An import table is any table</td>
</tr>
<tr>
<td></td>
<td>that extends the Import Set Row [sys_import_set_row] table. You can select</td>
</tr>
<tr>
<td></td>
<td>only tables within the currently selected application scope.</td>
</tr>
<tr>
<td>Active</td>
<td>Check box to make the transform map available for use.</td>
</tr>
<tr>
<td>Run business rules</td>
<td>Check box to run business rules, workflows, approval engines, auditing, and</td>
</tr>
<tr>
<td></td>
<td>field normalization while the transformation inserts or updates data into</td>
</tr>
<tr>
<td></td>
<td>the target table. Clearing this check box runs GlideRecord.setWorkflow()</td>
</tr>
<tr>
<td></td>
<td>with a value of false.</td>
</tr>
<tr>
<td>Enforce mandatory fields</td>
<td>Selects whether to enforce mandatory fields on the target table:</td>
</tr>
<tr>
<td></td>
<td>• No: Do not enforce mandatory fields.</td>
</tr>
<tr>
<td></td>
<td>• Only Mapped Fields: Enforce mandatory mapped fields only.</td>
</tr>
<tr>
<td></td>
<td>• All Fields: Enforce all mandatory fields.</td>
</tr>
<tr>
<td>Copy empty fields</td>
<td>Check box to copy empty field values and override existing target field</td>
</tr>
<tr>
<td></td>
<td>values.</td>
</tr>
<tr>
<td>Create new record on empty</td>
<td>Check box to create a new record when all coalesce fields are empty, instead</td>
</tr>
<tr>
<td>coalesce fields</td>
<td>of ignoring the record or overwriting an existing record.</td>
</tr>
<tr>
<td></td>
<td>If Coalesce empty fields is selected for any field in the record, the record</td>
</tr>
<tr>
<td></td>
<td>is coalesced.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope: global or per application.</td>
</tr>
<tr>
<td>Created</td>
<td>Transform map creation date (populated automatically).</td>
</tr>
</tbody>
</table>
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target table</td>
<td>The table in which you want the transformed data to be inserted. You can select only tables within the currently selected application scope or the global scope, or tables that grant write access to other applications.</td>
</tr>
<tr>
<td>Order</td>
<td>Order in which to apply transform maps if more than one map fits the conditions. The system runs transform maps from lowest to highest Order.</td>
</tr>
<tr>
<td>Run script</td>
<td>Check box to define a script that transforms field values in the source table to the target table.</td>
</tr>
<tr>
<td>Script</td>
<td>Transform map script that transforms field values in the source table to the target table. The system runs the transform map script in addition to any field maps.</td>
</tr>
</tbody>
</table>

**Important:** The string **NULL** is a reserved word. It should not be used as a field value in import set transform maps or anywhere in the **First name** or **Last name** fields. The reserved word is **NULL** in all capital letters. A field with the value **null** or **null**, for example, is acceptable. **NULL** should be used only to clear out a particular field.

## Mapping options

You can map fields in a number of ways depending on the circumstances of the import and whether data must be transformed prior to loading onto a production table.

It is also important to note that any given import operation may require taking advantage of multiple mapping methods, and these methods can be readily used in conjunction with one another.

### Automatic Mapping Utility

The simplest mapping method is where all of the field names of the import sets match the names of the fields on the production tables onto which the data will be transformed. In this case, simply click **Auto map matching fields** in the related list in the Table Transform Map form and confirm proper matching. If there are any discrepancies in terms of how fields were automatically matched, use the mapping assist utility to correct them. When all fields are matched properly, click the **Transform** related link to begin transforming data onto the destination table.

### Mapping Assist Utility

The mapping assist utility provides a visually intuitive environment for specifying mapping between import set fields and production table fields. The mapping assist utility makes it possible to map a single source field (field on an import set table) to multiple destination fields (fields on a production table).
Mapping assist

Changing the Date Format

If the date format of the source field does not match the format of the target field, you can set a date format mapping to transform dates from one format to another. For example, this mapping specifies that the date format of the CSV source file uses the **MM-dd-yyyy** format.
Field map date format

### Field map date format options

Date format options include:

#### Mapping Options

<table>
<thead>
<tr>
<th>Date Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dd-MM-yyyy</td>
<td>Day-month-year</td>
</tr>
<tr>
<td>dd-MM-yyyy hh:mm:ss</td>
<td>Day-month-year hours-minutes-seconds</td>
</tr>
<tr>
<td>dd-MM-yyyy hh:mm:ss z</td>
<td>Day-month-year hours-minutes-seconds timezone</td>
</tr>
<tr>
<td>MM-dd-yyyy</td>
<td>Month-day-year</td>
</tr>
<tr>
<td>MM-dd-yyyy hh:mm:ss</td>
<td>Month-day-year hours-minutes-seconds</td>
</tr>
<tr>
<td>MM-dd-yyyy hh:mm:ss z</td>
<td>Month-day-year hours-minutes-seconds timezone</td>
</tr>
</tbody>
</table>
You can specify a custom date format using **HH** to denote 24 hour time. Converting from a 24 hour to 12 hour date format may cause times from 12:00 to 12:59 to be formatted as 00:00.

### Mapping to a Duration Field

ServiceNow duration fields use a special data type that lists the number of milliseconds the duration value is. To map import data to a duration field use one of the following methods to transform source values into a duration.

- Calculate the duration from a start and end date
- Convert an existing duration value into a ServiceNow duration value

### Calculating a Duration Value from a Start and End Date

If the import source has a start and end date, you can calculate a duration with JavaScript.

1. Navigate to **System Import Sets > Transform Maps**.
2. Select the transform map you want to calculate a duration value. For example, the Notification transform map that imports into the Incident table.
3. Select the **Run script** check box.
4. Enter JavaScript to transform the start and end dates into a duration. See the sample script.
5. Click **Update**.

This sample script transforms the source.u_start and source.u_end fields to a duration value in the target.duration field. Change the field names to match your source and target fields as needed.

```javascript
target.duration = gs.dateDiff(source.u_start.getDisplayValue(), source.u_end.getDisplayValue(), false);
```

### Convert a Duration Value into a ServiceNow Duration Value

If the import source already contains a start date and a duration value, you can convert the existing duration into a ServiceNow duration. For example, you might have an Excel data source that lists a duration in seconds. ServiceNow expects durations to have millisecond values.

1. Navigate to **System Import Sets > Transform Maps**.
2. Select a transform map.
   - For example, the Notification transform map that imports into the Incident table.
3. Select the **Run script** check box.
4. Enter JavaScript to convert existing duration values into a ServiceNow duration values. See the sample script.

<table>
<thead>
<tr>
<th>Date Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>yyyy-dd-MM</td>
<td>Year-day-month</td>
</tr>
<tr>
<td>yyyy-MM-dd</td>
<td>Year-month-day</td>
</tr>
<tr>
<td>yyyy-MM-dd hh:mm:ss</td>
<td>Year-month-day hours-minutes-seconds</td>
</tr>
</tbody>
</table>
5. Click **Update**.

This sample script converts a duration in seconds (from the `source.u_duration` field) to a duration in milliseconds (in the `target.duration` field). Change the field names to match your source and target fields, as needed.

```javascript
//Transform the value in source.u_duration from seconds to milliseconds
target.duration.setDateNumericValue(source.u_duration * 1000);
```

This sample script converts a duration already in milliseconds (from the `source.u_duration` field) to a ServiceNow duration (in the `target.duration` field). Change the field names to match your source and target fields, as needed.

```javascript
//Transform the value in source.u_duration to ServiceNow format
target.duration.setDateNumericValue(source.u_duration);
```

**Using a Script to Calculate a Source Value**

You may want to use a source script instead of the **Source field** when:

- The source value is not in the format for the mapped target value.
- You want to look up a value before mapping to the target field.
- The source value must be computed from multiple fields.
- You need to create a compounded or calculated coalesce value in the target field.

For example, this example source script computes the value of the `user_name` field when it is blank in the source.

```javascript
if (source.user_id.nil()) {
  answer = source.first_name + "," + source.last_name;
} else answer = source.user_name;
```
A source script expects the calculated value to be set in the global variable `answer`.

**Mapping Binary or BLOB Fields**

ServiceNow uses a special process to import binary and binary large object (BLOB) data from JDBC data sources. All binary data is automatically converted into a record in the Attachment [sys_attachment] table before the transformation occurs. The import set table only stores the attachment record's sys_id value in the import table field instead of the actual binary value. For example, suppose you use a JDBC data source to import data from a CA Service Desk system, which stores each record's key value as binary data. When you import the Service Desk key values into a ServiceNow table, the ServiceNow field only contains a sys_id reference to the corresponding binary data in the Attachment Record [sys_attachment] table rather than the actual binary data.

To have a transform map access the attachment, use the `GlideRecord` API in an `onAfter` script. The script needs to run in an `onAfter` event because the `target.sys_id` object is only available after the data is placed in the import set table. For example, to map the resulting attachment to the target transform record, you can use the following script.

```javascript
var agr = new GlideRecord("sys_attachment");
agr.addQuery("sys_id", source.u_blob_field);
// the source field needs to be mapped to the source that is the BLOB
agr.query();
if(agr.next()) {
    agr.table_name = "cmdb_ci"; // the target table of the transform map
    agr.table_sys_id = target.sys_id; // the target record
    agr.content_type = source.u_contenttype;
    // the content type string if available,
    // this becomes the mime encoding when clicking an attachment link
    agr.update(); // finally, move/re-attach the attachment to the target
row }
```

If you are mapping directly to the `db_image` table, run the following `onAfter` script to display the image:

```javascript
var strTemp = source.u_file_name;
var fType = strTemp.substr(-3);
var iCont = "";
if(fType == 'jpg') {
    iCont = 'jpeg';
}
else {
    iCont = fType;
}
var agr = new GlideRecord("sys_attachment");
agr.addQuery("sys_id", source.u_blob_field);
agr.query();
if(agr.next()) {
    agr.table_name = "ZZ_YYdb_image";
    agr.table_sys_id = target.sys_id;
    agr.content_type = 'image/' + iCont;
    agr.file_name = 'image';
    agr.update(); }
```

**Create a field map**

Field maps establish a relationship between a field in an import set table and a field in the target table.

Role required: import_transformer, import_admin, or admin

The field map determines what values from the source table the transformation adds to the target table.

1. Navigate to System Import Sets > Transform Maps.
2. Open a transform map.
3. In the **Field Maps** related list, click **New**.
4. Complete the form.

### Field map fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Map</td>
<td>Transform map that uses this field mapping (populated automatically).</td>
</tr>
<tr>
<td>Source table</td>
<td>Table from which the raw import set data is loaded (the source for the transformation). Populated automatically from the transform map.</td>
</tr>
<tr>
<td>Source field</td>
<td>Field on the source table to be transformed. Can be blank if the Source table contains only raw data.</td>
</tr>
<tr>
<td>Choice action</td>
<td>Specifies the action to take if the import set contains a reference or choice value other than those available. Appears if the target field is a choice list or reference field.</td>
</tr>
<tr>
<td></td>
<td>• <strong>create</strong>: Create a new choice or record in the reference table.</td>
</tr>
<tr>
<td></td>
<td>• <strong>ignore</strong>: Ignore the new value from the source table.</td>
</tr>
<tr>
<td></td>
<td>• <strong>reject</strong>: Skip the entire row (record) containing the new value and continue to the next row.</td>
</tr>
<tr>
<td>Date format</td>
<td>Date format of the source field. Appears if the target field is a Date or Date/Time field.</td>
</tr>
<tr>
<td>Note: To learn more about allowable date formats, see Global date and time field format.</td>
<td></td>
</tr>
<tr>
<td>Use source script</td>
<td>Check box to use a script instead of the Source field.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope: global or per application.</td>
</tr>
<tr>
<td>Target table</td>
<td>Table in which the transformed data is inserted. You can select only tables within the currently selected application scope or the global scope, or tables that grant write access to other applications.</td>
</tr>
<tr>
<td>Target field</td>
<td>Field in the target table where the value from the source field is stored.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Referenced field value name</td>
<td>When the target field is a reference field, the transform map needs a way to match incoming source values to existing records in the reference field's source table. Since most imports do not provide a 32-character sys_id value, you must specify a column from the reference field's source table that contains values that match the incoming source values. When there is a matching record, the transform map stores the sys_id of the matching record in the target field. If there is no matching record, the transform map creates a new record in the reference field's table and stores the sys_id of the new record in the target field. If you leave this field blank, the transform map looks for matching values from the display value column of the reference field table. For example, suppose you are importing incident records and the incoming data lists user IDs for the Assigned to field. If you leave Referenced value field name blank, the transform map searches for matching values in the User table's display value column: name. By setting the Referenced value field name to the user_name column, you can match the user ID values to the appropriate user records.</td>
</tr>
<tr>
<td>Coalesce</td>
<td>Configuring a target field to coalesce causes the import set to treat the field as a unique key. When selected, the import set application attempts to match source values to records with values from an existing record. If a match is found, the transform map updates the record instead of creating a new record. When false, the import set application always creates new records for each transformation. If multiple fields are set to coalesce, all coalesce values must match an existing record. If two fields are set for coalescing and a matching value is found for one of the coalescing fields but not on the other, a new record is inserted. You must create an index on the target table if none of the coalesce fields are indexed. Indexing can improve performance for read and write operations. If one or more coalesce fields already has an index, you do not need to create an additional index. After setting the Coalesce value for all fields on the target table, use the Index Coalesce Fields related link to create an index. Before creating the index, ensure that the Coalesce value is set correctly for all fields on the target table to avoid creating unnecessary indexes for the same target table. The index needs to be concatenated; meaning all fields specified to be coalesced, need to be in the same index. The correct setup is for one index to include all fields being coalesced.</td>
</tr>
</tbody>
</table>
### Field map script variables

Several predefined variables are available in the **Source script** field.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>GlideRecord</td>
<td>The record from the source table that is currently being processed.</td>
</tr>
<tr>
<td>target</td>
<td>GlideRecord</td>
<td>The record from the target table that is currently being processed.</td>
</tr>
<tr>
<td>answer</td>
<td>String</td>
<td>The field value to set in the target record.</td>
</tr>
<tr>
<td>map</td>
<td>GlideTransformMap</td>
<td>Read-only information about the current transform map record.</td>
</tr>
<tr>
<td>log</td>
<td>Function</td>
<td>The log object for the current import run. Use this object to log messages such as <code>log.info(&quot;&lt;Message&gt;&quot;)</code> or <code>log.warn(&quot;&lt;Message&gt;&quot;)</code>. This object logs to the import log for standard import sets, or other log locations as required, such as for web service imports.</td>
</tr>
<tr>
<td>action</td>
<td>String</td>
<td>Contains either the value <strong>insert</strong> or <strong>update</strong>, depending on whether the current target row will be created or updated.</td>
</tr>
</tbody>
</table>

**Note:** The `action` variable is available only when the **Coalesce** field is **false**.
Run an import

You can manually run an import to immediately import data.

1. From a Transform Map, click Transform.

   When the import is done, you’ll see a link to go straight to the target table containing your imported records. The amount of time that it takes to run an import varies depending on the number of record to be imported and may take as long as several hours for very large import operations (tens of thousands of records).

2. [optional] Click on the link View the imported data to see the loaded import set table.

3. [optional] Click on the link Create transform map to create a new transform map to transform the data in the import set table to its target table.

4. [optional] Click on the link Run import to execute an existing transform map for the loaded data.

Three things to note at this point:

- The spreadsheet was imported, and a new table was created to hold the data.
- Within that table, the imported records are designated with their own "Set" value.
- A new module was created in the System Import Sets application for the new table.

Importing date/time values

Considerations when importing data containing date/time values.

- The field containing the date/time value should be a Date/Time type field in the target table.
- The user performing the import should have their timezone (in the Time zone [time_zone] field in the User [sys_user] record for that user) set to match the timezone of the date/time values in the import file.

To set the user timezone, do the following.

1. Click the user drop-down in the banner and select Profile.

2. Change the Time zone field value to the timezone of the date/time values in the import file and click Update.

Review the import set

After an import set completes, you can review the completed import and clean up import set tables. Even if no errors were reported by the progress indicator, review how your data was imported into the new import set.

1. Click View imported data.

   There are several fields that will be visible in the table that were not part of the original data source, these are system rows can be used to facilitate scripted import operations.

2. Review the data.

3. Return to the previous page.

Create a transform map to associate with this import set.

Viewing the import log

The import log is where you can find information about the internal processing that occurs during an import operation.

The log includes information generated by the system during the every step of the import operation from initialization of the import set table from a data source to transformation onto a target table. It is also possible to customize log outputs during the transformation by using log.info, log.warn, log.error statements.
Import Log

The import history gives status information about individual import operations.

Note: Functionality described here requires the Admin role.

Run import utility

The Run Import utility is used to run an import operation using an existing Transform Map and Import Set table.
Error Codes are related to a transformation. Not all errors produce error codes. If an error code does exist, it is in the [sys_import_set_row_error] table error code field.

**Error Codes**

- **100** Reference field value rejected.
- **200** Choice field value rejected.
- **300** List reference field rejected.
- **800** Invalid target record or field.
- **900** Transform script error.

**Schedule a data import**

Scheduled imports make it possible to specify that certain import operations should occur at some regular interval.

Role required: import_scheduler, import_admin, or admin

1. Navigate to **System Import Sets > Administration > Scheduled Imports**.
2. Complete the form.
Scheduled Data Import form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name for the scheduled data import.</td>
</tr>
<tr>
<td>Data source</td>
<td>Data source record that defines the data to import. If you select a remote data source, it is refreshed via the remote connection before the import begins.</td>
</tr>
<tr>
<td>Run as</td>
<td>Name of a user whose credentials the import job uses. If you do not specify a value, the import job runs as the guest user.</td>
</tr>
<tr>
<td>Active</td>
<td>Check box to activate the scheduled import.</td>
</tr>
<tr>
<td>Run</td>
<td>Frequency at which you want to run the import.</td>
</tr>
<tr>
<td>Day</td>
<td>Day on which to run the import. Visible only if you set Run to Weekly or Monthly.</td>
</tr>
<tr>
<td>Time</td>
<td>Time you want the import to begin. Do not schedule multiple imports at the same time. Running multiple imports at the same time may negatively impact performance or cause an instance outage.</td>
</tr>
<tr>
<td>Repeat interval</td>
<td>Period that must elapse before the import is repeated. Visible only if you set Run to Periodically.</td>
</tr>
<tr>
<td>Starting</td>
<td>Date on which the import should begin (selected using the calendar icon). Visible only if you set Run to Periodically.</td>
</tr>
<tr>
<td>Parent</td>
<td>The parent import set to which this import set belongs, and after which this import should run. Visible only if you set Run to After Parent Runs.</td>
</tr>
<tr>
<td>Conditional</td>
<td>Check box to specify a script that defines the conditions that must evaluate to true before the import runs.</td>
</tr>
<tr>
<td>Condition</td>
<td>Script that evaluates whether an import should run. Visible only if you select the Conditional check box.</td>
</tr>
<tr>
<td>Concurrent Import</td>
<td>Check box to run a concurrent import. A concurrent import splits the data into multiple import sets and runs the import sets concurrently to reduce processing time for large data sets.</td>
</tr>
</tbody>
</table>

**Note:** A concurrent import does not transform data in a predictable order. If order matters, do not run a concurrent import.

For more information, see Concurrent imports.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Partition Method</td>
<td>Method used to allocate each data set record to an import set:</td>
</tr>
<tr>
<td></td>
<td>- <strong>Round Robin</strong>: The system sets partitions automatically. Assume 20 records and 4 import sets. The system allocates record 1 to import set 1, record 2 to import set 2, record 3 to import set 3, and record 4 to import set 4. The system then allocates record 5 to import set 1, record 6 to import set 2, record 7 to import set 3, and record 8 to import set 4. This continues until all records are assigned to import sets. When allocation is finished, import set 1 contains records 1, 5, 9, 13, 17. Import set 2 contains records 2, 6, 10, 14, 18. Import set 3 contains records 3, 7, 11, 15, and 19. Import set 4 contains records 4, 8, 12, 16, and 20.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Custom Script</strong>: Sets the partitions with a Partition Script you provide.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Custom size</strong>: Sets the partition size to the Partition Size specified. Once the system processes the first partition, the data from that partition can be transformed, even though the other partitions have not finished processing.</td>
</tr>
<tr>
<td>Partition Script</td>
<td>Script to return a partition key. The system ensures that data set rows with the same partition key go to the same import set. Visible only if you set <strong>Partition Method</strong> to Custom Script.</td>
</tr>
<tr>
<td>Partition Size</td>
<td>The number of records in each partition. Visible only if you select a <strong>Partition Method</strong> of Custom size.</td>
</tr>
<tr>
<td>Execute pre-import script</td>
<td>Check box to specify a script to run before the import is performed.</td>
</tr>
<tr>
<td>Pre script</td>
<td>Script to run before the data is imported. Visible only if you select the Execute pre-import script check box.</td>
</tr>
<tr>
<td>Execute post-import script</td>
<td>Check box to specify a script to run after the import is performed.</td>
</tr>
<tr>
<td>Post script</td>
<td>Script to run after the import is performed. Visible only if you select the Execute post-import script check box.</td>
</tr>
</tbody>
</table>

**Note:** For concurrent imports, the script runs after the last Import Set Transformer job completes.
3. Click **Submit**.
To stop an import that is taking too much time, navigate to **System Import Sets > Advanced > Progress**.
   a. Open the Progress Worker that must be canceled.
   b. In the Related Links, click **Cancel job**.

**Scheduled data import scripting options**
Multiple JavaScript objects are available in the Scheduled Data Import **Pre script** and **Post script** fields.

### Data import scripting options

<table>
<thead>
<tr>
<th>Object</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>cancel</td>
<td>Set this object to <strong>true</strong> to stop the import action.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Use the <strong>Pre script</strong> field to evaluate the conditions of the import and determine whether to cancel the import process. To cancel the import process, use the following call:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>```</td>
<td></td>
</tr>
<tr>
<td></td>
<td>cancel = true;</td>
<td></td>
</tr>
<tr>
<td></td>
<td>```</td>
<td></td>
</tr>
<tr>
<td>import_set</td>
<td>Get the GlideRecord object for the new import set. This variable allows you to query the following columns from the sys_import_set table:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• number</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• sys_id</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• state</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• table_name</td>
<td></td>
</tr>
<tr>
<td>data_source</td>
<td>GlideRecord of the data source to be used for the scheduled import.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Typically, you define the data source with the Scheduled Data Import record. If you want to access this data source or modify the data source in certain conditions, you can use the following.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>```</td>
<td></td>
</tr>
<tr>
<td></td>
<td>data_source.import_set_table_name = 'new_set_from_scheduler';</td>
<td></td>
</tr>
<tr>
<td></td>
<td>data_source.update();</td>
<td></td>
</tr>
</tbody>
</table>

**Monitor concurrent import sets**

Check the status of import sets and import set jobs, resume or reprocess import sets, and view transform history.

When a scheduled concurrent import runs, each concurrent import creates a concurrent import set record. All related import sets, concurrent import set jobs, and transform histories are shown in the form view.

Role required: import_admin

1. Navigate to **System Import Sets > Concurrent Import Set Jobs**.
2. Select the scheduled import for which you want to check status.
3. In the Related Links, reprocess or continue import sets, check the status of import sets or concurrent import set jobs, or view transform history.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reprocess</td>
<td>Start another scheduled import to reprocess the records.</td>
</tr>
<tr>
<td>Continue</td>
<td>Restart a scheduled import that was not completed.</td>
</tr>
<tr>
<td>Import Sets</td>
<td>State of import sets.</td>
</tr>
<tr>
<td></td>
<td><strong>State</strong></td>
</tr>
<tr>
<td></td>
<td>• Pending if the system has not started processing the import set.</td>
</tr>
<tr>
<td></td>
<td>• Running if the system is processing the import set.</td>
</tr>
<tr>
<td></td>
<td>• Processed if the system has completed processing the import set.</td>
</tr>
<tr>
<td></td>
<td>• Error if the import set processing failed.</td>
</tr>
</tbody>
</table>

Select an import set to see processing details for Import Set Runs and Import Set Rows for the import set.

<table>
<thead>
<tr>
<th>Concurrent Import Set Jobs</th>
<th>Type and state of concurrent import set jobs:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Type</strong></td>
</tr>
<tr>
<td></td>
<td>• Regular if you are running the scheduled import for the first time.</td>
</tr>
<tr>
<td></td>
<td>• Reprocessing if you are rerunning the scheduled import.</td>
</tr>
<tr>
<td></td>
<td>• Resuming if you are resuming a scheduled import that had an error.</td>
</tr>
<tr>
<td></td>
<td><strong>State</strong></td>

<td>• Completed if the system has completed processing the import set.</td>
</tr>
<tr>
<td></td>
<td>• Error if the import set processing failed.</td>
</tr>
</tbody>
</table>

Select an import set job to see processing details for Import Set Runs and Import Set Rows for the import set job.

<table>
<thead>
<tr>
<th>Transform Histories</th>
<th>Check statistics in the transform histories for the scheduled import.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Select a start time to see Import Set Row Errors (including error codes and messages) and the Import Log for the scheduled import.</td>
</tr>
</tbody>
</table>

### Monitor concurrent import set jobs

Check the status of concurrent import set jobs.

Role required: import_admin

1. Navigate to **System Import Sets > Concurrent Import Set Jobs**.
2. Review the **Type** and **State** of each parent import set job.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>Type of concurrent import set job:</td>
</tr>
<tr>
<td></td>
<td>• Regular if you are running the scheduled import for the first time</td>
</tr>
<tr>
<td></td>
<td>• Reprocessing if you are rerunning the scheduled import</td>
</tr>
<tr>
<td></td>
<td>• Resuming if you are resuming a scheduled import that had an error</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td>State</td>
<td>Status of the import set job:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Pending</strong> if import processing has not started</td>
</tr>
<tr>
<td></td>
<td>• <strong>Running</strong> when import processing has started</td>
</tr>
<tr>
<td></td>
<td>• <strong>Completed</strong> when import processing has finished</td>
</tr>
<tr>
<td></td>
<td>• <strong>Error</strong> if import processing did not finish successfully</td>
</tr>
</tbody>
</table>

3. Select a parent import set job to review the **Type** and **State** of each of its child import set jobs.

**Post CSV or Excel files directly to an import set**

An administrator can post CSV or Excel files directly to an instance.

Role required: import_set_loader

The `sys_import.do` target lets you dynamically upload a CSV or Excel file into the import set table specified by the `sysparm_import_set_tablename` parameter. You must specify a name that matches an existing import set table name. If the import set table does not exist, pre-create it by performing a manual import. The `sysparm_transform_after_load=true` parameter causes the CSV transform to be executed immediately, if a transform map exists.

You can upload a file using POST to the following URL (replace placeholders with desired values):

```
https://<instance>.service-now.com/sys_import.do?
sysparm_import_set_tablename=<table_name>&sysparm_transform_after_load=<true>
```

**Important:** The body of the POST must contain the file as a multi-part attachment.

**Posting a CSV file - Perl and Java examples**

An example using Perl to post a CSV file with basic auth credentials and Java Apache HttpClient class to post a CSV file with basic auth credentials.

**Perl example**

```perl
# file: uploadafile.pl
# call me like this:
# uploadafile.pl --url="https://instance.service-now.com/sys_import.do?
sysparm_import_set_tablename=dloo_test&sysparm_transform_after_load=true"
# --uploadfile=/Users/davidloo/Desktop/test_files/test_users.csv
#
# the "sysparm_transform_after_load=true" parameter instructs the import set
to transform immediately after loading
#
# use strict;
use LWP::UserAgent;
use HTTP::Request::Common;
use Getopt::Long;
use File::Basename;

my ( $o_url, $o_fqn );
GetOptions(
   "url=s"      => \$o_url,
   "uploadfile=s" => \$o_fqn,
);
#
```
```perl
$usage unless ( $o_url && $o_fqn );
my $url   = $o_url;
my $fname = $o_fqn;

# put timeouts, proxy etc into the useragent if needed
my $ua  = LWP::UserAgent->new();

# setup basic authentication credentials
$ua->credentials(
    'demo.service-now.com:443',
    'Service-now',
    'admin' => 'admin'
);

my $req = POST $url, Content_Type => 'form-data',
    Content => [
        submit => 1,
        upfile => [ $fname ]
    ];
my $response = $ua->request($req);

if ($response->is_success()) {
    print "OK: ", $response->content;
} else {
    print $response->as_string;
}
exit;

sub usage {
    printf "usage:&nbsp;%s --url=%s --uploadfile=%s\n",
        basename($0),'https://....','c:/data/test.csv';
    exit
}
```

**Java example**

**Attention:** The Apache HttpClient may limit the amount of data you can import in a single transaction. This example is meant as a starting point and should not be used in production.

```java
HttpClient httpclient = new HttpClient();
PostMethod post = new PostMethod("https://instance-name.service-now.com/
    sys_import.do?sysparm_import_set_tablename=u_test_upload&sysparm_transform_after_load=true");
try {
    Credentials defaultcreds = new UsernamePasswordCredentials("admin",
        "admin");
    httpclient.getState().setCredentials(AuthScope.ANY, defaultcreds); // Prepare HTTP post
    httpclient.getParams().setAuthenticationPreemptive(true);

    File targetFile = new File("/Users/davidloo/Desktop/test_files/
        nodeinfo2736820198834983863.csv");
    Part[] parts = { new FilePart(targetFile.getName(), targetFile) };
```
post.setRequestEntity(new MultipartRequestEntity(parts, post.getParams()));

    int result = httpClient.executeMethod(post);

    // Display status code
    System.out.println("Response status code: "+result);

    // Display response
    System.out.println("Response body: "+post.getResponseBodyAsString());
} catch(Exception e) {
    System.err.println(e.getMessage());
} finally {
    // Release current connection to the connection pool
    // once you are done
    post.releaseConnection();
}

Delete import sets

Delete import sets to clean up your database on a scheduled basis, one time only, or on demand.

Role required: admin

1. Navigate to **System Import Sets > Import Set Tables > Scheduled Cleanup.**
2. Fill out the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Defaults to <strong>Import Set Deleter.</strong> You can change the name if desired.</td>
</tr>
<tr>
<td>Active</td>
<td>Checked if the schedule is active. Unchecked if the schedule is not active.</td>
</tr>
<tr>
<td>Run</td>
<td>Specifies the frequency of the Import Set Deleter: Daily, Weekly, Monthly, Periodically, Once, or On Demand.</td>
</tr>
<tr>
<td>Time</td>
<td>Specifies up to three times of day to run the Import Set Deleter.</td>
</tr>
<tr>
<td>Application</td>
<td>Defaults to <strong>Global</strong> and can't be changed.</td>
</tr>
<tr>
<td>Conditional</td>
<td>Checked if the Import Set Deleter must meet specified conditions. Unchecked if the Import Set Deleter doesn't have to meet any conditions.</td>
</tr>
<tr>
<td>Run this script</td>
<td>The script that performs the deletion. Defaults to deleting import sets and their related import set rows that were created more than seven days ago.</td>
</tr>
<tr>
<td>Day</td>
<td>The day of the week for weekly runs, or the day of the month for monthly runs.</td>
</tr>
<tr>
<td>Repeat Interval</td>
<td>The number of days in the repeat interval and up to three times of day for the repeat interval.</td>
</tr>
<tr>
<td>Starting</td>
<td>The starting date and time for the periodical run or the one-time run.</td>
</tr>
</tbody>
</table>

3. Click **Update** to update the schedule, or click **Execute Now** to run the Import Set Deleter immediately.
Delete import set tables

Delete import set tables, related transform maps, or data only (preserving the table structure) to clean up your database.

Role required: admin

1. Navigate to System Import Sets > Import Set Tables > Cleanup.
2. Move the tables you want to delete from Available tables for deletion to Delete these tables. Deleting any table deletes all records and removes the table.
3. Select the Delete related transform maps check box to delete the selected import set tables and their related transform maps. All records and all associated transform maps are removed. Deselect the check box if you don’t want to delete the related transform maps.
4. Select the Delete data only (preserve table structure) check box to delete the data only from the selected import set tables and preserve the table structure. All records are removed, but the tables remain intact. Deselect the check box if you want to delete the selected import set tables as well as the data in those tables.
5. Click Cleanup.

Import sets properties

Multiple properties control import set behavior.

Import sets properties

**glide.import_set.preserve.leading.spaces**

Specifies whether the import process preserves leading spaces in Excel data cells. When false, the import process removes leading spaces from Excel data cells. When true, the import process preserves leading spaces.

![Note: The import process always removes trailing spaces from Excel data cells.](image)

- Type: true | false
- Default value: false
- Location: Add the property

**glide.import_set_row.dynamically_add_fields**

Specifies whether an import set can add new columns to the staging table (true) or not (false). Instances that contain large numbers of import sets can sometimes become unresponsive when an import adds a column because the instance must alter every row in the staging table. In some cases, the database alter table action causes an outage. Setting this property to false prevents an import set from adding columns to the staging table and produces a log message. As a workaround, administrators can manually add a column to the staging table by creating a new dictionary entry and then reimporting the import set.

- Type: true | false
- Default value: true
- Location: Add the property

**com.glide.loader.verify_target_field_size**

Enables dynamic resizing of import set fields. By default, up to 20 records of the source data are sampled to determine the import set field length. If the field is empty in all the sampled records, the default length of 40 is used. Any data loaded that exceeds the import set table field length is truncated.

- Type: true | false
**glide.ds.file.http.variable_replacement**

Enables system property expansion for File-type data sources that are retrieved using HTTP or HTTPS.

- **Type:** true | false
- **Default value:** true
- **Location:** Add the property
- **More information:** Data source fields

**glide.scheduled_import.stop_on_error**

Set to true to stop the import process when the parent scheduled import generates an error. This behavior can be useful when one import set depends on the results of another import set.

- **Type:** true | false
- **Default value:** false
- **Location:** Add the property

**glide.impex.transformer.empty_value_nil**

Controls how empty string values are handled during transformation from an import set staging table. Set this property to true to preserve empty strings. Set this property to false to convert empty strings to the string NULL.

**Note:** An empty string is always stored as a null value in the database, regardless of this property value.

You can use this property when you run an onBefore script during transformation. Setting this property to true allows you to check for null values using hasValue() or nil() functions.

- **Type:** true | false
- **Default value:** false
- **Location:** Add the property

**com.glide.loader.max_scan_rows**

Controls how many rows of source data are sampled to automatically generate staging table fields when you import data. This property applies to JDBC, XLS, CSV, and XML imports but not to JSON and XSLX imports.

- **Type:** integer
- **Default value:** 20
- **Location:** Add the property

### Concurrent import sets properties

**glide.scheduled_import.max.concurrent.import_sets**

Maximum number of import sets for one concurrent import.

- **Type:** Integer
- **Default value:** 10
- **Location:** Add the property

**com.glide.concurrent_import_set_insert_mutex_spin_wait**
Wait time mutex spends if the lock is acquired (in milliseconds).

- Type: Integer
- Default value: 1000
- Location: Add the property

**com.glide.concurrent_import_set_insert_mutex_expiration**

Mutex expiration time (in milliseconds).

- Type: Integer
- Default value: 300000
- Location: Add the property

**com.glide.concurrent_import_set_mutex_fast_lock**

Specifies whether to use fast lock (true) or SQL-based slow lock (false).

- Type: true | false
- Default value: false
- Location: Add the property

### Web service import sets properties

**com.glide.ws_import_set.column_resize**

When true, enables dynamic column resizing on import staging tables for web service import sets.

- Type: true | false
- Default value: false
- Location: Add the property

**com.glide.ws_import_set.column_resize.max_row_count**

The maximum number of rows an import staging table can have for dynamic column resizing with web service import sets.

Import staging tables with more than this number of rows will not use dynamic resizing with web service import sets, even if **com.glide.ws_import_set.column_resize** is true.

This property has a maximum value of 500,000.

- Type: Integer
- Default value: 100,000
- Location: Add the property

### CSV properties

**com.glide.csv.loader.ignore_non_parseable_lines**

Allows an instance to ignore one or more lines (rows) that contain bad data in a CSV import, such as a row that is missing a column of data. By default, imports cannot ignore bad data in CSV files and fail on the first error.

- Type: true | false
- Default value: false
• Location: Add the property

**com.glide.csv.loader.max_errors_allowed**

Specifies the maximum number of lines (rows) that an import can ignore before failing. If the import succeeds, the import lists the number of rows the import ignored due to errors.

- Type: integer
- Default value: 100
- Location: Add the property

**glide.import.csv.charset**

The charset of the CSV file to import. Valid values are UTF-8 and WINDOWS-1252. You may need to use UTF-8 formatting when importing special characters.

- Type: String
- Default value: WINDOWS-1252
- Location: Add the property

**Excel import properties**

**glide.excel.multiplier**

The maximum amount of instance memory to allocate to an Excel import. This property applies when importing .XLS files only.

The value of this property is multiplied by the file size of the Excel file to determine the total memory allocation. The memory used cannot exceed the limit specified by the `glide.excel.max_memory_percent` property.

For example, with the default value 8 and a 10MB Excel file, the instance will use up to 80MB of memory for the import.

- Type: integer
- Default value: 8
- Location: Add the property

**glide.xlsx.multiplier**

The maximum amount of instance memory to allocate to an Excel import. This property applies when importing .XLSX files only.

The value of this property is multiplied by the file size of the Excel file to determine the total memory allocation. The memory used cannot exceed the limit specified by the `glide.excel.max_memory_percent` property.

For example, with the default value 10 and a 10MB Excel file, the instance will use up to 100MB of memory for the import.

**Note:** Do not modify the value of this property. The default value was selected for optimal performance.

- Type: integer
- Default value: 10
- Location: Add the property

**glide.excel.max_memory_percent**

The maximum amount of memory allowed for Excel imports, as a percentage of the total instance memory.
• Type: integer
• Default value: 20
• Location: Add the property

**glide.excel.use_disk_backed_strings_table**

Controls whether the instance uses disk storage to maintain large file data during XLSX import. Set this property to false to store XLSX file data only in memory. Setting this property to false increases the memory used during XLSX import.

• Type: true | false
• Default value: true
• Location: Add the property

**glide.excel.in_memory_strings_table_size_mb**

The maximum amount of memory, in megabytes, available to store XLSX file data before writing to disk storage when glide.excel.use_disk_backed_strings_table is true. Setting a lower value for this property will use less memory during XLSX import but may result in slower imports.

• Type: integer
• Default value: 5
• Location: Add the property

**glide.xlsx.import.debug**

Enables debug logging for XLSX imports.

• Type: true | false
• Default value: false
• Location: Add the property

**glide.import.excel.enhanced_number_conversions**

When true, numeric values greater than 10 million are preserved in import staging tables. When false, imported values greater than 10 million are converted to scientific notation that may not match the original imported value. This property should be set to true for importing most kinds of data.

• Type: true | false
• Default value: true
• Location: Add the property

**JDBC connection properties**

**glide.jdbcprobeloader.retry**

The number of times a JDBC probe loader attempts to process data returning from a JDBC data source. Sleeps on the value defined in glide.jdbcprobeloader.retry_millis between retries.

• Type: integer
• Default value: 60
• Location: Add the property

**glide.jdbcprobeloader.retry_millis**
How many milliseconds a JDBC probe loader waits in between retry attempts to process data from a JDBC data source.

- Type: integer
- Default value: 5000
- Location: Add the property

**Logging and debug properties**

**com.glide.import_set.importlog_level**

Specifies how much information import sets add to the log. Possible values are INFO, WARNING, and ERROR. You can set this to INFO in the dev environment and change it to WARNING or ERROR in production to reduce amount of logging noise traffic to the database.

**Note:** This property does not impact logging related to the cleanup of staging tables.

- Type: string
- Default value: INFO
- Location: Add the property

**glide.import.debug**

Enables debug logging for all import processes.

- Type: true | false
- Default value: false
- Location: Add the property

**glide.import.sftp.debug**

Enables additional debug logging for SFTP imports. Enabling this property will cause the instance to log all outgoing and incoming messages during the SSH session.

- Type: true | false
- Default value: false
- Location: Add the property

**glide.import.scp.debug**

Enables additional debug logging for SCP imports. Enabling this property will cause the instance to log all outgoing and incoming messages during the SSH session.

- Type: true | false
- Default value: false
- Location: Add the property
Web service import sets

Web service import sets complement direct web services and scripted SOAP web services providing a web service interface to import set tables.

Web service import set

By default, this type of web service transforms the incoming data synchronously based on the associated transform maps. If the associated import set mode is set to **Asynchronous**, the behavior is to save the data for transformation at a later time. Web service import sets tables publish all the default web service functions in the WSDL.

System web services

This plugin also provides the following standard import set tables:

- Computer
- Location
- Notification
- User

You can access a web service import set WSDL by specifying the import set table name + ".do?WSDL" on the URL. For example:

http://<instance name>.service-now.com/imp_notification.do?WSDL.
Creating an import set web service

Create a web service import set table to define how to stage and transform imported data.

Navigate to System Web Services > Create New.

![Create Web Service form]

Create Mapped Web Service

The Name of the web service is the table name of the import set table whereas the Label field is the resulting table field.

If you want to create a transform map after creating the web service, check the Create transform map checkbox and choose the target table you want the data to transform into. After the Create button is clicked, the web service will be created and you will be immediately put into the Table Transform Map form. You may then continue to specify the transform map or script.

Web Service Fields

The fields available for this web service. All fields by default are published as the XSD type of xsd:string. The Name is the field that is exposed for the web service and therefore appears as the name of the field in the WSDL. The Label is the label of the field as it appears for the import sets table.

You can Add, mark for Delete or modify (double-click the field) an existing web service field in this list.

Note: After adding web service fields, click Create to create the web service import set table.
To add other fields after the Web Service is created, find the target table, and add the fields to that table.

**Mapping web service import sets**

During the creation of the web service import set, you may optionally create the transform map for it. All transform maps are executed for the service when it is invoked and the import set mode is set as "Synchronous" (the default).

The following image is an example of the transform map associated with the Notification web service import set.
Soap Transform Map

Adding Web Service Response Values

In the transform map script associated with a web service import set, some variable values can change the response values of the web service. In addition to the normal variables that are available in a transform map script, the table documents the variables that are available and their effects.

**Adding Web Service Response Values**

<table>
<thead>
<tr>
<th>Variable name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>response</td>
<td>Output Object</td>
<td>Javascript object that holds dynamically created response elements used to customize the output response of a web service import set insert.</td>
</tr>
</tbody>
</table>

**Example**

```
// create new elements called "transaction_id"
// and "hello" in the web service response
response.transaction_id="abc123";
response.hello="world";

status_message="message 1";
// this is the normal status_message variable
```

The code snippet example results in the following response being generated back to the web service consumer

```xml
<soapenv:Envelope
 xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
 xmlns:imp="http://www.service-now.com/imp_notification"
><soapenv:Header/>
<soapenv:Body><soapenv:Header/>
<soapenv:Body><soapenv:Body>
<insertResponse
 xmlns="http://www.service-now.com/imp_notification"
><sys_id>969d157c0a0a0baf008ba5770ffa798c</sys_id>
<table>incident</table>
<display_name>number</display_name>
<display_value>INC0010091</display_value>
<status>inserted</status>
<status_message>message 1</status_message>
<transaction_id>abc123</transaction_id>
<hello>world</hello>
</insertResponse>
</soapenv:Body></soapenv:Envelope>
```

**Debugging web service import sets**

To debug a SOAP Request coming into the system, create the system property `glide.processor.debug.SOAPProcessor`. Once you have created it, set it to `true` to have all SOAP requests be logged in the System Log. Set it to `false` when you are done to keep the size of your System Log to a managed length.
Web service import set mode

When a SOAP message inserts a record into an import set table, and there is no import set for that table in the **Loading** state, a new import set will be created with the **Mode** set to **Synchronous**.

An import set with a **Mode** of **Synchronous** will transform the data as soon as it is inserted (provided that the transform map already exists). This import set will also have a default **State** of **Loading**. By default, all **Synchronous** import sets will automatically be modified to **Processed** at midnight. As a result, when a new insert happens to the same table, a new **Synchronous** import set will be created.

<table>
<thead>
<tr>
<th>Number</th>
<th>Created</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISET10009</td>
<td>2009-01-12 15:50:27</td>
</tr>
</tbody>
</table>

**Synchronous** import set

Changing this import set to a **mode** of **Asynchronous** and a **state** of **Loading** has the effect of not transforming the incoming data as it is inserted, but rather "loading" the import set and deferring the data transformation later, either manually, or with a scheduled script job.

<table>
<thead>
<tr>
<th>Mode</th>
<th>State</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Asynchronous</td>
<td>Loading</td>
<td>Data transformation is not occurring automatically and immediately. Data added to import set row has a state of &quot;Pending&quot;. Transform can be scheduled or executed manually when state is changed to <strong>Loaded</strong>.</td>
</tr>
<tr>
<td>Asynchronous</td>
<td>Loaded</td>
<td>Marks the completion of data loading. Data transformation can now occur in a scheduled fashion or manually.</td>
</tr>
<tr>
<td>Synchronous</td>
<td>Loading</td>
<td>Data transformation is occurring automatically and immediately whenever data is inserted into the associated import set row.</td>
</tr>
</tbody>
</table>
Controlling Insert Behavior

In imports sets that specify one or more coalesce fields, records with a matching coalesce value are transformed from source to target table serially (one at a time) to prevent duplicates. In import sets that do not specify any coalesce field, records are transformed concurrently. You can control this behavior using the `glide.import_set_insert_serialized_when_no_coalesce` property.

The `glide.import_set_insert_serialized.<table name>` system property controls how the instance inserts records from web service calls into a specific import set table. When true, this property prevents identical simultaneous inserts from creating duplicate records by serializing the database insert operations. If a target table does not have any coalesce fields defined in a transform map, set this property to `false` to improve web service import set performance.

**Note:** Setting this property to `false` can result in the creation of duplicate records.

**Note:** The `glide.soap.import_set_insert_serialized.<table name>` system property provides equivalent functionality to `glide.import_set_insert_serialized.<table name>`, but if both properties are defined, `glide.import_set_insert_serialized.<table name>` supersedes `glide.soap.import_set_insert_serialized.<table name>`.

Standard SOAP Response

The SOAP response from a web service import set `insert` call returns the following standard values:

```xml
 xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/"
  <SOAP-ENV:Body><insertResponse><sys_id>fa648f5f0a0a0b2b0048e7012448b8f1</sys_id><table>incident</table><display_name>number</display_name><display_value>INC10014</display_value><status>inserted</status></insertResponse></SOAP-ENV:Body></SOAP-ENV:Envelope>
```
### Standard SOAP Response

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sys_id</td>
<td>The Sys_id of the resulting record that was created or modified</td>
</tr>
<tr>
<td>table</td>
<td>The table name of the table that was affected. In the case of an <strong>Asynchronous</strong> call, the table name would be the import set table eg. imp_notification for the <strong>Notifications</strong> web service import set table</td>
</tr>
<tr>
<td>display_name</td>
<td>The name of the field that is set as the display field for the record that was created or modified</td>
</tr>
<tr>
<td>display_value</td>
<td>The value of the field designated as the display field. For example, the display field for the <strong>Incident</strong> table is the <strong>Number</strong> field and an example value would be INC10001</td>
</tr>
<tr>
<td>status</td>
<td>A string value that indicates the action that occurred as a result of the web service invocation, relating to the record defined by the sys_id and table field values</td>
</tr>
<tr>
<td></td>
<td>• <strong>inserted</strong> - the record was inserted</td>
</tr>
<tr>
<td></td>
<td>• <strong>updated</strong> - the record was updated</td>
</tr>
<tr>
<td></td>
<td>• <strong>ignored</strong> - the input was ignored, the record was not updated and no new record was created</td>
</tr>
<tr>
<td></td>
<td>• <strong>skipped</strong> - the input data was skipped (similar to ignored) due to missing coalesce values</td>
</tr>
<tr>
<td></td>
<td>• <strong>error</strong> - there was an error processing the input</td>
</tr>
<tr>
<td>status_message</td>
<td>This value translates to the value found in the Comment field of the import set row and usually contains information related to the status value eg. &quot;No field values changed&quot; when the status is &quot;ignored&quot;. Setting this value to a customized string value will cause the SOAP response to contain an optional status_message field to be returned</td>
</tr>
<tr>
<td>error_message</td>
<td>The message related to a status of <strong>error</strong>. When an error occurs, setting this value to a customized string value will cause the SOAP response to contain an optional error_message field to be returned</td>
</tr>
</tbody>
</table>

### Tailoring the SOAP Response

It is possible to include information other than the information specified in the WSDL by overwriting the contents of **status_message** using the transform script.

### Inserting multiple records using insertMultiple

You can insert multiple records in one SOAP request by using the insertMultiple operation.

By default, insertMultiple operations create new import sets in **Synchronous** mode. To process new import sets asynchronously, activate the business rule Insert multiple asynchronous mode.

The insertMultiple operation is available for the Direct Web Service API and Web Service Import Sets. To enable insertMultiple, activate the Insert Multiple Web Service plugin.
**Web service import sets security requirements**

Web Service Import Sets use the same security mechanisms as SOAP Web Services.

- Basic authentication requires a Web Service user provide a valid user name and password.
- Contextual security requires a Web Service user meet the access control rule of the queried table.

If your instance uses high security settings, the Web Service user may also need the `soap` role.

**Web service import sets related links**

When displaying a mapped web service table, you have the following related links.

- Import Sets — The import sets related to this web service import set.
- Transform Maps — A list of transform maps related to this web service.
- Transform History — The transformation history.
- Edit Web Service — Edit the web service.

The following image shows a record that was inserted into the web service import set Notification. The target record is the resulting creation or modification to the Incident table record as a result of the transform.
Web service import sets example

This example demonstrates the WSDL, SOAP envelope and response, Perl invocation, and result of a SOAP web service import.

Sample WSDL

```xml
<?xml version="1.0" encoding="UTF-8"?>
```
Sample SOAP Envelope

```xml
```

Sample SOAP Response

```xml
  <SOAP-ENV:Body>
    <insertResponse>
      <sys_id>b54aafbf0a8006f0058db95daa5b88d</sys_id>
      <table>incident</table>
      <display_name>number</display_name>
      <display_value>INC10008</display_value>
      <status>ignored</status>
      <status_message>No field values changed</status_message>
    </insertResponse>
  </SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

Example Invocation using Perl

The following example script uses the Notification web service to create an Incident as the itil user. It uses the Perl language and the SOAP::Lite package.

```perl
#!/usr/bin/perl -w
use SOAP::Lite ( +trace => all, maptype => {} );use SOAP::Lite;
sub SOAP::Transport::HTTP::Client::get_basic_credentials{return 'itil': 'itil';} // set basic auth credentials for the itil user
my $soap = SOAP::Lite->proxy('http://localhost:8080/glide/imp_notification.do? SOAP');
my $method = SOAP::Data->name('insert')->;attr({xmlns => 'http://www.service-now.com/'}); # insert into the web servicemy@params=( SOAP::Data->name(message =>'problem detected for database DB12DG'));push(@params, SOAP::Data->name(source =>'DB12DG'));push(@params, SOAP::Data->name(uuid =>'HGAF76251HGF2'));
my $result = $soap->call($method => @params);
print_fault($result); // print any SOAP faults
print_result($result); // print any results
sub print_result {my ($result) = @_; if ($result->body && $result->body->{insertResponse}) {
my $keyHash = %{$result->body->
```
The following is the result printed by the Perl script on the console:

```
name=display_value   value=INC10011
name=status   value=inserted
name=table   value=incident
name=display_name   value=number
name=sys_id   value=cd45649c0a0a0b2b00e6f27649d6b2c
```

The following image shows the resultant row created for the import set table **Notification** (imp_notification).

**Easy import**

Easy import is a simplified import process that enables you to import only the columns you want.

Only admins can use easy import. You can import data to tables within the current scope and tables that grant write access to other applications.

**Easy import template validation**

Each import template must pass two sets of validation:

<table>
<thead>
<tr>
<th>Type of validation</th>
<th>Stored in</th>
<th>Results of failing validation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Client-side validation</td>
<td>Import template</td>
<td>The template highlights the invalid cell.</td>
</tr>
</tbody>
</table>
### Download an import template

Select the list you want to import data to and create an import template from that list.

Role required: admin

1. Navigate to any list, such as **Self-Service > Incidents**.
2. Right-click the column heading.
3. Select **Import**.
4. Select if you want to **Insert** or **Update** records.

<table>
<thead>
<tr>
<th>Template</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Insert</td>
<td>Use this template to add new records to a table.</td>
</tr>
<tr>
<td>Update</td>
<td>Use this template to change values within existing records in a table. This template contains one row for each record in the list. The current list filter determines what records the template contains.</td>
</tr>
</tbody>
</table>

5. Optional: Clear the **Include all fields in the template?** check box to include only columns that appear in the list in the template. Certain fields in the table are updated by system processes, and you cannot import values into them. An example is the **Created by** field, which is populated during import with the logged-in user who performs the import.

   Leave this check box selected to include all columns from the table in the template, even those columns that are hidden in the list.

6. Select the **Export template format** you want, either **XLS** or **XLSX**.

   XLSX is the preferred format, XLS is available for legacy support. The **Export template format** field appears only if the property `glide.legacy.excel.export` is true.
7. Click **Create Excel template**.

Open the spreadsheet using your preferred application.

**Note:** Each template contains a **Directions** tab describing how to use the template.

**Add a record in the template**

Add rows to the template to create new records.

Role required: admin

**Note:** The template only imports records on the first page of the template. The import process ignores all other pages.

**Easy import insert template**

1. Add a row for each record you want to add to the table. Each column corresponds to a field in the target table. Use the UI field hints to learn about the purpose and content of the field.

   The template validates values as you enter them and highlights cells containing invalid data. While you do not have to provide a value for every column, certain fields may fail validation if you do not provide a value.

2. Review any highlighted cell and resolve the issue.

3. When you finish entering new rows, save the spreadsheet as an Excel Workbook.

   The insert templates use special processing for certain fields:
   - **Created by Field**: The insert template always lists the system administrator user (admin role) in the Created by field regardless of whether the import includes a Created by column. Even if you provide a different user value in the template, the import process overwrites this value with the system administrator user.
   - **Blank Values**: Leaving a cell blank in the insert template results in a blank value in the imported record, provided the field supports a blank value. Fields that do not support a blank value will produce a validation error if you provide a blank value.
Update a record in the template

Modify rows in the template to update existing records.

Role required: admin

Note: The template only imports records on the first page of the template. The import process ignores all other pages.

Easy import update template

1. Edit the row for each existing record to be updated. Replace existing values with new values. Use the UI field hints to learn about the purpose and content of the field.

   The template validates values as you enter them and highlights cells containing invalid data. While you do not have to provide a value for every column, certain fields may fail validation if you do not provide a value.

2. Review any highlighted cell and resolve the issue.

3. When you finish updating existing rows, save the spreadsheet as an Excel Workbook (.xls).

The insert templates uses special processing for certain fields:

- **Updated by Field**: The update template always lists the system administrator user (admin role) in the Updated by field regardless of whether the import includes an Updated by column. Even if you provide a different user value in the template, the import process overwrites this value with the system administrator user.

- **Blank Values**: The update template uses these rules when handling blank values in spreadsheet cells.

### Blank values

<table>
<thead>
<tr>
<th>Original Value</th>
<th>New Value</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blank value</td>
<td>Any non-blank value</td>
<td>Valid update: the update changes the blank value to the new value.</td>
</tr>
<tr>
<td>Any non-blank value</td>
<td>Blank value</td>
<td>Invalid update: the update preserves the existing non-blank value.</td>
</tr>
</tbody>
</table>
**Import a record from the template**

After updating the import template with new data, import the template to your instance.

Role required: admin

1. Navigate to the same list you used to download the import template.
2. Perform the appropriate action for the list version.

<table>
<thead>
<tr>
<th>Action</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>List v2</td>
<td>Right-click the column heading and select <strong>Import</strong></td>
</tr>
<tr>
<td>Action</td>
<td>Version</td>
</tr>
<tr>
<td>--------</td>
<td>---------</td>
</tr>
<tr>
<td>List v3</td>
<td>Open the list title menu and select <strong>Import</strong>.</td>
</tr>
</tbody>
</table>

To import external data into Incident:

1. Insert or update existing records using an Excel template file. Click **Upload** to preview the data to be imported. 

   ![Image of import options]

   **Do you want to insert or update data?**
   - [ ] Insert
   - [ ] Update

   **Do you want to create an Excel template to enter data?**
   - [x] Yes

   **Step 1: Create an Excel template file to enter data**
   - Include all fields in the template? [x]
   - [Create Excel template]

   **Step 2: Upload the template file**
   - Excel template file: [Choose File] No file chosen
   - [Upload]

2. From **Insert or update**, select the import type.
3. From **File**, select the import template to import.
5. Click **Upload and Preview Import Data**.

ServiceNow validates the template.

If the template passes validation and the imported preview matches your expectations, click **Complete Import** to import records into the current table. If the template fails validation, review the errors. Click **Ignore Errors and Complete Import** to continue the import by skipping any bad data cells.

---

**Show reference fields as lists in Excel templates**

Display selected reference fields as lists in Excel templates to simplify data selection and updates.

When you do an Easy Import and export the data to an Excel spreadsheet, you may want to convert some cells to lists. For example, in the Incident [sys_incident] record, you may want the **Assigned to** field options to appear as a list to enable you to select or update the person assigned to the incident.

Role required: admin

1. Navigate to the record for which you want to create lists.
2. Go to the field you want to appear as a list. Right-click the field name and select **Configure Dictionary**.
3. In the **Attributes** field of the Dictionary Entry page, enter the following attribute: `easy_import_ref_as_choice=true`. Save your dictionary entry.

You can also enter other **Attributes** for the dictionary entry. For example, there is a default limit of 250 entries in a list. If there are more than 250 entry options for a field, the entries do not appear in list format, but as a single entry. Assume that there are 500+ entry options. You can enter the following attribute in the dictionary entry for a field to set a higher limit of 600 entry options for that field: `easy_import_ref_query_limit=600`. The Excel spreadsheet now displays the field as a list of up to 600 options.

You can set a system-wide limit for the number of entry options at a field by entering a value for the `glide.easy_import.reference_query_limit` system property. If the system property is not present or not set and the `easy_import_ref_query_limit` attribute is not set for the field, the default limit of 250 entry options applies. The attribute always takes priority over the property: If both the attribute and the property are set, the attribute value is used.
4. Repeat steps 2-3 for any other fields you want to appear as lists in the Excel output. The field appears as a list on the Excel spreadsheet:

![Excel spreadsheet with list of names]

### Easy import template validation

Each import template must pass two sets of validation.

<table>
<thead>
<tr>
<th>Template validation</th>
<th>Stored in</th>
<th>Results of failing validation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Client-side validation</td>
<td>Import template</td>
<td>The template highlights the invalid cell.</td>
</tr>
</tbody>
</table>

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
<table>
<thead>
<tr>
<th>Type of validation</th>
<th>Stored in</th>
<th>Results of failing validation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side validation</td>
<td>Instance</td>
<td>The import pauses and displays an error message.</td>
</tr>
</tbody>
</table>

**Template data validation**
Some cells in the template contain calculations or validation rules. These rules are intended to help you enter data that is appropriate for the field (column).

If you want to paste data from another spreadsheet, use the **Paste Special** command to paste only values or match the existing formatting.

![Easy import paste special](image)
Paste special values only

Template type validations
Server-side validation verifies that the import template contains the necessary format.

Template type validation

<table>
<thead>
<tr>
<th>Template type</th>
<th>Validation done</th>
</tr>
</thead>
<tbody>
<tr>
<td>Insert template</td>
<td>• Template contains a header row with valid field names.</td>
</tr>
<tr>
<td></td>
<td>• Template contains one or more data rows.</td>
</tr>
<tr>
<td></td>
<td>• Template does not contain a sys_id column.</td>
</tr>
<tr>
<td>Update template</td>
<td>• Template contains a header row with valid field names.</td>
</tr>
<tr>
<td></td>
<td>• Template contains one or more data rows.</td>
</tr>
<tr>
<td></td>
<td>• Template contains a sys_id column to match a row to an existing record.</td>
</tr>
</tbody>
</table>
Data type validations
Both client-side and server-side validation verify that template cells contain data that matches the ServiceNow field type.

Data type validations

<table>
<thead>
<tr>
<th>ServiceNow field type</th>
<th>Validation done</th>
</tr>
</thead>
<tbody>
<tr>
<td>Choice list</td>
<td>Cell contains a value that matches a choice option from the choice list.</td>
</tr>
<tr>
<td>Integer</td>
<td>Cell contains a number without any decimal points.</td>
</tr>
<tr>
<td>Reference</td>
<td>Cell contains a value that matches an existing related record. This validation applies only to fields in which the list of possible choices is relatively small and mostly static. It does not apply to fields such as ‘Assigned To’ in which the list of possible choices is dynamic and large. Validation takes place when the data is inserted into the database, but not in Excel.</td>
</tr>
<tr>
<td>True</td>
<td>False</td>
</tr>
</tbody>
</table>

Note: When you enter reference field values in the Excel spreadsheet, enter the display value and not the sys_id of the referenced record. Enter this value the same as you would on a form. For example, for a reference to a user record, enter the username.

Easy import properties
Several properties control the behavior of easy import.

glide.import_template.row_limit
Controls the maximum number of rows included in an easy import template. By default, if a table contains more than 10,000 records, only the first 10,000 are exported.

- Type: Integer
- Default value: 10,000
- Location: Add the property

glide.easy_import.run_business_rules
When true, business rules, workflows, approval engines, auditing, and field normalization apply when easy import inserts or updates data. This functionality is equivalent to setting GlideRecord.setWorkflow() to true or false.

- Type: true | false
- Default value: true
- Location: Add the property

glide.import_template.field_types_to_ignore
A list of fields that will be ignored when a record is imported with easy import feature.

- Type: String
Troubleshoot import set performance

Review these performance issues to troubleshoot and improve the performance of your import set jobs.

Running business rules during transform

Running business rules during transform may cause the transform to take longer than expected, or cause the instance to slow down.

**Becomes an issue:** When importing a very large amount of data. For example, importing all data from an old system.

**Symptoms:** The transform takes much longer than expected. Also, the entire instance may be slow during that time.

**How to avoid this:** Do not run items like business rules, workflows, approval engines, and so on during a transform unless you want all insert and update business rules, notifications, and workflows to run. For example, when importing all data from an old system, you may not want notifications to run. To disable these items from running and to cease auditing and field normalization within the transform map for that import, deselect the Run business rules check box.

![Transform Map Checkbox](image)

**Note:** Consider using an onComplete transform script to run business logic such as calculations at the end of an import rather than on each record as business rules do.

Slow transform scripts

Using multiple GlideRecord queries or large loops may slow down transform scripts.

**Becomes an issue:** When the transform scripts are using multiple GlideRecord queries or looping through large collections of objects for each row. This issue may appear when the transform script is not efficient. In most cases, script goals can be accomplished using built-in functionality within the Import Set application. For example, you can script case-sensitive coalesce instead of writing scripts that use GlideRecord queries. GlideRecord queries typically slow down the import.
**Symptoms:** The transform takes much longer than would be expected. Depending on the script, the entire instance may be slow during that time.

**How to avoid this:** Use base system functionality whenever possible instead of writing custom scripts and if you do write scripts, avoid writing complicated scripts that use GlideRecord queries.

**Importing data that has not changed**
Repeatedly importing data that has not changed leads to many skipped rows.

**Becomes an issue:** When a customer is importing data from a table that is very large and most of the records are not getting updated on a regular basis.

**Symptoms:** The import set takes longer than expected. Under **System Import Sets > Progress**, expect to see an import with a **Total count** that is very high with a **Skipped count** that is also very high - this is found under the **Message** column. Indicating that most of the records imported had not actually changed. These records did not need to be imported.

**How to avoid this:** If you are running a JDBC import, use the last run datetime option in your import set **Data Source**. For a type of File import, be sure that whatever is generating your files is only adding data that is new, or has been changed.

**Coalescing on non-indexed fields**
Coalescing on non-indexed fields with a large amount of data may cause transforms to slow down.

**Becomes an issue:** When matching on fields that are not indexed, this causes the transform stage of an import to run slowly. However, it only becomes an issue if there is a large enough amount of data. In extreme cases, this causes performance issues with the database due to added load.

**Symptoms:** Time spent in the transform stage of the import is large relative to the time taken to load the data. Expect to see high transform times.

**How to avoid this:** If possible, you should coalesce on a field that unique and already indexed. To determine if a field is already indexed, navigate to **System Definition > Tables & Columns** and find the table. In the list of columns for that table, an indexed column has a blue icon with an i next to it if indexed. For assistance indexing a field contact ServiceNow Technical Support.

**Running imports simultaneously**
Running imports simultaneously may cause excessive load on the database.

**Becomes an issue:** When importing large amounts of data puts an additional load on the database. For example, importing 500,000 users and importing 200,000 configuration items at the same time. This can have a significant performance impact on all queries on the system due to the increased load on the database. This issue is especially severe when two imports are importing to the same table. In such a case, there is a possible contention issue for the table. Additionally, depending on which table is involved in processing, this can severely degrade performance of the import and the instance.

**Symptoms:** Multiple simultaneous imports running slowly combined with load on the database. You see large numbers of inserts and updates along; and if there is enough load or contention, high IO Wait times.

**How to avoid this:** Stagger your imports so they do not overlap.

**Large import set tables**
Failing to clean import set tables may lead to those tables becoming cluttered and slow.

**Becomes an issue:** When the **Import Set Deleter** job is not running.

**Symptoms:** This is a size issue. If the import sets are not cleaned on a regular basis (a cleanup is recommended after seven days worth of data) the table fills causing imports to stop.
**How to avoid this:** Verify the *Import Set Deleter* job is running. If it is not currently running, contact Customer Service and Support as they will truncate all import set tables before enabling this job.

**Altering table schema during import**

Changing the table schema, such as by importing a new column locks the import set table.

**Becomes an issue:** Any time a new column is imported, the entire import set table is locked during that schema change and depending on the size of the table, can take between five and ten minutes. During that time, no data can be selected or inserted. If that table is not used often, this may not cause any problems. However, if that table is frequently used, for example the LDAP import table, issues may arise.

**Symptoms:** The symptoms of this problem may vary. In our example of the LDAP import table, any transactions requiring a query of the LDAP import table will have to wait until the schema change has completed. As the LDAP import table is used when logging into the instance, no users are able to log in while the schema change is happening.

**How to avoid this:** Truncate the import table before importing with a new column.

**Importing very large data sets**

Importing a very large data set takes longer than importing multiple smaller data sets.

**Becomes an issue:** When very large data sets are imported in a single job.

**Symptoms:** The import job takes a long time to complete.

**How to avoid this:** Break a very large data set into multiple, smaller jobs for faster results. Consider import sets under 100,000 records as a guideline. For example, importing 10 sets of 100,000 records completes faster than one import of 1 million records even though the total data imported is the same.

**Importing from another ServiceNow instance**

There are several methods for moving data from one instance to another.

All of these methods assume you need to periodically move a collection of records from a table on one instance to a table on another instance. If you want an action on an individual record to trigger a corresponding action on another instance, consider using a REST web service instead.

**Identifying Needed Related Records**

All import processes work by fetching data from one table at a time. This process can produce unexpected results if the incoming data references new records in other tables such as users, locations, or companies. To prevent importing broken references to other tables you must identify the connections between your tables and import the common data prior to importing the application data.

For example, prior to importing incident data, you might want to first import related configuration items, users, and locations. Furthermore you might want to import incidents before importing problems or changes that refer to these incident records.

**Available Import Processes**

The system offers the following processes to move data from one instance to another.

- Export and import XML records directly from lists
- Create XML import sets and transform data as needed
- Export and import CSV files from lists
XML records from lists

You can directly export records as XML from any list or form.

This export process preserves all record field values including system generated field values such as:

- Sys ID
- Creation date
- Update date

The XML import process directly inserts records into the target table. During the import the system:

- Ignores any business rules that normally apply to the table.
- Does not provide any opportunity to transform incoming data.
- Automatically matches a reference field's display value to the local Sys ID for some tables.

This process is good for directly copying records from one system to another but does not remove the need to know the relationships between tables. If you need validate or transform data or reconcile the sys ID values of reference fields, use an XML import set instead.

Automatic matching of display values

During the import of XML records, the system attempts to match some reference field display values to a local sys_id value.

If the system finds an existing record with a matching display value on the local instance, the import uses the sys_id of the existing record rather than the sys_id of the imported record.

For example, suppose you export an incident record that is assigned to the user John Smith. In the exported XML file there is an entry such as:

```
<incident>
  ...
  <assigned_to display_value="John Smith">7712173d2ba80200c5244f74b4da159a</assigned_to>
  ...
</incident>
```

This user already exists on the target instance but has a different sys_id value such as:

```
<sys_user><name>John Smith</name>
  ...
  <sys_id>18cab8de2be80200c5244f74b4da15f7</sys_id>
  ...
</sys_user>
```

Since the display value matches an existing record, the system uses the local instance's existing sys_id value for the reference field such as:

```
<incident>
  ...
  <assigned_to display_value="John Smith">18cab8de2be80200c5244f74b4da15f7</assigned_to>
  ...
</incident>
```

The system can match display values for the following tables.

- User [sys_user]
- Group [sys_user_group]
- Role [sys_user_role]
Using XML import sets

Use an XML import set to import data from another instance.

This method allows you to:

- Apply business rules
- Transform incoming data
- Reconcile sys_id values if necessary

Note: Administrators cannot set the update_synch attribute in Dictionary records to move data as part of update sets. This attribute was being used incorrectly to migrate data in large tables and was causing significant performance problems.

Create an XML data source to another instance

Data sources are used to create an import set so that data can be processed, if necessary, prior to being mapped onto a production table.

Note: To import using XML with High Security Settings enabled, you must possess elevated privileges.

1. Navigate to System Import Sets > Administration > Data Sources.
2. Click New.
3. Complete the form using the following values:

<table>
<thead>
<tr>
<th>Format</th>
<th>XML</th>
</tr>
</thead>
<tbody>
<tr>
<td>Import set table label</td>
<td>&lt;import_set_table_label&gt;</td>
</tr>
<tr>
<td>Xpath root node</td>
<td>&lt;source_table_name&gt;</td>
</tr>
<tr>
<td>Expand node children</td>
<td>true</td>
</tr>
<tr>
<td>File retrieval method</td>
<td>HTTPS</td>
</tr>
<tr>
<td>File path</td>
<td>/&lt;source_table_name&gt;.do?XML</td>
</tr>
<tr>
<td>Server</td>
<td>&lt;instance name&gt;.service-now.com</td>
</tr>
<tr>
<td>User name</td>
<td>A user account on the remote instance. The username used cannot be an email address.</td>
</tr>
<tr>
<td>Password</td>
<td>The password for the same remote account.</td>
</tr>
</tbody>
</table>

4. Click Submit.
5. Click Test Load 20 Records to create the import set table and to ensure that your data source is functional.

Note: The 20 loaded records can't be transformed and are for testing purposes only.

Create a transform map

A transform map is a set of field maps that determine the relationships between fields in an import set and fields in an existing ServiceNow table, such as Incidents [incident] or Users [sys_user].

After creating a transform map, you can reuse it to map data from another import set to the same ServiceNow table.

1. Open the data source record that you just created.
2. In the Transforms related list, click New.
3. Populate all the usual fields and be sure to choose the proper **Target table**.
4. Submit the record.
5. Click **Auto map matching fields**.

**Add a field map for sys_id**
Add a field map to establish a relationship between the sys_id field in the source table (defined in the transform map) and the sys_id field in the target table.

1. Open the table transform map record you just created.
2. In the **Field Map** related list, click **New**.
3. Complete the form, using the following values
   - **Source field**: sys_id
   - **Target field**: Sys ID (You must do XML injection to make it work on older releases.)
   - **Coalesce**: Select the check box.

4. Click **Submit**.

**Add onBefore scripts to the transform map**
Create one onBefore transform map script to copy the sys_id of new records from the source to the target instance. Create a second onBefore transform map script to identify records on the target instance that have the same unique values but different sys_id values.

1. Open the table transform map record you created.
2. In the **Transform Scripts** related list, click **New**.
3. In the **When** field, select **onBefore**.
4. Enter the following script:
   ```javascript
   if (action == "insert") {target.setNewGuidValue(source.u_sys_id); }
   ```
5. Click **Submit**.
6. In the **Transform Scripts** related list, click **New**.
7. In the **When** field, select **onBefore**.
8. Enter the following **Script**:
   ```javascript
   /**
   * This script queries for a uniquely identifying value of the referenced record and then
   * updates the target reference field with the sys_id of the matching target record.
   * This sample assumes:
   * 1) The target table contains an assigned_to field which is a reference field.
   * 2) The reference field references the User [sys_user] table.
   * 3) You can use the email field to uniquely identify users. Alternatively you
   *    could use the user_name field.
   */
   var ref = new GlideRecord("sys_user"); //Replace sys_user with any reference table
   ref.addQuery("email", source.email); //Replace email with any unique field
   ref.query();
   if(ref.next()){
       target.assigned_to = ref.sys_id; //Replace assigned_to with any reference field
   }
   ```
9. Click **Submit**.

**Retrieving data from a CSV formatted file**

In this method, you import data from another instance using an HTTPS data source to return a CSV formatted file containing the rows to be imported.

This approach uses the Import Sets application to retrieve the data from the source and import it to the destination.

![CSV data source configuration](image)

**HTTPS Data Sources**

1. Create a new data source by navigating to **Import Sets > Data Sources** on the destination instance.
2. Provide the following field values:
   - **Import set table name**: Select a table.
   - **Type**: File
   - **Format**: CSV
• **File retrieval method**: HTTPS

  **Note:**
  If the **Server**, **File path**, **Username**, and **Password** fields are not visible when you select **HTTPS**, change the file retrieval method temporarily to **SCP** and enter this information. Remember to reset the **File retrieval method** to **HTTPS** after you enter these fields.

• **File path**: incident.do?CSV

  **Note:** To import specific change records, you can add qualifiers to the path. For example, the following path would return all active change records: 
  `incident.do?CSV&sysparm_query=active=true`

• **User name** and **Password**: Enter the user name and password for a valid user on the destination instance.

  3. Click the **Test load 20 records** related link to verify that the import is configured correctly.
  4. After setting up the data source, configure a standard transform map.

**System clone**

Use the System Clone application to copy everything in a database from one instance to another.

Cloning is typically used to copy a production instance to a pre-production instance to test changes. Cloning data comes from the most recent, nightly backup.
Clone process

In response to a clone request, the ServiceNow platform performs the following tasks:

1. Generates a file to preserve operational data on the target server.

   **Note:** This file contains the data preserved by data preservers.

2. Copies the database schema from the source instance to the target instance.

3. Creates tables in the target instance database using the source instance table definitions.
4. Copies data from the most recent nightly backup of the source instance to the target instance database.

Note: Certain exclusions are automatically large tables are normally excluded. These include audit, log, and email tables.

5. Briefly disables UI traffic and requests to the target instance server.

6. Displays the message **Clone in progress...** to any user accessing the target instance.

7. Restores operational data preserved from the target instance.

8. Runs any post-clone cleanup scripts on the target instance.

9. Briefly suspends all email functions on the target instance.

10. Queues an event to regenerate text indexes.

11. Enables UI traffic and requests to the target instance server.

During a clone, the target instance may be intermittently unavailable. After clone completion, you have up to 24 hours to contact Customer Service and Support and request a rollback of the target instance to its pre-clone state. You are notified when the rollback is complete.

**Clone to an instance on a different version**

The System Clone application can target an instance running a different instance version from the source.

A central web service controls clone processing and automatically modifies the target instance version to match the source instance version. This matching process starts up to 8 hours before the time specified in the **Date and time** field on the System Clone form. This web service also ensures that there is enough disk space on the target instance for the clone to proceed.

When cloning from a backup, the target instance does not need additional time to upgrade or downgrade. The ServiceNow platform performs any version changes during a brief window where the target instance is unavailable, after it copies data from the source instance backup.

**Clone from a backup**

The **ServiceNow** platform uses data from the most recent, nightly backup of the source instance when cloning. Backups that are used for cloning are a maximum of 36 hours old. System Clone begins the initial preparation, including selecting the latest backup to use, only at the date and time processing is scheduled to start.

If cloning from a source backup fails, the system uses the legacy clone engine instead. The legacy clone engine cannot preserve data from extended tables, relationships, hierarchies between tables, and dot-walked queries. You may want to restore the target instance from a backup and then reschedule the clone in such cases.

After cloning from a backup, the target instance is unavailable for several minutes before the clone is marked as complete in the source instance. If the source and target instances are on different versions of the **ServiceNow** platform, the target instance is modified to match the source instance version during this time.

When starting a clone from a backup, the date and time the backup was taken, as well as periodic progress messages, appear in the **Clone Log** related list.
System clone backup log

Clone over production instances

As long as the system property, `glide.db.clone.allow_clone_target` is TRUE, an instance can serve as a clone. Modifying data on the source instance during a clone can cause a data mismatch between records or duplicate record entries.

Request a clone

Request a clone to copy data from a production instance to a non-production instance or to copy data between non-production instances.

Role required: admin

The system uses data from the most recent, nightly backup of the source instance when cloning. Backups that are used for cloning are a maximum of 36 hours old. System Clone begins the initial preparation, including selecting the latest backup to use, only at the date and time processing is scheduled to start.

If cloning from a source backup fails, the system uses the legacy clone engine instead. The legacy clone engine cannot preserve data from extended tables, relationships, hierarchies between tables, and dot-walked queries. You may want to restore the target instance from a backup and then reschedule the clone in such cases.

For instances that use an Oracle database, see KB0538884 - System Clone Support for Oracle Customers.

You can automate cloning by scheduling it in the Options pane.

You cannot initiate a clone request when the source instance is in debug mode. If the source instance is in debug mode, contact Customer Service and Support to turn off debug mode before you submit a clone request.

1. Log in to the instance that you want to clone.
   This instance becomes the source instance of the clone request.
2. Create a clone target record for each target instance that you want to receive clone data.
3. Verify the list of tables that are excluded from cloning and add or remove tables to exclude from the target instance.
4. Verify the list of tables and system properties that you want saved on the target instance by data preservers. You can also create or modify data preservers, as needed.

   The legacy clone engine does not support data preservers for these records:
   - Tables that extend the Task table
   - Relationships
   - Hierarchies
   - Dot-walked queries

   If you are preserving any data that the legacy clone engine does not support, verify that there is a recent backup of the target instance available. If the clone-from-backup-process fails for any reason, you can restore the target instance from the backup.

5. Preserve any unpublished applications on the target instance.

7. Optional: Specify a predefined clone profile.

   A clone profile stores target and clone options. The clone profile automatically populates your clone request with your selected profile settings. See clone profiles for clone requests.

8. In the Target instance field, select the target instance that you want to receive the cloned data.

   Create a separate clone request for each target instance that you want to receive clone data.

9. In the Clone Scheduled Start Time field, select the time that you want the cloning to start.

   You can schedule multiple clone requests for the same source instance. For example, create one clone request to copy data to non-production instance A and another clone request to copy data to non-production instance B. The scheduling engine determines whether multiple clone requests against the same source instance can occur simultaneously or whether they must occur sequentially.

   The system verifies the scheduled start time and either accepts the date-time value that you selected or suggests an available date-time value. The validation process prevents scheduling conflicts with other automations using the same target instance.

10. In the Email upon completion field, enter your email address so that you can receive alerts after the cloning finishes, is canceled, or has an error.

11. Click the Options arrowhead so that it turns downward and use the following table to make appropriate selections in the Options pane.

   Clone options

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exclude tables specified in Exclusion List</td>
<td>Prevents cloning records from the source instance specified in the System Clone &gt; Exclude Tables module. Use this option to create empty but usable tables on the target instance. By default, the system excludes tables for auditing, license usage, logging, and notifications. This option is selected by default.</td>
</tr>
<tr>
<td>Exclude audit and log data</td>
<td>Prevents cloning audit and log records from the source instance. Use this option to create empty but usable audit and log tables on the target instance. This option is selected by default.</td>
</tr>
</tbody>
</table>

© 2021 ServiceNow, Inc. All rights reserved.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| Exclude large attachment data              | Prevents the cloning of large attachments such as video files, image files, and other large binary file types. Use this option to exclude all common binary file types, regardless of file size. When selected, the clone also excludes attachments from the Attachments [sys_attachment] and Attachment Documents [sys_attachment_doc] tables that meet all these criteria.  
  • The attachment table_name value does not indicate that it is a small file. Small attachments have table-name values that start with ZZ_.  
  • The attachment data type value indicates that it is a large file such as an application or video.  
  • The attachment table_name is not one of these system tables: sys_certificate, ecc_agent_jar, ecc_agent_mib, sys_store_app, or invisible.sys_store_app.  
  This option is selected by default. |
| Preserve theme                             | Preserves the theme and CSS elements on the target clone. This option is selected by default.                                                                                                                    |
| Lock settings for this clone request       | If you use a clone profile, this option locks the settings and options at the time of the clone request. Any subsequent changes to the clone profile, regardless of when the clone runs, do not affect the clone request. This option is not selected by default. |
| Amount of data copied from large tables    | Clones the number of days of historical data from large source tables, including task, pa_scores, and metric_instance. By default, the target instance receives the latest 90 days of historical data from the source instance. |
| Preserve In Progress Update Sets           | Preserves update sets during the clone process. This option eliminates the need to export in-progress, global update sets before you initiate a clone. The default is none. You can select the latest 90 days to preserve the in-progress update sets during this time.  
  **Note:** Review and commit the update sets after the clone. |
| Preserve users and related tables          | Prevents users and user-related tables from being overwritten on the target clone. This option is not selected by default.                                                                                           |
| Clone frequency                            | Defines how often this target automatically receives clone data. By default, the clone frequency is set to None. For more information about scheduling cloning, see Schedule cloning.                                          |

12. Click **Submit**.

If there are no issues with the clone request, the system displays the Authenticate Target modal.

If your clone request preserves large tables, a warning message displays the large tables from your preserver list. You can cancel your clone request and remove the tables from your preserver list, or you can specify a reason and continue the clone request.
13. In the Username and Password fields, enter the username and password for an administrator account on the target instance and then click Authenticate.

14. Review the clone settings and click OK.

An email is sent to the supplied address after the clone finishes, is canceled, or has an error.

You can:

- Schedule automatic clonings.
- Cancel your clone request.
- View the cloning history of completed clonings.

Create a clone target

A clone target record specifies the instance URL and credentials used for cloning.

- User credentials for the target instance: provide credentials for a user with the admin role. Use a local, user account, not an LDAP or SSO user account. The target instance credentials must exist in the User [sys_user] table as a user record or as part of an LDAP integration. Clone requests cannot redirect authentication requests to a single sign-on identity provider.
- System property on target instance: verify the system property glide.db.clone.allow_clone_target is set to True. By default, this property is enabled on instances whose name ends in Dev, Test, Stage, UAT, or QA.
- IP Access controls on target instance: if the target instance uses IP range based authentication, it must allow the IP range 10.0.0.0/10.255.255.255 to communicate on a local network.
- Role required: clone_admin or admin.

1. Navigate to System Clone > Clone Targets.

2. Click New.

3. Enter the URL for the receiving instance (target).

The system validates the instance allows clone targets and that High Availability Cloning is active. Production and demonstration instances fail these validation checks.
4. Enter the basic authentication credentials for a user account with the admin role on the target instance.

![ServiceNow Instance](https://instance.service-now.com)

**Note:** You cannot request cloning multiple targets from the same source. Instead, make a separate request for each target.

The system validates the user credentials have admin access to the target instance.

5. Click **Submit**.

The system checks connectivity and validates the user credentials against the target instance.

### Exclude a table from cloning

Exclude a table to create an empty but usable table on the target instance.

The **System Clone > Exclude Tables** module lists the tables that are not copied during a system clone. By default, the system excludes tables for logging, auditing, notifications, workflow contexts, and license usage.

**Note:** Excluded workflow context data includes records stored in the `wf_context` table, and in related tables with names starting with a prefix of `wf_`. This also includes the workflow scheduler table. This prevents occurrence of workflow timer syncing issues that might take place due to the length of the cloning process if workflow contexts were included.

The system cannot exclude tables that extend the Task table and are also flattened into it as part of the table per hierarchy extension model. Since these extended tables are actually part of the same physical database table, the system clones the data when it clones the Task table. You can exclude tables that extend the Task table under two conditions. Either the system stores the tables in their own physical tables as part of the table per class extension model, or you exclude the Task table itself.

You can use wildcards to exclude several tables from cloning with one entry. For example, `sys_script.*` excludes all tables starting with `sys_script`.

**Note:** The wildcard has to include the dot `. ` before the asterisk.

To preserve the existing data on the target instance, see Create a data preserver. Data on tables that reference the table, such as business rules, is not excluded.

1. On the source instance, navigate to **System Clone > Exclude Tables**.
2. Click **New**.
3. Enter the table **Name**.
   Entering a parent table results in the clone process also excluding its child tables. For example, excluding the Task table would also exclude the Change, Incident, and Problem tables.
4. Click **Submit**.

## Data preservation on cloning target instances

You can use data preservers to protect data on the target instance from being overwritten. If you have custom applications, you must also manually preserve unpublished application content.

### Data preservers

Sometimes, it is necessary to preserve some data on an instance targeted for cloning. For example, if the target is a MID Server, you must not overwrite the MID Server [ecc_agent] table. Preserved data is stored on the target instance before cloning begins and is restored on the target instance after cloning.

**Warning:** You must define data preservers on the source instance. Defining them on the target instance does not preserve the data.

Data preservers typically preserve system settings and themes, such as:
- Instance-specific authentication settings
- Bookmark [sys_ui_bookmark]
- Recent Selection [sys_ui_recent_selection]
- User Preference [sys_user_preference]

**Note:** A clone does not support preserving data from a database view.

Do not use data preservers to transfer large sets of data, such as user groups. If you must preserve table data, such as users, groups, and roles, consider exporting the records to a file and importing them after cloning.

### Data preservers for Multi-SSO

The system automatically creates the necessary data preservers for cloning when you activate Multiple Provider Single Sign-On integration.

<table>
<thead>
<tr>
<th>Name</th>
<th>Table</th>
<th>Conditions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Certificate</td>
<td>X.509 Certificates [sys_certificate]</td>
<td>None</td>
</tr>
</tbody>
</table>
### Core Instance Properties

<table>
<thead>
<tr>
<th>Name</th>
<th>Table</th>
<th>Conditions</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>System Property [sys_properties]</td>
<td>• [OR] [Name] [is one of] [glide.authenticate.external, glide.authenticate.external.logout_redirect]</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• [OR] [Name] [starts with] [com.snc.integration.saml_esig]</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• [OR] [Name] [is one of] [glide.smtp.port, glide.smtp.auth, glide.smtp.encryption]</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• [OR] [Name] [starts with] [glide.authenticate.multisso]</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• [OR] [Name] [is] [glide.authenticate.sso.redirect.idp]</td>
</tr>
</tbody>
</table>

**Note:** The properties `glide.smtp.port`, `glide.smtp.auth`, and `glide.smtp.encryption` are deprecated.

### Digest Properties

<table>
<thead>
<tr>
<th>Name</th>
<th>Table</th>
<th>Conditions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Digest Properties</td>
<td>Digest Properties [digest_properties]</td>
<td>None</td>
</tr>
</tbody>
</table>

### Identity Providers

<table>
<thead>
<tr>
<th>Name</th>
<th>Table</th>
<th>Conditions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identity Providers</td>
<td>Identity Providers [sso_properties]</td>
<td>None</td>
</tr>
</tbody>
</table>

### SAML2 Update1 Properties

<table>
<thead>
<tr>
<th>Name</th>
<th>Table</th>
<th>Conditions</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAML2 Update1 Properties</td>
<td>SAML2 Update1 Properties [saml2_update1_properties]</td>
<td>None</td>
</tr>
</tbody>
</table>

**Note:** Although you can modify these data preservers, it is good practice not to. The Digest Properties [digest_properties], Identity Providers [sso_properties], and SAML2 Update1 Properties [saml2_update1_properties] tables are required for multiple source, single sign-on (SSO) to function properly. If multiple source, single sign-on is disabled on the target instance, you can safely remove all three data preservers. Remove them at the same time, as the system terminates the clone with an error message when you attempt to clone with one or two of these tables being preserved.

---

### Data preservers for SAML

Preserving SAML SSO-related settings can prevent the target instance from using the wrong issuer and audience parameters when making authentication requests to your IdP. To preserve SAML settings, create data preservers for the following tables:

- System Property [sys_properties]: to preserve SAML properties.
- X.509 Certificates [sys_certificate]: to preserve SAML certificates.
- User [sys_user]: to preserve SAML users.

You also need to preserve properties and users that are involved in SAML.

### Preservation of unpublished applications

You cannot use data preservers to save unpublished applications. Instead, application developers must choose how they want to preserve unpublished applications.
The cloning process does not preserve version differences for applications in development. Instead, the system clone only copies the application version installed on the source instance onto the target instance. If the target instance had a development version of the same application, the application will be editable after the clone, but it will be at whatever version was installed on the source instance. If the application was missing from the source instance, the cloning process deletes the application from the target instance.

**Create a data preserver**

Data preservers maintain specified data on a target instance.

Role required: clone_admin or admin

Sometimes, preserving certain data on a target instance is desirable. For example, when using a MID Server, you can avoid overwriting the MID Server [ecc_agent] table. Preserved data is stored in a dynamically generated list on the target instance before the clone and restored on the target instance after the clone is complete. You define data preservers on the source instance.

Data preservers are primarily intended to preserve system settings and themes, such as instance-specific authentication settings. Do not use data preservers to transfer large sets of data, such as user groups. If you must preserve table data such as users, groups, and roles, consider exporting the records to a file and importing it after the clone is complete.

Consider whether to preserve the data in the following tables.

- Bookmark [sys_ui_bookmark]
- Recent Selection [sys_ui_recent_selection]
- User Preference [sys_user_preference]

If you set a data preserver on a table where the source instance has more records than the target instance, the data preserved on the target instance also includes the additional records from the source instance.

For example, assume that the data preserver is already in place.

- In the source instance, the sys_temp table contains 100 records.
- In the target instance, the sys_temp table contains 20 records.

After the clone, the sys_temp table in the target instance contains 100 records.

- The 20 records in the target sys_temp table are preserved successfully (per the data preserver specification). These records were part of the 100 records in the source sys_temp table.
- The source sys_temp table brings over the remaining 80 records to the target sys_temp table.

To resolve this issue and to preserve only the records in the target table, create an exclude table record for the target table, in addition to setting the data preserver on the source table.

### Important: Configure preservers on the source instance.

1. On the source instance, navigate to **System Clone > Preserve Data**.
2. Click **New**.
3. Enter the table label as the **Name**, for example, User Preference for the [sys_user_preference] table. The data preserver must have a table name or it cannot be submitted.
4. Select the **Table** to be preserved.
   The data preserver must have a table selected or it cannot be submitted.
5. Select the **Theme** check box if the data being preserved is a UI property.
6. Define the data to be preserved using the **Condition Builder**.

You can use conditions to define particular records you want to preserve during a clone. For example, to only preserve particular system properties, you can add conditions for each property name you want to preserve.

**Note:** The condition to match regular expressions [match regex] is no longer supported.

**Warning:** If the clone from backup fails for some reason, the clone process fails over to the legacy clone engine. The legacy clone engine cannot preserve data from extended tables, relationships, hierarchies between tables, and dot-walked queries. You may want to reschedule a system clone or manually transfer data in such cases.
7. Click **Submit**.

    If you want to delete the data preserver later, make sure not to modify or delete the following data preserver records:
    
    - Core Instance Properties
    - Semaphores
    - Email Accounts

*Preserve SAML properties*

If you want a clone target instance to keep its existing SAML integration, you must edit the **Core Instance Properties** data preserver to include the SAML properties.

Role required: admin

1. Navigate to **System Clone > Preserve Data**.
2. Select **Core Instance Properties**.
3. Add the following **Conditions**.

   - [OR] [Name] [is one of] [glide.authenticate.external, glide.authenticate.external.logout_redirect, glide.authenticate.failed_requirement_redirect]
   - [OR] [Name] [starts with] [glide.authenticate.sso.saml2]
   - [OR] [Name] [starts with] [com.snc.integration.saml_esig]
<table>
<thead>
<tr>
<th>Name</th>
<th>Condition</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>is</td>
<td>glide.sys.schedulers</td>
</tr>
<tr>
<td>Name</td>
<td>starts with</td>
<td>glide.db</td>
</tr>
<tr>
<td>Name</td>
<td>is</td>
<td>glide.ui.max.transaction</td>
</tr>
<tr>
<td>Name</td>
<td>starts with</td>
<td>glide.email</td>
</tr>
<tr>
<td>Name</td>
<td>starts with</td>
<td>glide.op3</td>
</tr>
<tr>
<td>Name</td>
<td>is</td>
<td>instance.id</td>
</tr>
<tr>
<td>Name</td>
<td>is</td>
<td>instance.name</td>
</tr>
<tr>

</tr>
<tr>
<td>Name</td>
<td>starts with</td>
<td>com.snc.integration.ssan</td>
</tr>
</tbody>
</table>
Note: Ensure the Theme check box is cleared so these properties are preserved regardless of whether you preserve the instance theme.

4. Click Update.

Preserve unpublished applications during a system clone
Application developers must manually save a copy of each application currently in development prior to cloning over their development instance.

- Role required: admin
- Write access to the application record
- A source control repository

The cloning process does not preserve version differences for applications in development. Instead, the system clone only copies the application version installed on the source instance onto the target instance. If the target instance had a development version of the same application, the application will be editable after the clone, but it will be at whatever version was installed on the source instance. If the application was missing from the source instance, the cloning process deletes the application from the target instance.

1. Use one of these actions to preserve the application on the clone target instance.

<table>
<thead>
<tr>
<th>Version differences between instances</th>
<th>Action to take</th>
</tr>
</thead>
<tbody>
<tr>
<td>The application version on the clone target instance is different than the source instance version.</td>
<td>Export each application from the clone target instance. Choices include:</td>
</tr>
<tr>
<td></td>
<td>- (Recommended) Link each application to a source control repository.</td>
</tr>
<tr>
<td>The application is only available on the clone target instance.</td>
<td></td>
</tr>
<tr>
<td>The application version on the clone target instance is the same as the source instance.</td>
<td>None. The system clone process will copy this application version onto the target instance during the clone.</td>
</tr>
</tbody>
</table>

2. Request a system clone of the source instance over the target instance.
For example, clone your production instance over your development instance.

3. After the clone process finishes, log in to the clone target instance.

4. If you saved each application to a source control repository, use one of these actions to retrieve them from the source control repository.

Retrieve applications from a source control repository

<table>
<thead>
<tr>
<th>Application installation state</th>
<th>Action to take on clone target</th>
</tr>
</thead>
<tbody>
<tr>
<td>The application was previously installed on the source instance.</td>
<td>Apply remote changes from source control repository.</td>
</tr>
<tr>
<td>The application was never installed on the source instance.</td>
<td>Import the application from source control repository.</td>
</tr>
</tbody>
</table>
5. If you saved each application to an update set, use one of these actions to retrieve them from the update set.

**Retrieve applications from an update set**

<table>
<thead>
<tr>
<th>Application installation state</th>
<th>Action to take on clone target</th>
</tr>
</thead>
<tbody>
<tr>
<td>The application was previously installed on the source instance.</td>
<td>a. Delete the application version cloned from the source instance.</td>
</tr>
<tr>
<td></td>
<td>b. Load the update set containing the current application version.</td>
</tr>
<tr>
<td>The application was never installed on the source instance.</td>
<td>Load the update set containing the current application version.</td>
</tr>
</tbody>
</table>

The applications previously in development are available for further development on the clone target instance.

**Preserve the Marketing Events application**

Suppose your company previously created version 1.0 of a custom application called Marketing Events. You have already published version 1.0 of the Marketing Events application to the application repository and installed it on your production instance.

Over time, users have submitted enhancement requests for the application, and you decide to develop version 2.0 of the Marketing Events application on a non-production instance to address these requests. As development nears completion, you want to update your non-production instance to the latest copy of production for some comprehensive testing.

Since you previously used a source control integration to develop version 1.0 of the Marketing Events application, you have already linked the Marketing Events application to a source control repository. You commit version 2.0 of the Marketing Events application to the source control repository.

You schedule a clone of the production instance over the development instance. After completion, you log in to the development instance and see that it has version 1.0 of the Marketing Events application, because that was the version installed on the source instance.

Since the application was already installed on the source instance, you apply remote changes from the source control repository to receive the latest application version. The development instance now has version 2.0 of the Marketing Events application available for further development and testing.

**Clone profiles for clone requests**

A clone profile enables you to store predefined target and clone options. The clone profile automatically populates your clone request with your selected profile settings.

**Clone profiles**

Navigate to **System Clone > Clone Profiles** to view your clone profiles. With a clone profile, you can:

- Create a profile with specific target instance and option settings, tables to exclude, data to preserve, and cleanup scripts to run
- Create a clone request directly from the clone profile
- Apply the clone profile to a clone request

You can create, edit, and delete clone profiles from the **Clone Profile** view. The system profile is a read-only clone profile that you can't delete. It shows a predefined list of table exclusions, data preservers, and cleanup scripts. This list is based on the plugins that your instance contains.
After you create a clone profile, you can select the **Make Default** option so that the clone is referenced as the clone profile when you request a clone.

**Cancel a clone**

You can cancel requested, scheduled, and active clones without negatively impacting system stability or usability. Canceling a clone restores the target instance to the pre-clone state, retaining all original data.

Role required: admin
Active system clone

After starting a clone, the **Clone Log** and **Database Table Clones** related lists appear on the form. These related lists show general log messages, and the details of individual tables respectively.

The duration a clone remains active varies upon the amount of data being cloned, and whether the source and target instance are in the same physical location. If a clone takes longer than anticipated, ServiceNow Technical Support can identify additional details about the clone progress.

1. Navigate to **System Clone > Live Clones > Active Clones**.
   - The system displays the list of currently active clones.
2. Select the clone you want to cancel.
   - The system displays the System Clone record.
3. From Related Links, click Cancel Clone.
   The Cancel Clone modal displays.

4. In Specify Reason, select a reason for the cancellation and click OK, or select Others, enter a reason in the text box and click OK.
   The system stops any current clone activities and sets the State to Canceled.

If you want to restart a canceled clone, you must create a new clone request.

Schedule cloning

You can use System Clone to schedule automatic clonings, which is the easiest way to keep your cloned instances up to date.

Role required: admin

Instead of manually cloning instances, you can schedule clonings that happen automatically. You create a cloning schedule in the same interface you use to create a clone. This topic assumes that you created a clone but not a cloning schedule for it.

1. Click System Clone > Active Clones > <one-of-your-clones>.
2. Click the **Options** arrowhead so it turns downward.

   The **Options** panel appears.

3. Enter values in the following fields to schedule automatic clonings.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clone frequency</td>
<td>Defines how often this target automatically receives clone data.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>No. of occurrences</td>
<td>Specify the number of automatic clonings. The maximum value you can enter depends on the value selected for the clone request in the</td>
</tr>
<tr>
<td></td>
<td>Clone Frequency field. The following are the maximum value for each selected the clone frequency:</td>
</tr>
</tbody>
</table>

4. Click **Submit**.
   The system displays the Authenticate Target modal.
5. Enter the **Username** and **Password** for an administrator account on the target instance and click **Authenticate**.
   The System Clone form displays for the target clone.
6. To see the cloning schedule for this target, click the **Recurring Clones** tab.
   Each line in the list shows a separate, scheduled cloning session.
7. To see log messages for past clonings on this target, click the **Clone Log** tab.
8. To see cloning schedules for all the clones in the system, click System Clone > Live Clones > Clone History.
   The **System Clones** page lists all the cloning instances in the system along with their scheduled clonings.

**Modify cloning schedules**

You can cancel scheduled clonings but not modify them.

Role required: admin

This topic assumes that you have a cloning schedule that you want to modify. Cloning schedules cannot be modified. Instead, you have to cancel scheduled clonings and create a new cloning schedule.

1. Click **System Clone > Active Clones > <one-of-your-clones>**.
   The System Clone record opens for your cloning instance.
2. To delete one or more scheduled clonings, on the **Recurring Clones** tab, select the check box next to the row(s) you want to cancel and on **Actions on selected rows**, click **Delete**.
3. If you deleted all future clonings, you can create a new cloning schedule.
   You cannot create more than one cloning schedule for a target instance.
4. To stop a cloning that is already in progress, under **Related Links**, click **Cancel Clone**.
   The system stops any current cloning activities and sets the **State** to **Canceled**. Future, scheduled clonings are not deleted.

**View clone status**

You can view the status of a clone to make sure the cloning process isn't stuck.

Role required: admin

1. Navigate to **System Clone > Live Clones > Active Clones**.
   The system displays the list of currently active clones.
2. Select the clone you want the status of.
   The system displays the System Clone record of that clone.
3. Under **Related Links**, click **Check Clone Status**.
   The system updates the **State** field and produces a log entry in the **Clone Log** that shows the status of the clone.

   ![Clone Log](image)

   If a cloning status is failed, you might **roll back the cloning** and **schedule a new cloning**.

**View clone history**

You can view the status and history of any system clone request.
Role required: clone_admin or admin
The System Clone [clone_instance] table stores records for all previously and currently scheduled clones.

1. **Navigate to System Clone > Live Clones > Clone History.**

   Clone history also displays the **State** for current and past clones. Clones in the **Draft** state do not appear on the Clone History table.

<table>
<thead>
<tr>
<th>Clone state</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Requested</td>
<td>The clone was requested and is awaiting approval.</td>
</tr>
<tr>
<td>Scheduled</td>
<td>The clone is ready to begin at the scheduled time and date.</td>
</tr>
<tr>
<td>Active</td>
<td>The clone is currently running.</td>
</tr>
<tr>
<td>Completed</td>
<td>The clone completed successfully.</td>
</tr>
<tr>
<td>Canceled</td>
<td>A user canceled the request.</td>
</tr>
<tr>
<td>Hold</td>
<td>The server rejected the clone request. This can happen either because the clone was not ready to proceed by the scheduled time or because additional clone requests were submitted before the first one completed.</td>
</tr>
<tr>
<td>Error</td>
<td>The clone encountered an error while running. Contact technical support for help resolving this issue.</td>
</tr>
<tr>
<td>Draft</td>
<td>The clone is scheduled to be created. This state never appears in the Clone History table.</td>
</tr>
</tbody>
</table>

2. **Select a System Clone record to view its history.**

**Roll back a clone**

Return a clone target to its state before the latest cloning. Roll back cloning if something went wrong in the cloning process.

Role required: admin

Rollbacks remove the latest cloning updates on a cloning target. You can only roll back the latest cloning updates. Rollbacks must occur no more than seven days after the cloning.

1. **Navigate to System Clone > Live Clones > Clone History.**

2. **Select the clone to roll back.**

4. In Specify Reason, select a reason for the rollback and click OK, or select Others, enter a reason in the text box and click OK.

The system rolls back the clone and sets the State to Rollback Requested, and, if successful, to Rolled Back, or, if unsuccessful, to Rollback Failure.

You can retry a rollback but if you get repeated failures, contact ServiceNow Customer Support.

The instance contains the same data it had before the clone was applied.

Post-clone cleanup scripts

Cleanup scripts automatically run on the target instance after the cloning process finishes. Use cleanup scripts to modify or remove bad data. Cleanup scripts run after data preservers and the clone are complete.

You can add new post-cloning scripts on the source instance to perform any action that can normally be accomplished through script includes or business rules. To add a script, navigate to System Clone > Clone Definition > Cleanup Scripts and click New.

You can make post-clone scripts active or inactive to control whether these scripts run or do not run. You can also set an order number on each script, which enables you to set the order that the active scripts run, with lower numbers having a higher priority.
The following post-clone cleanup scripts perform various actions on the target instance.

**Post-clone cleanup scripts**

<table>
<thead>
<tr>
<th>Script</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bad MID Server credentials after clone</td>
<td>Runs a script include called BadMIDCredentialAfterClone on a cloned instance to detect <strong>bad MID Server user credentials</strong>. This script include creates scheduled jobs that log MID Servers in the <strong>Down</strong> state to the MID Server Issue [ecc_agent_issue] table after an instance clone.</td>
</tr>
<tr>
<td>Script</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Clear scheduled job node association</td>
<td>Resets any scheduled jobs that were active on the source instance to the <strong>Ready</strong> state. This script also clears the value of the <strong>System ID</strong> and <strong>Claimed by</strong> fields on all scheduled jobs.</td>
</tr>
<tr>
<td>Configure Email Accounts</td>
<td>Migrates email accounts that existed on the source instance to the target instance if they are not enabled there. This script also migrates the email properties to the target instance.</td>
</tr>
<tr>
<td>Disable emails</td>
<td>Disables email on the target instance. A default data preserver maintains other email settings from the target instance.</td>
</tr>
<tr>
<td>Install deactivated plugin</td>
<td>Enables the Domain Separation plugin for instances that use this feature.</td>
</tr>
<tr>
<td>Regenerate all text indexes</td>
<td>Rebuilds text indexes on the target instance after a clone. Text indexes are not cloned from the source to the target instance.</td>
</tr>
<tr>
<td>Schedule drop backup tables</td>
<td>Schedules the deletion of the data that is contained in the target instance database prior to the clone. This original data is preserved for 24 hours following a clone to enable you to roll back an instance to the pre-clone state. If the target instance is downgraded as part of the clone, backup data is not available.</td>
</tr>
</tbody>
</table>

**Database rotation**

Database rotation involves managing table size growth and archiving old data.

Data within an instance grows quickly, and as these tables grow in size they require management. Database Rotation preserves instance performance and averts risk associated with querying growing data sets utilizing three techniques. These techniques are based on the concept of managing large quantities of data by separating whole sets into individual tables. After this task is performed, each technique handles data in a different manner:

- Table Rotation works by rotating among a small set of tables, and deleting and reusing the old tables for new data.
- Table Extension works by periodically starting a new table and allowing old tables to be easily archived and removed from the system.
- Table Sharding works by enabling records to be grouped in a single table by document ID.

**Table rotation plugins**

- **Database Rotations Plugin** activates Table Rotation and Extension without any tables automatically included (com.snc.db.rotation)
- **Database Rotations Default Tables Plugin** applies Table Rotation and Extension to specific tables (com.snc.db.rotation_default_tables)
Database Rotation

<table>
<thead>
<tr>
<th>Functionality</th>
<th>Tables applied to</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table Rotation</td>
<td>syslog, sys_querystat, ecc_queue, ecc_event, cmdb_metric, sysevent</td>
</tr>
<tr>
<td>Table Extension</td>
<td>sys_audit, sys_email</td>
</tr>
</tbody>
</table>

Reference values converted to strings

Archived data is stored as a flat file with no reference fields to other tables. The archive process converts any references to other tables to string values.

In the case of a reference field, the string uses the display value such as the caller's user name. For example, the Caller reference field in an incident would display the string ITIL User. If the reference was a document ID and the archive rule included the option to archive related document IDs, then the string is the document ID of the related record.

It is important to note that archive records do not receive any future changes to referenced values. For example, if you change the user name for "John Smith" to "John A Smith", all active incident records automatically show the caller as "John A Smith" because of the reference between the Incident and User tables. However, all archived incident records display the user name that existed at the time of the archive. Any incident for "John Smith" continues referencing this user. Likewise, if you delete a user from the system, current incidents no longer display the deleted user as a caller. However, there can be archived incidents that still display the string "John Smith" as the user because the user existed at the time of the archive.

Table rotation and extension

The System Definition Table Rotation module allows you to define a new table rotation, a new table extension, a new table shard, or modify an existing one.
Table rotation groups

- **Name**: auto-generated from table name
- **Duration**: overall time parameter for function
- **Initialized**: sets function as active (true) or inactive (false)
- **Rotations**: number of tables to be created within Duration
- **Type**: indicates Extension (archiving), Rotation (deletion), or Shard (doc ID) functionality

When you define a new rotation, a schedule is created and new data is subsequently written to one of the tables in the rotation group. You'll notice the that the group includes the original table plus a number of additional tables. Be aware that deleting a rotation will delete the additional tables and all the data, therefore the rotation should not be deleted if the data is needed.

See these topics for more information on managing tables:
- **Table Rotation**
- **Table Extension**

**Activate database rotation**

For new instances, database rotation is active by default. If you are upgrading from a previous version, you can activate the Database Rotations plugin if it is not already active.

**Note**: Deployment of this plugin should be executed in partnership with a ServiceNow representative.

If it is not already active, you can activate the Database Rotations plugin if you have the admin role.

1. Navigate to **System Applications > All Available Applications > All.**
2. Find the plugin using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel. For more information, see Request a plugin.

3. Click **Install**, and then in the Activate Plugin dialog box, click **Activate**.

   **Note:** When domain separation and delegated admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: **Application installation is unavailable because another operation is running:** Plugin Activation for <plugin name>.

Do not activate the **Database Rotations Default Tables** plugin. Instead, specify the tables manually, after consulting a ServiceNow representative.

### Domain separation and Data Management

Domain separation is supported in Data Management. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

**Support level: Basic***

- There is business logic to ensure data goes into the proper domain for the application’s service provider use cases.
- In the application, the user interface, cache keys, reporting, rollups, aggregations, and so on, all consider domain at run time.
- The owner of the instance needs to be able to set up the application to function normally across multiple tenants.

Use case: As a service provider when I use chat to respond to a tenant-customer’s message, the client must be able to see my response.

### Integration with third-party applications and data sources

ServiceNow integrates with many third party applications and data sources.

The most common integrations are with CMDB, Incident Management, Problem Management, Change Management, User Administration, and Single Sign-on. A variety of techniques can be used, most notably Web Services, JDBC, LDAP, Excel, CSV, and Email, as well as any industry standard technologies that use SOAP, REST, or WSDL. Additionally, API and command-line integrations can be done using a MID Server. ServiceNow has performed the following integrations with enterprise systems and platforms.

This podcast offers additional information on integrations.

### Technologies

The ServiceNow platform is based on service-oriented architecture (SOA), in which all data objects can use web services to access bi-directional data-level integration. The interface is also direct and dynamic because all modifications to existing objects and all new objects are automatically published as a Direct Web Service. A more indirect web service creation and usage can be achieved through Mapped Web Service where a transform map is used to gather incoming web service data into the final targeted tables. Finally, an advanced Scripted Web Service technique is available for defining process-based web services, where data is irrelevant, but serves more as a trigger for a process or a composite of actions that execute at the server.
Additionally the platform offers a rich interface for loading external data using import sets. Using this feature, you can load from various data sources such as HTTPS, FTPS, and SCP using file formats such as XML, CSV, and Microsoft Excel XLS files. Information can also be pulled from a data source using a direct JDBC connection, provided the network connectivity allows.

Information can be pulled from the platform to an external platform using an ODBC Driver.

Forms, lists, and reports on the platform can be accessed directly using a URL, which facilitates integration on the UI level between two or more web applications.

A handful of single sign-on technologies is identified and implemented out of the box to allow fast integration with your portal, however, the technique is customizable in a script to allow for flexibility in the different SSO environments our customers have.

### Integration between ServiceNow Instances

There are times when you find you need to perform a specific integration between your instance and another ServiceNow instance. Instance-to-Instance integrations are a snap because all of the integration points exist between the two instances.

### Integration options

Nearly all ServiceNow customers obtain additional value by integrating with third-party applications.

ServiceNow customers have the following options for integrating with third-party applications.

- Activate a ServiceNow provided integration.
- Install a certified integration from the ServiceNow Store.
- Install an integration from Share.
- Contact your sales representative for available custom-built integrations.
- Build your own custom integration using the platform's integration interfaces.

**Note:** Certified integrations have passed a set of interoperability, security, and performance test criteria defined by ServiceNow.

### ServiceNow provided integrations

ServiceNow provides many integrations as part of the platform.

These integrations are considered part of the platform and are provided at no additional charge.

Set up Google Maps API

You enable the geolocation feature using the appropriate entries from a Google Maps API for Business license, or a Google Maps Javascript API Key.

Role required: admin

You can generate maps using basic JavaScript, and they are flexible enough to display even the most complicated of queries. These maps use standard Google Maps API for Business or Google Maps Javascript API Key mapping features, including various link types to records in your instance. Use of this feature requires installation of the Google Maps plugin.
1. Google Maps APIs for Business licenses are no longer available from Google, so, depending on whether you have an existing license, use one of the following procedures.

<table>
<thead>
<tr>
<th>Existing Google Maps API for Business license available?</th>
<th>Tasks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Existing license available</td>
<td>a. In the System Properties &gt; Google Maps property form:</td>
</tr>
<tr>
<td></td>
<td>• In the google.maps.client field, enter the Client ID for your organization. This ID is from Google and starts with gme-, such as gme-mycompanyname.</td>
</tr>
<tr>
<td></td>
<td>• In the google.maps.private.key field, enter the private key for Google Maps API for Business. An example of an encoded key is vNIXE0xscrmjlyV-12Nj_BvUPaw=. The Now Platform® requires this key to retrieve accurate driving time estimates from Google for some Geolocation features.</td>
</tr>
<tr>
<td></td>
<td>• Fill out the remaining values on the form.</td>
</tr>
<tr>
<td></td>
<td>b. Configure your maps using the property definitions from the table.</td>
</tr>
</tbody>
</table>

**Note:** See the Getting Started Guide on the Google website for details on obtaining a key, using the API, and relevant terms of service.
Existing Google Maps API for Business license available?

<table>
<thead>
<tr>
<th>Tasks</th>
</tr>
</thead>
<tbody>
<tr>
<td>a. Obtain a Google Maps Javascript API Key from Google.</td>
</tr>
<tr>
<td>b. In the <strong>System Properties &gt; Google Maps</strong> property form, enter the API key into the <code>google.maps.key</code> field. Geolocation in the Now Platform® uses the API Key, which Google Maps also uses for Geolocation and map view billings.</td>
</tr>
<tr>
<td>c. Fill out the remaining values on the form.</td>
</tr>
<tr>
<td>d. Configure your maps using the property definitions from the table.</td>
</tr>
</tbody>
</table>

To learn more about Google Maps API for Business, and Google Maps Javascript API Key, see [https://developers.google.com/maps/gmp-get-started](https://developers.google.com/maps/gmp-get-started).

2. After you complete and save the configuration, create Map pages, or use the default pages included with the plugin.

Map pages define what data appears on the map, and the appearance of the links. For a tutorial on how to view all of the markers that link to your records, see the [Display Map Markers on Google Maps](https://community.service-now.com/) blog post on the Now Community.

<td></td>
<td>• Type: string</td>
</tr>
<tr>
<td></td>
<td>• Default value: cmn_location</td>
</tr>
<tr>
<td></td>
<td>• Location: <strong>System Properties &gt; Google Maps</strong></td>
</tr>
<tr>
<td>google.maps.zoom</td>
<td>Starting zoom level of the map (1 is the lowest)</td>
</tr>
<tr>
<td></td>
<td>• Type: string</td>
</tr>
<tr>
<td></td>
<td>• Default value: 4</td>
</tr>
<tr>
<td></td>
<td>• Location: <strong>System Properties &gt; Google Maps</strong></td>
</tr>
</tbody>
</table>

3. **Perform these configurations:**
   a) Navigate to **System Properties > All.**
   b) Set values for these system properties:

<table>
<thead>
<tr>
<th>System property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>google.maps.refresh.latlong.duration</td>
<td>Number of days after which the location details are updated.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> The maximum value is 30.</td>
</tr>
<tr>
<td>System property</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>google.maps.refreshlatlong.record_count_per_table</td>
<td>Maximum number of records in a table that can be processed using the scheduled job in one refresh.</td>
</tr>
</tbody>
</table>

c) Specify the tables that store the location details in the Map Coordinates Refresh Configuration [cmn_coordinate_refresh_config] table.

d) If there are no fields to track when the coordinates are last retrieved in your tables:

1. Create the coordinates_retrieved_on field of the type Date/Time in your tables.
2. Ensure that the value of the field that tracks time when the coordinates are last retrieved, is populated correctly in the Map Coordinates Refresh Configuration [cmn_coordinate_refresh_config] table. Refer to the sample fix script Update coordinates updated on field to update values in the coordinates_retrieved_on field.

e) Navigate to System Definition > Scheduled Jobs.

f) Open the record, Refresh Latitude Longitude info of Records.

g) Select the Active check box.

h) Specify the frequency at which the location details should be refreshed by providing frequency details in Run and Repeat Interval.

**Note:** Ensure that you refresh the location details at least once every 30 days.

---

**Request Google custom search integration**

The Google Custom Search Integration plugin is available by request.

Role required: admin

There are two ways to request a plugin:

- Access the Now Support Service Catalog directly by clicking Service Catalog > Activate Plugin on Now Support.
- Access the Now Support Service Catalog through the All Applications page on your instance by following these steps.

1. Navigate to System Applications > All Available Applications > All.
2. On the All Applications page, click **Request Plugin** to open the Request form on HI.
3. On Now Support, select the redirect link to access the Now Support Service Portal Service Catalog.

<table>
<thead>
<tr>
<th>Activate Plugin</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>In order to enhance the user experience, we have redesigned Activate a Plugin service catalog. Please use the new HI Service Portal 'Activate a Plugin' service catalog item. You can also use Manage Instances page on Service Portal to Activate a Plugin.</td>
<td></td>
</tr>
<tr>
<td>Take me to the HI Service Portal Activate a Plugin Service Catalog.</td>
<td></td>
</tr>
</tbody>
</table>

4. On the form, fill in the fields.

**Activate Plugin request form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target Instance</td>
<td>Instance on which to activate the plugin.</td>
</tr>
<tr>
<td>Plugin Name</td>
<td>Name of the plugin to activate.</td>
</tr>
<tr>
<td>Specify the date and time you would like this plugin to be enabled</td>
<td>The date and time must be at least two business days from the current time.</td>
</tr>
</tbody>
</table>

**Note:** Plugins are activated in two batches, once in the morning and once in the evening, on every business day in the US Pacific time zone. If the plugin must be activated at a specific time, enter the request in the Reason/Comments field.

| Reason/Comments | Information that would be helpful for the ServiceNow personnel who are activating the plugin. For example, if you need the plugin activated at a specific time instead of during one of the default activation windows, specify that in the comments. |

5. Click Submit.

**Microsoft SCCM integration**

The Microsoft SCCM integration is a one direction import of SCCM data into the ServiceNow's Configuration Management Database (CMDB).

Scheduled imports bring relevant SCCM data into the ServiceNow instance from an SQL Server database and map it to tables in the CMDB. You can configure either a full or incremental data import. The import is achieved using a JDBC connection via the MID Server. The integration keeps the ServiceNow CMDB synchronized with the SCCM SQLServer database, so that only relevant data is imported from the SCCM database to the CMDB. The SCCM database is considered an authoritative source and is not written to.
Supported versions

These are the plugins for the currently supported SCCM versions, all of which support Asset Intelligence and Incremental Software Reconciliation:

- Microsoft SCCM 2007
- Microsoft SCCM 2012 v2
- Microsoft SCCM 2016

Note: If you upgrade your instance to a version of the Now Platform that does not provide support for your version of SCCM, you can continue to use that version. However, all new instances require the use of a supported SCCM version.

Service Graph connector for Microsoft SCCM

To import SCCM data into the CMDB, you can use the Service Graph connector for Microsoft SCCM instead of using the legacy SCCM connector.

Using the Service Graph SCCM connector provides these advantages:

- Adherence to the Common Service Data Model (CSDM) data model.
- Use of Identification and Reconciliation engine (IRE) to avoid duplicate records.
- Support for removed software detection and delta detection.
- Use of the IntegrationHub ETL which allows for easy data mapping and customizations.
- Higher performance during data processing.

For information on how to update from using the Microsoft SCCM connector plugin to using the Service Graph connector for Microsoft SCCM, see Update Microsoft SCCM 2016 plugin for Service Graph connector for Microsoft SCCM

Available modules

- **Setup:**
  - Configure the data sources.
  - Specify database server settings and the MID Server.
  - Test the configuration.

- **Scheduled Import**: Schedule the import or execute the import immediately.
- **Data Sources**: A list of the pre-configured data sources defining the external CMDB database.
- **Progress**: The progress log for scheduled imports.
- **Transform History**: A log of transformations performed by scheduled imports.
- **CI Identification**: Identifiers used by SCCM to match import set data with the CMDB.
- **Import Set Data**: Tables that store imported SCCM data.
- **Web Services**: List of web services used to add or remove fields in the transform maps.
Asset intelligence

Asset Intelligence is an SCCM feature that can filter, normalize and clean up software records. When enabled, it populates normalized software data in a separate table within the SCCM database. You can target this separate table instead of the raw software data table. When you import software records into the CMDB with this feature enabled, you get a cleaner set of software data. To use this feature, you must Activate SCCM Asset Intelligence scheduled imports in the target ServiceNow instance, as well as in the source SCCM database.

Activate a supported Microsoft SCCM plugin

The SCCM plugins can be activated by an administrator and requires the Integration - JDBC and CI Identification plugins. These dependent plugins are activated automatically with SCCM activation.

For a complete listing of the plugins that need to be activated, see Activate SCCM Asset Intelligence scheduled imports.

1. Navigate to System Applications > All Available Applications > All.
2. Find the plugin using the filter criteria and search bar.
   
   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel. For more information, see Request a plugin.
3. Click Install, and then in the Activate Plugin dialog box, click Activate.

   **Note:** When domain separation and delegated admin are enabled in an instance, the administrative user must be in the global domain. Otherwise, the following error appears: Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.

SCCM data import process and source tables

The Microsoft SCCM versions supported in the ServiceNow® platform offer identical features and the same imported data.

Data import process

1. A schedule called SCCM System <version> Import determines when the SCCM tables are imported into the ServiceNow® instance. Imports can be executed immediately or scheduled to run at defined intervals.
2. A MID Server retrieves the SCCM data and imports it into staging tables on the instance.
3. Transforms run on the data in the staging tables and map the SCCM data to existing fields in the CMDB.
**SCCM data imported**

This table shows the SCCM source tables, the corresponding import set staging tables in the ServiceNow® instance, and the target tables in the CMDB.
The ServiceNow® SCCM integration uses JDBC data sources to import software data from the SCCM database. Each data source contains the connection specifics for the SCCM database and names the MID Server the instance will use to import the data. The transforms that map the SCCM fields to the CMDB are defined in a related list in each data source record.

### Transform maps

Transform maps are accessed from the Transforms related list in each data source record. The source fields in SCCM and the target fields in the CMDB are listed in the Field Maps related list in each Table Transform Map record. The SCCM integration uses the transform map utility provided with the ServiceNow® platform. For instructions on editing or creating a transform map, see Transform maps.

The SCCM integration provides two transform maps for incremental software imports. Only one transform map can be enabled (Active) at a time.

- **Incremental Import**: Enabled by default. This map should be configured as Active when ServiceNow® Software Asset Management is not enabled on the instance.

*For more information about Software Asset Management and how to enable it, see Request Software Asset Management.*

### SCCM data sources

The ServiceNow® SCCM integration uses JDBC data sources to import software data from the SCCM database. Each data source contains the connection specifics for the SCCM database and names the MID Server the instance will use to import the data. The transforms that map the SCCM fields to the CMDB are defined in a related list in each data source record.

### Transform maps

Transform maps are accessed from the Transforms related list in each data source record. The source fields in SCCM and the target fields in the CMDB are listed in the Field Maps related list in each Table Transform Map record. The SCCM integration uses the transform map utility provided with the ServiceNow® platform. For instructions on editing or creating a transform map, see Transform maps.

The SCCM integration provides two transform maps for incremental software imports. Only one transform map can be enabled (Active) at a time.

- **Incremental Import**: Enabled by default. This map should be configured as Active when ServiceNow® Software Asset Management is not enabled on the instance.

*For more information about Software Asset Management and how to enable it, see Request Software Asset Management.*
• **Incremental Import (SAM enabled):** If the Software Asset Management plugin is activated, set this transform to *Active*

**Note:** To force a one-time full import of all software data from the SCCM database, clear the value in the "Last run datetime" field on the data source. This operation can take a long time to execute, so the most efficient method is to use an incremental transform after the first full import.

### Transforming the assigned user

The SCCM <version> Computer Identity transform script attempts to set the **Assigned to** field in the CMDB record by looking up the name of the user in the SCCM source table and comparing the value with the matching field in the ServiceNow sys_user table. If a match is found, that user is assigned to the record. If no match is found, the **Assigned to** field is left blank. The matching field is controlled by the `glide.discovery.assigned_user_match_field` system property, which is set to *user_name* by default.

### Identifiers

The SCCM integration uses CI identification to update CIs created from data imported from SCCM with a resource ID. The Hardware Rule identifier returns the resource ID of a computer from SCCM and stores it in the Source [sys_object_source] table. When resource IDs are first imported, either from SCCM or Discovery, the [sys_object_source] table is populated with IDs for each CI it identifies. In subsequent imports, if an incoming ID matches that of an existing CI, IRE (Identification and Reconciliation Engine) updates the information for that CI in the CMDB. If the incoming resource ID does not match that of an existing CI, IRE creates a new CI and populates it with the resource ID.

For more information about CMDB Identification and Reconciliation and IRE, see [CMDB Identification and Reconciliation](#).

Upgrades from pre-Geneva versions still preserve the legacy identifiers, but you can switch to the new identifiers using a property: `glide.discovery.use_cmdb_identifiers`. If you upgraded from a pre-Geneva version, you must manually add this property and set it to *true* to use the new identifiers. If you upgraded from Geneva, this property is available in the System Properties [sys_properties] table. To preserve functionality in custom legacy identifiers, convert them to the new CMDB identifier rules format before enabling this property. The system does not reconfigure your custom identifiers to the new framework automatically.

### Scripts

Data population scripts populate the related data in the CMDB for each target CI discovered by the Hardware Rule identifier.

### Software

The Microsoft SCCM integration reconciles the software package count in the records for a CI and removes a software instance from the Software Instance [cmdb_software_instance] table if the software package is uninstalled from the CI. For a full software import, the transform populates the Software [cmdb_ci_spkg] and Software Instance [cmdb_software_instance] tables. If the Software Asset Management plugin is enabled, the transform populates the Software Installation [cmdb_sam_sw_install] table.
**CAUTION:** The table data imported from SCCM must contain complete data for the CI. The instance assumes that the import represents all relationships that exist and adjusts the CMDB accordingly. Partial data received from SCCM tables can cause the deletion of active relationships.

**Configure the SCCM integration and schedule an import**

Importing data from Microsoft SCCM requires a connection to the SCCM database via a JDBC data source and a schedule that tells the MID Server when to fetch the data.

You must have sufficient credentials to query the SQL Server that contains the SCCM database. Create a SQL Server account in order to connect to the SCCM database on the MID Server to use the data sources.

Connect to your SCCM SQL Server and configure the following:

1. Create a new login user name and password for SQL Server authentication.
2. Choose the SCCM database that ServiceNow data sources will connect to.
3. Assign the 'db_datareader' role membership to the new user.

Role required: admin

The system uses the details of the database connection you create in this procedure to configure the default SCCM data sources automatically.

**Note:** If you want to configure the JDBC data source to authenticate on your SQL Server database using the Windows MID Server service user, select the **Use integrated authentication** box on each of the existing data sources.

1. Navigate to **Integration - Microsoft SCCM <version> > Setup.**
2. Complete the required fields to configure connection to the SCCM SQL database. Make sure to include a valid MID Server that has access to the SQL database server.

### SCCM data import setup

3. Under Related Links, click **Test data source connections** to test the connection to the SCCM database.
4. If the data source connects to the SCCM database, navigate to **Integration - Microsoft SCCM > Scheduled Import**.

The Scheduled Data Import form appears for your version of the SCCM integration. The Computer Identity data source runs first. The other data sources listed on the form run in sequence, based on their default order.
5. Select a calendar interval (Day, Week, etc.) in the **Run** field and specify the time of day the import should run. Your selection displays additional fields required to complete the schedule.

6. Click **Update** to schedule the import or click **Execute Now** to perform the import immediately.

   After the instance imports data using the **SCCM <version> Computer Identity** data source, the other data sources run in the order configured to retrieve the remainder of the SCCM data.

**Activate SCCM Asset Intelligence scheduled imports**

To prevent duplicate software imports, activate either the Asset Intelligence (AI) or the non-AI scheduled import.

Role required: admin

Make sure to limit the software import frequency to be no greater than the frequency of the table cleanup that tracks deleted software in SCCM.

Asset Intelligence is supported in these SCCM plugins:

- Integration - Microsoft SCCM 2007
- Integration - Microsoft SCCM 2012 v2
- Integration - Microsoft SCCM 2016

**Important:** To improve the performance of your initial SCCM import, you can prevent the system from checking against deleted software prior to the import date. Navigate to **Integration - Microsoft SCCM <version> > Data Sources > SCCM <version> Removed Software** and enter the current date in the **Last run datetime** field, using the format `yyyy-mm-dd 00:00:00.0`. This field is populated automatically for each subsequent run of the removed software data source, so it is not necessary to alter the value after the initial import.

1. Navigate to the **System Import Sets > Administration > Scheduled Imports**.
2. Set **Active** to **false** for these data import schedules:
   - SCCM <version> Software
   - SCCM <version> Removed Software
3. Set **Active** to **true** for these data import schedules:
   - SCCM <version> Software (with AI)
   - SCCM <version> Removed Software (with AI)

**Upgrade the SCCM integration version**

If you are using an earlier version of an System Center Configuration Manager(SCCM) plugin, you can switch over to a later version to take advantage of new features.

Role required: admin

The ServiceNow SCCM integrations are self-contained and can exist independently. They each use their own import set tables, data sources and transform maps. However, all SCCM integrations will transform data into the same tables within the ServiceNow CMDB. To avoid the data being overwritten by another source:

- Use one SCCM integration and disable all other SCCM scheduled imports.
- Perform a **full import** to clear the cmdb_software_instance table, the cmdb_sam_sw_install table, and other tables of old SCCM data.

**Note:** It is possible to configure each plugin to integrate with SCCM 2007 or 2012 because the mechanism of the integration is actually the same, which is to leverage Java Database Connectivity (JDBC) imports.
However, a data source must be modified if it is used for an SCCM version for which it was not written. Use the plugin version that corresponds to the SCCM version for which the data source is intended.

To change the SCCM integration:

- Disable the current integration by deactivating the SCCM import schedule.
- Activate the new SCCM plugin.
- Reimport all the software records when you are switching to an integration that supports incremental imports of removed software.

To disable the SCCM import schedule:

1. Navigate to Integration - Microsoft SCCM 20xx > Scheduled Import.
2. Clear the **Active** check box.

   ![Scheduled Data Import Form](image)

   **Scheduled Import form**

3. Click **Save** or **Update**.
4. To activate the new SCCM plugin, navigate to **System Definition > Plugins**.
5. Search on the name *SCCM* to see all the available SCCM integrations plugins.
6. Activate the plugin.
Migrate the Verizon eBonding Integration to a Production System

This topic outlines the tasks required for moving the Verizon eBonding integration from a Dev/Test environment to a Production environment.

This process requires coordination with your assigned Verizon implementation manager.

General Tasks

The following work can be performed any time:

- Obtain a production SOAP password from Verizon. Your Verizon SOAP user ID is the same as that used against the Verizon test broker.
- Create an integration user for Verizon in the ServiceNow Production instance. Use the same user name and password that was created for the development instance, so that the communication between Verizon and ServiceNow is properly authenticated.

Migrating to a Production Environment

Perform these tasks in order.

- Task 1: Request the Verizon eBonding plugin for the production instance. When the plugin is installed, the only immediate user interface change is an additional **Category** field named **VZ eBonding**. All of the triggers for the integration are dependent on the category being set to **VZ eBonding**. Enabling the plugin on the production instance should not affect your users. If you wish to take additional precautions, disable the **VZ eBonding** category from the list when the plugin is activated for the instance.
- Task 2: Set up the Verizon certificate and keystore. Copy these directly over from the Dev instance or regenerate them so that you have separate versions for the Dev and Production instances.
- Task 3: Configure the integration properties to work with the Production Verizon eBonding system. This is userID, password, and other properties provided by your Verizon representative.
- Task 4: Change all the Verizon eBroker SOAP Message functions to use Verizon’s production SOAP Endpoint. In most cases, the endpoint URL will be: https://pubwebsvc.vzbi.com:443/Trouble_Management_v3r0. Verify this URL with the Verizon implementation specialist.
  - In the **SOAP Message Functions** related list, click each function, clear the **Lock** check box, and enter the production endpoint.
  - Configure the **SOAP Message Functions** related list and add the **SOAP endpoint** column. In the **SOAP Message Functions** list view, unlock and update the endpoint for all records by editing multiple records.
- Task 5: Apply any customizations. If customizations to the integration on the Dev system were captured in an update set, apply that update set to the Production system.
- Task 6: Provide Verizon with the production SOAP Endpoint. The SOAP endpoint should look something like this: https://yourproductioninstance.service-now.com/ETMSPublish.do?WSDL.
- Task 7: Coordinate a Production turn up with your Verizon representative to do basic testing.

**Warning:** Do not create test tickets against the production system without working with the Verizon team. Any tickets created are treated as real tickets.

Legacy: Altiris integration 2.0

The Altiris integration is deprecated in the Istanbul release.

The Altiris integration a one direction import of the Altiris data into ServiceNow CMDB (Configuration management database). The integration keeps the ServiceNow CMDB up to date with Altiris SQLServer database.
**Data Import**

Relevant data is imported from the Altiris database to the CMDB. The Altiris database is not written to, it is considered an authoritative source. The import is achieved using a JDBC connection via the MID Server.

Information pulled from Altiris includes:

- PC Hardware (Model, Manufacturer, memory, clock speed, number of CPUs, etc.)
- Operating System Information (Name, Service Pack)
- Printers
- Disk information (physical, network, and logical)
• Network (IP Address, Netmask)

**Configuration and Operational Modules**

Enabling this integration will create the Integration - Altiris application. The following are the configuration and operational modules for this integration.

**Setup**

- Configure the data sources from one form
  - Provide the Database Server IP Address
  - Provide the Database Name
  - Provide the Database User ID and Password (this will need to be created on SQL DB side, see this article for help with this step: [http://technet.microsoft.com/en-us/library/aa337562.aspx](http://technet.microsoft.com/en-us/library/aa337562.aspx))
  - Find and select the MID Server
- Specify Database server settings and MID server
- Test configuration

**Scheduled Import**

- Schedule the execution of the import or import immediately

**Data Sources**

- A list of the pre-configured data sources defining the external CMDB database

**Progress**

- A historical list of progress on scheduled imports

**Transform History**

- A historical list of transformations performed during scheduled imports

---

**Warning:** If you have activated an existing integration of the previous version:

1. Activating the 2.0 plugin does not "add to" or "remove" anything from the existing integration.
2. If transitioning from the old integration to this new one, considerations need to be given to customizations already done eg. mapping enhancements or using different coalesce values, these will have to be re-implemented.
3. Both plugins could run at the same time, provided data is coalescing the same way - until there is no need for the older plugin at which time it can be turned off.

---

**Supported Versions**

The Altiris integration only supports Altiris version 6.5. The integration does not currently Altiris version 7.0.
Legacy Import set data for Altiris
This topic lists module names displayed by the Altiris import set data.

The Altiris import set data section shows a list of Import sets tables used in containing data retrieved from using JDBC to query the Altiris database. The module names (hence the import set tables they point to) match Altiris's table names and structure that it is loading from.

Module names

<i>Note:</i> Functionality described here requires the Integration - Altiris 2.0 plugin.

- Scheduled Cleanup
  - Configure a schedule to cleanup/delete import set data that have already been transformed
  - vComputer
  - Inv_AeX_OS_Operating_System
  - Inv_AeX_HW_CPU
  - Inv_AeX_HW_Memory
  - Inv_AeX_HW_Serial_Number
  - Inv_AeX_HW_Logical_Disk
  - Inv_AeX_OS_Add_Remove_Programs
  - Inv_AeX_AC_TCPIP

When viewing each of these table lists, at the end of the list you have links to other operational functions of the import set.

</tr>
<tr>
<td>REST API</td>
</tr>
<tr>
<td>SSO - SAML 2.0</td>
</tr>
<tr>
<td>Digest token authentication</td>
</tr>
<tr>
<td>ODBC</td>
</tr>
<tr>
<td>Data Export</td>
</tr>
<tr>
<td>CTI</td>
</tr>
<tr>
<td>Syslog probe</td>
</tr>
</tbody>
</table>

**Computer Telephony Integration**

Computer Telephony Integration (CTI) is accomplished by the CTI client on the user machine sending a URL to the instance.

The URL must have the following components:
1. The base URL. For example: https://<instance name>.service-now.com/cti.do? would get to the instance and ask for CTI processing.

2. Parameters identify what parts of the incident form to display.
   - **sysparm_caller_name**=name where 'name' is the name for a user.
   - **sysparm_caller_phone**=phone where 'phone' is the user's phone number. Either a name or phone should be provided if you want to identify the user on the call. Other parameters may be supplied to identify the user as discussed later.
   - **sysparm_task_id**=taskID where 'taskID' identifies an existing issue that the caller is calling about.
   - **sysparm_view**=view where 'view' is the name of the view to be used to display the data.
   - **sysparm_xxxx**=value where 'xxxx' is the name of a field within the 'incident' record that should be populated with the specified 'value'. For example sysparm_priority=1 would result in the priority field set to value of 1 when the new incident screen is shown.
   - **sysparm_cti_rule**=name where 'name' is the name of a function to be invoked for CTI processing rather than using the default script. The function must be defined in a sys_script entry marked client callable. If the function needs to insert, update, or delete any GlideRecord(s), it must call a separate non-client callable function to perform the update(s).

   **Note:** While the CTI Processing script has been changed to be client callable, the code implementing the task view has been commented out. You must implement a new non-client-callable function for the code that performs the task.update().

   **Note:** To make a script client-callable you must check the client-callable checkbox on the form that displays when the sys_script entry is displayed. The client-callable checkbox might not show by default. To show the client-callable checkbox, you may need to modify the fields that show on the form using the gear icon and slushbucket mechanism.

Parameters on the URL are available to the business rule as global values. For example:

```javascript
var name = sysparm_caller_name;
```

The business rule you specify must return the URL for the pop-up screen, and set the 'answer' global variable.

An example URL to bring up a screen shot for user Don Goodliffe would look like the following. https://<instance name>.service-now.com/cti.do?sysparm_caller_name=Don%20Goodliffe

Multiple sysparm parameters can be used, separated by ampersands (&).

**CTI Processing script**

When the **sysparm_cti_rule** parameter is not specified, the system uses the CTI Processing script to provide the following functionality.

The CTI Processing script does the following:

1. Tries to identify the user by the **sysparm_caller_name** value if it was supplied.
2. If no user has been found, the script tries to identify the user by the **sysparm_caller_phone** value if it was supplied.
3. If a user has been identified then one of the following is done
   a. If the user has open incidents, the popup screen shows information about the current caller and all the user's open incidents.
   b. If the user does not have any open incidents, the popup screen shows a new incident with information provided in the URL shown.
4. If a user was not identified and a taskID is given and the taskID exists, then nothing happens. The code to handle this case is commented out. If you want the popup screen to show the details for the task, you must modify the CTI Processing script to put the functionality in a separate non-client-callable function.

Integrating ServiceNow with your Intranet

You can add a ServiceNow login link to your intranet.

To deliver ServiceNow content from a web page, see Service Portal.

JDBCProbe

A JDBC probe runs on the MID Server to query an external database via [JDBC] and returns results to ServiceNow.

Probes interact with the MID Server via the ECC Queue, therefore the response of a JDBC probe returns as an XML payload in an "input" ECC Queue record. By default, each response payload will contain up to 200 returned rows, this value can be modified by setting the probe parameter `jdbcprobe_result_set_rows` to the desired number.

Activating the Plugin

Contact Customer Service and Support to activate the Integration - JDBC (com.snc.integration.jdbc) plugin.

1. Navigate to System Definition > Plugins.
2. Right-click the plugin name on the list and select Activate/Upgrade.

   If the plugin depends on other plugins, these plugins and their activation status are listed.
3. [Optional] Select the Load demo data check box.
   Some plugins include demo data—sample records that are designed to illustrate plugin features for common use cases. Loading demo data is a good policy when first activating the plugin on a development or test instance.
   You can load demo data after the plugin is activated by repeating this process and selecting the check box.
4. Click Activate.

Direct JDBC Probe

A direct JDBC probe specifies all the parameters necessary in the outbound ECC Queue XML payload.

It is a standalone probe that is decoupled from a JDBC Data Source and does not insert into an import set. The required field in the ECC Queue record for a direct JDBC probe is Topic and it must equal JDBCProbe. The Source field is reserved for the sys_id of the data source record in the case of a JDBC data source.

Note: If you have ServiceNow Discovery enabled on your platform, add the skip_sensor parameter to the probe to avoid the discovery sensors from processing the probe and resulting in a "No sensors defined" error.

XML Structure

A direct JDBC probe has the following XML payload structure

```xml
<parameters>
  <parameter name = "skip_sensor" value = "true" />
  <parameter name = "parameter_name" value = "parameter_value" />
...
  <parameter name = "work" >
    <select ... >
      ...
    </select>
  </parameter>
</parameters>
```

JDBC Probes via Data Source

JDBC probes are executed via a JDBC data source when an import is running against the data source.
A JDBC data source JDBC probe is described by the JDBCProbe Topic and the `sys_id` of the data source in the Source field of the ECC Queue output record.

The data source record would look like this

![Data Source](image)

**JDBC Data Source**

The following ECC Queue output probe will be created when you `load` from the data source.
JDBC Data Source Probe

Select * JDBC Probe short cut
Alternatively, you may specify a table_name parameter instead of a work element and the following query could be executed.

```
select * from <table_name>
```

For example, using the following XML payload

```
<?xml version= "1.0" encoding= "UTF-8" ?><parameters><parameter name = "jdbc_driver" value = "com.microsoft.sqlserver.jdbc.SQLServerDriver" />
<parameter name = "connection_string" value = "jdbc:sqlserver://xxx.service-now.com;databaseName=SMS_CRICKET;user=sms;password=sms" />
<parameter name = "table_name" value = "System_DATA" /></parameters>
```

Counting Rows

To count the number of rows in a table, you can indicate a select count(*) type query by including the count_rows parameter with a value of true.

For example

```
<?xml version= "1.0" encoding= "UTF-8" ?><parameters><parameter name = "jdbc_driver" value = "com.microsoft.sqlserver.jdbc.SQLServerDriver" />
<parameter name = "connection_string" value = "jdbc:sqlserver://xxx.service-now.com;databaseName=SMS;user=sms;password=sms" />
<parameter name = "count_rows" value = "true" /><parameter name = "table_name" value = "System_DATA" /></parameters>
```

The resulting response XML payload

```
<parameters>
...  
<result query = "SELECT count(*) as row_count FROM System_DATA" ><row id = "1" ><row_count class = "java.lang.Integer" length = "11" type = "4" >2312</row_count></row></result>
```
Parameters
The following parameters are available in a direct JDBC probe.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>jdbc_driver</td>
<td>Required. Java class name for the JDBC driver to use, the currently supported drivers are:</td>
</tr>
<tr>
<td></td>
<td>• Oracle: oracle.jdbc.OracleDriver</td>
</tr>
<tr>
<td></td>
<td>• Microsoft SQL Server: com.microsoft.sqlserver.jdbc.SQLServerDriver</td>
</tr>
<tr>
<td></td>
<td>• MySQL: com.mysql.jdbc.Driver</td>
</tr>
</tbody>
</table>

Example

com.microsoft.sqlserver.jdbc.SQLServerDriver

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>connection_string</td>
<td>Required. JDBC connection string/URL for defining the connection, usually contains information about the database server and name, the user ID and password for connection to the database. The syntax is vendor specific, refer to the following links for reference:</td>
</tr>
<tr>
<td></td>
<td>• Oracle: [jdbc:oracle:thin:&lt;username/password&gt;@&lt;database&gt;]</td>
</tr>
<tr>
<td></td>
<td>• Microsoft SQL Server: [jdbc:sqlserver://localhost;user=MyUserName;password=*****;]</td>
</tr>
<tr>
<td></td>
<td>• MySQL - [jdbc:mysql://localhost/database?user=username%26password=passwd]</td>
</tr>
</tbody>
</table>

Example

jdbc:sqlserver://xxx.service-now.com;
databaseName=SMS;
user=sms_user;
password=sms_password;

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>work</td>
<td>Required if not using the table_name parameter short cut.</td>
</tr>
<tr>
<td></td>
<td>Parent element of an XML fragment describing the SQL command to execute.</td>
</tr>
</tbody>
</table>

Example

...
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query_timeout</td>
<td>Optional during SELECT. Number of seconds the JDBC driver will wait for a query (SELECT) to complete. Zero means no timeout. If timeout is exceeded, the integration considers the JDBC result inaccessible and places it in an error state.</td>
</tr>
<tr>
<td>table_name</td>
<td>Optional (except required during count_rows == true). Alternate way of executing a select * query; instead of using the work element. Equivalent to executing select * from &lt;table_name&gt;.</td>
</tr>
<tr>
<td>count_rows</td>
<td>Optional. Indicates whether a select count(*) query should return the number of rows (true/false). The result of the count will be returned as a row_count element in the result element.</td>
</tr>
<tr>
<td>query</td>
<td>Optional. Type of query. Possible choices are &quot;All Rows from Table&quot; or &quot;Specific SQL&quot;. If &quot;Specific SQL&quot;, the sql_statement will be required to specify the SQL statement.</td>
</tr>
<tr>
<td>sql_statement</td>
<td>Optional. Use a specific SQL query. The presence of this element executes a direct query specified in the value attribute.</td>
</tr>
<tr>
<td>skip_sensor</td>
<td>Optional. Determines if Discovery will attempt to process the ECC input from the JDBCProbe. Default = true</td>
</tr>
</tbody>
</table>
For example, to query a table using a direct JDBC probe, requires the following parameters:

- JDBC driver class name
- JDBC connection string
  - Database server
  - Database name
  - User name
  - User password
- The table name

```xml
<?xml version="1.0" encoding="UTF-8"?>
<parameters>
    <parameter name="jdbc_driver" value="com.microsoft.sqlserver.jdbc.SQLServerDriver"/>
    <parameter name="connection_string" value="jdbc:sqlserver://xxx.service-now.com;databaseName=SYS;user=sms_user;password=sms_password"/>
    <parameter name="work">
        <select table="System_DATA"/>
    </parameter>
</parameters>
```

Queue form

**Using the Work Element**

The work element encodes SQL statements to be executed by the probe.

The following are the valid **work** child elements.

- select
- update
- insert
- delete
**SELECT**

Retrieve rows from the specified table in the database specified by the JDBC connection string. The simplest `select` work just specifies the table name and will retrieve all fields in a row, for example:

```xml
...<parameter name= "work" ><select table = "System_DATA" /></parameter>...
```

To specify a search criteria, specify the `where` attribute on the `select` element, for example:

```xml
...<parameter name= "work" ><select table = "System_DATA" where = "InstanceKey=692" /></parameter>...
```

To specify the fields you want returned, embed the fields as child elements of the `select` element, for example:

```xml
...<parameter name= "work" ><select table = "System_DATA" where = "InstanceKey=692" ><MachineID /><SMSID0 /></select></parameter>...
```

To use a direct SQL statement, specify it in the `query` parameter

```xml
...<parameter name= "query" value= "Specific SQL" /><parameter name = "sql_statement" value = "select * from any_table where value='test'" />
...```

**UPDATE**

An `update` SQL can be executed by specifying the `table`, optional `where` clause and required child elements for the fields and their values to update.

```xml
...<parameter name= "work" ><update table = "alerts.status" where = "ServerName = 'NCOMS' AND ServerSerial=3935" ><Agent>ServiceNow - INC10020</Agent><URL>http://Macintosh-9.local:8080/glide/incident.do?sys_id=17a31f380a0abaee048ca875e8891d0</URL><Severity quoted = "false" >3</Severity><Acknowledged quoted = "false" >0</Acknowledged></update></parameter>...
```

**INSERT**

An `insert` SQL can be executed by specifying the `table`, and required child elements for the fields and their values to insert.

```xml
...<parameter name= "work" ><insert table = "alerts.status" ><Agent>ServiceNow - INC10020</Agent><URL>http://Macintosh-9.local:8080/glide/incident.do?sys_id=17a31f380a0abaee048ca875e8891d0</URL><Severity quoted = "false" >3</Severity><Acknowledged quoted = "false" >0</Acknowledged></insert></parameter>
```
DELETE

A delete SQL can be executed by specifying the table, and optional where clause.

```xml
<parameter name= "work" ><delete table = "alerts.status" where = "ServerName \%= 'NCOMS' AND ServerSerial=3935" /></parameter>
```

Build a search provider for your instance

ServiceNow Search Providers allow you search and our Forums from the IE and Firefox search bar.

In Firefox 3.x you can also assign a keyword to each Search Provider and access them from the address bar.
For example, assign w to the wiki search provider and you can search the wiki for Business Rules by typing: w business rules in the address bar.

```
<?xml version="1.0" encoding="UTF-8"?>
<OpenSearchDescription xmlns="http://a9.com/-/spec/opensearch/1.1/">
  <ShortName>Demo Search</ShortName>
  <Description>Demo Search provider</Description>
  <InputEncoding>UTF-8</InputEncoding>
  <Url type="text/html" template="https://www.service-now.com/demo/nav_to.do?
      uri=incident_list.do?sysparm_query=active%3Dtrue^123TEXTQUERY321%3D{searchTerms}"/>
</OpenSearchDescription>
```

Search Bar

1. Create an opensearch description document. You can review the OpenSearch standards for details on additional attributes of this document such as including an icon.

```
<?xml version="1.0" encoding="UTF-8"?>
<OpenSearchDescription xmlns="http://a9.com/-/spec/opensearch/1.1/">
  <ShortName>Demo Search</ShortName>
  <Description>Demo Search provider</Description>
  <InputEncoding>UTF-8</InputEncoding>
  <Url type="text/html" template="https://www.service-now.com/demo/nav_to.do?
      uri=incident_list.do?sysparm_query=active%3Dtrue^123TEXTQUERY321%3D{searchTerms}"/>
</OpenSearchDescription>
```

2. Save the file to a web server with xml extension. The method used to install doesn't allow local file calls.
3. Create a simple html page to install the provider.

```
<a href="javascript:window.external.AddSearchProvider('http://yourServer/
      yourFile.xml');">
```
You could try running the JavaScript command from the browser location box instead of using the html file. This works with FF not IE.

**Syslog probe**

The ServiceNow Syslog probe uses the MID Server to deliver log messages from a ServiceNow instance to another machine, such as a dedicated log server, using the syslog protocol over an IP network.

**How the Syslog probe works**

The syslog probe is launched by a ServiceNow Script Include (called Syslog) that can be invoked from a business rule, event, or Orchestration activity and is launched by a MID Server. A syslog server or any server that can receive messages using the syslog protocol must be installed on the recipient (target) machine. Typically, a dedicated log server in the network is configured to receive all internal syslog messages. Some products that accept syslog messages are:

- ArcSight
- Splunk
- LogLogic
- syslog-ng

**Example**

The Acme Corporation wants to send a log message from their ServiceNow instance to an ArcSight syslog server inside their corporate firewall each time a user login fails. The system administrator uses the login.failed event to trigger a business rule that invokes the Syslog Script Include each time a login fails. Acme’s MID Server checks the ECC Queue for work and picks up the syslog probe, which contains the log entry. The MID Server then sends the log message to the ArcSight server, which gathers log messages from all the machine in the internal network.
The following code sample, included in an event or a business rule, directly calls the Syslog Script Include and sends a syslog message to a designated syslog server:

```javascript
var sl = new Syslog('FQDN of your syslog server', 'mid.server.Eclipse', 16);
sl.log('This is a sample log message', 6);
```

This code does the following:

- Sends the log message to facility 16
- Sets the priority to 6 (informational)
• Sends the message to your syslog server
• Launches the probe via the MID Server named "Eclipse"

Domain separation in third-party application and data source integration

This is an overview of domain separation and integration of third-party applications and data sources. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

Support level: Basic-Standard

The Basic-Standard level of domain separation is achieved through data visibility as well the integration design.

Basic
• There is business logic to ensure data goes into the proper domain for the application’s service provider use cases.
• In the application, the user interface, cache keys, reporting, rollups, aggregations, and so on, all consider domain at run time.
• The owner of the instance needs to be able to set up the application to function normally across multiple tenants.

Standard
• Includes Basic level
• Business logic: Processes can be created or modified per customer by the service provider. The use cases reflect proper use of the application by multiple service provider customers in a single instance.
• The owner of the instance needs to be able to configure MVP business logic and data parameters per tenant as expected for the specific application.

Overview

Team should define a few examples with data-driven properties. There should be three different buckets with short description for each one

User administration

Manage the individuals who can access your instance by defining them as users in the system. Create user groups, and assign users to them. Use roles to specify what different users and user groups can see and do.

A group is a set of users who share a common purpose. Members of groups perform tasks such as approving change requests, resolving incidents, receiving email notifications, or performing change request tasks. Assign every user to at least one group.

A good practice is to assign roles to groups rather than to users. Administrators can assign roles quickly to multiple users by adding the users to the group. If a user moves to another group, the role assigned to the new group is applied automatically.

Manage user administration system properties

The administrator can add or modify system properties to let users view their profile, automatically create a user record from a registration request, and modify the impersonate option

© 2021 ServiceNow, Inc. All rights reserved.
Allow a user to view a profile

Users are able to view their profile by clicking their name in the Welcome banner. If your users cannot do this, enable a system property.

Role required: admin

2. Search for the `glide.ui.welcome.profile_link` property.
3. Set the value to `true`.

Enable auto processing of a request

You can enable auto processing of user self-registration requests by setting a property.

Role required: admin

When the `Enable auto processing of user registration requests` property is enabled, user accounts are automatically created upon registration.

1. Activate the User Registration Request (com.snc.user_registration) plugin. The User Registration Request plugin provides the ability for unregistered users to request access to a ServiceNow instance. For more information, see Activate a plugin.
2. Navigate to System Properties > System.
3. Select the check box for the property Enable auto processing of user registration requests.
4. Click Save.
   
   If enabled, registration requests do not require approval. Instead, the business rule Auto-Process User Registration creates the user record from the information provided.

Show or hide impersonation button

You can set a system property to show or hide the impersonation button. By default, the system shows the impersonation button.

Role required: admin

The system property only controls the visibility of the impersonation button, which is rendered by the `impersonate_button` UI macro. The impersonation button opens the `impersonate_dialog` UI page. Modifying either the impersonation UI macro or impersonation UI page are not recommended.

1. Navigate to System Properties > UI Properties.
2. Clear Enable impersonation button in banner line to hide the impersonation button, or select it to show the impersonation button.
3. Click Save.

Administrators can still access impersonation by navigating directly to the `impersonate_dialog` UI page.
Add a new company

You can add companies that represent vendors, manufacturers, or customers with whom you do business. These companies provide a way to categorize users, groups, and assets.

Role required: user_admin or admin

1. Navigate to User Administration > Companies.
2. Click New.
3. Complete the fields, as appropriate.

**Company fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the company.</td>
</tr>
<tr>
<td>Phone</td>
<td>Company phone number.</td>
</tr>
<tr>
<td>Fax phone</td>
<td>Company fax number.</td>
</tr>
<tr>
<td>Manufacturer</td>
<td>Whether the company is a manufacturer.</td>
</tr>
<tr>
<td>Vendor</td>
<td>Whether the company is a vendor.</td>
</tr>
<tr>
<td>Stock symbol</td>
<td>Three or four letter stock symbol for the company.</td>
</tr>
<tr>
<td>Stock price</td>
<td>Current price at which company stock is sold.</td>
</tr>
<tr>
<td>Street</td>
<td>Mailing street address of the company.</td>
</tr>
<tr>
<td>City</td>
<td>City in which the company is located.</td>
</tr>
<tr>
<td>State</td>
<td>State or province in which the company is located.</td>
</tr>
<tr>
<td>Zip/Postal code</td>
<td>Zip or postal code for the company.</td>
</tr>
<tr>
<td>Notes</td>
<td>Any information about the company that would be helpful for others to know.</td>
</tr>
</tbody>
</table>

Fields that can be added by configuring the form:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Latitude</td>
<td>The latitude of the company, if applicable. This field is populated by a business rule called <strong>get_lat_long</strong>. Deactivate this business rule to prevent the system from overwriting any values populated in the field manually. Latitude is expressed as a floating point data type. Latitude from upgraded versions of ServiceNow expressed in any format other than floating point appears in a column called <strong>Old Latitude</strong>. The system attempts to convert all latitude values from previous versions to the floating point notation, where possible.</td>
</tr>
</tbody>
</table>
### Longitude

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Longitude</td>
<td>The longitude of the company, if applicable. This field is populated by a business rule called get_lat_long. Deactivate this business rule to prevent the system from overwriting any values populated in the field manually. Longitude is expressed as a floating point data type. Longitude from upgraded versions of ServiceNow expressed in any format other than floating point appears in a column called Old Longitude. The system attempts to convert all longitude values from previous versions to the floating point notation, where possible.</td>
</tr>
</tbody>
</table>

**Note:** The IT Finance application adds a Finance view to the Company form. The Finance view adds a chart that shows expenses that were allocated to the company. For more information, see Finance Service Management.

### Add a department

Departments provide another way to categorize users, groups, and assets. You can add departments and assign them to users.

Role required: user_admin or admin

An administrator may need to configure the form to show all the fields listed in the steps.

1. Navigate to **User Administration > Departments** and create a new record.
2. Enter or modify the department name, ID, and description.
3. Optional: Select the company the department is associated with.
4. Optional: Add a department head, primary contact, or both from your list of users.
5. Optional: Add the parent department, if applicable.
6. Click **Submit**.

### Create a user

You can add a user to your instance to allow them to log in and use the features.

Role required: user_admin

1. Navigate to **User Administration > Users**.
2. Click **New** and enter the following information:

<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>User ID</td>
<td>Create a unique identifier for this user’s ServiceNow login user name. Typical examples of user IDs are cwitherspoon and charlie.witherspoon. You cannot create a new user whose User ID duplicates an existing user. If you do import duplicates from an update set, the more recently created name takes the duplicate User ID.</td>
</tr>
<tr>
<td>First name</td>
<td>Enter the user's full first name.</td>
</tr>
<tr>
<td>Field</td>
<td>Input Value</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Last name</td>
<td>Enter the user's last name.</td>
</tr>
<tr>
<td><strong>Note:</strong> You can clear the First Name field, or the Last Name field in an existing user record, but you cannot clear both at the same time.</td>
<td></td>
</tr>
<tr>
<td>Title</td>
<td>Enter a title or job description, or select one from the list.</td>
</tr>
<tr>
<td>Department</td>
<td>Select the user's department from the list.</td>
</tr>
<tr>
<td>Password</td>
<td>Assign a password to the user. This password can be permanent or temporary.</td>
</tr>
<tr>
<td>Password needs reset</td>
<td>Select this check box to require the user to change the password during the first login.</td>
</tr>
<tr>
<td>Locked out</td>
<td>Select this check box to lock the user out of the instance and terminate all their active sessions. The system prevents users with the admin role from locking themselves out.</td>
</tr>
<tr>
<td>Active</td>
<td>Select this check box to make this user active. Only the administrator sees inactive user in:</td>
</tr>
<tr>
<td></td>
<td>• Lists of users</td>
</tr>
<tr>
<td></td>
<td>• The selection list on reference fields (magnifying glass icon)</td>
</tr>
<tr>
<td></td>
<td>• The auto-complete list that appears when you type into a reference field</td>
</tr>
<tr>
<td>Web service access only</td>
<td>Select this check box to designate this user as a non-interactive user. This field is available with Non-Interactive Sessions.</td>
</tr>
<tr>
<td>Internal Integration User</td>
<td>Select this check box to designate this user as an internal integration user.</td>
</tr>
<tr>
<td>Date format</td>
<td>Select the user's preferred format for dates.</td>
</tr>
<tr>
<td>Email</td>
<td>Enter the user's email address. To enter a non-standard email address that does not pass field validation, you must deactivate the validation script first.</td>
</tr>
<tr>
<td>a.</td>
<td>Navigate to System Definition &gt; Validation Scripts.</td>
</tr>
<tr>
<td>b.</td>
<td>Select the email record.</td>
</tr>
<tr>
<td>c.</td>
<td>Clear the Active check box and save the change.</td>
</tr>
<tr>
<td>d.</td>
<td>Complete the user profile, including the email address, and update or submit the record.</td>
</tr>
<tr>
<td>e.</td>
<td>Reactivate the email validation script.</td>
</tr>
<tr>
<td>Field</td>
<td>Input Value</td>
</tr>
<tr>
<td>----------------------------</td>
<td>-------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Notification</td>
<td>Specify if email notifications should be sent to this user. Select <strong>Enable</strong> if an email notification should be sent to this user. Select <strong>Disable</strong> if the user can still receive notifications if they subscribe to the notification, or are specified as a recipient in the Email Notifications form. To prevent notification completely, set a condition on the Email Notification form itself that does not deliver the notification if this field is set to <strong>Disable</strong>.</td>
</tr>
<tr>
<td>Calendar integration</td>
<td>Select <strong>Outlook</strong> to have this user receive meeting notifications via email directly to the calendar. Otherwise, select <strong>None</strong>.</td>
</tr>
<tr>
<td>Time zone</td>
<td>Select the user's time zone.</td>
</tr>
<tr>
<td>Business phone</td>
<td>Enter this user's business phone number.</td>
</tr>
<tr>
<td>Mobile phone</td>
<td>Enter this user's mobile phone number.</td>
</tr>
<tr>
<td>Photo</td>
<td>Attach a photo of the user, if appropriate.</td>
</tr>
<tr>
<td>Geolocation tracked</td>
<td>Select the check box to enable location tracking. The <strong>Geolocation tracked</strong> field, which is available when Geolocation is activated, provides the option to track a user's location.</td>
</tr>
<tr>
<td>Location</td>
<td>Select the user's usual location. This field is visible when geolocation is active.</td>
</tr>
</tbody>
</table>

3. Optional: Customize the form to add the **Schedule** field and assign a **schedule** to the user.

4. Optional: Customize the form to add a **Language** field or a **Country code** field to associate a specific language or location with a user.

5. Click **Submit**.
   The new user record appears at the top of the list.

### Deactivate the validation script during user creation

To enter a non-standard email address that does not pass field validation, you must deactivate the validation script first.

Role required: admin

1. Navigate to **System Definition > Validation Scripts**.
2. Select the **email** record.
3. Clear the **Active** check box and save the change.
4. Complete the user profile, including the email address, and update or submit the record.
5. Reactivate the email validation script.
User preferences

Individual users can configure many UI features, such as the number of rows per page in a list or whether the response time displays at the bottom of a v2 list or form.

These user customizations are stored as records in the User Preference [sys_user_preference] table, and are updated each time the user changes the setting.

The UI displays according to each user's preferences.

For example, by default the response time may appear at the bottom of v2 lists and forms. If a user hides the response time, a user preference record is created showing the response time indicator as hidden. During the user's future sessions, the response time indicator is hidden. If the same user later displays the response time, the user preference record is updated appropriately and future sessions open with the response time indicator visible.

Navigate to User Administration > User Preferences for a list of user preference records. Click a preference name to display that preference in form view.

Note: Having more than 10,000 user preferences causes system degradation and UI performance issues.

User Preferences form
### User preference fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name of the feature or functionality.</td>
</tr>
<tr>
<td>Description</td>
<td>An optional short description of the feature or functionality.</td>
</tr>
<tr>
<td>System</td>
<td>Shows whether this record indicates the system-wide default (TRUE), or not (FALSE).</td>
</tr>
<tr>
<td>Type</td>
<td>Shows the data type of entry accepted for the Value. For example, you can select string or integer.</td>
</tr>
<tr>
<td>User</td>
<td>Shows the name of the user for whom the setting is customized. If User is blank, the record is for a system-wide default.</td>
</tr>
<tr>
<td>Value</td>
<td>The current setting for this record. Compare this value to the User field and System field to determine whether the value shown is a system-wide default or a specific user’s preference.</td>
</tr>
</tbody>
</table>

Records for the system-wide value, which applies to users who have not customized the feature, have these values: **System=True** and **User=blank**. For each user who customizes the features, a separate record is created with these values: **System=False** and **User=<username>**. As a result, the same customizable UI feature may have multiple user preference records.

For some features, the system-wide record does not appear in the User Preferences module initially. The system-wide record may be added to the User Preferences list when a user record is created for the same feature.

When an administrator manually changes a user's preference value through this module, the user's next session uses the administrator's setting. However, the user can customize the features again through the UI, which updates their user preference record. If the administrator deletes the user preference record for a particular user, that user's next session uses the system-wide value for that feature. When the user later customizes the feature, the system creates a user preference record for the user.

### Global user preferences

Create global preferences to set a default preference for your users. To make a preference the default, create a preference, check the **System** check box, and leave the **User** field blank. The preceding image is an example of a global preference. This preference is applied to all users. This preference is overridden for a specific user by creating a preference with the same name that has a value in the **User** field.

**Note:** You should never have more than one preference with the same name set as a global user preference.

### User preferences and update sets

User preference records for system-wide values, also called the default or global values, are stored in update sets. Any changes are implemented when you import the update set and affect all users who have not customized the feature.

User preference records for specific users are not stored in update sets, so user customizations are retained when you import an update set.
Troubleshooting user-specific UI differences

If a user encounters an unexplained behavior in the user interface, an administrator can check their user preferences. Navigate to User Administration > User Preferences. Search for the user name to find all that user's records. Delete the record that affects the behavior in question.

The system-wide preference is active during the user’s next session. If the user customizes the behavior, a new user preference record is created and used for subsequent sessions.

User self-registration

The User Registration Request [com.snc.user_registration] plugin provides the ability for unregistered users to request access to a ServiceNow instance. An administrator can activate the plugin.

A user can request an account by navigating to the instance. If the plugin is installed, the following section is added to the welcome screen.

Request a user account

If you do not yet have a user account your can request one using the self registration form.

The user can complete and submit the self-registration form, and see a confirmation that it was submitted. The user receives an email when the account is registered.

Note: If the email address entered in the self-registration form is already in the system, the request is not submitted.

Approve an account

When a user submits a self-registration form, it can be reviewed and approved.

Role required: admin

1. Navigate to User Administration > Pending User Registrations and open the request.
2. Use the Create User and Reject related links on the registration request form to approve or deny the request.

   • If Create User is selected, a new user is created using the email address as the User ID.
   • If Reject is selected, the request is marked Rejected.

The user is sent an email notification with the login information if the request was accepted, or the rejection information.
3. Optional: To view past registration requests, remove the [State] [is] [Pending] condition from the filter in the list view.

Impersonate a user

Administrators can impersonate other authenticated users for testing purposes and view impersonation logs.

When impersonating another user, the administrator has access to exactly what that user can access in the system, including the same menus and modules. The instance records anything the administrator does while impersonating another user as having been done by that user.

Impersonation limitations

- When you impersonate any user, all scope-protected roles and encryption context roles are removed from the user being impersonated. However, if the impersonating user (the admin, for example) has a scope-protected role, that role is not removed from the list of roles for the user being impersonated.
- When you impersonate a user with an application-specific admin role (for example, an application admin for Human Resources or Security Incident Response), you cannot access features granted by the application admin role, including security incidents, profile information, or other scope-protected features, unless you already have those roles. Access to modules and applications in the navigation bar is also restricted. Admins cannot change the password of any user with an application admin role.
- The following actions or conditions cause a user impersonation to end:
  - The user impersonates a different user
  - The user session ends, for example after a user logs out of their instance

Note: The Impersonate Begin event appears in the system log (syslog.list) when impersonation begins, and the Impersonate End event appears in the system log when impersonation ends according to one of the two conditions listed above.
Impersonation requirements

The user account to be impersonated must have a user ID. You can find this ID in the User [sys_user] record for the account. If this value is missing, the message The user you selected could not be impersonated appears.

You need several different logins to test the system:

• An admin account to do work.
• An itil (or similar) login to test as a technician.
• An ess login to test as an end user.

More logins may be required to adequately test the system.

Note: When you attempt to impersonate a user who is locked out or is inactive, the system forces a logout after you generate an event or click a link. All changes made while using impersonation affect the current session. Make sure you properly logout, then login after impersonation is completed.

Mobile impersonation

Mobile impersonation is available on ServiceNow mobile apps. For information on mobile impersonations, see Mobile impersonation

Impersonate a user in UI16

You can select a user or enter a different user name to perform impersonation.

Role required: impersonator

1. In the banner frame, click your user name to open the user menu.
2. Select Impersonate User.
   The Impersonate User dialog box appears.
3. Select a user from the Recent Impersonations list or enter a different user’s name in the user selection field.
4. To return to your original login, follow these same steps then select your name from the list.

Impersonate a user in UI15

You can click the impersonate icon and select a user name to perform impersonation.

Role required: impersonator

1. Click the impersonate icon ( ) in the banner frame.
   The Impersonate User dialog box appears.
2. Select the user from the Recent Impersonations list, click the lookup icon and select the user's name from the full list, or type the user's name.
3. Click OK.

Impersonation logs

Impersonations are logged in the System Log.

Log impersonations for either interactive (UI) or non-interactive sessions.
Impersonation logging for interactive sessions

Interactive sessions are performed through the user interface (UI). Enable or disable impersonation logging for interactive sessions using the `glide.sys.log_impersonation` property.

If you enable impersonation logging for interactive sessions by setting `glide.sys.log_impersonation` to `true`, all interactive sessions are recorded in the impersonate log.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>glide.sys.log_impersonation</code></td>
<td>Enables (true) or disables (false) impersonation logging for interactive sessions.</td>
</tr>
</tbody>
</table>

Impersonation logging for non-interactive sessions

Non-interactive sessions are performed by applications and scripts, not through the UI.

Impersonation logging of non-interactive sessions is turned off by default. If you enable impersonation logging by setting the `glide.sys.log_impersonation.non_interactive` property to `true`, impersonations of non-interactive sessions are recorded in the impersonate log.

Even with `glide.sys.log_impersonation.non_interactive` set to `true`, the system does not log certain common impersonation tasks performed on behalf of the default users (`system`, `soap.guest`, and `guest`) because the application impersonates those default users to perform a variety of tasks.

Use the `glide.sys.log_impersonation.non_interactive.exclusion` property to exclude impersonations by other users in addition to the default users.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>glide.sys.log_impersonation.non_interactive</code></td>
<td>Enables (true) or disables (false) impersonation logging for non-interactive sessions.</td>
</tr>
<tr>
<td><code>glide.sys.log_impersonation.non_interactive.exclusion</code></td>
<td>Excludes impersonation logging of non-interactive sessions for specified users. Enter user names as a comma-separated list. Default users (<code>system</code>, <code>soap.guest</code>, and <code>guest</code>) do not need to be included in the list.</td>
</tr>
</tbody>
</table>

Force logout

In some cases, impersonating a user might cause an issue that makes it difficult to switch back (for example, if in a test environment, the user is being presented with a broken page).

To return to the user, navigate to `http://<instance name>.service-now.com/logout.do` and log back in.

Manage user sessions

The Now Platform provides the ability to view and terminate individual user sessions, lock out users from the system, and make users inactive.

- Terminating a specific user session effectively logs that user out of the next transaction, which is usually the next browser click. Use the terminate sessions feature when you want to perform system maintenance.
- Locking a user out of the system means the user can no longer log in or generate any actions from any email messages that the user sends to the instance. Locking out users also terminates their user sessions.
• Making a user inactive means that the user does not show up in any fields that reference active users on the User table.

Modify session timeout

The base system uses the default Apache session timeout of 30 minutes.

Role required: admin

After 30 minutes of inactivity in the application, the platform logs the user out automatically, unless the Remember Me check box in the login screen is selected. Making the interval longer can lead to the unnecessary maintenance of inactive sessions in memory. Adjust this timeout setting to no more than a few hours, although up to 24 hours is workable.

**Note:** Regardless of how many windows a user has open in a browser, it is considered to be one session. However, if a user has two separate browsers open (such as Internet Explorer and Firefox), it is considered to be two separate sessions.

1. Clear the Remember Me check box in the login screen.
2. In the Navigator pane, enter `sys_properties.list`.
3. In System Properties, search for `glide.ui.session_timeout`.
4. If `glide.ui.session_timeout` does not exist, click **New** to add a new property using the following values:
   * **Name**: glide.ui.session_timeout
   * **Description**: Type a brief description. In this case, enter something like Override the default session timeout (30). This value is in minutes.
   * **Type**: Select the appropriate data type. In this case, select **Integer**.
   * **Value**: Change the default value from 30 minutes to a value of your choice.

**Note:** The session timeout can also be set through installation exit customizations.

• Ajax calls to the server keep the session alive (such as Labels and Refreshing homepages).
• Polling keeps the session alive when the chat desktop is open (requires the Chat plugin).
• Administrators can add the following properties to the System Properties table.
  * `glide.security.csrf.handle.ajax.timeout`: Handles errors for timed out Ajax requests when set to `true`.
  * `glide.security.auto.resubmit.ajax`: Automatically resubmits timed-out Ajax requests when set to `true` and the Remember Me check box is selected or automatically set. A popup appears to users asking them to continue.
  * `glide.ui.auto_req.extend.session`: When set to `true`, the system automatically extends a user's session by the value the user selects for the homepage refresh time. If there is no homepage refresh time, the standard timeout value applies. Tablet and mobile devices do not support this property. When set to `false`, user sessions time out when the Remember me check box is clear. The timeout is based on whether there is a homepage refresh time. When there is no homepage refresh time, the standard timeout value applies. When there is a homepage refresh time, the user session times out after the timeout value plus one interval of the homepage refresh time. For example, if a user selects to refresh interval of five minutes, then user sessions expires after the timeout value plus five minutes.

**Note:** Users who select the Remember me check box are unaffected by session timeout properties.
• Administrators can also add the following properties to configure an alternate session timeout value for guest sessions. You can do this to conserve system resources:

  • **glide.session.unauthorized.timeout.enabled**: If set to **true**, enables an alternate session timeout for unauthenticated, guest sessions. Guest sessions are created for HTTP requests to the instance that do not contain authentication information. By default this property is set to true.

  • **glide.unauthorized.session_timeout**: The session timeout value in minutes that controls the lifespan of an unauthenticated (unauthenticated) guest session. Set the property to a value greater than 0 and less than the value in the **glide.ui.session_timeout** property.

**Lock out a user**

Lock out a user when you do not want the user to access the instance.

Role required: user_admin or admin

1. Navigate to **User Administration > Users** and select the user from the list.
2. Select the **Locked Out** check box, and update the record.

**Mark a user inactive**

You can mark a user inactive so the user does not show up in any fields that reference active users on the User table.

**Note:** By default, when you mark a user inactive, you lock out that user. The Lock Out Inactive Users business rule governs this behavior.

1. Navigate to **User Administration > Users** and select the user from the list.
2. Clear the **Active** check box, and update the record.

**Terminate a specific user session**

You can terminate a user session, for example, if you are going to perform system maintenance and users are still logged in.

1. Navigate to **User Administration > Logged in users**.
   You can only see users who are logged into the same application node as you. If the Active field on a user record value is false, the user is logged in but not currently running a transaction. Most users appear as inactive at any given time.
2. Select the session you want to end.
3. Click **Lock Out Session**.
   The session is terminated, and the user is redirected to the login page at the next attempted transaction. The user is not locked out. Multiple user sessions may be associated with one user. Terminating a user session only affects the specific session.

**Groups**

A group is a set of users who share a common purpose.

Groups may perform tasks such as approving change requests, resolving incidents, receiving email notifications, or performing work order tasks. Any business rules, assignment rules, system roles, or attributes that refer to the group apply to all group members automatically. Users with the user_admin role can create and edit groups.
Create a user group

Create groups and assign roles to them. Users assigned to the group inherit the roles.

Role required: user_admin

Navigate to User Administration > Groups and create a new record (see table for field descriptions).

To see some of the fields, you may need to personalize the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the group.</td>
</tr>
<tr>
<td>Manager</td>
<td>Group manager or lead.</td>
</tr>
<tr>
<td>Type</td>
<td>Category for this group. For example, a group designated as type catalog is a service catalog group and can also be accessed under the Service Catalog &gt; Catalog Policy &gt; Fulfillment Groups module. You may need to personalize the form to add the Type field. Activating the Work Management plugin adds the Type field automatically.</td>
</tr>
<tr>
<td>Group email</td>
<td>Group email distribution list or the email address of the point of contact, such as the group manager.</td>
</tr>
<tr>
<td>Parent</td>
<td>Other group of which this group is a member. If a group has a parent, the child group inherits the roles of the parent group. The members of the child group are not members of the parent group. For example, if an incident is assigned to the parent group and you click the Assigned to lookup icon, only the members in the parent group are available. The members of the child group are not available.</td>
</tr>
<tr>
<td>Active</td>
<td>Check box that indicates whether the group is active or inactive. Inactive groups still appear in any reference field that already references the group, but are not visible by non-admin users in:</td>
</tr>
<tr>
<td>Exclude manager</td>
<td>Check box that controls whether the group manager receives email notifications.</td>
</tr>
</tbody>
</table>

Note: ITIL is added for groups with an empty group type. Also, the default reference qualifier for tasks allows these groups to assign tasks and other task types to the group.
### Field | Description
--- | ---
Include members | Check box that controls whether the group members receive individual emails when someone sends an email to the Group Email address. The only exception to this functionality is for approval notifications, whereby all members of a group receive an approval notification, regardless of the Include members selection. See Receive notifications for more information.

| Description | Helpful information about the group.

### Add a user to a group

Add a user to a group so the user inherits all the roles assigned to the group.

Role required: user_admin

If you are a non-admin user, you cannot add a user to a group that contains the admin role. If you do not have a security_admin role, you cannot add a user to a group that contains the security_admin role.

1. Navigate to User Administration > Groups.
2. Click a group Name.
3. In the Group Members related list, click Edit.
4. Select one or more names in the Collection list.
5. Click Add.
6. Click Save.

### Remove a user from a group

Remove a user from a group when they change roles.

Role required: user_admin or itil

1. Navigate to User Administration > Groups.
2. Click a group Name.
3. In the Group Members related list, select the check box next to each group member name you wish to remove.
4. From the Actions on selected rows menu, select Delete.

**Note:** Before selecting Delete, first make sure you have properly selected the rows containing the specific users you wish to remove from the group.

### Hide groups

You can hide groups by introducing a hidden field to the group form and then creating a business rule to filter out groups marked as hidden.

Only users in the hidden group will be able to see the hidden field when selecting a group in a reference field.

### Add a hidden field to a group form

Add a custom check box field to the group form to allow the group to be hidden by the business rule.

Create a new true/false field labeled Hidden on the Group form.
The system creates a new field called `u_hidden` on the `[sys_user_group]` table and enables use of the Hidden check box to designate a hidden group.

**Add a business rule to filter out hidden groups**

After creating a custom field on the group form to hide the group, add a business rule to filter out hidden groups. Only users within the hidden group and users marked admin or groups_admin can see the group.

Create a new **before query** business rule on the `[sys_user_group]` (Group) table with the following script:

```javascript
if (!gs.hasRole("admin") && !gs.hasRole("groups_admin") && gs.getSession().isInteractive()) {
  var qc = current.addQuery("u_hidden", "!=", "true"); //cannot see hidden groups...
  qc.addOrCondition("sys_id", "javascript:getMyGroups()"); //...unless in the hidden group
}
```

**Configure group types for assignment groups**

Use the **Type** field to define categories of groups. Once defined, you can use these categories to filter assignment groups based on the group type using a reference qualifier.

For example, when selecting an assignment group from the Incident form, **Type** can be used to filter groups based on whether they are typically involved in the Incident management process. Groups such as Network or Help Desk are displayed as they are typically involved. Groups such as HR or New York are omitted.

The following items are provided in the base system.

- The types `catalog`, `itil`, and `survey`.
- The reference qualifier on `[task.assignment_group]` filters on `[Type] [equals] [null]`.
- A reference qualifier named `GetGroupFilter` is available to filter for group types using dynamic filters.

**Note:** Dictionary overrides allow administrators to filter for a group type on an extended table with a simple reference qualifier override.

**Add a new group type**

You can add additional group types to filter assignment groups for tasks.

Role required: admin

You may need to configure the form to display the **Type** field.

1. Navigate to **User Administration > Groups**.
2. Select a group record.
3. Click the lock icon beside **Type**.
4. Click the lookup icon beside the selection field. The Group Types dialog opens.
5. Complete the following steps.
   a) Click **New**.
   b) Enter the group type name and description.
      For example, to define a type for a group as `incident` and `problem`, enter: `incident,problem`. Click **Submit**.

The Group form reopens with the new type listed.

6. Optional: Add additional group types if needed.
7. Click **Update**.

**Assign a group type**

You can assign group types to filter assignment groups for tasks.

Role required: admin

1. Navigate to **User Administration > Groups** and select the desired group.
2. Click the lock icon beside **Type**.
3. Click the lookup icon beside the selection field and select one or more group types.

   **Note:** Because the default behavior of `task.assignment_group` is to filter out groups with group types defined, adding a type to a group filters it out of the **Assignment Group** field on tasks. To change the behavior, set up the reference qualifier.

4. Click **Update**.

**Roles**

Roles control access to features and capabilities in applications and modules. The admin role provides access to all features and capabilities.

After access has been granted to a role, all the groups or users assigned to the role are granted the access. Roles can contain other roles, and any access granted to a role is granted to any role that contains it.

For a complete list of the roles included with the ServiceNow platform, see **Base system roles**.

**Create a role**

Create a role to control access to features and capabilities in applications and modules. The new role does not have access to any application or module until you add other roles to it, or add it to the appropriate applications and modules.

Role required: admin

Once access has been granted to a role, all groups or users assigned to the role are granted the access. Roles can contain other roles, and any access granted to a role is granted to any role that contains it.

For a complete list of the roles included with the base instance, see **Base system roles**.

   **Note:** You cannot rename roles of any kind in the Now Platform. If you manually create a role, you cannot rename it once you save it.

1. Navigate to **User Administration > Roles** and create a new record.
2. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a name for the role.</td>
</tr>
</tbody>
</table>
### Field Description

<table>
<thead>
<tr>
<th>Requires Subscription</th>
<th>Indicates if users with this role require allocation to a subscription in the Subscription form in Subscription Management to stay in compliance.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yes</td>
<td>Chargeable user role that requires allocation of users with this role to subscriptions. These user roles appear in the Associated Roles related list in the Subscription form when you associated with downloaded plugins for a subscription. To learn more, see Subscription form.</td>
</tr>
<tr>
<td>No</td>
<td>Not a chargeable role.</td>
</tr>
<tr>
<td>Unspecified</td>
<td>Neither</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Application</th>
<th>Select the application that contains this record.</th>
</tr>
</thead>
</table>

| Elevated privilege | A role that requires elevated privilege prevents the system from assigning it to a user at login. Instead, a user must manually elevate privileges to receive the elevated role. Select this option to mark this role as required to elevate it to high security. See Elevated privilege roles for more information. |

<table>
<thead>
<tr>
<th>Description</th>
<th>Select the roles to delegate to the group member.</th>
</tr>
</thead>
</table>

### Grant a role access to applications and modules

Roles control access to features and capabilities in applications and modules. You add a role to an application or module to enable the role to grant access to the application or module for all users with the role.

**Role required: admin**

1. Navigate to **System Definition > Applications** or **System Definition > Modules**.
2. Click the appropriate application or module to open it in form view.
3. Click the lock to open the **Roles** field.
4. Use the slushbucket to add the desired roles to the application or module.
5. Click the lock to close the **Roles** field, and then save your changes.

### Create a group role

Create a group role to control access to features and capabilities in applications for all members in a group.

**Role required: admin**

1. Navigate to **User Administration > Group Roles**.
2. Click **New**.
3. Fill in the fields on the form and then click **Submit**.
### Add a role to an existing role

When you add a new role to an existing role for a user, the user inherits the access that is granted by the new role.

Role required: admin

1. Navigate to **User Administration > Roles** and open the existing role.
2. Click **Edit** in the Contains Roles related list.
3. Use the slushbucket to add one or more roles to the existing role.
4. Click **Save**.

The users with the existing role inherit the access that is granted by the new role.

### Assign a role to a group

You can assign a role to a group to grant access to applications and modules to group members.

Role required: user_admin or admin

When you assign roles to groups rather than to individual users, members of the group inherit the role. When a user switches groups, the new group role is assigned automatically. For information about the Service Mapping roles, see **Control user access to application services**.

1. Navigate to **User Administration > Groups**.
2. Click the group to assign a role.
3. In the **Roles** related list, click **Edit**.
4. Use the slushbucket to add the desired roles to the group.
5. Click **Save**.

### Assign a role to a user

A user inherits roles from all groups to which the user belongs. You can also assign roles directly to a user. Whenever a user is assigned a new role, it only takes effect after logging in with a new session.

Role required: user_admin or admin

To grant the admin role to a user, you must also have the admin role. To grant the security_admin role to a user, you must also have the security_admin role, and must elevate to the security_admin role before granting the security_admin role to other users. See **Elevate to a privileged role**.

You cannot delete roles that are assigned to the group from the user record. You must remove the user from the group record.

1. Navigate to **User Administration > Users** and then open a user record.
2. In the **Roles** related list, click **Edit**.
3. In the **Collection** list, select the desired roles, and then click **Add**.
4. Click **Save**.
### Base system roles

Administrators can assign one or more base system user roles to grant access to base system platform features and applications.

The following standard roles are included in the base ServiceNow system with a new instance.

**Note:** You cannot rename roles of any kind in the Now Platform.

<table>
<thead>
<tr>
<th>Role</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>admin</td>
<td>The administrator role. This role has special access to all system features, functions, and data because administrators can override ACL rules and pass all role checks. Consider these implications when using admin overrides on ACLs. If you have sensitive information, such as HR records, that you need to protect, you must create a custom admin role for that area and train a person authorized to see those records to act as the administrator. Also note the Special Administrative Roles.</td>
</tr>
<tr>
<td>agent_admin</td>
<td>Can manage MID Server-related scripts.</td>
</tr>
<tr>
<td>ais_admin</td>
<td>Can query, create, update, and delete indexing and search settings and log messages through the AI Search application.</td>
</tr>
<tr>
<td>approval_admin</td>
<td>Can approve or reject approvals.</td>
</tr>
<tr>
<td>approver_user</td>
<td>Can modify requests for approval routed to them. They also have all capabilities of Requesters.</td>
</tr>
<tr>
<td>assignment_rule_admin</td>
<td>Can manage Assignment Rules.</td>
</tr>
<tr>
<td>asset</td>
<td>Can manage hardware and software assets.</td>
</tr>
<tr>
<td>catalog</td>
<td>Has access to service catalog requests.</td>
</tr>
<tr>
<td>catalog_admin</td>
<td>Can manage the Service Catalog application, including catalog categories and items.</td>
</tr>
<tr>
<td>catalog_editor</td>
<td>Can create, modify, and publish items within categories they are assigned to.</td>
</tr>
<tr>
<td>catalog_item_designer</td>
<td>Can view the status of their category requests.</td>
</tr>
<tr>
<td>catalog_manager</td>
<td>Can view and assign catalog editors to their categories. Can also create, modify, and publish items within their categories.</td>
</tr>
</tbody>
</table>

**Warning:** Grant this privilege carefully.
<table>
<thead>
<tr>
<th>Role</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>category_manager</td>
<td>Can create, edit, and delete model categories.</td>
</tr>
<tr>
<td>cmdb_read</td>
<td>Can read any CMDB table. Contained in admin and itil.</td>
</tr>
<tr>
<td>communication_manager</td>
<td>Manages communication for major incidents and is responsible for communicating with all stakeholders.</td>
</tr>
<tr>
<td>contract_manager</td>
<td>Can create, edit, and delete contracts through the Contract Management application.</td>
</tr>
<tr>
<td>data_classification_admin</td>
<td>Administers all aspects of the Data Classification application, data classification code setup and assignment,</td>
</tr>
<tr>
<td>data_classification_auditor</td>
<td>Audits Data Classification code assignments.</td>
</tr>
<tr>
<td>ecmdb_admin</td>
<td>Can administer the CMDB.</td>
</tr>
<tr>
<td>filter_admin</td>
<td>Can manage filters.</td>
</tr>
<tr>
<td>filter_global</td>
<td>Can create global filters.</td>
</tr>
<tr>
<td>filter_group</td>
<td>Can create filters that belong to groups of which the user is a member.</td>
</tr>
<tr>
<td>gauge_maker</td>
<td>Can create gauges from reports. Starting with Helsinki, reports are no longer made into gauges.</td>
</tr>
<tr>
<td>guided_tour_admin</td>
<td>Can manage and administer Guided Tour functionality.</td>
</tr>
<tr>
<td>image_admin</td>
<td>Can manage image files on the Images [db_image] table.</td>
</tr>
<tr>
<td>impersonator</td>
<td>Can impersonate users. Does not allow impersonation of admin users.</td>
</tr>
<tr>
<td>import_admin</td>
<td>Can manage all aspects of import sets and imports.</td>
</tr>
<tr>
<td>import_scheduler</td>
<td>Can schedule imports.</td>
</tr>
<tr>
<td>import_set_loader</td>
<td>Can load import sets.</td>
</tr>
<tr>
<td>import_transformer</td>
<td>Can manage import set transform maps and run transforms.</td>
</tr>
<tr>
<td>incident_manager</td>
<td>Manages Incident properties and Major Incident trigger rules.</td>
</tr>
<tr>
<td>inventory_admin</td>
<td>Can create and delete stock information. Only users with the inventory_admin role can edit stock rules, stockrooms, and stockroom types.</td>
</tr>
<tr>
<td>inventory_user</td>
<td>Has access to stock information. Can create and manage transfer orders.</td>
</tr>
<tr>
<td>itil</td>
<td>Can perform standard actions for an ITIL helpdesk technician. Can open, update, close incidents, problems, changes, configuration management items. By default, only users with the itil role can have tasks assigned to them.</td>
</tr>
<tr>
<td>itil_admin</td>
<td>Possesses more privileges than the itil role and is intended for team leads. This role has the ability to delete incidents, problems, changes, and other related entities when both the itil and itil_admin roles are assigned.</td>
</tr>
<tr>
<td>knowledge</td>
<td>Can create, edit, and review knowledge base articles.</td>
</tr>
<tr>
<td>Role</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>knowledge_admin</td>
<td>Can manage the knowledge base.</td>
</tr>
<tr>
<td>list_updater</td>
<td>Can use Update Entire List and Update Selected menu options on lists.</td>
</tr>
<tr>
<td>maint</td>
<td>Reserved for ServiceNow use.</td>
</tr>
<tr>
<td>mid_server</td>
<td>Role that any MID server user should be granted. This role gives the MID server access to the tables it ordinarily uses.</td>
</tr>
<tr>
<td>model_manager</td>
<td>Can create new CMDB models. Model manager can control the base models and any model extensions that are not software or consumables. Consumable models are controlled by the asset manager role (asset). Software models are control by the software asset manager role (sam).</td>
</tr>
<tr>
<td>major_incident_manager</td>
<td>Initiates the major incident process by assessing and approving major incident candidates or creating a major incident. Maintains the ownership and accountability for the lifecycle of the incident. Identifies the users and groups to be involved in the resolution activities and sets up communication channels.</td>
</tr>
<tr>
<td>nobody</td>
<td>The nobody role means that no user has access - not even admin or maint. Use the nobody role carefully. The nobody role takes precedence over the admin override option on ACLs, so even admins cannot have access. See Create an ACL rule. Do not assign it to specific users. You can use this role in ACLs that control access to resources, such as UI pages, processors, script includes, and records. <strong>Warning:</strong> Applying the nobody role may be irreversible if applied to some important system functions.</td>
</tr>
<tr>
<td>personalize</td>
<td>Can configure forms, lists, rules, controls, scripts.</td>
</tr>
<tr>
<td>personalize_choices</td>
<td>Can configure choices and predefined responses for non-journal fields designated as choice or suggestion fields.</td>
</tr>
<tr>
<td>personalize_control</td>
<td>Can configure controls on lists, such as filters, links, and buttons.</td>
</tr>
<tr>
<td>personalize_dictionary</td>
<td>Can configure dictionary entries and labels.</td>
</tr>
<tr>
<td>personalize_form</td>
<td>Can configure forms.</td>
</tr>
<tr>
<td>personalize_list</td>
<td>Can configure lists and list calculations.</td>
</tr>
<tr>
<td>personalize_responses</td>
<td>Can configure predefined responses for journal fields designated as suggestion fields.</td>
</tr>
<tr>
<td>Role</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>personalize_rules</td>
<td>Can configure business rules and scripts. This role contains the following specialized roles for granting selective, administrative access to rules and scripts:</td>
</tr>
<tr>
<td></td>
<td>• business_rule_admin</td>
</tr>
<tr>
<td></td>
<td>• client_script_admin</td>
</tr>

</tbody>
</table>

**Special administrative roles**

Certain roles grant specific administrative rights without the full privileges of the admin role. For example, an administrator can grant a user the right to change UI policy but not client scripts.

These roles do not change the behavior of the admin role, which grants full administrative privileges.

**Note:** You cannot rename roles of any kind in the Now Platform.

**Special administrative roles**

<table>
<thead>
<tr>
<th>Role</th>
<th>Privilege</th>
</tr>
</thead>
<tbody>
<tr>
<td>assignment_rule_admin</td>
<td>Allows management of Assignment Rules.</td>
</tr>
<tr>
<td>ui_script_admin</td>
<td>Allows management of UI Scripts.</td>
</tr>
</tbody>
</table>
Read-only role

The read-only role (snc_read_only) restricts a user or a group of users to read-only access on the tables to which the user already has access.

This role is not intended to be the only role a user has. It is intended to be an extra role to restrict insert, update, and delete operations on the tables that the user can access as defined by the other roles.

After you assign this role to a user, they can no longer create, update, or delete records on ANY tables.

Note: Assign this role only to users. Do not assign this role to other resources in the system, including applications, ACLs, and so on.

The snc_read_only role can be assigned to any user to limit access to data without having to create ACLs for system tables, custom tables and fields. This practice is useful for performing internal or external audits without allowing a user to have insert or update access to data.

Users with the snc_read_only role have the following restrictions regardless of other roles and privileges they have.

- Cannot insert, update, or delete records from the UI or when using the GlideRecord API.
- Cannot activate or upgrade plugins.
- Cannot directly run SQL.
- Cannot upload XML files.
- Can only run background scripts when on an instance in the public sandbox environment.

Note: These role restrictions are in place even if impersonating another user with write access such as an admin.

Activate the read-only role

If it is not already active, an administrator can activate the Read-Only User Role (com.snc.read_only.role) plugin.

Role required: admin

1. Navigate to System Applications > All Available Applications > All.
2. Find the Read-Only User Role (com.snc.read_only.role) plugin using the filter criteria and search bar.
   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel. For more information, see Request a plugin.
3. Click Install, and then in the Activate Plugin dialog box, click Activate.
Read-only role properties

These system properties control the snc_read_only role. The following default values are used for the properties.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| glide.security.snc_read_only_role.tables.exempt_create | Specifies which tables are exempt from the read-only role enforcement and allow the creation of new records.  
- Type: string  
- Default value: sys_user_session, sysevent, syslog, syslog_transaction, sys_user_preference, sys_ui_list, sys_ui_list_element, sys_db_cache, user_multifactor_auth  
- Location: System Properties [sys_properties] table |
| glide.security.snc_read_only_role.tables.exempt_write | Specifies which tables are exempt from the read-only role enforcement and allow the updating of existing records.  
- Type: string  
- Default value: sys_user_session, sysevent, syslog, syslog_transaction, sys_user_preference, sys_ui_list, sys_ui_list_element, sys_db_cache, user_multifactor_auth  
- Location: System Properties [sys_properties] table |
| glide.security.snc_read_only_role.tables.exempt_delete | Specifies which tables are exempt from the read-only role enforcement and allow the deletion of existing records.  
- Type: string  
- Default value: sys_user_preference, sys_ui_list, sys_ui_list_element, sys_db_cache, user_multifactor_auth  
- Location: System Properties [sys_properties] table |

After you configure these properties, assign the read-only role as needed. When users log in, they are restricted from creating, updating, or deleting records on ANY tables unless you modified these properties.

Note: Test the read-only role by assigning it to a user and then impersonating that user.
Delegating roles

Administrators can authorize users to be role delegators to assign roles to users who are in a particular group. Role delegators can assign only the roles that are assigned to them.

Role delegation and record producers

These graphical workflows include the following:

- Grant role_delegator role to user in group
- Delegate roles to group member

These workflows can be customized as desired to add approval steps.

Group manager change business rule

The Group Manager Change business rule, which is disabled by default, automatically grants the role_delegator role to a user who is designated manager of a group in the Manager field on the Group form. The role is removed when the user is no longer the manager of the group.

Activate the business rule to take advantage of it.

View delegated roles

An administrator can view role designation in user records, the Role Delegators module, or the Role Audit module.

User records

Open a user record by navigating to User Administration > Users and selecting the user. You can see all the roles assigned to that user in the Roles related list.

Role Delegators module

To view existing role delegators and the groups in which they can delegate roles, navigate to User Administration > Role Delegators.

Role Audit module

The Audit Role list view displays all the role changes made in the instance by user and group. To access the Audit Role list, navigate to System Security > Reports > Role Audit.

Define role delegators and delegate roles

You can designate role delegators. A role delegator can assign roles to users who are in a particular user group.

Role required: admin to define role delegators, and role_delegator to delegate roles

The roles that delegators can assign to other users include the roles that the delegator inherits from a group and those roles that the administrator assigns to the delegator.

1. Navigate to User Administration > Designate Role Delegator.
2. Select the group that includes the user who you want to be the role delegator.
3. Select the user.
4. Click **Submit**.
   A change request for the role delegator request is created and automatically approved.

5. If you are a role delegator, complete the following steps to delegate a role.
   a) Navigate to **User Administration > Delegate Roles in Group** and fill out the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group</td>
<td>Select the group in which to delegate a role or roles to a member. Any group can be selected, including groups that the role_delegator does not belong to or groups that the role_delegator does not manage.</td>
</tr>
<tr>
<td>User</td>
<td>Select the group member to delegate a role or roles.</td>
</tr>
<tr>
<td>Roles to delegate</td>
<td>Select the roles to delegate to the group member. The roles available for delegating are only the roles that the role_delegator has.</td>
</tr>
</tbody>
</table>

   b) Click **Submit**.

   Upon submission, a change request is created for the delegation request. This change request is approved automatically, and the specified roles are granted to the named user in the group selected.

   Delegated roles can be removed in the same form by reversing the process. Select the group and user, remove the unwanted roles from the Roles slushbucket, and then resubmit the request.

   c) Optional: To remove a delegated role from a user, open the delegation record and remove the unwanted role or roles.

**Prevent a role from being delegated**

You can prevent roles from being delegated to users.

Role required: admin

By default, the following roles cannot be delegated.

- admin
- public
- nobody
- role_delegator, a user with the role_delegator role cannot delegate this role to other group members

1. Navigate to **User Administration > Roles**.
2. Open the role.
3. Configure the form to add the **Grantable** or **Can delegate** fields.
4. Clear the check box for one or both of these fields.
5. Click **Update**.

**Security jump start - ACL rules**

The Security Jump Start (ACL Rules) Plugin is installed automatically on all new instances.
**Note:** The Security Jump Start (ACL Rules) plugin is required for the following functionality. The plugin is automatically installed for new instances.

These rules were written to provide a jump start on securing many system tables, to make it easier for an organization to more quickly get into production.

This plugin is not intended for existing instances, as it might modify security access to tables that are already in use in a production environment. If an admin is interested in the new ACL rules provided by this plugin, one or more of them may be created manually in an existing instance as specific needs dictate. This list of ACLs may be used as a guideline in that case. Should an admin strongly want this plugin installed on an existing instance, we highly recommend the plugin be tested extensively in a test instance first, to ensure that the rules do not conflict with the operational needs of the organization's current implementation.

The following ACLs are included in this plugin. Click the icon in a header row to sort that column in ascending or descending order. The Operation key is as follows:

- **R**=read
- **W**=write
- **D**=delete
- **C**=create

**Note:** To learn more about this plug, see Security jump start (ACL rules) (instance security hardening) in Instance Security Hardening Settings.

### Audit user roles

Changes to user roles are automatically tracked in the Audit Roles [sys_audit_role] table.

Role required: admin

**Note:** If the Contextual Security: Role Management V2 plugin is installed, you must Enable role auditing with Contextual Security: Role Management V2.

Navigate to the Audit Roles [sys_audit_role] table.

The Audit Roles table displays changes to user roles.

<table>
<thead>

<td>The affected role.</td>
</tr>
<tr>
<td>User</td>
<td>The affected user.</td>
</tr>
</tbody>
</table>

### Non-interactive sessions

The Non-Interactive Sessions plugin creates a distinction between interactive and non-interactive users.

**Interactive users**

New users added to the instance automatically become interactive users. Interactive users can perform the following actions:
• Use their user name and password to log in to the UI or a service portal.
• Connect to an instance from a URL that calls a UI page, form, or list, for example, https://<instance name>.service-now.com/incident.do.
• Connect with single sign-on, for example, digest authentication or SAML.
• Use their credentials to authorize SOAP connections if allowed by strict security.
• Use their credentials for other API connections such as WSDL, JSON, XML, or XSD without restriction.

Non-interactive users

Non-interactive users can only use their credentials to authorize API connections such as JSON, SOAP, and WSDL. They cannot log in to the ServiceNow UI. The strict security high security setting determines if non-interactive users are subject to Contextual Security requirements.

Distinguishing between interactive and non-interactive users increases instance security by ensuring that users conform to the principle of least privilege.

Installed with Non-Interactive Sessions

Note: Non-Interactive Sessions is enabled for all new instances since the Calgary release. If you do not see it in the list of plugins, request it using the Activate Plugin service catalog item in Now Support.

• Adds a column Web Service Access Only [web_service_access_only] to the User [sys_user] table.
• Changes all existing users to be interactive users (web_service_access_only=false).
• Updates the User form to display the Web Service Access Only [web_service_access_only] field by default.

Create a non-interactive user for web services

Non-interactive users can only connect to a ServiceNow instance from an API protocol. Use this feature to set up user accounts for web service authentication purposes.

Role required: user_admin or admin

Non-interactive users cannot log in to an instance or a service portal or connect through single-sign-on, but can be used as a MID Server user if they are flagged as an Internal Integration User.

1. Navigate to User Administration > Users.
2. Search for the user to be updated.
   For example, SOAP user.
3. Select the Web Service Access Only check box.
4. Click Update.

Note:
The ServiceNow platform always uses any user name and password credentials supplied with a request even if the High Security Settings do not require authorization for a given API protocol. For example, if a SOAP request supplies a user name and password, the instance verifies those credentials even if SOAP requests do not require authorization. To avoid verifying user credentials, the request must not include them.
Make a non-interactive user record interactive

Manually switch a non-interactive user to an interactive user.

Role required: user_admin or admin

1. Navigate to User Administration > Users.
2. Search for the user you want to update. For example, System Administrator.
3. Clear the Web Service Access Only check box.
4. Click Update.

Update web service user accounts for strict security

If your instance requires strict security, add the soap role to any user accounts used for web services.

Role required: user_admin or admin

1. Navigate to User Administration > Users.
2. Select a web service user from the list.
3. From the Roles related list, click Edit.
4. Add soap to the Roles List.
5. Click Save.
6. Click Update.

Require authentication

You can specify whether non-interactive sessions require authentication from the High Security Settings module.

Role required: admin with elevated privileges

A non-interactive session bypasses the UI to connect to the instance at an API level. Typically, non-interactive sessions use set protocols such as JSON, SOAP, XSD, or WSDL. By default, all non-interactive sessions require authentication.

1. Log in with an administrator user with the security_admin role.
2. Elevate your privileges to use security_admin.
4. Select the matching Requires authorization... option for the protocol you want to set. For example, Requires authorization for incoming SOAP requests.
5. Select the check box to require authentication for the non-interactive session method. Clear the check box to allow the non-interactive session method to connect without providing any credentials.

Note: Activating the Non-Interactive Sessions plugin on an existing system may prevent any existing users that authorize SOAP and WSDL-based integrations from logging in unless they already have the soap role.

Instance Usage

The Instance Usage modules track usage for ServiceNow applications and for ServiceNow Store apps.

The usage analytics process collects data on all your instances and regularly updates the reports in the Application Usage Overview and ServiceNow Store Usage Overview modules. Application usage data is collected whenever an application is opened, and counts on tables are collected once a day. Data is collected on:
- The number of active users in the system
- The hardware CIs discovered (for instances that use Discovery)
- The number of cloud management service catalog items available to users in instances that use Cloud Management

Users with the admin or usage_admin role can view Application Usage Overview and ServiceNow Store Usage Overview reports.

**Application Usage Overview reports**

The Application Usage Overview module displays reports on the use of ServiceNow applications and ServiceNow Store applications on your instance.

See the illustration for tips on using the charts. Navigate to **Instance Usage > Application Usage Overview** and **Instance Usage > ServiceNow Store Usage Overview** to view the following reports and charts.

### Application Usage Overview reports

<table>
<thead>
<tr>
<th>Chart or report</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Usage of ServiceNow Applications and Usage of ServiceNow Store Applications</td>
<td>Shows the number of views or operations performed for each of the listed applications, grouped by month.</td>
</tr>
<tr>
<td>Users of ServiceNow Applications and Users of ServiceNow Store Applications</td>
<td>Shows the number of active users who have used the instance, grouped by month. An active user is any user who could have accessed the applications, not only users who actually did access the applications.</td>
</tr>
<tr>
<td>Usage of Custom Applications</td>
<td>Shows the number of views or operations performed for each of the listed custom applications, grouped by month.</td>
</tr>
<tr>
<td>Users of Custom Applications</td>
<td>Shows the number of active users who have used custom applications, grouped by month. An active user is any user who could have accessed the custom applications, not only users who actually did access the applications.</td>
</tr>
<tr>
<td>Chart or report</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| **Additional Metrics** | Shows any of the following items, depending on your licensing agreement:  
  • Size of the primary database in the instance  
  • Performance analytics of all indices  
  • NotifyNow messages  
  • Discovery plugin active  
  • Password reset plugin active  
  • Cloud management — VMWare instance  
  • Vendor custom applications  
  • Custom applications  
  • Event management plugin active  
  • Active benchmark indicators  
  • Customer updated PA indicator  
  • Active users  
  • Cloud management — EC2 instances  
  • Orchestration core plugins active  
  • Custom tables extending out-of-box tables other than Task  
  • Virtual node count  
  • Active users for subscriptions  
  • NotifyNow conference calls  
  • Number of Google map page hits during the current month  
  • ServiceNow Edge Encryption plugins active  
  • Physical node count  
  • Cloud provisioning plugins active |
Working with charts on the Application Usage Overview report

- Click to add content like gauges, labels, or clocks to the chart.
- Save the chart as an image.
- Point to a data point to view details.
- Click a data point to view the underlying data.
- Click to view data for applications during the specified month.
- Refresh, Configure, or Close the chart.
Authentication

ServiceNow authentication validates the identity of a user who accesses an instance, and then authorizes the user to features that match the user's role or job function.

Available authentication methods

You can use several different methods to authenticate users. User credentials are matched to different saved credentials for each method.

Note: The OKTA SSO plugin has been deprecated.

Note: To learn more about the security properties that affect authorization processing, see Access Control in Instance Security Hardening Settings.

<table>
<thead>
<tr>
<th>Authentication methods</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local database</td>
<td>Username and password in their user record in the instance database.</td>
</tr>
<tr>
<td>External Single Sign-on (SSO)</td>
<td>Username and password configured in identity providers, which have a matching user account in the database.</td>
</tr>
<tr>
<td>LDAP</td>
<td>Username and password in their LDAP account, which has a matching user account in the database.</td>
</tr>
<tr>
<td>OAuth 2.0</td>
<td>Username and password of OAuth identity provider, which has a matching user account in the database.</td>
</tr>
<tr>
<td>Digest Token</td>
<td>Encrypted digest of the username and password in the user record.</td>
</tr>
<tr>
<td>Multifactor</td>
<td>Username and password in the database and a passcode sent to the user's mobile device that has Google Authenticator installed.</td>
</tr>
<tr>
<td>Adaptive authentication</td>
<td>Policy framework that uses authentication policies to evaluate access requests</td>
</tr>
<tr>
<td>Certificate based authentication</td>
<td>Unique PEM encoded certificates mapped to users instead of user name and password</td>
</tr>
</tbody>
</table>

Note: You can use SAML and Digest Authentication through the Multiple Provider SSO application.

External single sign-on (SSO)

External SSO allows organizations to use several SSO identity providers (IdPs) to manage authentication as well as retain local database (basic) authentication.

The integration supports any combination of local and external authentication methods on a single instance:

• LDAP
• SAML 2.0
• Digest Authentication
• OpenID Connect
• Local database authentication

For example, a globally dispersed corporation might require one SSO provider for their employees, a different one for their vendors, and local database authentication for their administrators. Alternatively, a company might implement SAML 2.0 and a digest token authentication solutions on the same instance.

Multi-Provider SSO properties, tables, and scripts

The Integration - Multiple Provider Single Sign-On Installer plugin includes the following system properties, tables, and scripts.

Properties

Multi-Provider SSO adds the following system properties.

Multi-Provider SSO properties

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.authenticate.auth.validate.url</td>
<td>Enables (true) or disables (false) the URL for the multi-provider SSO integration. This must be set to false if the instance is upgraded and SSO is not working in order to check the SAML script.</td>
</tr>
<tr>
<td></td>
<td>• Type: true</td>
</tr>
<tr>
<td></td>
<td>• Default value: false</td>
</tr>
<tr>
<td>glide.authenticate.multisso.debug</td>
<td>Enables (true) or disables (false) debug logging for the multi-provider SSO integration.</td>
</tr>
<tr>
<td></td>
<td>• Type: true</td>
</tr>
<tr>
<td></td>
<td>• Default value: false</td>
</tr>
<tr>
<td>glide.authenticate.multisso.enabled</td>
<td>Enables (true) or disables (false) multi-provider SSO.</td>
</tr>
<tr>
<td></td>
<td>• Type: true</td>
</tr>
<tr>
<td></td>
<td>• Default value: false</td>
</tr>
</tbody>
</table>

Tables

Multi-Provider SSO adds the following tables.

Multi-Provider SSO tables

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSO Properties [sso_properties]</td>
<td>Stores data for each IdP, schema, common SSO data, and so on.</td>
</tr>
<tr>
<td>SAML 2 Update 1 Properties</td>
<td>Stores data for SAML 2.0 Update 1 configurations such as SAML certificates.</td>
</tr>
<tr>
<td>Digest Properties [digest_properties]</td>
<td>Stores data for digest token authentication configurations.</td>
</tr>
</tbody>
</table>
### Scripts

Multi-Provider SSO adds the following scripts.

**Multi-Provider SSO scripts**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MultiSSO</td>
<td>Allows a customer to have an SSO type defined on a company basis.</td>
</tr>
<tr>
<td>MultiSSOLogin</td>
<td>Allows each domain to have their own login script.</td>
</tr>
<tr>
<td>MultiSSOLogout</td>
<td>Allows each domain to have their own logout script.</td>
</tr>
<tr>
<td>MultiSSO_OIDC_custom</td>
<td>Allows a user to define a custom Single Sign-on script for OIDC connection.</td>
</tr>
<tr>
<td>MultiSSO_OIDC_logout_custom</td>
<td>Allows a user to define a custom logout script for OIDC connection.</td>
</tr>
<tr>
<td>MultiSSO_Abstract_Core</td>
<td>Provides a base class for all multi-provider SSO classes.</td>
</tr>
<tr>
<td>MultiSSO_ClientHelper</td>
<td>Provides a client callable utility functions for multi-provider SSO.</td>
</tr>
<tr>
<td>MultiSSO_DigestedToken</td>
<td>Provides a base system logic for digested token authentication.</td>
</tr>
<tr>
<td>MultiSSO_SAML2_Update1</td>
<td>Provides logic to process SAML 2.0 Update 1 authentication for a multi-tenant single sign-on.</td>
</tr>
</tbody>
</table>

### Activate Multi-Provider SSO plugin

This integration requires the Integration - Multiple Provider Single Sign-On Installer (com.snc.integration.sso.multi.installer) plugin.

Role required: admin

1. Navigate to **System Applications > All Available Applications > All.**
2. Find the Integration - Multiple Provider Single Sign-On Installer (com.snc.integration.sso.multi.installer) plugin using the filter criteria and search bar.
   - You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel. For more information, see Request a plugin.
3. Click **Install**, and then in the Activate Plugin dialog box, click **Activate**.

**Note:** When domain separation and delegated admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.
Set up Multi-Provider SSO

You must perform several steps to set up Multi-Provider SSO, including configuring properties, creating identity providers (IdPs), and configuring users to use SSO.

Multi-Provider SSO (SAML) IdP authentication flow
Describes the different entities that can authenticate a user through the SAML multi-SSO.

You can follow the authentication flow to understand when an entity authenticates a user using Multi-SSO.
Multi-SSO (SAML) IdP authentication flow

Access SNC Instance → Multi-SSO enabled? → No → Local DB

Yes → SAML SSO Cookie exist?

Yes → IdP used to create cookie

No → Auto-redirect IdP?

Yes → Auto-redirect IdP

No → Is IdP sso:xxx or federation:xxx?

Yes → Does user exist?

Yes → User Auto-provisioning IdP?

Yes → Auto-provisioning IdP

No → SSO:xxx → SSO associated IdP

No → Active default IdP?

Yes → Default IdP

No → Redirect fails. Contact your administrator.
If Multi-SSO is not enabled, authentication directs to a local DB.

**SAML SSO Cookie IdP**

If a SAML SSO cookie exists, the IdP which is specified with this cookie authenticates the user.

**Auto-redirect IdP**

If the auto-redirect IdP is enabled, this IdP authenticates the user.

**Federated IdP**

If the user browser is redirected to the external authorization (login_locate_sso.do) login screen, and the user exists in the user table with the IdP set in the **SSO Source** field as federation: xxx, then the federated IdP authenticates the user.

**Associated IdP**

If the user browser is redirected to the external authorization (login_locate_sso.do) login screen, and the user exists in the user table with the IdP set in the **SSO Source** field as sso: xxx, then the associated IdP authenticates the user.

**Auto-provisioning IdP**

If the user browser is redirected to the external authorization (login_locate_sso.do) login screen, and the user does not exist in the user table, but auto-provisioning is enabled, then the auto-provisioning IdP authenticates the user.

> **Note:** If there is more than one auto-provisioning IdP enabled, the user can choose the auto-provisioning IdP they can use.

**Default IdP**

If the user browser is redirected to the external authorization (login_locate_sso.do) login screen, and the user either:

- Does not exist in the user table, auto-provisioning is not enabled, and there is an active default IdP
- Exists in the user table, an IdP is not specified on the SSO source user or company record, and there is an active default IdP

then the default IdP authenticates the user.

Configure Multi-Provider SSO properties

Configure SSO properties and also add a property to the System Properties table to configure an IdP inclusion list.

Role required: admin

1. Navigate to **Multi-Provider SSO > Administration > Properties**.
2. Select the **Enable Multi-Provider SSO** check box. This selection adds the link Use external login to the login page.
3. To update the user table with the users in the IdP, select the **Enable Auto Importing** option.
4. To enable the debug messages to appear at the bottom of the content frame, select the **Enable debug logging for the Multi-Provider SSO integration** check box.

If enabled, the debug logging feature slows down performance and uses up disk space to generate logs.
5. In the property **The field on the user table that identifies a user accessing the User identification login page**, enter the field on the User table that contains the value the IdP uses to identify the user. The default value is **user_name**.

<table>
<thead>
<tr>
<th>Multiple Provider SSO Properties</th>
</tr>
</thead>
<tbody>
<tr>
<td>Please edit your changes and press Save</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Customization Properties for Multiple Provider SSO</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable multiple provider SSO</td>
</tr>
<tr>
<td>Enable Auto Importing of users from all identity providers into the user table</td>
</tr>
<tr>
<td>Enable debug logging for the multiple provider SSO integration</td>
</tr>
</tbody>
</table>

The field on the user table that identifies a user accessing the "User identification" login page. By default, it uses the 'user_name' field.

<table>
<thead>
<tr>
<th>user_name</th>
</tr>
</thead>
</table>

| Save |

| Multiple Provider SSO properties |

6. Click **Save**.

7. Instruct your users to click the **Use external login** link when they log in to the instance.

**Use OpenID Connect (OIDC) as a Single Sign-On (SSO) identity provider (IdP)**

OpenID Connect (OIDC) is an identity layer built on top of the OAuth protocol, which provides a modern and intuitive Single Sign-on (SSO) experience to you and your end users. OIDC also improves the login experience for mobile applications by enabling users to log in to ServiceNow applications using their social identity provider. For example, administrators can configure Single Sign-on with a third-party identity provider that supports OpenID Connect. Users then have the option to log in to your custom ServiceNow application using their identity provider credentials.

You can choose to use social identity providers like Google for your business-to-customer (B2C) users and enterprise identity providers like Okta, Microsoft Azure AD for your business-to-business users.

**Create an OpenID Connect (OIDD) configuration for Single Sign-On (SSO)**

You can create or update an OpenID Connect (OIDC) configuration using the Multi-Provider SSO plugin. If you have client ID, client secret, and well-known configuration URL of the identity provider, you can directly import the OIDC configuration for SSO. If you do not have the required information about the identity provider, you can manually configure OIDC for SSO. After completing the configuration, users can log in to ServiceNow applications using third-party social identity providers like Google, Okta.

- Register an OIDC application with your Identity Provider (IdP) and note the Client ID, Client Secret, and Well-known configuration URL.
- **Activate Multi-Provider SSO plugin**
- **Configure Multi-provider SSO properties**
- **Activate Approval with e-Signature plugin** to enable eSignature for the OIDC IdP.
• Role required: admin

1. Navigate to Multi-Provider SSO > Identity Providers.

2. Choose one of the following options:
   • To update an existing configuration, click an OIDC Identity Provider record.
   • To create a new configuration, click New > OpenID Connect.

3. For a new configuration, enter the OIDC configuration information in one of the following methods:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Import OpenID Connect Well Known Configuration</td>
<td>If you have the well-known configuration URL along with your associated client credentials, you can directly import an OIDC configuration. <strong>Note:</strong> If you import the OIDC well-known configuration, all related fields are auto-populated.</td>
</tr>
<tr>
<td>Manually configure the OIDC Identity Provider form</td>
<td>If you do not have an existing OAuth OIDC Entity, close the Import OpenID Connect Well Known Configuration pop-up and manually fill the fields in the OIDC Identity Provider form.</td>
</tr>
</tbody>
</table>

**Import OpenID Connect Well Known Configuration fields**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Unique name for the OIDC identity provider configuration.</td>
</tr>
<tr>
<td>Client ID</td>
<td>The client ID of the application registered in the third-party OIDC identity provider.</td>
</tr>
<tr>
<td>Client Secret</td>
<td>The client secret of the application registered in the third-party OIDC identity provider.</td>
</tr>
<tr>
<td>Well known Configuration URL</td>
<td>The URL that contains metadata about the third-party OIDC identity provider.</td>
</tr>
</tbody>
</table>

All required fields must be filled-in on the OIDC Identity Provider form.

Before you manually fill the OIDC Identity Provider form, ensure that you already have an OAuth Entity Profile for the OIDC IdP. If you do not have a OAuth Entity Profile, you can create it using the default External OIDC Provider templates, like Okta, Azure and others. The grant type of the OAuth Entity Profile must be authorization code. For more information, see Configure an OAuth OIDC provider on the Now Platform.

**Note:** You can use the templates of third-party identity providers, Auth0, Azure AD, Google, and Okta are available in the demo data of the Multiple Provider Single Sign-On Installer plugin.

**OIDC Identity Provider fields**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the OIDC identity provider record.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Active</td>
<td>Option to make the OIDC IdP configuration active.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option can only be set to active after a successful test connection.</td>
</tr>
<tr>
<td>Default</td>
<td>Option to set the OIDC IdP configuration as default when there are more than one OIDC configurations.</td>
</tr>
<tr>
<td>Auto Redirect IdP</td>
<td>Option to enable auto redirection of the users to the login page of the identity provider. This field shows when the Set as Auto Redirect IdP option is set under the Related Links section.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> If you make a new Auto Redirect IdP configuration active, the glide_sso_id cookie automatically updates with the new Auto Redirect IdP. The glide.authenticate.sso.update.idp.cookie system property controls this feature.</td>
</tr>
<tr>
<td>OIDC Entity Profile</td>
<td>OAuth Entity Profile for the OIDC configuration.</td>
</tr>
<tr>
<td>ServiceNow Homepage</td>
<td>The URL of the login page used for authentication. This field is automatically set to your instance URL. The format of the URL is: https://&lt;yourinstance&gt;.service-now.com/navpage.do</td>
</tr>
<tr>
<td>External logout redirect</td>
<td>The URL where the integration redirects users after they log out. Typically, the portal which is used for SSO. This field is automatically set to external_logout_complete.do For example, https://&lt;yourinstance&gt;.service-now.com/external_logout_complete.do</td>
</tr>
<tr>
<td>Show as Login option</td>
<td>Option to display the OIDC IdP as a login option on the login page. The login option appears as the Login with &lt;Identity provider&gt; button.</td>
</tr>
<tr>
<td>SSO label</td>
<td>Label of the OIDC IdP displayed on the login page. This field appears only when Show as Login option is enabled.</td>
</tr>
<tr>
<td>Logo URL</td>
<td>Publicly available URL that contains logo of the OIDC IdP provider. This field appears only when Show as Login option is enabled.</td>
</tr>
</tbody>
</table>
4. Optional: User Provisioning tab

You can choose to enable automatic user provisioning during user login. When automatic user provisioning is enabled, a user record is automatically created in the ServiceNow instance if that user record does not exist.

**User Provisioning fields**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Automatically provision users</td>
<td>Option to enable automatic user provisioning. This property creates a user in the instance User (sys_user) table when the user exits on IdP but does not exist in the User table.</td>
</tr>
<tr>
<td>Provision using</td>
<td>The data source to use to transform, an ID Token, User Info endpoint, or Both ID Token and User Info to a ServiceNow user. Use the Lookup list to select the pre-defined data source template, then open the record to configure the Transforms table mapping.</td>
</tr>
<tr>
<td>Provision data source</td>
<td>The ID token data source used for user provisioning.</td>
</tr>
<tr>
<td>User Info Datasource</td>
<td>The user info endpoint datasource used for user provisioning. This field is displayed when User Info or Both ID Token and User Info are selected for the Provision using field.</td>
</tr>
<tr>
<td>Update User on next login</td>
<td>Option to enable user update during the next login.</td>
</tr>
<tr>
<td>Update User Interval Time (Seconds)</td>
<td>Minimum time interval in seconds to update a user record between subsequent logins. This field is automatically set to 3,600 seconds. For example, after a user logs in, the user record will be updated after 3,600 seconds until the next login. This field is available only when the Update User on next login field is enabled.</td>
</tr>
<tr>
<td>User roles applied to provisioned users</td>
<td>List of roles applied to the newly provisioned users.</td>
</tr>
</tbody>
</table>

5. OIDC Entity tab

You can view and modify the OIDC client configuration and OIDC connect flow using the entity record.

6. OIDC Provider Configuration tab

You can view and modify the well-know configuration URL of the OIDC IdP or ID token claim validation.

7. Optional: Advanced tab

Scripts that are run during single sign-on and logout.

**Advanced fields**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single Sign-On Script</td>
<td>The script that executes during Single Sign-On. This field is automatically set to MultiSSO_OIDC_custom.</td>
</tr>
<tr>
<td>Logout Script</td>
<td>The script that executes after user logs out. This field is automatically set to MultiSSO_OIDC_logout_custom.</td>
</tr>
</tbody>
</table>
8. Optional: eSignature Approval
You can configure eSignature for the OIDC IdP.

**Note:** The eSignature Approval tab appears only when you install the **Approval with e-Signature** plugin (com.glide.e_signature_approvals).

### eSignature Approval fields

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Assertion Consumer URL for eSignature authentication</td>
<td>If you employ a customized method of handling the OIDC authentication for eSignature, you can set up your own consumer URL. For example, if you are using Multi-Provider SSO, you do not need to use this property. This format of the URL is https://&lt;yourinstance&gt;.service-now.com/consumer.do</td>
</tr>
<tr>
<td>Authentication Pop-up Dialog Width</td>
<td>Width of the authentication pop-up dialog. This field is automatically set to 800.</td>
</tr>
<tr>
<td>Authentication Pop-up Dialog Height</td>
<td>Height of the authentication pop-up dialog. This field is automatically set to 900.</td>
</tr>
</tbody>
</table>
9. Optional: Navigate to the login page of the instance to verify that IdP appears as a login option. The URL should be in the following format.

https://<yourinstance>/login_with_sso.do?glide_sso_id=sysId_IdP

**Note:** If you have enabled **Selected as Login Option**, you can go to the login URL of the instance.

---

Create a SAML 2.0 configuration using Multi-Provider SSO

You can create or update a SAML 2.0 SSO configuration from the Multi-Provider SSO feature.

Role required: admin

**Note:** New to the Jakarta release, you must validate your configuration by using the Test Connection functionality before you can activate your IdP configuration. You can still use the Update functionality to save your configuration data, but it is not an active configuration without a successful test connection.

1. Navigate to **Multi-Provider SSO > Identity Providers**.
2. Do one of the following options:
   - To update a configuration, click an SSO configuration record.
   - To create a new configuration, click **New > SAML**.
3. For a new configuration, enter the IdP information by one of the following methods:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Using a metadata descriptor URL</td>
<td>Click the URL check box and enter the URL of the IdP that you are using.</td>
</tr>
<tr>
<td>Using metadata descriptor XML file</td>
<td>Click the XML check box and paste in the XML data generated from the IdP you are using.</td>
</tr>
<tr>
<td>Entering metadata manually</td>
<td>Close the popup window and manually enter the data in the property fields.</td>
</tr>
</tbody>
</table>

All required fields must be filled-in on the Identity Provider form.

**Multi-provider single sign-on fields**

<table>
<thead>
<tr>
<th>Property</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Yes</td>
<td>Enter the name for the SSO property record.</td>
</tr>
<tr>
<td>Active</td>
<td>Yes</td>
<td>Active should be set to true for the IdP to be used for authentication.</td>
</tr>
<tr>
<td>Default</td>
<td>No</td>
<td>The Auto Redirect IdP, formerly known as the Primary IdP, automatically redirects users to access the base instance URL. This property sets this IdP configuration as the default.</td>
</tr>
<tr>
<td>Auto Redirect IdP</td>
<td>No</td>
<td>Sets this IdP configuration as the Auto Redirect IdP.</td>
</tr>
<tr>
<td>Identity Provider URL</td>
<td>Yes</td>
<td>Enter the URL to your IdP. Each IdP URL must be unique.</td>
</tr>
</tbody>
</table>

Note: The option to set this property only comes after a successful test connection.

Note: If you make a new Auto Redirect IdP configuration active, the glide_sso_id cookie updates with the new Auto Redirect IdP. The glide.authenticate.sso.update.idp.cookie system property, automatically enabled, controls this feature.
<table>
<thead>
<tr>
<th>Property</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identity Provider's AuthnRequest</td>
<td>Yes</td>
<td>Enter the URL to the HTTP-Redirect binding obtained from the SingleSignOnService element.</td>
</tr>
<tr>
<td>Identity Provider's SingleLogoutRequest</td>
<td>No</td>
<td>Enter the URL obtained from the SingleLogoutService element.</td>
</tr>
<tr>
<td>ServiceNow Homepage</td>
<td>Yes</td>
<td>Enter the URL, including login page, of the instance for which the IdP authenticates. For example: <a href="https://yourinstance.service-now.com/navpage.do">https://yourinstance.service-now.com/navpage.do</a></td>
</tr>
<tr>
<td>Entity ID/Issuer</td>
<td>Yes</td>
<td>Enter the base URL, excluding login page, of the instance for which the IdP authenticates. For example: <a href="https://yourinstance.service-now.com/">https://yourinstance.service-now.com/</a></td>
</tr>
<tr>
<td>Audience URI</td>
<td>Yes</td>
<td>Enter the base URL, excluding login page, of the instance for which the IdP authenticates. For example: <a href="https://yourinstance.service-now.com/">https://yourinstance.service-now.com/</a></td>
</tr>
<tr>
<td>NameID Policy</td>
<td>Yes</td>
<td>Enter the value of the NameIDFormat element the integration uses.</td>
</tr>
<tr>
<td>External logout redirect</td>
<td>No</td>
<td>Enter the URL where the integration redirects users after they log out.</td>
</tr>
<tr>
<td>Failed Requirement Redirect</td>
<td>No</td>
<td>Enter the URL for redirecting failed authentication requests. Typically, the URL endpoint is an error page or logout page.</td>
</tr>
</tbody>
</table>
4. Optional: Encryption And Signing tab

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Signing/Encryption Key Alias</td>
<td>Enter the alias of the key entry stored in SAML 2.0 SP Keystore.</td>
</tr>
<tr>
<td>Signing Key Password</td>
<td>Enter the password of the key entry stored in SAML 2.0 SP Keystore.</td>
</tr>
<tr>
<td>Encrypt Assertion</td>
<td>Select the check box to encrypt the assertion in the SAML response. The metadata generated for the IDP embeds the x509 certificate, which the IDP uses to encrypt the assertion in the SAML response that it generates.</td>
</tr>
<tr>
<td>Signing Signature Algorithm</td>
<td>Enter the URL that points to the SAML 2.0 Identity Provider AuthnRequest Consumer for eSignature Authentication.</td>
</tr>
<tr>
<td>Sign AuthnRequest</td>
<td>Select the check box to enable the IdP single-sign on service to receive a signed AuthnRequest.</td>
</tr>
<tr>
<td>Sign LogoutRequest</td>
<td>Select the check box to enable the IdP single-sign on service to receive a signed LogoutRequest.</td>
</tr>
</tbody>
</table>
5. Optional: User Provisioning tab

User Provisioning fields

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto Provisioning User</td>
<td>Enable automatic user provisioning, which creates a user in the instance User table when the user exists on the IdP but does not exist in the User table.</td>
</tr>
<tr>
<td>Update User Record Upon Each Login</td>
<td>Updates user information in the instance User table with the information in the IdP each time the user logs in using SAML.</td>
</tr>
</tbody>
</table>

6. Optional: Advanced tab

Advanced fields

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Field</td>
<td>Enter the field on the User table that contains the value the IdP requires to identify the user.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>NameID Attribute</td>
<td>Leave this field blank unless you configure a new NameID policy. If you configure a new policy, the system requires the User table it must use to identify the user logging in. The system matches the NameID token to the name of that User table field here.</td>
</tr>
<tr>
<td>Create AuthnContextClass</td>
<td>Select the check box to specify a particular context class such as Password Protected Transport. If the check box is cleared, the IdP selects the most appropriate context class.</td>
</tr>
<tr>
<td>AuthnContextClassRef Method</td>
<td>Enter the URN of the login mechanism you want the IdP to use to authenticate users.</td>
</tr>
<tr>
<td>Force AuthnRequest</td>
<td>Select the check box to force AuthnRequests to occur.</td>
</tr>
<tr>
<td>Is Passive AuthnRequest</td>
<td>Select the check box if the AuthnRequest is passive.</td>
</tr>
<tr>
<td>Single Sign-On Script</td>
<td>Select the Single Sign-On script. The default is MultiSSO_SAML2_Update1.</td>
</tr>
<tr>
<td>Clock Skew</td>
<td>Enter the number of seconds between the two attributes that make up the SAMLResponse nonce. The default is 60. A valid SAMLResponse must fall between the notBefore and notOnOrAfter date-time values. See Sample SAML 2 Response with the SubjectConfirmation and SubjectConfirmationData Elements and Sample SAML 2 Response with the AudienceRestrictions and Audience Elements for a sample SAMLResponse message.</td>
</tr>
<tr>
<td>Protocol Binding for the IDP's SingleLogoutRequest</td>
<td>Enter one of the supported values listed in the Binding attribute from the SingleLogoutService element.</td>
</tr>
<tr>
<td>Metadata URL from which IDP properties are imported</td>
<td>The IdP properties import from this URL. If set, it enables the automatic import of SAML certificate from the IdP if the previous certificate has expired.</td>
</tr>
</tbody>
</table>

**Note:** If you upgrade from SAML2 Update 1 to Multi-Provider SSO or if you manually set up your SSO connection, the IdP Metadata URL does not automatically populate.

---

**X.509 certificates for SAML**

Store and activate the necessary IdP certificates for your SAML configuration.

The X.509 certificates are the IdP certificates that a SAML configuration uses. After you install a certificate, you can add as many certificates as necessary. When there are multiple certificates, the system uses the first active certificate that is found. If you set the URL for the Metadata URL from which IDP properties are imported field, the system automatically polls the IdP for a current, valid certificate when your certificate is no longer valid. It appends this certificate to your instance, and uses it for your active SAML configuration.

**Note:** Polling occurs if the IdP is accessible outside of your network.
Create and update identity providers

After you have configured the multi-provider SSO properties, you can update or create new SAML 2.0 Update 1 or digest token identity providers.

Role required: admin

1. Navigate to Multi-Provider SSO > Identity Providers.
2. To edit an identity provider record, click the record.
   - For digest token configurations, manually update the properties.
   - For SAML2 Update 1 configurations, automatically update the identity provider metadata with the Import Identity Provider Metadata related link or update the properties manually.
   - For OpenID Connect configurations, manually update the properties.
3. To create a new identity provider, click **New**.
   - For digest token configurations: Click **Digest SSO** and enter the digest properties for multi-provider single sign-on.
   - For SAML2 Update 1 configurations: Click **SAML2 Update 1** and import the identity provider metadata from a URL, as XML, or manually enter the identity provider information.
   - For OpenID Connect: Click **OpenID Connect** and enter client ID, client secret, and well known configuration URL.

4. To make the IdP the failover IdP that is used when the default IdP is not available, select the **Default** check box.
   - If you have SAML 2 Update 1 active and you upgrade to the Fuji release, the SAML 2 Update 1 IdP is selected as the default failover. No default failover IdP is selected for new instances or if you are upgrading from a release on which SAML 2 Update 1 is not active.

   **Note:** The metadata import process automatically creates a certificate record for the identity provider. Navigate to the **x509 Certificate** module to see the certificate.

   **Note:** Certificates for single-sign on should always be in PEM format to work with SAML certificates.

5. If E-Signature is active, configure the Identity Provider form and add the **Assertion Consumer URL for eSignature authentication** field.
   - In most cases, this URL is: `https://YOURINSTANCE.service-now.com/consumer.do`. However, if you employ a customized method of handling the SAML authentication for E-Signature, you can set up your own consumer URL. If you are only using SAML 2.0 Update 1 and not using Multi-Provider Single Sign-on, configure the assertion consumer URL with E-signature SAML properties.

Generate instance service provider (SP) metadata for SAML
   - As part of your SSO configuration, you can generate the instance SP metadata to provide to the IdP.

Role required: admin
The IdP needs the instance SP metadata to authenticate and forward requests.

1. Choose your installed SSO plugin:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Multi-Provider SSO</td>
<td>Navigate to Multi-Provider SSO &gt; Identity Providers. Choose an IdP and click the Generate Metadata button. The integration automatically generates the instance's SP metadata from the system property settings.</td>
</tr>
<tr>
<td>SAML 2 SSO</td>
<td>Navigate to SAML 2 Single Sign-on &gt; Metadata. The integration automatically generates the instance's SP metadata from the system property settings.</td>
</tr>
</tbody>
</table>

2. Copy the SP metadata in the text box.

For example:

```
<EntityDescriptor xmlns="urn:oasis:names:tc:SAML:2.0:metadata"
    entityID="https://yourinstance.service-now.com">
  <SPSSODescriptor AuthnRequestsSigned="false"
      WantAssertionsSigned="true"
      protocolSupportEnumeration="urn:oasis:names:tc:SAML:2.0:protocol">
    <SingleLogoutService Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-Redirect"
                            Location="https://yourinstance.service-now.com/navpage.do" />
    <NameIDFormat>urn:oasis:names:tc:SAML:1.1:nameid-format:emailAddress</NameIDFormat>
    <AssertionConsumerService isDefault="true" index="0"
     Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST"
     Location="https://yourinstance.service-now.com/navpage.do" />
    <AssertionConsumerService index="1"
     Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST"
     Location="https://yourinstance.service-now.com/consumer.do"/>
  </SPSSODescriptor>
</EntityDescriptor>
```

3. Provide the instance SP metadata to the IdP.
   For example, SSOCircle allows a user to provide the SP metadata online.

**Configure users for Multi-Provider SSO**

Administrators can configure Multi-Provider SSO for individual users or for all users who belong to a company. You cannot configure Multi-Provider SSO for groups.

Role required: admin

1. Navigate to Multi-Provider SSO > Identity Providers.
2. Right-click an identity provider record and select Copy sys_id.
3. Copy the data to your clipboard.
4. Navigate to a user record or a company record.
5. Configure the form and add the SSO Source field.
6. In the SSO Source field, enter one of the following:
   - SAML users: enter sso: followed by the sys_id of the identity provider's record.
   - SSO Federation users: enter federation: followed by the sys_id of the federation record.
7. Click Update.

**Testing IdP connections**

Testing the connection to an IdP validates the settings before enabling external authentication.

Role required: admin
The Jakarta release supports the test connection within a pop-up window. If your IdP does not work correctly with this option, you can turn off this default setting.

1. Navigate to **Multi-Provider SSO > Identity Providers**.
2. Select a defined IdP or click **New** to define a new IdP.
3. Optional: Configure an identity provider if setting up a new IdP.
4. Click **Test Connection**, enter login credentials for the IdP to check login.
   
   You cannot activate the IdP until you have a successful test connection. If the test fails, you can update to save your configuration information, but you cannot activate this configuration.

5. Verify results using the **SSO Test Results/Summary** or the **Testing SSO Logs** section to see log messages.
   
   If there are any errors, refer to the **Multi-SSO (SAML 2.0) errors and fixes**
6. Click **Cancel** when testing is complete.
SSO Login Test Results

- SAML Login response received
- SAML Assertion retrieved
- Signature Validated
- Certificate Validated
- Authorization/Condition Validated
- Certificate Issuer Validated
- Subject Confirmation Validated

SSO Logout Test Results

- SAML Logout response received
- SAML Logout Response 'inResponseTo' validated
- SAML Logout Response 'Status' validated

SSO Test Connection Summary

- Test connection is successful.

Click the "Activate" button to save and activate this configuration. Click the "Close" button to close this window and continue editing the SSO configuration.

```
02/21/17 17:10:01 (000) Issue Instant: 2017-02-22T01:10:01.000Z
02/21/17 17:10:01 (081) Session inResponseTo: SNcc17366dc961c8f8e6333eb974e22f9
02/21/17 17:10:01 (081) It is a logout response
02/21/17 17:10:01 (081) SAML LogoutResponse validated.

Common IdP connection errors
The following table describes some of the common IdP connection errors and their solutions.

### Troubleshooting IdP test connections

<table>
<thead>
<tr>
<th>Error messages</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Field validation failed. Invalid User Field <code>&lt;field name&gt;</code> is not a field on <code>sys_user</code> table.</td>
<td>Verify the contents of the User table field you selected matches the SAML NameID token.</td>
</tr>
<tr>
<td>Assertion issuer is invalid.</td>
<td>Verify <strong>Identity Provider URL</strong> contains a valid URL to your IdP. Each IdP URL must be unique.</td>
</tr>
<tr>
<td>AudienceRestriction validation failed.</td>
<td>Verify the <strong>Audience URI</strong> contains a valid URL to your instance.</td>
</tr>
<tr>
<td>Cannot logout of IdP's session.</td>
<td>Verify the <strong>SingleLogoutRequest URL</strong> contains a valid URL to your IdP's logout service.</td>
</tr>
<tr>
<td>Signature did not validate against the credential's key.</td>
<td>Verify the IdP has a valid certificate installed.</td>
</tr>
</tbody>
</table>

Multi-SSO (SAML 2.0) errors and fixes
A list of common errors and associated fixes for a Multi-SSO (SAML 2.0) setup and configuration.

### Errors during Multi-SSO (SAML 2.0) setup

<table>
<thead>
<tr>
<th>Error in instance logs</th>
<th>Test Connection Message</th>
<th>SAML property</th>
<th>Diagnosis</th>

</tbody>
</table>
| Assertion audience mismatch. Expect: &lt;propAudience&gt;, actual: &lt;audienceUri&gt;.  
  or  
  AudienceRestriction validation failed. No matching audience found. | Ensure that the 'Audience URI' field is set correctly.  
  The audience URI that accepts the SAML2 token. (Normally, it is your instance URI. For example: https://demo.service-now.com.) | The SNC instance configured audience URI must match the value in the IdP.  
  or  
  AudienceRestriction validation failed. No matching audience found. | Locate &lt;saml2:Audience&gt; in the SAMLResponse in the logs and verify that the value matches the one on the instance. |  |
| Assertion issuer is invalid. Expect: &lt;value on instance&gt;, actual: &lt;value returned by IdP&gt; | Assertion issuer is invalid.  
  The Identity Provider URL that issues the SAML2 security token with user info. | The IdP entity id (issuer) does not match the value defined in the SNC instance. |  
  or  
  AudienceRestriction validation failed. No matching audience found. | Check if IdP or SP is not configured properly.  
  Confirm that the SAML property (the Identity Provider URL that issues the SAML2 security token with user info) is set correctly. |
| Subject is valid in the future.  
  Now: &lt;now&gt;, NotBefore: &lt;notBefore&gt;  
  or  
  Subject is expired. Now: &lt;now&gt;, NotOnOrAfter: &lt;notOnOrAfter&gt; | Subject validation confirmation failed.  
  The number in seconds before notBefore constraint, or after notOnOrAfter constraint, to consider still valid. | The IdP clock is not synced with SP clock.  
  or  
  AudienceRestriction validation failed. No matching audience found. | Update the SAML property glide.authenticate.sso.saml2.clockskew to a larger value. The default is 180 seconds. Some cases require a setting of 300 or higher. You may also need to check the time on your IdP server. | |
| Assertion is valid in the future, now: &lt;now&gt;, notBefore: &lt;notBefore&gt;  
  or  
  Assertion is expired, now: &lt;now&gt;, notOnOrAfter: &lt;notOnOrAfter&gt; | Assertion is invalid.  
  The number in seconds before notBefore constraint, or after notOnOrAfter constraint, to consider still valid. | Idp clock is not synced with SP clock  
  or  
  AudienceRestriction validation failed. No matching audience found. | Update the SAML property to a larger value. Default of 60 seconds. Some cases require a setting of 300 or higher. You may also need to check the time on your IdP server. |  |
Common login and IdP errors

<table>
<thead>
<tr>
<th>Error or Symptom</th>
<th>Diagnosis</th>
<th>Fix</th>
</tr>
</thead>
</table>
| Login requests generate an infinite loop between the system and the IdP when High Security is active. | • Typically the URL endpoint is an error page or logout page.  
• The logout_redirect.do might create this loop when you define glide.security.url.whitelist without adding the IdP host name to the property value. | Set (or create) the system property glide.authenticate.failed_redirect to redirect failed authentication requests to this URL. |
| The token used to authenticate the user or the request is signed with the signature algorithm http://www.w3.org/2001/04/xmldsig-more#rsa-sha256 which is not the expected signature algorithm http://www.w3.org/2000/09/xmldsig#rsa-sha1. | Check the Alert Context tab for event details.                                                | Navigate to the Advanced tab of the Relying Party Trust configuration dialog and verify that the algorithm is set to SHA-1 and not SHA-256. |

Troubleshoot script issues with SAML

You might encounter script issues if SAML is already active at the time you activate Multiple Single Sign-On and if you already customized the installation exits.

Role required: admin

1. Back up the modified installation exit SAML2SingleSignon_update1 and script include SAML2_update1.
2. Revert both the installation exit and script include to the version that is available with the baseline system.
3. Activate or upgrade the Integration - Multiple Provider Single Sign-On Installer plugin. The system upgrades SAML and all necessary files to SAML 2 Update 1.
4. Open the Multiple SSO properties page and select the Enable Multi-Provider SSO check box to enable it.
5. Put the SAML2SingleSignon_update1 installation exit changes into the baseline script include MultiSSO_SAML2_Update1 and the SAML2_update1 script include changes into the baseline SAML2_update1 script include.

Log in using Multi-Provider SSO

The recommended and most efficient method for users to log in using Multi-Provider SSO is to use a specifically configured URL.

Role required: admin

After multi-provider SSO is configured, you can send a URL to your users with the correct IdP in the parameter string. For example:

```
/login_with_sso.do?glide_sso_id=<sys_id of the sso configuration>
```

After a user successfully logs in to the IdP page, a cookie containing the IdP sys_id is added to the browser. The next time the user attempts to log in, the system redirects the user to log in to the IdP server, which automatically logs in to the instance.
If a URL parameter is not set or the browser cache has been cleared, users can also do the following:

1. Click the **Use external login** link on the login page.

   The external login page appears. Users can click **Use local login** to return to the standard login page.

2. Enter the value for the specified field on the user table that you configured in Multi-Provider SSO properties.

   The user is redirected to the IdP server, where they log in.

After users successfully log in to an IdP, they are automatically redirected to that IdP whenever they attempt to access the instance. To have a user access a different IdP, send the user a URL with the new IdP information in the parameter. The new IdP overwrites the old IdP in the cookie if the user successfully logs in. If the user does not log in successfully, the old IdP information is retained in the cookie.

**Allow users to choose the identity provider for login**

SSO federation support allows users to choose which IdP to log into.

Role required: admin

SSO federations aggregate metadata from multiple IdPs and service providers, including your instance. Federations then publish the metadata as an XML file, which includes information like IdP names and IdP certificates. Administrators can then instruct the instance to read the XML file and automatically populate the SSO Properties table with all the necessary IdP information.

1. Navigate to **Multi-Provider SSO > SSO Federation**.
2. Click **New**.
3. Fill in the fields, as appropriate (see table).
4. Click **Submit**.
5. After you configure a federation, enable the Refresh SSO Metadata scheduled job, and then configure the users who you want to access the federation IdPs. Use the sys_ID of the federation record you just created.

The instance populates the SSO properties table with the IdP information. When users who are configured to use the federation log in, they are redirected to the discovery service URL you configured. Then they select the IdP and provide the necessary credentials. Alternatively, you can send users a URL with the IdP in the parameter.

### Allowing users to choose the identity provider for login

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a descriptive name for the federation.</td>
</tr>
<tr>
<td>Active</td>
<td>Select the check box to enable the instance to pull the XML file from the federation.</td>
</tr>
<tr>
<td>Type</td>
<td>Select the type of authentication this federation supports.</td>
</tr>
<tr>
<td>Discovery Service URL</td>
<td>Enter the URL of the discovery service for this federation. This is the site where users are directed to select an IdP and log in.</td>
</tr>
<tr>
<td>Meta Data URL</td>
<td>Enter the URL of the XML file that holds the federation metadata.</td>
</tr>
<tr>
<td>x509 Certificate</td>
<td>Select the federation certificate.</td>
</tr>
<tr>
<td>Domain</td>
<td>Select the domain that the data will belong to.</td>
</tr>
</tbody>
</table>

**Note:** The InCommon federated identity management IdP is preconfigured.

**Use Service Portal with Multi-Provider SSO to redirect a URL**

Service Portal uses a combination of system properties and script includes to determine how the system handles URL redirects for users logging in to the portal.

Role required: admin
If you are using the system property to automatically redirect to your primary Identity Provider (IdP), then Service Portal automatically redirects to that IdP. If you have multiple IdPs, Service Portal shows a link on the login page to **Use external login**.

1. Configure the Service Portal login page
2. Redirect to Service Portal after login

**Use Multi-Provider SSO to set up an SSO approval for a SAML 2.0 authentication**

An SSO approval with e-signature requires configuration on the SAML IdP and the ServiceNow instance.

The SAML IdP must support and honor the forceAuthn attribute in SAML assertion requests. E-signature does not function without this IdP setting. Set up an approval with e-signature using credentials from a SAML 2.0 authentication.

1. Activate or upgrade to SAML 2.0 with the Integration - Multiple Provider Single Sign-On Installer plugin.
2. Activate the Approval with E-Signature plugin.
3. Navigate to Multi-Provider SSO > Identity Providers and verify your 2.0 SAML IdP configuration.
   
   Advanced tab shows the **Force AuthnRequest** attribute checked.

   Your SAML 2.0 IdP must support the **Force AuthnRequest** attribute, or e-signature is not supported.

4. On the eSignature Approval tab, enter the following e-signature SAML properties:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Assertion Consumer URL for eSignature authentication</strong></td>
<td>This property defaults to the appropriate URL. To configure this property, click the lock icon to make this field editable. After edits, click the icon to lock the field.</td>
</tr>
<tr>
<td><strong>Assertion Consumer Index for eSignature authentication</strong></td>
<td>If your Service Provider has more than one URL set for the AssertionConsumerURL, you can set the index to use for eSignature, starting with index 1 or more.</td>
</tr>
<tr>
<td><strong>AuthnRequest URL for eSignature Authentication</strong></td>
<td>You can enter the URL that points to the SAML 2.0 IdP AuthnRequest URL for eSignature authentication. If the URL is the same as the Assertion Consumer URL, you can leave this setting blank.</td>
</tr>
<tr>
<td><strong>Authentication Pop-up Dialog Width</strong></td>
<td>When a user approves a request using eSignature, a dialog opens and a user can enter credentials. This setting controls the width of that dialog box. The default is 500.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Authentication Pop-up Dialog Height</td>
<td>When a user approves a request using eSignature, a dialog opens and a user can enter credentials. This setting controls the height of that dialog box. The default is 300.</td>
</tr>
</tbody>
</table>

5. Click the **Generate Metadata** button underneath the tabs to regenerate the service provider metadata. Copy this data and update it on the SAML IdP.

**Activate Approval with e-Signature plugin**

The Approval with e-Signature plugin (com.glide.e_signature_approvals) allows users to approve requests by re-entering their login credentials.

Role required: admin

1. Navigate to **System Applications > All Available Applications > All**.
2. Find the plugin using the filter criteria and search bar.

You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel. For more information, see Request a plugin.
3. Click **Install**, and then in the Activate Plugin dialog box, click **Activate**.

**Note:** When domain separation and delegated admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.

**Changes to SAML 2.0 and digest token configuration**

Multiple provider single sign-on allows administrators to configure SAML 2.0 Update 1 and digest token as authentication methods.

Multiple provider single sign-on should be activated before you configure your SAML 2.0 Update 1 and digest token properties. After you request and activate multi-provider SSO, you must then set it up. After setting up multi-provider
SSO, you can create or update the SAML 2.0 Update 1 and digest token configurations. You can use either or both authentication solutions with multi-provider SSO.

**Note:** The Integration - Multiple Provider Single Sign-On Installer plugin removes the SAML application from the navigator. The necessary SAML settings are migrated to the Multi-Provider SSO application into the SAML2 Migrated table. You can still modify items like the x509 certificate, IdP details, and so on through the Multi-Provider SSO application.

### LDAP integration

An LDAP integration allows your instance to use your existing LDAP server as the master source of user data.

Administrators integrate with a Lightweight Directory Access Protocol (LDAP) directory to streamline the user login process and to automate administrative tasks such as creating users and assigning them roles. An LDAP integration allows the system to use your existing LDAP server as the primary source of user data. Typically, an LDAP integration is also part of a single sign-on implementation.

The integration uses the LDAP service account credentials to retrieve the user distinguished name (DN) from the LDAP server. Given the DN value for the user, the integration then rebinds with LDAP with the user's DN and password. The password that the user enters is contained entirely in the HTTPS session. The integration never stores LDAP passwords.

The integration uses a read-only connection that never writes to the LDAP directory. The integration only queries for information, and then updates its internal database accordingly.
Example LDAP Integration - User Import

**Note:** For detailed information about setting up the integration, see LDAP integration setup.

**Note:** If your instance is using an LDAP integration and the Active Directory settings require users to reset their password upon login, your users will not be able to log in the instance. The instance cannot change any user’s active directory password.

**Features of LDAP integration**

LDAP integration features include the following.

**Scheduled LDAP refresh**

A scheduled scan of your LDAP server is usually run once a night. It queries all applicable user records' attributes and compares them with the account on our servers. If there is a difference, we modify our user record with the changed attribute. The load placed upon the LDAP server during the refresh depends on how many records are queried, and the number of attributes being compared. We recommend scheduling the refresh during off-peak hours.
A large refresh operation can affect other scheduled operations, such as running reports, and should be planned to minimize any conflicts.

**LDAP listener**

LDAP listener is our version of a persistent query (or persistent search). We issue a standing query for changes made to your LDAP server, and constantly listen for a response. Assuming your server supports a persistent search, any changes made to any of your applicable LDAP accounts are returned to the LDAP listener and sent to your instance within approximately 10 seconds. This is an extremely useful tool, allowing us to have a nearly real-time copy of your users' account details, without having to wait for the next scheduled refresh.

**On-demand LDAP login**

After an LDAP integration is established, the instance can allow new users to log in to the system even if they do not yet have an account on the instance. When a new user attempts to log in to the instance, the integration checks to see if this user has an account in the instance. If the integration does not find an existing user account, it automatically queries the LDAP server for the username that was entered. If a matching LDAP account is found, the integration tries to authenticate with the password the user entered. If the password is valid, the instance creates an account for the user, populates the account with all applicable LDAP information, and logs the user in to the instance.

On-demand login uses the LDAP User Import transform map. For more information on transform map requirements, see [LDAP transform maps](#).

**LDAP data population**

- **Note:** Functionality described in this integration is not available by default. This integration involves post-deployment customization performed by an experienced administrator or by ServiceNow professional services consultants.

An integration to the LDAP servers allows you to quickly and easily populate the instance's database with user records from the existing LDAP database. To prevent data inconsistencies, you can create, ignore, or skip incoming LDAP records.

You can also limit the data the integration imports by specifying LDAP attributes, thereby importing only the data that you want to expose to an instance. Typically, the LDAP attributes you specify become part of the integration transform map. If you do not specify any LDAP attributes, the integration imports all available object attributes from the LDAP server. The instance stores imported LDAP data in temporary import set tables, so the more attributes you import, the longer the import time. For more information, see [Specify LDAP attributes](#).

**LDAP authentication**

Use LDAP authentication to access using LDAP credentials.

When a user enters network credentials in the login page:

1. The instance passes the credentials to an LDAP server to find the instance.
2. With RDNs, it validates the user's DN string. It validates only if at least one of the LDAP OU configurations with `table=sys_user` has an RDN configured.
3. The LDAP server responds with an authorized or unauthorized message that the system uses to determine whether access should be granted.

By authenticating against your LDAP server, users access the platform with the same credentials that they use for other internal resources on your network domain. Also, you can reuse any existing password and security policies that are already in place. For example, the LDAP server may already have account lockout and password expiration policies.

When you enable LDAP, the system updates user records with these fields.
**LDAP user record updates**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source</td>
<td>Identifies whether or not LDAP is used to validate a user. If the source starts with ldap, then the user is validated via LDAP. If the source does not start with ldap, then the password on the user record is used to validate the user upon login.</td>
</tr>
<tr>
<td>LDAP Server</td>
<td>Identifies which LDAP server authenticates the user when there are multiple LDAP servers.</td>
</tr>
</tbody>
</table>

**Note:** The system does not support LDAP password authentication through a MID Server. An instance must be able to directly connect with an LDAP server to support password authentication.

**Understanding LDAP integration**

An LDAP integration allows your instance to use your existing LDAP server as the primary source of user data.

**LDAP integration prerequisites**

- The directory services server must be LDAP v3 compliant
- Inbound network access through the firewall must be allowed (to the LDAP server)
- External IP or Name of the LDAP server
- User credentials with read-only access
- For LDAPS, a PKI certificate

**LDAP integration timing**

LDAP integrations are usually done before the instance Go Live, but can be integrated at any time.

**LDAP server data integrity**

Some users are concerned about a third party (the instance in this case) making changes (writing) to your LDAP server. In an LDAP integration, your instance does not write to the internal LDAP directory. The instance queries for information, and updates its database accordingly.

No changes are made to the internal LDAP server by the instance. The service account is read only.

Most changes (including additions) to your LDAP server are available to the instance within seconds, depending on how many components of the full LDAP integration are in place.

To keep LDAP records synchronized, schedule a periodic scan of the LDAP server to pick up changes.

The instance does not synchronize department records. Users and group memberships are kept up-to-date by the LDAP Listener mechanism and a daily full LDAP Browse, but the instance does not delete any of these entries once they disappear from LDAP.

If an entry were to be deleted, the entire history would also get deleted, and any references to it would be cleared or deleted. Configuration Items (CIs), SLA Agreements, Software Licenses, Purchase Orders, and Service Catalog Entries all have a reference to Department, and if Department is deleted, then those references get cleared. There are
many references to Users, and so deleting a user would lose all history of what that user did. Currently, the decision to
delete or not to delete is made by our customers.

Security

The connection is made from a single machine using a fixed IP address through a specific port on your firewall.
Authentication is done with a read-only LDAP account of your choosing. You can use standard LDAP, or load the
public side of an SSL certificate installed on your directory, in which case we can use LDAPS. To add another layer
of security, we also offer the option of a point-to-point IPSEC VPN tunnel. Speak to your account manager for details
and pricing.

Secure LDAP connections

<table>
<thead>
<tr>
<th>Connection</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MID Server</td>
<td>To shield your LDAP server from external network traffic, install a MID Server on the local network and configure the system to communicate with the MID Server over a secure channel.</td>
</tr>
<tr>
<td>LDAPS</td>
<td>To establish an encrypted LDAPS connection, load the public side of your LDAP server's SSL certificate. The integration uses the certificate to encrypt all communication between the LDAP server and the instance.</td>
</tr>
<tr>
<td>VPN</td>
<td>To secure the LDAP server with an encrypted point-to-point IPSEC VPN tunnel, speak to your account manager for details and pricing.</td>
</tr>
</tbody>
</table>

Another security aspect to consider is the data shared in an LDAP integration. To limit the data exposed to your
instance, specify attributes in your transform map. For more information, see LDAP transform maps.

Importing LDAP data to the instance

It is recommended that attributes are defined to import only required data. Defined attributes get mapped into the
instance user database.

We cannot answer the question of which specific attributes are needed because this is determined by the scope of the project and business requirements.

Supported types of LDAP servers

The instance has successfully integrated with Microsoft Active Directory, Novell, Domino (Lotus Notes), and Open LDAP. We use JNDI to interface with the LDAP Server. As long as your LDAP server is LDAP v3 compliant, the integration is successful.

LDAP single-sign-on

Along with the data population functionality provided with the LDAP import, you can use the External Authentication functionality supported by the application to prevent your users from needing to sign on each time.
Multiple LDAP domains

The recommended method for handling multiple domains is to create a separate LDAP server record for each domain. Each LDAP server record must point to a domain controller for that domain. This means the local network must allow connections to each of the domain controllers.

After expanding to more than one network domain, it is critical that you identify unique LDAP attributes for the application usernames and import coalesce values. A common unique coalesce attribute for Active Directory is `objectSid`. Unique usernames may vary based on the LDAP data design. Common attributes are `email` or `userPrincipalName`.

Handling query limits

By default, Active Directory 2000/2003 has an LDAP query limit (`maxPageSize`) of 1000 objects to prevent excessive loads and denial of service attacks. We have two methods of dealing with this limit.

The default method is to break up the query to return less than 1000 objects at a time. For example, query only for object starting with the letter 'a', then query for 'b' objects. The more efficient method for large environments is to enable paging. Paging is supported by default on all Microsoft Active Directory servers. It automatically splits the results into multiple result sets, so we don't have to split up the query into multiple requests.

LDAP query type

If an LDAP password is supplied then a "Simple Bind" is performed. If no LDAP password is supplied then "none" is used, in which case the LDAP server must allow anonymous login.

LDAP authentication

We use provided service account credentials for LDAP to retrieve the user DN from the LDAP server. Given the DN value for the user, we then rebind with LDAP given the users DN and the provided password.

Password storage

The password that the user enters is contained entirely in their HTTPS session. We do not store that password anywhere.

Setting up LDAP authentication

These fields on the user record pertain to LDAP:

- **Source**: The Source field identifies whether or not a user is validated using LDAP. If the source field starts with "ldap", then the user is validated via LDAP. If the Source field does not start with "ldap", then the password on the user record is used to validate the user upon login.
- **LDAP Server**: The instance supports multiple LDAP servers, so the LDAP Server field determines which server should be used to authenticate the user.

LDAP integration requirements

Review the requirements for LDAP integration, which include a PKI certificate an LDAP compliant directory services server.

LDAP integration requires:
• An LDAP v3 compliant directory services server
  • Allows inbound network access through the firewall (to the LDAP server)
  • (Optional) Accepts anonymous login
  • (Optional) Supports paging for large LDAP queries

• The external IP address or fully-qualified domain name of the LDAP server. You can also use a MID server.
• A read-only LDAP account of your choosing
• For multiple domains, network access for each domain controller
• For LDAPS, a PKI certificate
• For LDAP listener, a Microsoft Active Directory server that supports persistent queries (ADNotify)

Supported LDAP servers

Using JNDI to interface with the LDAP server, the instance has successfully integrated with the following servers:
• Microsoft Active Directory
• Novell
• Domino (Lotus Notes)
• Open LDAP

LDAP query limits

By default, Active Directory 2000/2003 has an LDAP query limit (maxPageSize) of 1000 objects to prevent excessive loads and denial of service attacks. The system has two methods of dealing with this limit.
• The default method is to break up the query to return fewer than 1000 objects at a time. For example, query only for objects starting with the letter a, then query for b objects.
• The more efficient method for large environments is to enable paging, which is supported by default on all Microsoft Active Directory servers. Paging automatically splits the results into multiple result sets so the integration does not have to split up the query into multiple requests.

LDAP integration setup

Administrators can enable LDAP integration to allow sign-on of users from their company LDAP directory.

LDAP typically uses one of these types of communication channels.
## LDAP communication channels

<table>
<thead>
<tr>
<th>Connection</th>
<th>Description</th>
<th>LDAP import support?</th>
<th>LDAP authentication support?</th>
</tr>
</thead>
<tbody>
<tr>
<td>MID Server connection</td>
<td>Communicates over HTTP on port 80 by default. This communication channel does not require a certificate. The connection between the MID Server and the instance is over HTTPS (port 443). You can use the MID Server to import data over LDAP, but you cannot use the MID Server for LDAP authentication. Proceed to Define the LDAP Server.</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Standard LDAP integration</td>
<td>Communicates over TCP on port 389 by default. This communication channel does not require a certificate. Proceed to Define the LDAP Server.</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>SSL-encrypted LDAP integration (LDAPS)</td>
<td>Communicates over TCP on port 636 by default, This communication channel requires a certificate. Proceed to Install the LDAP X.509 SSL certificate to obtain and upload the certificate.</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>VPN connection</td>
<td>Communicates over an IPSEC tunnel. Purchase or create an IPSEC tunnel on your local network. Proceed to Define the LDAP Server.</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

If using a MID Server, the MID Server connects to the instance and the MID Server also connects to the LDAP server. In both cases, the MID Server initiates the connection:

1. First, the MID Server connects to the LDAP server via LDAP on Port 389.
2. Then, the MID Server initiates an HTTPS encrypted connection to the instance on Port 443 to push the data to the instance.

For more information about VPNs, Mid Servers, and LDAP, see You Don't Need A VPN Part II on the community.

### Install the LDAP X.509 SSL certificate
You can install an X.509 certificate for your LDAP integration.

Role required: admin

1. Purchase or generate an SSL certificate on your LDAP server.
3. Fill in the form fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The certificate name.</td>
</tr>
<tr>
<td>Expiration notification</td>
<td>Select this option to send a notification to the users selected in the Notify on expiration field. By default, this is enabled.</td>
</tr>
<tr>
<td>Notify on expiration</td>
<td>Select the users to revive the notification regarding certificate expiration. If no users are selected, the logged in user is added by default, along with the last two logged in users with the administrator role.</td>
</tr>
<tr>
<td>Warn in days to expire</td>
<td>The number of days before expiration that the instance send the notification. Enter a value of at least 20. Instances upgraded to Istanbul and later releases have this value set to 20 unless a greater value is specified.</td>
</tr>
<tr>
<td>Active</td>
<td>A check box to indicate that this certificate is active.</td>
</tr>
<tr>
<td>Format</td>
<td>The format of the certificate.</td>
</tr>
<tr>
<td>Type</td>
<td>The certificate container. The instance recognizes certificates from trust stores, Java keystore, and PKCS#12 keystores.</td>
</tr>
<tr>
<td>Valid from</td>
<td>The instance automatically adds the certificate valid from date to this field. Attach the certificate to the X.509 certificate record to populate this field.</td>
</tr>
<tr>
<td>Expires</td>
<td>The instance automatically adds the certificate expiration date to this field. Attach the certificate to the X.509 certificate record to populate this field.</td>
</tr>
<tr>
<td>Expires in days</td>
<td>The calculated number of days to expiration.</td>
</tr>
<tr>
<td>Short description</td>
<td>A description for the certificate.</td>
</tr>
<tr>
<td>Issuer</td>
<td>The instance automatically adds the certificate issuer to this field. Attach the certificate to the X.509 certificate record to populate this field.</td>
</tr>
<tr>
<td>Subject</td>
<td>The instance automatically adds the certificate subject to this field. Attach the certificate to the X.509 certificate record to populate this field.</td>
</tr>
<tr>
<td>PEM Certificate</td>
<td>Enter the value of the X509 certificate.</td>
</tr>
</tbody>
</table>

**Note:** The integration does not currently sign the certificate in communications between the instance and the IdP.

4. Click **Save**.

Click **Validate Stores/Certificates** to test the trust store and certificate.

**Define an LDAP server**

Create a new LDAP server record in the instance.

Role required: admin

1. Navigate to **System LDAP > Create New Server**.
2. Fill in the form fields.

In the **Server URL** field, the valid URLs of all servers appear separated by a space. Servers are first ordered by operational status, with servers that are **Up** listed first, then ordered by the **Order** value that you specify. The first server listed is the primary LDAP server. The others are redundant servers.

**Note:** There is a slight delay between the change in the actual operational status and the display.

Alternatively, you can add a redundant LDAP server by navigating to an existing LDAP server record and inserting a row in the LDAP Server URLs embedded list.
3. Click **Submit**.

**Note:** You can also modify an existing LDAP server record by navigating to **System LDAP > LDAP Servers** and making the needed changes.

4. Make changes to the fields as necessary.

### LDAP server form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter the name of the server.</td>
</tr>
<tr>
<td>Active</td>
<td>Select this check box if the server is active.</td>
</tr>
<tr>
<td>LDAP Server URLs</td>
<td>Enter the URLs of the primary and backup LDAP servers. Servers are first ordered by operational status, with servers that are Up listed first, then ordered by the Order value that you specify. The first server listed is the primary LDAP server. The others are redundant servers.</td>
</tr>
<tr>
<td>Server URL</td>
<td>Enter the URL of the server. Configure the form to add this field if necessary. It is a calculated read-only field that shows the list of LDAP servers that you can also see in the <strong>LDAP Server URLs</strong> field, separated by a space, and ordered by operational status and the order values of the URLs.</td>
</tr>
</tbody>
</table>
| Login distinguished name | Enter the distinguished name (DN) of the user authenticating the LDAP connection. To access an LDAP directory server, the username must be in the full distinguished name format:  
  ```
  servicenow@service-now.com
  ``` |
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Login password</td>
<td>Enter the server’s password.</td>
</tr>
<tr>
<td>Starting search directory</td>
<td>Enter the relative distinguished name (RDN) of the default search directory. All queries to this LDAP server will start from this RDN.</td>
</tr>
<tr>
<td>MID Server</td>
<td>Select the MID Server you want to use to connect to the LDAP server. Using a MID Server to establish an LDAP connection prevents you from having to expose the LDAP server to external network traffic. It also eliminates the need to establish a VPN tunnel between your LDAP server and ServiceNow data centers.</td>
</tr>
<tr>
<td>Connect timeout</td>
<td>If a MID Server is configured, the connection times out after 10 seconds, regardless of this setting. This setting is hard-coded and cannot be altered.</td>
</tr>
<tr>
<td>Read timeout</td>
<td>Specify the number of seconds the integration has to read LDAP data. The integration stops reading LDAP data after the connection exceeds the read timeout. If you enable an SSL connection, you can also set a read timeout value with the <code>com.glide.ssl.read.timeout</code> system property. If you enter timeout values for both this field and the system property, the lowest timeout value takes precedence.</td>
</tr>
<tr>
<td>SSL</td>
<td>Select this check box to require the LDAP server to make an SSL-encrypted connection. If you selected a MID Server, this field is not available. If you use an LDAPS integration and the default SSL port is 636, no further configuration is necessary; SSL is automatically enabled. If the LDAPS integration uses another SSL port, define the alternate SSL connection properties.</td>
</tr>
</tbody>
</table>

**Note:**
- The MID Server user must have the `user_admin` role in order to be able to read LDAP server configuration records.
- The following are not available with the MID Server:
  - LDAP authentication
  - SSL connection

**Note:**
Be sure a network administrator configures the local firewall to allow the application server to access the LDAP server. If the LDAP server is located within an internal network, the firewall forwards (or NATs) the application server’s IP address through the firewall on the correct port.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Listener</td>
<td>Select this check box to enable the integration to periodically poll Microsoft Active Directory servers or LDAP servers that support persistent search request control. Additionally, if you selected a MID Server, the listener functionality is available for that MID Server. See Enable an LDAP listener and set system properties for more information.</td>
</tr>
<tr>
<td>Listen interval (timeout value)</td>
<td>Specify the listener timeout value in the number of minutes that the integration listens for LDAP data with every connection. The integration stops listening for LDAP data after the connection exceeds the listen interval.</td>
</tr>
<tr>
<td>Paging</td>
<td>Select this check box to have the LDAP server split up LDAP attribute data into multiple result sets rather than submit multiple queries.</td>
</tr>
</tbody>
</table>

**Note:** If you provide an LDAP password, the integration performs a Simple Bind operation. If you do not provide an LDAP password, the LDAP server must allow anonymous login or the integration cannot bind to the LDAP server.

When an LDAP Server record is set to active, the system automatically tests every connection to validate it.

Validations include:
- The LDAP server is accessible at the provided URL and port
- The LDAP server URL is properly formatted
- The login credentials are valid

Starting with the Fuji release, the system displays colored dots next to each server URL:

**LDAP server connection icons**

<table>
<thead>
<tr>
<th>Color</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Green</td>
<td>The server if active and operational.</td>
</tr>
<tr>
<td>Gray</td>
<td>The server is neither active nor operational.</td>
</tr>
<tr>
<td>Red</td>
<td>The server is active but not operational.</td>
</tr>
</tbody>
</table>
LDAP server connection status
**Enable an LDAP listener and set system properties**

Enabling a listener is optional. If enabled, a listener notifies the system to process LDAP records soon after there is an update on the LDAP server.

Role required: admin

A **listener** is a dedicated process that periodically searches for changes on the LDAP server.

The listener can be deployed on a Microsoft Active Directory server that supports persistent queries (ADNotify), or on an LDAP server that supports persistent search request control (with OID 2.16.840.1.113730.3.4.3).

If the LDAP server supports a persistent search, the LDAP listener recognizes any user and group changes made to any of the applicable LDAP accounts and forwards them to your instance within approximately 10 seconds. This allows the instance to have a nearly real-time copy of your users' account details without having to wait for the next scheduled refresh. The LDAP listener can only synchronize objects that map to the User [sys_users] and Group [sys_user_group] tables.

**Note:** If a user is added via the listener, but the user does not meet the requirements as defined by the OU filter, then the instance ignores the record on the LDAP server. If it meets the criteria, the user is added to the instance.

To enable a listener:

1. Navigate to **System LDAP > LDAP Servers**.
2. Select the LDAP server to configure.
3. Select the **Listener** check box.
4. Click **Update**.

**Note:**

The system only imports user records that match the LDAP OU filter. Incoming user records that do not meet the filter requirements are flagged as invalid and ignored by the import. Administrators can enable verbose LDAP logging to determine if incoming records are not matching the LDAP OU filter.
5. Optionally navigate to the sys_properties table and set LDAP listener system properties.

### LDAP listener properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.ldap.listener.use_background_transaction</td>
<td>When true, the LDAP listener is started as a background transaction. By running the LDAP listener as a background transaction, the quota rule LDAP Listener Start/Stop Transaction can cancel the transaction after the maximum duration is reached, 5 minutes by default. This behavior prevents an LDAP listener from waiting indefinitely.</td>
<td>This property applies only to LDAP connections that do not use a MID Server. Use glide.ldap.listener.mid.use_background_transaction to control the behavior of LDAP connections that go through a MID Server.</td>
</tr>
<tr>
<td>glide.ldap.listener.mid.use_background_transaction</td>
<td>When true, the LDAP listener is started as a background transaction. By running the LDAP listener as a background transaction, the quota rule LDAP Listener Start/Stop MID Transaction can cancel the transaction after the maximum duration is reached, 5 minutes by default. This behavior prevents an LDAP listener from waiting indefinitely.</td>
<td>This property applies only to LDAP connections that use a MID Server. Use glide.ldap.listener.use_background_transaction to control the behavior of LDAP connections that do not go through a MID Server.</td>
</tr>
<tr>
<td>glide.ldap.listener.mid.one_listener</td>
<td>When true, only a single ECC queue message is created to start or stop the LDAP listener through a MID Server. When false, multiple ECC queue messages can be created, leading to the creation of multiple threads to start or stop the LDAP listener.</td>
<td></td>
</tr>
</tbody>
</table>
Specify LDAP attributes

Specify the attributes included in LDAP server queries using the LDAP server Attributes field. This can enhance performance as well as security.

Role required: admin

By default, the system loads all of the attributes for each object that it has permission to read from your LDAP server. Using the Attributes field, you can specify and thereby limit the attributes the LDAP query returns. Using this approach for large LDAP imports can greatly improve the speed of those imports.

Explicitly define attributes where possible. If there is information that you do not want exposed to the instance, exclude the attribute.

If you do not specify LDAP server attributes, user transactions may freeze for extended periods of time when new attributes are added to an LDAP server object because the system will be busy loading data from the new attributes.

Note: To use the manager lookup scripts described in Select or Create a Transform Map for LDAP Data, specify manager and dn (distinguished name) in the Attributes field. Neither attribute is required to be a part of a transform map.
Test an LDAP connection
The instance tests the connection automatically every time a user opens the LDAP Server form. Alternatively, you can manually test the connection to the LDAP server from the LDAP server form.

Role required: admin

By default, error messages appear on the LDAP server form if there are any issues connecting to the LDAP server.

**Note:** Employees can also verify connectivity between the instance and the LDAP server. Contact Technical Support for assistance verifying LDAP connectivity.

To manually test a connection:

1. Navigate to System LDAP > LDAP Servers.
2. Select the LDAP server to test.
3. Under Related Links, click Test connection.
4. Under Related Links, click Browse to verify that the appropriate LDAP directory structure is visible to the system.
5. (Optional) If the connection was successful, click **Browse** to view the source LDAP directory structure that is visible to the instance.

   ![Note: The Filter and RDN fields on the left of the Browse window are ignored when you use the search field on the right.]

The instance changes the operational status of LDAP servers depending on the result of the connection test.

- If your instance establishes a connection to a server that has a **Operational Status** value of **down**, the **Operational Status** value is automatically changed to **up**. This functionality is supported for both automatic and manual connection tests.
- If a connection cannot be established to a server that has a **Operational Status** value of **up**, the **Operational Status** value is automatically changed to **down**. This functionality is supported for automatic connection tests only, not manual tests.

**Define LDAP organizational units**
An organizational unit (OU) definition specifies the LDAP source directories available to the integration.

Role required: admin

OU definitions can contain locations, people, or user groups. Every LDAP server definition contains two sample OU definitions: one for importing groups into the system and the other for users.

1. Navigate to **System LDAP > LDAP Servers**.
2. Select the LDAP server to configure.
3. In the **LDAP OU Definitions** related list, select either the **Groups** or **Users** sample OU definition.
4. Complete the LDAP OU Definition form (see table).
5. Click **Update**.

   The system automatically tests the connection to the LDAP server.
6. Under **Related Links**, click **Browse** to view the LDAP directory records that the OU definition returns.

---

**OU Definition form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Specify the name the integration uses when referencing this OU. The name you enter here becomes an LDAP target in the data source record.</td>
</tr>
<tr>
<td>RDN</td>
<td>Specify the relative distinguished name of the subdirectory you want to search. This RDN is combined with the start-searching directory from the LDAP server definition to identify the subdirectory containing information for this organizational unit. For example, the sample OU definition uses the RDN value of CN=Users to search the LDAP directory <code>CN=Users,DC=service-now,DC=com</code> and any directory below this point. This field must match a subdirectory in your LDAP system.</td>
</tr>
<tr>
<td>Query field</td>
<td>Specify the name of the attribute within the LDAP server to query for records. The query field must be unique in both single and multiple domain instances. For best results, use email addresses or other credentials that uniquely identify the user in a multiple domain instance. Active Directory uses the <code>sAMAccountName</code> attribute. Other LDAP servers tend to use the <code>cn</code> attribute. Note: The Query field must map to the User ID field in the User [sys_user] table. For example, if an Active Directory user logs in as <code>joe.example</code>, there must be a user record with a User ID value of <code>joe.example</code> and an LDAP record with an sAMAccountName value of <code>joe.example</code>.</td>
</tr>
</tbody>
</table>
### Example organizational unit definitions

Suppose you have an LDAP server with the following directory structure:

- dc=my-domain,dc=com
  - ou=Groups
    - cn=Development
    - cn=HR
    - cn=Sales
  - ou=Users
    - ou=Development
    - ou=HR
    - ou=Sales

Further suppose that you want to exclude the HR group and HR users from the application. Do the following:

1. Create an LDAP server record with a starting search directory of dc=my-domain,dc=com.
2. Create an OU definition record for ou=Groups with a filter to exclude cn=HR.
3. Create an OU definition record for ou=Users with a filter to exclude ou=HR.

If you do not specify additional attributes or filters with an OU definition, the LDAP query returns the entire sub-tree from the starting directory and RDN.

In these examples, an OU definition with the RDN value of ou=Groups and no filter would have returned all groups. Likewise, an OU definition with the RDN value of ou=Users and no filter would have returned all users and child organizational units.
Create a data source for LDAP
Each LDAP organizational unit (OU) definition has its own related list of data sources.

Role required: admin

**Note:** Both the LDAP Server and LDAP OU Definition must be active for the test load action to function properly. When the test load is activated for the first time, the system samples up to 20 records to determine the length of the import set fields. If the sampled records do not contain values for the User ID field, the system sets the field length for all subsequent imports to the default length of 40. The import truncates any imported data that exceeds the import set table field length. Additionally, the User ID field is truncated to a maximum of 40 characters. Be aware that the 20 loaded records cannot be transformed and are for testing purposes only. If the test records contain values for the User ID field, the field length is set based on the field length of the longest user ID in the test records.

To create a new data source:

1. Navigate to System LDAP > LDAP Servers.
2. Select the LDAP server to configure.
3. In the LDAP OU Definitions related list, select an item, such as Groups or Users.
4. In the Data Sources related list, click New.
5. Complete the Data Source form (see table).
6. Click Submit.
7. Under Related Links, click Test Load 20 Records to test whether the data source can bring LDAP data into the import table.

**Data Sources form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Specify the name the integration uses when referencing this data source.</td>
</tr>
<tr>
<td>Import set table name</td>
<td>Enter the name of the staging table where the system temporarily places the imported LDAP records and attributes. Review this table to view imported LDAP records. You can use the same import set table name for all LDAP data sources.</td>
</tr>
<tr>
<td>Type</td>
<td>Select LDAP to indicate the imported data is LDAP data. After you select the type LDAP, the form displays the LDAP target field.</td>
</tr>
<tr>
<td>LDAP target</td>
<td>Select the LDAP OU definition associated with this data source.</td>
</tr>
</tbody>
</table>

**Auto provision LDAP users**
You automatically provision users who are in the LDAP server but not yet in your instance.

Role required: admin

- Create the following properties in the System Properties [sys_properties] table:

**LDAP properties**

<table>
<thead>
<tr>
<th>LDAP property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.ldap.authentication</td>
<td>Enables LDAP authentication by using LDAP to authenticate users. Set this property to true (the default value).</td>
</tr>
<tr>
<td>LDAP property</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>glide.ldap.user.autopropvision</td>
<td>Enables LDAP the system to automatically create users in the User [sys_user] table when the user exists in LDAP but is not yet in the instance. Set this property to true (the default value).</td>
</tr>
</tbody>
</table>

Both of these properties must be set to true for auto-provisioning to work.

**LDAP integration via MID Server**

Administrators can integrate using an LDAP data source over a Management, Instrumentation, and Discovery (MID) Server.

The MID Server enables communication and movement of data between the Now Platform and external applications, data sources, and services. For details on installing a MID Server, see MID Server installation.

Using a MID Server to establish an LDAP connection prevents you from having to expose the LDAP server to external network traffic. It eliminates the need to establish a VPN tunnel between your LDAP server and datacenters. The MID Server user must have the user_admin role to be able to read LDAP server configuration records.

**Note:** The MID Server does not allow using the UI action `<instance>/sys_ui_action.do?sys_id=1b4f7ef30a0001060058e223c9a5744c` to refresh user and group records from LDAP.

A MID Server connection communicates over HTTP on port 80 by default. This communication channel does not require a certificate. The connection between the MID Server and the instance is over HTTPS (port 443). The instance connects to the LDAP server directly, using LDAP or LDAPS. This connection can either be over the internet or through a VPN tunnel.

**Note:** LDAP cannot communicate via the MID Server with password authentication.

For a secure communication over SSL, you must add an SSL certificate for the MID Server. Change the LDAP server URL from LDAP to LDAPS and change to port 636.

**Note:** If you create a new LDAP server, the MID Server SSL flag sets to false by default. You can ignore this behavior.

To set connection properties for a specific LDAP server, see Define an LDAP server.

Configure LDAP connection monitoring

Change or disable LDAP connection monitoring and notifications.

Role required: admin

© 2021 ServiceNow, Inc. All rights reserved.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
The instance automatically sends an email to users configured in the LDAP Admins group when an LDAP server connection fails. This uses the email notification, which is launched by the **LDAP Connection Test** scheduled job. This email notification is enabled by default.

**Note:** The instance does not send the email notification unless there is at least one member in the LDAP Admins group. Make sure to populate this group with the users you want to receive the email.

By default, the scheduled job tests the connection every 15 minutes. To change this interval or disable monitoring:

1. Navigate to **System Definition > Scheduled Jobs**.
2. Open **LDAP Connection Test**.
3. Do one of the following:
   - Change the interval in the **Repeat Interval** field.
   - Disable monitoring by clearing the **Active** check box.

Import binary data through a MID Server

As an administrator, you can import binary large object (BLOB) data with an LDAP integration through the MID Server.

**Role required: admin**

1. Add the name of the LDAP column you want to import binary data from to the system property `glide.ldap.binary_attributes`.
2. Add a MID Server property with the Name `glide.ldap.binary_attributes` and the same value you set for the system property.

Troubleshooting LDAP integration via MID Server

You may encounter issues in the following areas while integrating LDAP via MID Server.

You can troubleshoot these issues by viewing the outputs found in the External Communication Channel (ECC) Queue (**Discovery > Output and Artifacts > ECC Queue**).

**Test Connection Issues**

When defining OUs within the server, there is a **Test connection** related list that is used to verify the LDAP connection. When you click this link, the ECC Queue should show a single output message with a topic name of `LDAPConnectionTesterProbe`. After the test has completed on the MID Server, the ECC Queue should show an input message with the same topic name. If the **Name** column for the input message shows `true`, the test was successful. Drill down into the record to view the payload and ensure it does not contain error messages.

**Browse Issues**

When defining OUs within the server, there is a **Browse** related list that is used to view the LDAP directory records that the OU definition returns. When you click this link, the ECC Queue should show a single output message with a topic name of `LDAPBrowseProbe`. After data has been returned from the MID Server, the ECC Queue should show
an input message with the same topic name. If the **Name** column for the input message shows **true**, the test was successful. Drill down into the record to view the payload and ensure it does not contain error messages.

**Load Import Issues**

When uploading data (for example, using the Test Load 20 Records feature), the ECC Queue should show a single output message with a topic name of **LDAPProbe**.

After data has been returned from the MID Server, the ECC Queue should show another input message called **LDAPProbeCompleted**. The **Name** column for this input message shows the total number of records returned.

An additional input messages, also named **LDAPProbe**, is displayed. The **Name** column for this input message displays the highest record number in the batch. If the total number of records returned is 258 and the batch size is 200 (the default), two LDAPProbe (200, 258) incoming messages will be received, and one LDAPProbeCompleted (258) incoming message will be received.

Drill down into the record to view the payload and ensure it does not contain error messages.

![LDAPProbe and LDAPProbeCompleted messages](image)

**Import Load**

Also keep an eye out for an output message called **LDAPProbeError**.

![LDAPProbeError message](image)

**Error message**

Click the link in the **Name** column to view the details of the error.

**LDAP paging**

LDAP paging does not work if the paging size on the LDAP server is less than 1000. Set the MID Server property **glide.ldap.max_results** to a value less than or equal to the LDAP server paging size.

**LDAP fails to import binary data**

To import binary data via LDAP, such as a user photo, you must include the binary attribute in the MID Server property **glide.ldap.binary_attributes**. For the user photo example, the attribute may be **jpegphoto**.

**Import and map data**

LDAP import maps match fields in your LDAP database to fields in your instance.

---

Note: LDAP mapping has a performance effect, so the recommended approach is to schedule it during off-peak hours, or process a few records at a time to maintain system availability.
Define a transform map that only imports the needed or required attributes. Depending on the version of the instance you are using, the method for specifying LDAP mapping relationships varies.

The easiest way to know whether or not you are running a version which uses the System LDAP application for LDAP integration is to find the application from the application navigator.

The **Run Business Rules** option is applied only for the target table. Only transform maps associated to the target table run the business rules associated with different tables. If you are updating a user group and have business rules running on a user group table, the group must have roles defined.

### LDAP import mapping options

<table>
<thead>
<tr>
<th>System LDAP application?</th>
<th>Map</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yes</td>
<td>Use a transform map to specify your mapping.</td>
</tr>
<tr>
<td>No</td>
<td>Use a LDAP legacy import map to specify your mapping, or the default LDAP transform that is included in baseline instances. Remember to adjust the <strong>Coalesce</strong> field to match against the correct fields.</td>
</tr>
</tbody>
</table>

### Scheduled imports

A scheduled import allows administrators to import LDAP data on a regular schedule. By default, the LDAP integration includes two sample scheduled imports:

- Example LDAP User Import
- Example LDAP Group Import

Neither example is active by default. Change these scheduled imports to meet your company's business needs.

### LDAP transform maps

The transform map moves data from the import set table to the target table (User or Group).

The LDAP integration uses standard import sets and transform maps. You can also create custom LDAP transform maps.

**Important:** Whether you select or create custom LDAP transform maps, there should be one active transform map for a set of source and target tables. Enabling multiple transform maps for the same source and target tables can produce duplicate entries in the target table unless you coalesce against the matching fields.

### Default LDAP transform maps

By default, the system provides two transform maps for LDAP data.

<table>
<thead>
<tr>
<th>Transform Map</th>
<th>Source Table</th>
<th>Target Table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDAP User Import</td>
<td>[ldap_import]</td>
<td>[sys_user]</td>
<td>Default transform map for creating user records from LDAP credentials as part of LDAP on-demand login. Contains mappings for an Active Directory LDAP server.</td>
</tr>
</tbody>
</table>
## Transform Map

<table>
<thead>
<tr>
<th>Transform Map</th>
<th>Source Table</th>
<th>Target Table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDAP Group Import</td>
<td>[ldap_group_import]</td>
<td>[sys_user_group]</td>
<td>Default transform map for creating group records from LDAP OUs. Contains mappings for an Active Directory LDAP server.</td>
</tr>
</tbody>
</table>

**Note:** By default, the system does not have a transform map for LDAP department records.

### Requirements for custom LDAP transform maps

If you choose to create a custom transform map, the transform map must meet the following mapping requirements.

#### Requirements for custom LDAP transform maps

<table>
<thead>
<tr>
<th>Source Table</th>
<th>Source Field</th>
<th>Target Table</th>
<th>Target Field</th>
<th>Coalesce</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ldap_import</td>
<td>u_source</td>
<td>sys_user</td>
<td>source</td>
<td>false</td>
<td>The <code>u_source</code> field identifies the LDAP DN of the imported user or group. The system uses this field to determine that a user requires LDAP authentication, to find a user's manager, and to put users into groups.</td>
</tr>
</tbody>
</table>

If LDAP integrates to Active Directory, select `u_samaccountname` as the source field. If other LDAP directories are used, select `u_dn` or `u_cn` as the source field.

### Differences between LDAP transform maps and legacy import maps

When specifying LDAP mapping relationships using transform maps, there is a major difference in how reference fields are set for manager and department.

When using a transform map, it is necessary to use a transform script to create references. This is because the value associated with an LDAP attribute like "manager" is the distinguished name (DN) of the manager.
Without some extra logic in place, the result is the creation of a user record with a manager name that is the distinguished name of that user in LDAP. The integration includes a transform script to facilitate the creation of these references. The default transform map "LDAP User Import" includes transform scripts for these references.

**Existing mapping relationships**

When updating legacy import maps to transform maps, you can retain the LDAP mapping relationships that existed prior to the addition of the System LDAP application. The LDAP server has a **Map** field that is a reference to the legacy import map.

**Note:** By default this field is hidden, so you have to configure the form to display it.

If you want to transition to using a transform map, clear the reference to the legacy import map.

**LDAP import map settings**

Verify and use attributes to limit the fields the integration imports from the LDAP source. Additionally, it is important to map the user_name field to the LDAP attribute that contains the user's login ID. For Active Directory this is usually the sAMAccountName attribute. If you would like to import and coalesce on a binary attribute (such as objectSID or objectGUID), you have to create a custom transform script.

**Note:** Any value mapped to the user_name field must be unique.

If you do not specify a transform map (such as LDAP User Import), the integration uses the following default mappings:

**LDAP import default mapping**

<table>
<thead>
<tr>
<th>User field or variable</th>
<th>LDAP attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_name</td>
<td>sAMAccountName</td>
</tr>
<tr>
<td>email</td>
<td>mail</td>
</tr>
<tr>
<td>home_phone</td>
<td>homePhone</td>
</tr>
<tr>
<td>mobile_phone</td>
<td>mobile</td>
</tr>
<tr>
<td>first_name</td>
<td>givenName</td>
</tr>
<tr>
<td>last_name</td>
<td>sn</td>
</tr>
<tr>
<td>title</td>
<td>title</td>
</tr>
<tr>
<td>department</td>
<td>department</td>
</tr>
<tr>
<td>manager</td>
<td>manager</td>
</tr>
<tr>
<td>middle_name</td>
<td>initials</td>
</tr>
<tr>
<td>u_memberof</td>
<td>groups</td>
</tr>
<tr>
<td>u_member</td>
<td>members</td>
</tr>
<tr>
<td>u_manager</td>
<td>manager</td>
</tr>
</tbody>
</table>
**LDAP data transformation**

If an LDAP attribute contains simple data, the transform map links an imported LDAP attribute to an appropriate field in the target table (User or Group). For example, sample data in the sAMAccountName attribute maps to the **User ID** field in the User table.

If the imported LDAP data maps to a reference field, the instance searches for an existing matching record. If no matching record exists, the instance creates a new record for the reference field unless the field mapping specifies otherwise.

For example, suppose the LDAP attribute l maps to the **Location** reference field in the User table. Whenever the import brings in an attribute value that does not match an existing location record value, the transform map creates a new location record. The new location record has the same value as the imported attribute, and the imported user record now has a link to the new location record.

However, there are times when LDAP attribute returns a distinguished name (DN), which is essentially a reference to another record within the LDAP directory. For example, the manager attribute typically contains the distinguished name for the manager of the current LDAP directory entry. An imported DN typically uses a long text string such as: `cn=Beth Anglin,ou=Users,dc=my-domain,dc=com`.

**Warning:** Make sure your target fields are long enough to contain a DN. Many text fields use the default length of 40, which may not be long enough for some DN values. The ServiceNow system truncates any value that exceeds the field length.

Administrators do not typically want the system to create new users from the DN value because the new user has no association with an existing user. Instead, administrators want the import to locate the manager's existing user record and associate it with the newly imported user. The **LDAPUtils** script include contains the **setManager** and **processManagers** functions that can parse a DN and search for an existing user. For best results, use these functions to create a custom transform map.

For example, the **LDAP User Import** transform map script calls the **setManager** function:

```java
// The manager coming in from LDAP is the DN value for the manager. // The line of code below will locate the manager that matches the // DN value and set it into the target record. If you are not // interested in getting the manager from LDAP then remove or // comment out the line below
ldapUtils.setManager (source , target ) ;
```

In some cases, the integration imports a user's record before importing the associated manager's user record. To handle such cases, you may want to call the **processManagers** function after the transform completes. For example, the **LDAP User Import** transform map uses an **onComplete** transform script to call the **processManagers** function.

```java
// It is possible that the manager for a user did not exist in the database when // the user was processed and therefore we could not locate and set the // manager field. // The processManagers call below will find all those records for which a manager could // not be found and attempt to locate the manager again. This happens at the end of the // import and therefore all users should have been created and we should be able to // locate the manager at this point
ldapUtils.processManagers ( ) ;
```

Remove or comment out the **setManager** and **processManagers** function calls if your LDAP integration does not use the manager attribute.
LDAP scripting
Create custom transform maps, scripts, and business rules to specify requirements when importing data.

Custom transform maps should include **onStart** and **onAfter** transform scripts.

The **onStart** script should call the **LDAPUtils** script include and start logging. For example, the **LDAP User Import** transform map has an **onStart** script that uses this code:

```javascript
gs.include ( "LDAPUtils" ) ;
var ldapUtils  = new LDAPUtils ( ) ;
ldapUtils. setLog (log ) ;
```

The **onAfter** script should call the **addMembers** function. For example:

```javascript
ldapUtils.addMembers (source , target ) ;
```

Set disabled Active Directory users to inactive
Use the following script to automatically deactivate users when the associated AD user is disabled.
Role required: admin
You can identify disabled Active Directory users by checking the value of the **userAccountControl** attribute. This rule executes whenever the **userAccountControl** value changes and deactivates user accounts if the **User Account Control** signifies a disabled AD account.

Use the following script to automatically deactivate users when the associated AD user is disabled.

1. Configure the User form and create a new integer field called **User Account Control**.
2. Add mapping for userAccountControl (external) to the new field.
3. Create a new business rule with the following properties:

<table>
<thead>
<tr>
<th>Business rule field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Disable AD Users</td>
</tr>
<tr>
<td>Table</td>
<td>User [sys_user]</td>
</tr>
<tr>
<td>When</td>
<td>Before</td>
</tr>
<tr>
<td>Condition</td>
<td>current.u_user_account_control.changes()</td>
</tr>
</tbody>
</table>

The Script field should contain the following:

```javascript
var disabledFlag = 2;
//perform a bitwise comparison on userAccountControl to see if the 2 bit flag is enabled
if (current.u_user_account_control && disabledFlag) {
    gs.log('Disabling user: ' + current.user_name + 'userAccountControl=' + current.u_user_account_control);
    current.active='false';
    current.locked_out='true';
}
```

Assign LDAP field values
You can use a script to assign a value to any field for which there is a field mapping.

For example, to assign a value to the sys_user.company field, create a field map for the company field and add a transform script of:

```javascript
company = "Don's Sporting Goods";
```
Exclude particular LDAP users

If you cannot completely filter the LDAP user list using LDAP filter properties, you can exclude users with a map script.

After you have run the logic to identify a user that should not be imported, set the user_name field to an empty string and this user will not be imported.

```javascript
user_name='';
```

One way to identify users to filter out is to look for a string in the distinguishedName attribute. For example, this script excludes accounts that are not in a Users OU. You might use this script if you have too many Users OU to include in the target OU LDAP Option.

```javascript
//vdn is a variable mapped to distinguishedName
gs.include("LDAPUtils");
var vdn = source.getElement(this.distinguishedName);
if (vdn.indexOf('OU=Users')<0) {
  user_name='';
  gs.log('LDAP Import Skipping User: ' + vdn);
}
```

A more complex method of filtering is to use regular expressions.

```javascript
//vcn is a variable mapped to cn
//vdn is a variable mapped to distinguishedName
//c is the regular expression string
//c=/^[a-z][a-z][a-z][0-9][0-9][0-9]$/;
gs.include("LDAPUtils");
var vdn = source.getElement(this.distinguishedName);
var vcn = source.getElement(this.cn);
var c = /^\[a-z\][a-z][0-9][0-9][0-9]$/;
var nvcn = vcn.toLowerCase();
//test to see if the cn is in the form of 3 letters followed by 3 numbers, only import these
if (c.test(nvcn)) {
  user_name = nvcn;
} else {
  gs.log("LDAP import rejected username: " + vcn + " for DN: " + vdn);
  user_name = "";
}
```

Set choice action for reference field imports

The LDAP transform map determines how fields in the Import Set table map to fields in existing tables such as Incident or User.

Role required: admin

If the LDAP transform map updates a field in the import set table, the integration automatically creates a new record whenever there is a new record in the LDAP data. If the LDAP transform map updates a reference field storing data from another table, the administrator can choose to create, ignore, or reject new LDAP records.

For example, if the integration receives a new department record that does not match any existing department, you may want to update all of the other LDAP record fields without creating a new department record in the instance. The transform map allows you to set the record creation options for each reference field.

1. Navigate to System LDAP > Transform Maps.
2. In the Field Maps related list, select one of the following actions from the **Choice action** field:

   • **create** – creates a new reference field record if a matching record does not exist.
   • **ignore** – ignores new records in the reference field and completes processing of all other fields in the transform map.
   • **reject** – stops the transform for the entire record.

   **Note:** The field map only displays the **Choice action** field for reference fields.

**Verify LDAP mapping**

After creating an LDAP transform map, refresh the LDAP data to verify the transform map works as expected.

**Role required:** admin

1. Navigate to **System LDAP > Scheduled Loads**.
2. Click your LDAP import job.
3. Click **Execute Now**.

**LDAP integration troubleshooting**

If you are integrating your LDAP server and have questions, these items may help you troubleshoot the issue.

**Preliminary checks**

- If the LDAP is unavailable, users cannot log in to the instance. A good practice is to have local accounts for administrators so that if the LDAP is down, administrators can still access the instance.
- Check the service account to ensure that it is not expired or locked out.
- Check the format of the username. Instead of using just the username, try using the domain with the username, or username@domain.
- Verify that you have changed the **system_id** entry on the **ldap_server_config** record. If you modify the **system_id** unintentionally with an update set, **system_id** points to the wrong node for the target instance and does not work.

**Error codes**

The LDAP log file lists industry standard error codes for both LDAP and Active Directory (AD). The LDAP log file is contained in the wrapper file. The LDAP error codes are two-digit numbers, while the Active Directory error codes are three-digit numbers. For a list of the most-common error codes, see [LDAP Error Codes](#).

**Multiple domain integration**

You can integrate multiple domains within the same forest or in completely non-trusted domains. It is recommended that you create a separate **LDAP server record** for each domain. Each LDAP server record must point to a domain controller for that given domain. This means you will have to allow connections to each of the domain controllers. Multiple AD forests through LDAP with one LDAP account is not supported.

When you expand to more than one domain, it is critical that you identify unique LDAP attributes for the application usernames and import coalesce values. A common unique coalesce attribute for Active Directory is **objectSid**. Unique usernames will vary based on your LDAP data design. Common unique attributes are **email** or **userPrincipalName**.
Incoming records

See LDAP transform maps to set how the integration processes incoming LDAP records that are missing matching values in reference fields.

Common authentication errors

- User Cannot Log In (Invalid DN)
- Invalid CN
- Invalid Connection

Automatic LDAP connection tests

You can manually test connections to LDAP servers or allow ServiceNow to automatically test the connections.

The system tests the connection automatically:

- Every time a user opens the LDAP Server form.
- Through the LDAP Connection Test scheduled job, which runs every 15 minutes by default.

  You can change how often this scheduled job runs. If this scheduled job is not able to establish a connection, a new one-time schedule job retries the connection test after either five minutes, or half the repeat interval value in the scheduled job, whichever occurs first.

Error messages appear on the form if there are any issues connecting to the LDAP server. Also supported are test connections for servers behind a MID server.

View the LDAP monitor

You can view current information about LDAP servers and listeners using LDAP monitor.

Role required: admin

The available states are:

- Active
- Inactive
- Error
- Active (Shutting down...)
- Error (Shutting down...)

In addition to its current state, the monitor also shows:

- The last message detected by the listener, such as waiting for LDAP changes, error connecting, and so forth.
- The last LDAP user change, such as new user, updated user, and so forth.
- The last error that occurred.
To view LDAP monitor:

Navigate to **LDAP > System LDAP > LDAP Monitor.**

See the table for descriptions of the properties and fields in the screen.

<table>
<thead>
<tr>
<th><strong>LDAP monitor</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Field</strong></td>
</tr>
<tr>
<td>Refresh</td>
</tr>
<tr>
<td>Connection Status</td>
</tr>
<tr>
<td>Field</td>
</tr>

</tbody>
</table>
**LDAP error codes**

The LDAP Log file lists industry standard error codes for both LDAP and Active Directory (AD).

### Standard error codes

#### Standard LDAP errors

<table>
<thead>
<tr>
<th>Error / data code</th>
<th>Text</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>LDAP_SUCCESS</td>
<td>Indicates the requested client operation completed successfully.</td>
</tr>
<tr>
<td>2</td>
<td>LDAP_PROTOCOL_ERROR</td>
<td>Indicates that the server has received an invalid or malformed request from the client.</td>
</tr>
<tr>
<td>3</td>
<td>LDAP_TIMELIMIT_EXCEEDED</td>
<td>Indicates that the operation's time limit specified by either the client or the server has been exceeded. On search operations, incomplete results are returned.</td>
</tr>
<tr>
<td>4</td>
<td>LDAP_SIZELIMIT_EXCEEDED</td>
<td>Indicates that in a search operation, the size limit specified by the client or the server has been exceeded. Incomplete results are returned.</td>
</tr>
<tr>
<td>5</td>
<td>LDAP_COMPARE_FALSE</td>
<td>Does not indicate an error condition. Indicates that the results of a compare operation are false.</td>
</tr>
<tr>
<td>6</td>
<td>LDAP_COMPARE_TRUE</td>
<td>Does not indicate an error condition. Indicates that the results of a compare operation are true.</td>
</tr>
<tr>
<td>7</td>
<td>LDAP_AUTH_METHOD_NOT_SUPPORTED</td>
<td>Indicates that during a bind operation the client requested an authentication method not supported by the LDAP server.</td>
</tr>
<tr>
<td>8</td>
<td>LDAP_STRONG_AUTH_REQUIRED</td>
<td>Indicates one of the following: In bind requests, the LDAP server accepts only strong authentication. In a client request, the client requested an operation such as delete that requires strong authentication. In an unsolicited notice of disconnection, the LDAP server discovers the security protecting the communication between the client and server has unexpectedly failed or been compromised.</td>
</tr>
<tr>
<td>9</td>
<td>Reserved</td>
<td></td>
</tr>

<td>Error / data code</td>
<td>Text</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>10</td>
<td>LDAP_REFERRAL</td>
<td>Does not indicate an error condition. In LDAPv3, indicates that the server does not hold the target entry of the request, but that the servers in the referral field may.</td>
</tr>
<tr>
<td>11</td>
<td>LDAP_ADMINLIMIT_EXCEEDED</td>
<td>Indicates that an LDAP server limit set by an administrative authority has been exceeded.</td>
</tr>
<tr>
<td>12</td>
<td>LDAP_UNAVAILABLE_CRITICAL_EXTENSION</td>
<td>Indicates that the LDAP server was unable to satisfy a request because one or more critical extensions were not available. Either the server does not support the control or the control is not appropriate for the operation type.</td>
</tr>
<tr>
<td>13</td>
<td>LDAP_CONFIDENTIALITY_REQUIRED</td>
<td>Indicates that the session is not protected by a protocol such as Transport Layer Security (TLS), which provides session confidentiality.</td>
</tr>
<tr>
<td>14</td>
<td>LDAP_SASL_BIND_IN_PROGRESS</td>
<td>Does not indicate an error condition, but indicates that the server is ready for the next step in the process. The client must send the server the same SASL mechanism to continue the process.</td>
</tr>
<tr>
<td>15</td>
<td></td>
<td>Not used.</td>
</tr>
<tr>
<td>16</td>
<td>LDAP_NO_SUCH_ATTRIBUTE</td>
<td>Indicates that the attribute specified in the modify or compare operation does not exist in the entry.</td>
</tr>
<tr>
<td>17</td>
<td>LDAP_UNDEFINED_TYPE</td>
<td>Indicates that the attribute specified in the modify or add operation does not exist in the LDAP server's schema.</td>
</tr>
<tr>
<td>18</td>

Send a one-time password when the LDAP server is down

An LDAP property is available to send a one-time password to a user if the user is unable to log in because the LDAP server is down. You can also configure another property to control how long the password is valid.

Role required: admin

To receive a one-time password, the user must have notifications enabled on their user profile. The notification is an email message only. SMS messages are not supported.

Both properties are enabled by default. The default value for property that controls password validity is 10 minutes.

1. Open the list of system properties by entering `sys_properties.list` in the filter of the application navigator.
2. Find the `glide.ldap.onetime.password.enabled` property.
3. Set the property to `true`.
4. To change the password validity time for a user, set the following property to an integer number of minutes: `glide.authenticate.onetime.password.validity`.

LDAP record synchronization

Administrators can synchronize inactive, disabled, or deleted LDAP records with their LDAP records.

LDAP record synchronization is the process of detecting inactive records on the LDAP server and updating the corresponding LDAP records. Detecting inactive LDAP records involves defining consistent data indicators for each user object, importing LDAP data, and evaluating the data indicators.

A data indicator can be:
- a date field
• membership in a specific OU (identify by parsing the dn attribute), using the useraccountcontrol attribute
• a combination of these indicators

Imported data comes into the instance through import set tables where the data can be evaluated and processed.

The import process can use:

• **LDAP extraction**: a single import job to gather all user records into the import set temporary tables for evaluation
• **LDAP refresh filters**: multiple import jobs to divide different types of user records, segregating records for separate processing

**LDAP refresh filters**

Filters on the LDAP refresh process can be used to specify processing that ignores inserts of disabled users.

You can loosen the LDAP OU filter to bring all of the data in to your import set table (including inactive users) and then specify processing that ignores inserts of disabled users. The sample ‘Users’ OU definition that the instance provides in its out-of-box LDAP sample contains a filter.

This filter is important because it defines which user records are brought into the import set table to be evaluated. While achieving a smaller data load, a limitation of this filter is that it filters out inactive users, so the inactive user records are not imported into the import set temporary tables. Since there is not visibility of the inactive user records, there is no ability to evaluate the record indicators.

**LDAP OU filter**

To use filtering within the main LDAP refresh process, change the filter to bring in all of the user records. The result is that all the records will be loaded into the import set temporary table where they can be evaluated and transformed.

**Note**: There is a precaution here: because the filtering brings in all the records, you may end up with a vast amount of older inactive LDAP accounts that should not be inserted into the instance. A user record should never be created for a disabled user.

**Alternative method**

**LDAP extraction** uses a single import job to gather all user records into the import set temporary tables for evaluation.
**LDAP extraction**

An LDAP extraction process can be implemented to detect disabled users.

An extract from your LDAP source can filtered for disabled users using an active flag that can be set for every record in the import to ‘false’. Specify (‘target.active=false’) and copy into the **Script** field directly on the Table Transform Map record.

**Benefits**

Benefits to this method include:
- Simple scripting
- Existing user records are not involved in processing
- Inactive users are not loaded into a temporary import table
- No performance impact

**Drawbacks**

Drawbacks to this method include:
- An additional process is created
- The extract set must be placed in a location where your data source can access it

**Alternative method**

**LDAP refresh filters** use multiple import jobs to divide different types of user records, segregating records for separate processing.

**Inactive LDAP user accounts**

Detect that an existing, current, user account is inactive or has been disabled or deleted from an Active Directory (AD) LDAP.

A common LDAP integration issue is how to detect disabled or deleted users in an Active Directory (AD) and then deactivate them in the instance. In an Active Directory LDAP, a filter is usually set to exclude inactive users when refreshing, so the instance is not aware of users that are disabled or deleted in AD. The issue is how to detect that an existing, current user is inactive or has been deleted from AD.

| Note: | The recommended approach is to deactivate user records and all other types of records, not delete them. Each record is linked to other records, and deleting a record destroys all the relationships to those other records. Deactivating records keeps those relationships in place. |

Find inactive LDAP accounts using the userAccountControl field

Identify when an Active Directory (AD) user is deleted (or made inactive).

Role required: admin

One method is to track the active status of AD users and create a business rule to update corresponding accounts when an AD account is inactive.

1. Create a new string field on the User [sys_user] table to track the value of the AD **userAccountControl** field. For example: `u_ad_user_account`.
2. Create an LDAP transform script to set the field value.

```plaintext
target.u_ad_user_account = source.userAccountControl
```
3. Update the LDAP filter to show disabled AD accounts. Here is an example of a filter.

```
(&(objectClass=person) (sn=*)(!(objectClass=computer))(!
(userAccountControl:1.2.840.113556.1.4.803:=2)))
```

Here is an example of a replacement filter you can use.

```
(&(objectClass=person) (sn=*)(!(objectClass=computer)))
```

4. Create an onChange business rule to set the active field to false whenever the u_ad_user_account field has the value 514. '514' indicates an inactive account.

**LDAP script examples**
The following script examples assume you use an Active Directory (AD) for your LDAP server.

**userAccountControl attribute values script**
This example tests the source for the userAccountControl attribute values associated with a disabled user (514 or 546).

```javascript
//Deactivate LDAP-disabled users during transform based on 'userAccountControl' attribute
if(source.u_useraccountcontrol == '514' || source.u_useraccountcontrol == '546'){
    target.active=false;
    target.locked_out=true;
}
```

Here is an example using a bitwise check:

```javascript
if(source.u_useraccountcontrol & 2){
    active = false;
}
```

**userAccountControl attribute script**
This example examines the userAccountControl attribute but does not test for specific values. It also contains the option of reactivating LDAP user accounts.

```javascript
/*
 * Deactivate LDAP-disabled users during transform based on 'userAccountControl' attribute
 * Convert the userAccountControl attribute back to a hex value
 */
var ctrl = parseInt(source.u_useraccountcontrol, 10);
ctrl = ctrl.toString(16);

/*
 * The only digit we care about is the final one
 * A final hex digit value of '2' in 'ctrl' means disabled
 */
if(ctrl.substr(-1) == "2"){
    //Deactivate and lock the user account
    target.active = false;
}
```
onBefore transform map script

Here is an example of an onBefore transform map script. The script identifies disabled records and records being inserted. If an insert of a disabled user is occurring, then the operation transform ignores the record.

```javascript
//Ignore any insert of a disabled record as defined by the 'userAccountControl' attribute
var uc = source.u_useraccountcontrol;
if((uc == '514' || uc == '546') && action == 'insert')
  ignore = true;
}

/* Optional: Uncomment else block to reactivate and unlock the user account
else {
  target.active = true;
  target.locked_out = ctrl.substr(-2, 1) == "1";
}
*/
```

DN member script

This script example introduces flexibility by not relying on the 546 and 514 userAccountControl values, but instead checking whether the user is a member of a particular Distinguished Name (DN). You can use this script either in the Script field of the ‘Table Transform Map’ record or in an onBefore transform map script.

```javascript
//Deactivate LDAP-disabled users during transform based on OU membership in 'dn'
if(source.u_dn.indexOf('OU=Disabled Accounts') > -1)
  target.active = false;
  target.locked_out = true;
}
```

Active Directory Application Mode (ADAM)

Active Directory Application Mode (ADAM) is an Lightweight Directory Access Protocol (LDAP)-compliant directory service.

**Note:** A basic level of understanding with Microsoft Windows Server and Active Directory is needed for understanding this topic. You must also have administrator permissions on the server you are configuring for ADAM.

These are sample procedures. Due to installation and environment variations, we cannot offer direct support. We recommend working with a Microsoft consultant.

ADAM has a simple install and runs as a service on Windows operating systems. It can be fully customized and distributed as an application component or used as a stand-alone LDAP directory. ADAM uses the same technologies found on Active Directory Domain Controllers (including replication and delegation features) and has its own administration and customization features. It can be run as a Windows service. ADAM can be installed on Windows XP, 2000, 2003, and 2008 operating systems. ADAM is included as part of Windows Server 2003 R2 and Windows

**Security**

Some company security policies prohibit external vendors and partners from connecting directly to an Active Directory (AD) Domain Controller. If exposing certain AD objects or attributes to an external vendor or partner is prohibited, access to objects and attributes can be blocked using AD Security Access Control Entries (ACE or ACL). Depending on security requirements, this method can introduce complexity in the integration. Consolidating multiple domains and forests is recommended. If all LDAP imports and authentications need to be channeled through a single source, ADAM can be used as a consolidated source. With the release of Windows 2008 this functionality has been renamed to Light-Weight-Directory Service, LDS. Installation and configuration is similar to Windows Server 2003 R2.

**Recommended Knowledge**

For this task, you must understand AD, object classes and attributes. To have a successful integration, you need to be knowledgeable of the current AD object structure, familiar with Active Directory delegations, and have a strategy on how to use ADAM and for what purposes. If you are not familiar with AD or ADAM, work with your AD administrator to configure a new ADAM environment.

**Trusts**

If `userProxy` objects is used, the computer hosting ADAM needs to be a member of the domain that has the AD accounts, or a member of a trusted domain.

**Internal Connectivity**

If `userProxy` objects is used, the ADAM computer must be able to connect to the related Domain Controllers to perform proxy authentication.

*Configuring an instance with ADAM*

The first install copies the ADAM files to your computer, registers requires components, and creates the application shortcuts.

Role required: admin

By default, all of the application files are installed to `%systemroot%\ADAM`.

- Windows Server 2003 R2 - ADAM can be installed using the Control Panel > Add and Remove Programs > Optional Component Manager.

Create the first instance service which functions as the first directory service hosted by ADAM. Do one of the following:

- Run `adaministall.exe` from the ADAM folder.
• Use the **Create an ADAM instance** shortcut from the **Start Menu > Programs > ADAM** folder.
  
a) Select the **A unique instance** install option.

  **Note:** You can use this option to install an instance replica on a second server to provide a fault tolerant system.

b) Complete the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Instance Name</td>
<td>used primarily to identify the Windows Service name and display name</td>
</tr>
<tr>
<td>Ports</td>
<td>sets the port numbers to be used for LDAP and LDAPS Listeners. The default LDAP port is 389, LDAPS is 636. If these ports are in use on the server, the setup wizard selects new ports. Work with your network administrator to determine the best ports to use</td>
</tr>
<tr>
<td>Application Directory Partition</td>
<td>creates an application directory partition. Not needed at this step, we recommend creating the new partition now. A good practice is to use the same distinguished name as your forest or domain, but replace the highest level domain with adam instead of com or local. For example, if your forest partition is <strong>dc=myCompany,dc=com</strong>, you could create the ADAM partition as <strong>dc=myCompany,dc=adam</strong>.</td>
</tr>
<tr>
<td>File Locations</td>
<td>selects the location(s) for the ADAM partition data.</td>
</tr>
<tr>
<td>Service Account Selection</td>
<td>selects a service account that the instance runs as. For stand-alone services, you can use the default network service account. If you plan on using replicas, you need to use an account that has access to all ADAM instances.</td>
</tr>
<tr>
<td>ADAM Administrators</td>
<td>the delegation on the ADAM directory that leverages Windows integrated authentication. This is how the initial access is granted for administration. Once the initial account is granted rights, this user or group delegates rights to other Windows users or ADAM users. You can select the default to only grant admin access to the current user, or grant access to a different user or group based on your needs.</td>
</tr>
<tr>
<td>Import LDIF Files</td>
<td>the files to import. MS-UserProxy is the most important file to import, but it’s worth adding all available files since there is little overhead to the schema and you won’t have to worry about extending it later if your needs expand. Confirm the details and the wizard complete the configuration.</td>
</tr>
</tbody>
</table>
Setting up the ADAM console

Even though there are many similarities between ADAM and Active Directory, the administration can be very different since there is no **Users and Computers** management console.

Role required: **admin**

Most of the general administration is performed using the ADAM ADSI MMC console available from the **ADAM** start menu. The first time you run the ADAM ADSI console, you must connect to the partition you created.

1. Right-click the **ADAM ADSI Edit** item in the left frame.
2. Give the new connection a name and update the server name, port fields with the information used when you created the instance.
3. Select **distinguished name** or **naming context** and specify the distinguished name of the application partition you created earlier. You can connect to the **Configuration** and **Schema** partitions for advanced configuration options.
   
   You should now be able to see into the partition and the default containers for LostAndFound, NTDS Quotas, and Roles. The Roles container has not been configured yet.

Create containers and organizational units for ADAM

Objects stored in ADAM can be logically grouped into containers and organizational units (OU) just as they would in Active Directory.

Role required: **admin**

1. Right-click the root partition and select **New > Object > organizationalUnit**. You can also view the list of other objects that are available. This list varies based on the schema extensions installed when you imported the LDF files.

   **Note:** You can also view the list of other objects that are available. This list varies based on the schema extensions installed when you imported the LDF files.

2. When prompted for a value, enter the name of OU, for example **Users**.
3. The next screen displays a **More Attributes** button; use this to assign values to additional attributes. For OUs and containers, no additional values are needed.

   After creating OUs, the new OUs are listed as a child of the root object.

Delegation with ADAM

Once the OU structure is created, define the permission delegations to properly secure the objects to limited users.

As with Active Directory, there are two general ways to grant permissions:

- Add users to a group that already has the appropriate permissions assigned.
- Define new permissions on the ADAM objects.

For this task, we discuss object level permissions. Refer to the Group Administration section for information on group memberships.

Since we don’t have a Users and Computers console for ADAM, all object level permissions are defined using the Active Directory utility **DSACLs.exe**. This file is found in the ADAM program directory. When running ADAM utilities it is best to launch the ADAM Tools Command Prompt. This ensures the proper versions of the tools. DSACLCS is used to view and set object access rights.

Example: "**dsaclcs \\localhost:50010\dc=myCompany,dc=adam**" displays the permissions assigned to the root of partition **dc=myCompany,dc=adam** running on the localhost, port 50010. DSACLCS is a complex tool used to create complex delegation. Run "**DSACLCS /?**" for usage notes.
Populating ADAM Objects
ADAM Objects include User Objects, UserProxy Object, and Group Objects.

User Objects

Users can be created using the ADAM ADSI Edit console just as we did for OU creation. Users can also be administered using AD command line tools, which is beyond the scope of this document. The only mandatory attribute for new user objects is the `cn`, which is a short name or the user’s full name. There are also a wide range of optional attributes similar to Active Directory user attributes. You can access the full list of attributes by selecting properties from the user object.

UserProxy Objects

For ServiceNow LDAP integration we recommend you use UserProxy objects in ADAM which creates a proxy account that links to the related AD user account. This allows you to have ADAM authenticate logon credentials using AD usernames and passwords from the domain without ServiceNow directly connecting to the Domain Controller. UserProxy objects are very similar to AD and ADAM User objects except that do not store passwords and has an `objectSID` attribute that contains the SID from the linked AD User object. This is how the proxy works. UserProxy objects are created using the ADSIEdit console or command line tools, but this can be tedious. It is recommended that you use an automated process as defined below.

Group Objects

Groups are created using the ADSIEdit console and AD command-line tools. Group concepts are similar to AD and are used to integrate groups and members to ServiceNow. The biggest difference is ADAM groups can contain members from ADAM or from trusted AD Domains.

Automating ADAM Object Creation

If you are interested in synchronizing Active Directory accounts to ADAM, we recommend you use Microsoft ADAMSync tool. This is the most common use of ADAM for ServiceNow LDAP integration.

About Permission Delegation

ADAM contains some built-in groups with default permissions. These groups are found in the container `cn=roles,dc=myCompany,dc=adam`. These are similar to domain level groups and have rights to objects in the current partition. Similar to AD Forests you can also set a higher level of permissions using the default groups in `cn=roles,cn=configuration,dc=myCompany,dc=adam`. You must connect to the configuration partition in ADSIEdit. The Administrators group by default includes the account specified during the setup. This member is not always visible since it’s inherited through the configuration groups. Administrators have full control of all partition objects. The Readers group does not contain any members by default and has read access to all objects in the partition. The Users group is a dynamic group just as it is in Active Directory. Transitivity it includes all ADAM users created in the partition.

Testing and troubleshooting ADAM setup

The primary tool used for testing is LDP. This allows you to fully test user authentication.

Most of the object management can be completed using the ADAM ADSI Edit console which will provide access to the entire collection of objects and attributes. The highest level of control and troubleshooting ADAM services is using the Windows service created during the instance setup. The service name will vary and depends on the name of the instance created. This service must be running in order for the ADAM service to run. If you are experiencing connection problems, you should review the network configurations to ensure you have the appropriate network.
access to connect to the server and ADAM port. For each ADAM instance installed, a Windows Event Log is created. This is also a great tool for troubleshooting ADAM services.

The Windows Security Event Log is also helpful when troubleshooting userProxy authentications. All userProxy logon attempts are logged in the Security Log and reference the remote client device address, the distinguished name of the user trying to log on, and the result or status code.

**Backup and recovery with ADAM**

All ADAM data can be backed up using standard file system backup methods.

**Redundancy**

ADAM has built-in replication utilities based on the same technology as AD. A full read and write replica of an ADAM partition can exist on the same or different computer. You can use this replica in a variety of ways to provide a fault-tolerant LDAP integration with the instance. One option is to expose both partitions to the instance through the firewall and define both servers in the LDAP Properties server field.

**Use LDAPS with ADAM**

The default configuration for userProxy object authentication is to enforce LDAPS (secure LDAP) communications. LDAPS requires SSL certificates to secure the network traffic.

To remove this requirement make the following change using the ADSIEdit console connected to the configuration partition.

```plaintext
Object: CN=Directory Service, CN=Windows NT, CN=Services, CN=Configuration
Attribute: msDS-Other-Settings
Value: change RequiresSecureProxyBind from 1 (enforced) to 0 (disabled)
```

Restart the ADAM service to use the new setting.

To support secure binds and encrypt the user and password information being transmitted, a SSL certificate must be installed on the server and any LDAP client. Since there is limited and controlled uses to the ADAM service, it is feasible to use a self-signed certificate which would meet the needs without incurring certificate costs or building a Certificate Authority (CA) infrastructure. If you already have a CA, you can issue a certificate. Otherwise, create a self-signed certificate.

**Creating a Self-Signed Certificate**

To use the selfssl utility, Internet Information Services (IIS) must be installed. This service can be removed after you generate the certificate. You can get the selfssl.exe utility from the IIS Resource Kit. If IIS is already installed, create a new website so that the current sites will not be impacted during the certificate generation. Selfssl needs to temporarily attach the new self-issued certificate to a valid web site.

Selfssl is a command-line tool and has the following common parameters.

**Selfssl Parameter Descriptions**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/T</td>
<td>Adds the cert to ‘Trusted Certificates’ on the local machine</td>
</tr>
<tr>
<td>/N:cn</td>
<td>Set the common name of the certificate. This must match the fully qualified domain name of the server running the web service using the certificate</td>
</tr>
<tr>
<td>/K</td>
<td>Sets the strength of the key size in bits</td>
</tr>
<tr>
<td>/V</td>
<td>Number of days the cert is valid</td>
</tr>
</tbody>
</table>
The common name attribute should match the external name or address that the instance will use to connect to your ADAM computer. You will need to get the IIS Website site id unless you are using the default website which is 1 and does not need to be defined in the selfssl command. A sample command to generate a certificate for myCompany would be:

```
selfssl /N:CN=myCompany.externaldomain.com /K:1024 /V:3650 /S:12345 /P:50001 /T
```

This statement creates a certificate that is valid for 10 years. Set the value to any duration, but be aware the new certificate must be generated and submitted to the instance before the old one expires. We recommend making a note of the expiration date on the certificate.

Once the certificate is generated you can remove it from the website, or delete the entire web site if you created a temporary site.

### Assigning the Certificate to ADAM

To support secure binds and encrypt the user and password information being transmitted, a SSL certificate must be installed on the server and any LDAP client.

Role required: admin

Since there is limited and controlled uses to the ADAM service, it is feasible to use a self-signed certificate which would meet the needs without incurring certificate costs or building a Certificate Authority (CA) infrastructure.

To assign the certificate to ADAM.

1. Open the Certificates MMC console. Create two console connections, one for Local Computer Certificates, and the other for Local Computer Services Certificates on the new ADAM service. The new certificate can be found under Certificates (Local Computer)\Personal\Certificates.
2. Copy the certificate to the container for the ADAM service, Certificates – Service (ADAM Service Name)\ADAM_ADAM Service Name\Trusted Root Certificates \Certificates. Also copy the certificate to Certificates – Service (ADAM Service Name)\ADAM_ADAM Service Name\Personal\Certificates.
3. Open the details tab on the certificate you copied. Note the Valid from date stamp. Now assign read access to the certificate key file. Go to C:\Documents and Settings\All Users\Application Data \Microsoft\Crypto\RSA\MachineKeys and identify the certificate with the matching time stamp. Assign Read & Execute rights to the service account running ADAM. By default this is Network Service.
4. Restart the ADAM service to activate the new certificate.

### Exporting the Public Key Certificate

LDAPS clients, including the instance need the public key certificate in order to make a secure connection to ADAM.

Role required: admin

From the server certificate consoles you used above, export a public key to be used by the clients.

1. Select the certificate, right-click, select all tasks/export. Do not export the private key. Select the default DER encoded binary X.509 format and specify the export file name.
2. Install the public certificate on the LDAP clients that connect to the server using LDAPS. When prompted, add the certificate to the Trusted Root Certificate Authorities store.
Active Directory Application Mode (ADAM) Access Account

The system requires a user account to read the Active Directory Application Mode (ADAM) object information that is imported into the application instance.

Create the account by using one of the following methods:

- Create a local ADAM user account and assign it a password and assign permissions.
- Assign permission to a Windows domain account on the ADAM partition.
- Use a userProxy account.

When using ADAM as an LDAP source, you must specify the fully qualified distinguished name (FQDN) of the ADAM account in the instance's LDAP server's Login distinguished name field.

Testing LDAPS Connections

There are two console connections, one for Local Computer Certificates, and the other for Local Computer Services Certificates on the new ADAM service.

Role required: admin

1. Run LDP.exe from the ADAM install folder c:\windows\adam. Verify that the ADAM version is selected because this is not the standard Windows LDP client.
2. Open a new connection using the Connection/Connect menu. The server name must match the CN assigned to the certificate.
3. Enter the LDAPS port and select the SSL checkbox.
   The results of a successful connection are some general server information and no errors.
4. Bind (log in) to the service. To replicate typical LDAP client connections select the Simple bind option. Enter a valid ADAM user or userProxy distinguished name in the user field and the associated password.
   If you see a return message stating ‘Authenticated as:….’ then you have successfully connected using LDAPS.

Use ADAMSync to populate ADAM

Administrators use MS ADAMSync to populate LDAP directories that use MS ADAM.

Note:

This document assumes you have at least a basic level of understanding with Microsoft Windows Server, Active Directory, and ADAM and that you already have a functional Active Directory Application Mode (ADAM) instance with a partition.

These are sample procedures. Due to the complexity and the fact that it is running in your environment, we cannot offer direct support. We recommend you work with Microsoft or a Microsoft consultant if you run into any trouble.

Once ADAM has been installed and the first partition has been created, you can populate it with objects.

The following options are available:

- Manual object creation using GUI or scripts. This option is inefficient and slow.
- Integrate with Active Directory using Microsoft Integration Information Server. This option ultimately provides the most flexibility and functionality but does require some advanced configurations. There is a free version of MIIS available that is compatible with Active Directory, ADAM, and Microsoft Global Address Lists from Exchange. Unless you already have experience with MIIS we advise that you don’t attempt to implement a new environment for LDAP integration only.
- Use ADAMSync, a synchronization tool that Microsoft provides with ADAM. This is the option that is explained here.

Define ADAM user accounts
Define the following user accounts in ADAM. One is used for the instance to connect with and the other for ADAMSync.

Role required: admin

These accounts can be local ADAM User objects, UserProxy objects, or a Windows account from a trusted domain.

User Account

This account requires read-only access to the directory structure you are importing to your instance. The best way to accomplish this is to add the account to the member attribute on the Readers group found in cn=roles,dc=myCompany,dc=adam.

New ADAM User accounts are disabled by default. You will need to enable the new accounts and set a password.

1. Enable users by changing the attribute msDS-UserAccountDisabled to FALSE.
2. Right-click the user object and reset the password.
3. Test the new accounts using LDP as defined in Active Directory Application Mode (ADAM) to make sure they can connect. Use the LDAP > View/Tree option, leaving the Base DN blank to make sure you can view the objects in the directory using the new accounts. The Configuration, Schema, and the domain partition should be visible in the left pane. Traverse the domain partition. If you are using a new local ADAM account, it will show ‘No Children’ which means you don’t have read access to the objects. Verify the Setup group memberships and re-test.

ADAMSync User Account

ADAMSync uses this account to manage objects in the ADAM partition. This account requires admin level rights since it will create, update, and delete ADAM objects.

ADAMSync AD Account

ADAMSync uses this account to read the AD objects that will be synchronized to ADAM.

Set up ADAMSync

ADAMSync is included with Windows Server 2003 R2. Download and install ADAMSync if you are using a different OS.

Extending the schema

The ADAM schema needs to be extended to support ADAMSyncc.

1. Run the following command from c:\windows\adam to import the ADAMSync schema extensions. You may have to change the server:port and add credentials if the current user doesn’t have access. See the AdamSyncMetadata.ldf file for details.

   `ldifde -i -f MS-AdamSyncMetadata.LDF -s localhost:50000 -j . -c "cn=Configuration,dc=X" #configurationNamingContext`

2. Do the same with MS-AdamSchemaW2K3.ldf to support Windows 2003 attributes.

   `ldifde -i -u -f MS-AdamSchemaW2K3.LDF -s localhost:50000 -j . -c "cn=Configuration,dc=X" #configurationNamingContext`

Recommended schema changes

Here are some additional schema changes we recommend.

1. Open a new MMC console and add the ADAM Schema Snap-in.
2. Connect to the ADAM instance.

3. Expand the Classes folder and locate the userProxy class, open Properties.

4. Verify the following optional attributes on the Attributes tab, add any that do not already exist.
   - company
   - department
   - givenName
   - mail
   - physicalDeliveryOfficeName
   - sAMAccountName
   - sn
   - telephoneNumber
   - title
   - userAccountControl
   - userPrincipalName

5. Restart the ADAM Service to enable the new settings.

Install the ADAM configuration file
You can install the ADAM configuration file through the Windows command line.

Role required: admin

1. Install the configuration file.

   C:\WINDOWS\adam>adamsync /install localhost:50000 MS-AdamSyncConf-SNC.XML

2. Run the synchronization file. This will log to the console and may run for a long time.

   C:\WINDOWS\adam>adamsync /sync localhost:50000 "ou=users,dc=service-now,dc=adam" /log -

3. Review the results by using the ADSIEdit console. You should see the new objects and attributes that were created by ADAMSync.

4. Run ldap to test the UserProxy authentication.

   Automating the sync process
   Setup the sync process as a Windows Scheduled Task. You must either provide the credentials in the config file, command line, or run the Scheduled Task with an account that has access.

   Special notes
   - You can create multiple configuration files and scheduled jobs to sync ADAM from multiple sources.

     This example imports the sAMAccountName attribute which can be used as the application logon. If you are going to sync source you need to make sure you have a unique attribute value that can be used for the logon credentials. sAMAccountName is guaranteed to be unique within a domain, but not across multiple domains.
   - If you are using Microsoft Exchange, we recommend excluding cn=SystemMailbox* objects as part of the object-filter configuration.

Example ADAM configuration files
All of the configurations for ADAMSync are stored in xml files.

**Default configuration file with comments**

There is a default configuration file called MS-AdamSyncConf.xml included with the ADAMSync install. Make a copy of this file so you have a base example to refer to in the future. This example is the default configuration file with comments added.

```xml
<?xml version="1.0"?>
<doc>
  <configuration>
    <!-- Sync File Description -->
    <description>MyCompany ADAMSync Configuration</description>
    <security-mode>object</security-mode>;
    <!-- source-ad-name = fqdn of the domain controller -->;
    <source-ad-name>;fully.qualified.domain.name.of.domain.controller</source-ad-name>;
    <!-- source-ad-partition = root AD domain partition -->;
    <source-ad-partition>;dc=myCompany,dc=com</source-ad-partition>;
    <!-- source-ad-account = use this to specify an account to connect to AD -->;
    <source-ad-account>;</source-ad-account>;
    <!-- target-dn = target ADAM OU -->;
    <target-dn>;ou=servicenow users,dc=myCompany,dc=adam</target-dn>;
    <query>;
      <!-- base-dn = should be the root AD partition if you want all users -->;
      <base-dn>;dc=myCompany,dc=com</base-dn>;
      <!-- object-filter = standard ldap query format, this will grab all users -->;
      <object-filter>;(objectCategory=person)</object-filter>;
      <attributes>;
        <!-- include=userproxy requires objectSID to link back to the AD account -->;
        <include>;objectSID</include>;
        <include>;givenName</include>;
        <include>;sn</include>;
        <include>;description</include>;
        <include>;title</include>;
        <include>;company</include>;
        <include>;department</include>;
        <include>;mail</include>;
        <include>;physicalDeliveryOfficeName</include>;
        <include>;telephoneNumber</include>;
        <include>;sAMAccountName</include>;
      </attributes>;
      </query>;
      <!-- map for user-to-userproxy object types -->;
      <user-proxy>;
        <source-object-class>;user</source-object-class>;
        <target-object-class>;userProxy</target-object-class>;
      </user-proxy>;
      <schedule>;
        <aging>;
          <frequency>;0</frequency>;
          <num-objects>;0</num-objects>;
        </aging>;
        <schtasks-cmd>;</schtasks-cmd>;
      </schedule>;
  </configuration>
</doc>
```
LDAP filters configuration file

You can provide any level of filtering in the object-filter value in the configuration file. Use standard LDAP query syntax with the following XML escape characters in place of the standard operators.

- **AND** = "&" replace with &amp;#38;
- **OR** = "|" (vertical line) replace with &amp;#124;
- **NOT** = "!" replace with &amp;#33;

Reference configuration file

Here's an actual configuration file that can be referenced as a sample.

```xml
<?xml version="1.0"?>;
<doc>
<configuration>
<description>;SNCTest ADAMSync Configuration</description>
<security-mode>;object</security-mode>
<source-ad-name>;domaincontroller.service-now.com</source-ad-name>
<source-ad-partition>;dc=service-now,dc=com</source-ad-partition>
<source-ad-account>;</source-ad-account>
<account-domain>;</account-domain>
<target-dn>;ou=servicenow users,dc=service-now,dc=adam</target-dn>
<query>
<base-dn>;dc=service-now,dc=com</base-dn>
<object-filter>;(objectCategory=person)</object-filter>
<attributes>
<include>;objectSID</include>
<include>;givenName</include>
<include>;sn</include>
<include>;description</include>
<include>;title</include>
<include>;company</include>
<include>;department</include>
<include>;mail</include>
<include>;physicalDeliveryOfficeName</include>
<include>;telephoneNumber</include>
<include>;userAccountControl</include>
</attributes>
</query>
</configuration>
</doc>
```
Configure Microsoft Active Directory for secure LDAPS communication

Use certificate pairs to enable Microsoft Active Directory (AD) LDAPS communications.

**Note:** These procedures were designed and tested using Windows 2003 R2 Standard Edition and work with all versions of Windows 2003.

Secure LDAP (LDAPS) communication is similar to SSL (HTTPS) communication in that both encrypt the data between servers and clients. To accomplish this, the server and clients share common information by using certificate pairs. The server holds the private key certificate and the clients hold the public key certificate. These certificates are required to enable Microsoft Active Directory (AD) LDAPS communications.

To configure LDAPS for Active Directory you must:

- Ensure that the Active Directory domain is set up and that the instance is able to connect to the Active Directory server through the firewall.
- Verify that there is a Certificate Authority (CA) that can issue a certificate for the domain controller (DC). If you don't already have a CA infrastructure there are two options.
  - Setup a stand-alone CA to issue the certificate
  - Request a third party certificate
- If you already have a CA in place, you can generate a certificate from an internal CA.

All certificates have a defined expiration date which can be viewed in the certificate properties. If the certificate expires, all LDAPS traffic fails, and your users can no longer log into the instance. To resolve this, a new certificate must be issued and installed on your instance.

The default expiration for Microsoft CA certificates is one year. External CA certificates are usually purchased in one year increments. Note when your certificate expires, or use the application's Expiration Notification function (located in System LDAP > Certificates). Ensure that you have a new certificate ready before the old one expires. This gives you time to install and test the new certificate before the old one expires.
Set up a stand-alone certificate authority for active directory
The first step to configure Microsoft Active Directory for SSL access is to set up a stand-alone Certificate Authority (CA).

Role required: admin

Do not worry about addition resource utilization because both of the required services (IIS & CA) can be disabled after issuing the certificate(s).

1. Install Internet Information Server (IIS).
2. Install Certificate Authority Services in stand-alone mode.
3. Verify the Certificate Services web application is installed and active.

Using the IIS Manager console, expand the local computer and select Web Sites. The state of Default Web Site should be Running. You should also see a CertSvc application listed under the Default Web Site. If the site is not running or the application is missing, you must resolve the issue before you proceed.

Generate a certificate from an internal certificate authority
When you configure Microsoft Active Directory for SSL access, you must generate an internal certificate and request the external certificate.

Role required: admin

These steps apply to Microsoft CA services. If you have a different internal CA platform, see your local CA administrator for assistance.

1. From the domain controller (DC) you want to create a certificate for, browse to http://localhost/certsrv or specify the CA server name if it is on a remote server.
2. From the Welcome page, click Request a certificate and select advanced certificate request.
3. On the Advanced Certificate Request page, select Create and submit a request to this CA.
4. Complete the Advanced Certificate Request as follows:

<table>
<thead>
<tr>
<th>Advanced Certificate Request fields</th>
<th>Entry</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The fully qualified domain name (FQDN) of the DC that is requesting the certificate.</td>
</tr>
<tr>
<td>E-Mail</td>
<td>The email address of the person responsible for the certificate.</td>
</tr>
<tr>
<td>Company</td>
<td>Your company name.</td>
</tr>
<tr>
<td>Key Options settings</td>
<td></td>
</tr>
<tr>
<td>Create new key set</td>
<td>Select it.</td>
</tr>
<tr>
<td>CSR</td>
<td>Microsoft RSA SChannel Cryptographic Provider.</td>
</tr>
<tr>
<td>Key Usage</td>
<td>Exchange.</td>
</tr>
<tr>
<td>Key Size</td>
<td>1024 is recommended. The instance supports up to 2048.</td>
</tr>
<tr>
<td>Automatic key container name</td>
<td>Select it.</td>
</tr>
<tr>
<td>Store certificate in the local computer certificate store</td>
<td>Select it.</td>
</tr>
</tbody>
</table>

5. Click Submit.
You are directed to a page that provides your Request ID, make note of this ID.
6. To process the pending request, complete the following:
   a) Open the Certificate Authority management console.
   b) Expand the server node and select Pending Requests.
   c) Locate the Request ID for the request you just submitted, right-click, and select All Tasks/Issue to approve the request and issue the certificate.

7. To retrieve the issued certificate, complete the following:
   a) From the DC you made the request from, browse to http://localhost/certsrv, or specify the CA server name if it is on a remote server.
   b) Select View the status of a pending certificate request.
   c) Select the link to the new certificate.
   d) Select the link to Install this certificate.

You need to request a third party certificate. Certificates from external CAs can be purchased for as little as $30 per year. For detailed procedures on requesting a certificate from an external CA, see Microsoft article 321051. After it is received, installed, and tested, follow the export procedure.

Test the LDAPS Connectivity Locally
When you configure Microsoft Active Directory for SSL access, you must test the LDAPS connectivity after installing the internal and third party certificates.

Role required: admin

1. Ensure that Windows Support Tools are installed on the domain controller (DC).
   The Support Tools setup (suptools.msi) can be found in the \Support\Tools directory on your Windows Server CD.
2. Select Start > All Programs > Windows Support Tools > Command Prompt. On the command line, type ldp to start the tool.
3. From the ldp window, select Connection > Connect and supply the local FQDN and port number (636). Also select the SSL.
   If successful, a window displays and lists information related to the Active Directory SSL connection. If the connection is unsuccessful, try restarting your system and repeat this procedure.

Export the public key certificate to trust the LDAP certificate
When you configure Microsoft Active Directory for SSL access, you must export the public key certificate and import it into the application.

Role required: admin

If your Certificate Authority is not a trusted third party vendor, you must export the certificate for the issuing CA so we can trust it, and, by association, trust the LDAP server certificate. For MS Certificate Services users, you can view the certificate path by viewing the certificate in the console used to export; select the Certificate Path tab. You must export all certificates in the chain. You can find the CA certificate in the same folder as the LDAP certificate by looking for the name in the Certificate Path. Submit all certificates for importing to your instance.

1. From a current or new MMC console, add the Certificate (Local Computer) snap-in.
2. Open the Personal/Certificates folder.
3. Locate the new certificate. The Issued To column shows the FQDN of the domain controller.
4. Right-click the certificate and select All Tasks/Export.
5. Export to DER or Base-64 format. Name the file using the format: MyCompany.cer.
   This is the public key certificate the needs to be used on the instance to communicate securely with your domain controller.
6. Test LDAPS locally before you submit the certificate to the instance.

After completing this procedure, import the public key certificate into the application.

See Install the LDAP X.509 SSL certificate to upload the certificate into the application.

**LDAP global catalog usage**

A DC can be granted the Global Catalog (GC) role. Global Catalog (GC) role is an LDAP-compliant directory consisting of a partial representation of every object from every domain within a forest.

Administrators configure Active Directory to host Lightweight Directory Access Protocol (LDAP) directory information using one of the following hosting methods.

- The common method of hosting LDAP directory information is to use the default LDAP or LDAPS (secure LDAP) on ports 389 or 636. These standard LDAP ports always exist on a Domain Controller (DC) and are rarely changed. Accessing this directory partition provides access to all of the objects within the domain that is hosted on the DC. There is no way to access objects from other domains using this method.

- A DC can also be granted the Global Catalog (GC) role. Global Catalog (GC) role is an LDAP-compliant directory consisting of a partial representation of every object from every domain within the forest. This LDAP directory can be accessed on port 3268, with LDAPS on port 3269. LDAPS and the default LDAP ports' certificate requirements are the same.

**Global Catalog LDAP dependencies**

- The domain controller that your instance connects to must have the Global Catalog role enabled.
- Firewall rules must allow inbound traffic to the domain controller on port 3268 (LDAP) or 3269 (LDAPS).

**Special notes**

- Not all attributes are replicated to the GC partition. Common attributes such as first name, last name, email, phone number, description, and address are included. Additional attributes can be added to the GC but should be limited to minimize the impact to forest replication traffic.
- Standard LDAP integrations usually use sAMAccountName as the instance's UserID and as the coalesce key in the LDAP import map since this is guaranteed to be unique within a domain. This attribute is no longer unique when viewing an entire forest of domains. A new unique attribute needs to be identified and as the UserID and the coalesce key. These do not need to be the same attribute and may vary based on your forest design. Consult your Active Directory administrator. Typically, the userPrincipalName is a unique attribute across domains but this may not be a user-friendly name to login with, but it could be used for the unique identifier on imports. A common attribute that is used for the UserID is email address. These decisions impact the LDAP Properties and LDAP Mapping.
- The value used for the coalesce key on the LDAP import map must be unique and exist on every object being imported. If it is not unique or does not exist, incorrect records are updated with changes.
- If you already have an LDAP integration and wish to change it to a GC, change the import coalesce key. The new key values must be imported before you can change the coalesce key.
- If you make any changes to your LDAP integration that break your integration, your first step should be to revert those changes. After that, contact Customer Service and Support with complete information about what you're attempting.

**OpenLDAP minor schema modification**

In OpenLDAP 2.3 systems that use the back-bdb (Berkley backend), administrators make a minor modification to their schema to facilitate the integration.
CAUTION: The customization described here was developed for use in specific instances, and is not supported by ServiceNow Technical Support. This method is provided as-is and should be tested thoroughly before implementation. Post all questions and comments regarding this customization to our community forum.

In OpenLDAP 2.3, back-bdb has limited support for inequality indexing (ordering). It is implemented only for generalizedTime and ChangeSequenceNumber syntax. It cannot be supported on syntax that support substrings. Search filters containing inequalities are processed using the presence index.

We recommend creating a custom attribute for this purpose, instead of changing what is already indexed or present in the schema (for example, `servnowid`).

Modify the OpenLDAP schema
These steps detail a schema modification to OpenLDAP 2.3 provided by one of our customers that helped them integrate with their instance.

Role required: admin

CAUTION: The customization described here was developed for use in specific instances, and is not supported by ServiceNow Technical Support. This method is provided as-is and should be tested thoroughly before implementation. Post all questions and comments regarding this customization to our community forum.

To modify the OpenLDAP schema for integration with the instance:

1. Create a custom attribute.

```plaintext
attribute ( 1.3.6.1.4.1.3403000.2.1.8
    NAME 'servnowid'
    ORDERING caseIgnoreOrderingMatch
    EQUALITY caseIgnoreMatch
    SYNTAX '1.3.6.1.4.1.1466.115.121.1.15' )
```

2. Include the attribute in the selected objectclass OID.

```plaintext
objectclass ( 1.3.6.1.4.1.3403000.2.2.1
    NAME 'BcfUserIdentifiers' SUP top AUXILIARY
    MAY ( uniqid $ unixid $ servnowid ) )
```

In OpenLDAP 2.3, you can dynamically change the server configurations, but you can only extend the schema. You cannot modify or delete the existing schema. Instead of creating another objectclass for this attribute in the dynamic configuration, use the static configuration file, slapd.conf.

3. In slapd.conf, include indexing for the new attribute in the bdb section of your main database backend.

```plaintext
database bdb (configs here) ....
    index servnowid pres
    (other indexes here) .....  
```

4. As root, run slapindex to index this attribute to make it available in search filters. Make sure that the OpenLDAP daemon is not running or is in read-only mode before starting slapindex.

Record LDAP deletions
By default, the instance does not delete any entries after they disappear from LDAP.

Deleting an entry, also referred to as a record, also deletes the entire history and references to the deleted entry.
For example, configuration items (CIs), SLA agreements, software licenses, purchase orders, and service catalog entries all have a reference to Department, and if a department is deleted, then the integration clears all references to the department. Also, deleting a user results in losing all history of what that user did.

Decide whether to retain or manually delete records according to your organization's needs.

**Adaptive authentication**

Adaptive authentication is a policy framework that allows enforcement of contextual authentication controls to the right persona at the right time. Adaptive authentication uses authentication policies to evaluate authentication requests and then either deny or allow access based on the specified policy conditions.

You can use the authentication policies to restrict access of users and APIs based on various criteria like IP address, user role, and user group. You can configure the built-in authentication policies according to your security requirements.

For example, an administrator can configure the Allow Access Policy to allow users only from a trusted range of IP addresses and users of a specific role. The configured access policy denies access from untrusted IP addresses.
REST API access policies

You can use the filter criteria of Adaptive Authentication framework to restrict access to inbound ServiceNow REST APIs. For more information, see REST API access policies.

Activate adaptive authentication

You can activate the Adaptive Authentication plugin (com.snc.adaptive_authentication) for Adaptive Authentication if you have the admin role.

Role required: admin

1. Navigate to System Applications > All Available Applications > All.
2. Find the Adaptive Authentication plugin (com.snc.adaptive_authentication) using the filter criteria and search bar.
   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel. For more information, see Request a plugin.
3. Click Install, and then in the Activate Plugin dialog box, click Activate.

   Note: When domain separation and delegated admin are enabled in an instance, the administrative user must be in the global domain. Otherwise, the following error appears: Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.

Filter criteria

Filter criteria (Policy Inputs) are used as inputs for policy conditions to verify and meet the requirements of an authentication request. For example, an IP Filter Criteria defines an IP address in the Subnet (Classless Inter-Domain Routing - CIDR format) or a range of IP addresses.

You can create filter criteria based on the user's IP address, role, and the user group to which they belong. Filter criteria is also called as policy inputs.

Create IP filter criteria
IP filter criteria allows you to filter users based on the user's IP addresses. You can configure an authentication policy to allow or deny access to a specific address or range of addresses.

Role required: admin

2. Click New.
3. On the form, fill in these fields.
4. Right-click the form header and click **Save**.

5. From the **IP Range** tab, double-click **Insert a new row**.

You can enter a single IP address or multiple ranges of IP addresses. For example, for a range of IP addresses enter `192.0.2.0` in the **Start IP** column and `192.0.2.255` in the **End IP** column.

![IP Filter Criteria form](image)

**Note:** For a single IP addresses, make sure that you enter the same IP address in the **Start IP** address and **End IP** columns. When you enter an IP address in the **Start IP** column, leave the **End IP** column blank and then save the record. The **End IP** column is auto-populated with the same **Start IP** address.
6. From the **Subnet (CIDR)** tab, double-click **Insert a new row**.
Enter the Network IP address and Netmask in the Classless Inter-Domain Routing (CIDR) format. For example, enter `255.255.255.0` as Network IP and `25` as Netmask.

<table>
<thead>
<tr>
<th>IP Range</th>
<th>Subnet (CIDR)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Network IP</td>
</tr>
<tr>
<td></td>
<td>255.255.255.0</td>
</tr>
<tr>
<td></td>
<td>Netmask</td>
</tr>
<tr>
<td></td>
<td>25</td>
</tr>
</tbody>
</table>

**Create role filter criteria**
Role filter criteria allows you to filter users based on the roles. You can configure an authentication policy to allow or deny access to a list of user roles.

Role required: admin

1. Navigate to **Adaptive Authentication > Filter Criteria > Role Filter Criteria**.
2. Click **New**.
3. On the form, fill in these fields.

<table>
<thead>
<tr>
<th><strong>Role Filter Criteria form</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Field</strong></td>
</tr>
<tr>
<td>Name</td>
</tr>
<tr>
<td>Application</td>
</tr>
<tr>
<td>Description</td>
</tr>
</tbody>
</table>

4. From the **Roles for criteria**, double-click **Insert a new row**.
5. Create a condition for a specific role using the Condition Builder. For example, you can create a condition that allows only users with admin, itil, or snc_internal roles. For more information about Condition Builder, see Create a condition statement using the condition builder.

**Note:** Currently, Dot-walking is not supported in Role filter criteria.

<table>
<thead>
<tr>
<th>Name</th>
<th>Admins only</th>
<th>Application</th>
<th>Global</th>
</tr>
</thead>
</table>

Condition builder example:

- Role is admin
- Role is itil
- Role is snc_internal

---

Create group filter criteria

Group filter criteria allows or denies user access based on the user group to which the user belongs.

Role required: admin

2. Click New.
3. On the form, fill in these fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name to identify the group.</td>
</tr>
<tr>
<td>Description</td>
<td>Short description of the group.</td>
</tr>
<tr>
<td>Application</td>
<td>Scope of the application.</td>
</tr>
</tbody>
</table>

4. From the Groups for criteria tab, double-click Insert a new row.
5. Click the search icon
   ![Search Icon]
   look up, and select a user group.

6. Click the save icon
   ![Save Icon]

**Authentication policies**

Authentication policies evaluate authentication requests based on the specified policy conditions and either allow or deny access depending on the output of policy conditions evaluation. For example, access is allowed only if all the policy conditions specified in Allow Access Policy evaluate to true.

You can use the built-in authentication policies or create an authentication policy according to your security requirements.

**Note:** At any point of time, either Allow Access Policy or Deny Access Policy can be executed but not both.

<table>
<thead>
<tr>
<th>Policy</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allow Access Policy</td>
<td>Denies all the authentication requests by default. Allows only the authentication requests that match the specified policy conditions.</td>
</tr>
<tr>
<td>Deny Access Policy</td>
<td>Allows the authentication requests by default. Denies only the authentication requests that match the specified policy conditions.</td>
</tr>
<tr>
<td>Global Blocking Policy</td>
<td>Denies the access requests of users and APIs before authentication. This policy can be used as an alternative to the IP Address Access Control.</td>
</tr>
</tbody>
</table>

**Configure allow access policy**

Allow access policy denies all the authentication requests by default. Allows only the authentication requests that match the specified policy conditions.

Role required: admin

2. From the Policy Inputs tab, click Edit.
3. Select one or more filter criteria from the **Collection** list and move them to **Policy Inputs List** of **Allow Access Policy** list.

4. From the **Policy Conditions** tab, click **New**.

   **Note:** When there are multiple policy conditions, the final output of the access policy depends on the logical OR output of all policy conditions.

5. On the form, fill in the fields:

   **Condition form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Label</td>
<td>Name to identify the condition.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the condition.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Condition</td>
<td>Logical combination of multiple policy inputs(filter criteria) that is used to evaluate authentication requests. For example, you can create conditions that allow only contractors from a list of trusted IP addresses.</td>
</tr>
</tbody>
</table>

**Configure deny access policy**

Deny access policy allows all the authentication requests by default. Denies only the authentication requests that match the specified policy conditions.

Role required: admin

1. Navigate to **Adaptive Authentication > Authentication Policies > Deny Access Policy**.
2. From the **Policy Inputs** tab, click **Edit**.
3. Select one or more filter criteria from the **Collection** list and move them to **Policy Inputs List** of **Deny Access Policy** list.
4. From the **Policy Conditions** tab, click **New**.

**Note:** When there are multiple policy conditions, the final output of the access policy depends on the logical OR output of the all policy conditions.

5. On the form, fill in the fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Label</td>
<td>Name to identify the condition.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the condition.</td>
</tr>
<tr>
<td>Condition</td>
<td>Logical combination of multiple policy inputs(filter criteria) that is used to evaluate authentication requests. For example, you can create conditions that deny access to employees from a range of untrusted IP addresses.</td>
</tr>
</tbody>
</table>

**Configure global blocking policy**

Global blocking policy denies the authentication requests of users and APIs based on the specified policy conditions. This policy can be used as an alternative to the IP Address Access Control.

Role required: admin

1. Navigate to **Adaptive Authentication > Pre-Authentication Policies > Global Blocking Policy**.
2. From the **Policy Inputs** tab, click **Edit**.
3. Select one or more IP filter criteria from the Collection list and move them to Global Blocking Policy list.

**Note:** Global blocking policy supports only IP Filter criteria.

4. From the Policy Conditions tab, click New.

**Note:** When there are multiple policy conditions, the final output of the access policy depends on the logical OR output of the all policy conditions.

5. On the form, fill these fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Label</td>
<td>Name to identify the condition.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the condition.</td>
</tr>
</tbody>
</table>
Configure adaptive authentication properties

After activating the Adaptive Authentication, configure adaptive authentication properties according to your security requirements.

Role required: admin

2. Configure these properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable Authentication Policy</td>
<td>Option to enable the authentication policy.</td>
</tr>
</tbody>
</table>
## Property Description

Execute Deny Access Policy by default and access is denied only if conditions defined in deny access policy evaluates to true

This property is selected by default when you activate the Adaptive Authentication plugin. When you select the **Enable Authentication Policy** property, Deny Access Policy is executed by default and all users are allowed access. Access is denied only when the specified Deny Access Policy conditions evaluate to true.

When you clear this property, Allow Access Policy is executed by default. Allow Access Policy allows users only when the specified Allow Access Policy conditions evaluate to true.

**Note:** Before you clear this property, make sure that Allow Access Policy is configured accurately. Otherwise, Allow Access Policy denies access to the users who do not match the specified policy conditions.

For example, an administrator configures Allow Access Policy to allow only employees from the IP range of 192.0.2.0 to 192.0.2.24 and Deny Access Policy to deny access for the contractors.

**Note:** At any point of time, either Allow Access Policy or Deny Access Policy can be executed but not both.

When an administrator selects the **Enable Authentication Policy** property as 'Yes' and sets the **Execute Deny Access Policy by default and access is denied only if conditions defined in deny access policy evaluates to true** property as 'No', only employees from the IP range of 192.0.2.0 to 192.0.2.24 are allowed. Rest of the employees from other IP addresses are denied access, even though they have valid credentials.

Enable debug logging for authentication policies

Option to enable debug logging for the authentication policies.

HTTP error code to be displayed to the user when access is blocked by Global Blocking Policy

HTTP error code that displays during login when the Global Blocking Policy blocks a user login.

Error message to be displayed to the user when access is blocked by Global Blocking Policy (only applicable when Forbidden(403) HTTP error code is selected)

Error message that displays when the Global Blocking Policy blocks access.

### Authentication with SAML

The Security Assertion Markup Language (SAML) is an XML-based standard for exchanging authentication and authorization data between security domains.

SAML exchanges security information between an identity provider (a producer of assertions) and a service provider (a consumer of assertions). SAML is a product of the OASIS Security Services Technical Committee. When implemented correctly, SAML is one of the most secure methods of single sign-on (SSO) available.
The SAML 2.0 integration enables SSO by exchanging XML tokens with an external Identity Provider (IdP). The IdP authenticates the user and passes a NameID token to the system. If the system finds a user with a matching NameID token (for example, the email address), the instance logs that user in.

If you are using the SAML 2.0 plugin for SSO authentication, you need to set the glide.ui.rotate_sessions property to false. Otherwise, it interferes with the session information sharing that takes place between the instance and the Identity Provider. Users with the security_admin elevated privilege can access this property.

**Note:** It is recommended that customers using an existing SAML 2.0 integration upgrade to the Multi-Provider SSO plugin.

To learn more about the properties that affect SAML 2.0 processing, see SAML 2.0 web browser SSO profile SAML 2.0 web browser SSO profile (instance security hardening).

### Activate and set up SAML 2.0

SAML 2.0 activates through the Integration - Multiple Provider Single Sign-On Installer plugin.

**Note:**

Activate the Integration - Multiple Provider Single Sign-On Installer plugin to set up SAML 2.0 authentication. Refer to this plugin when directed to find and click the plugin name.

1. Navigate to **System Applications > All Available Applications > All.**
2. Find the plugin using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel. For more information, see [Request a plugin](#).
3. Click **Install**, and then in the Activate Plugin dialog box, click **Activate**.

**Note:** When domain separation and delegated admin are enabled in an instance, the administrative user must be in the global domain. Otherwise, the following error appears: Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.

### Clone an instance with a SAML integration

Before cloning an instance that uses SAML 2.0, preserve the SAML SSO-related settings on the target instance. Failing to do so might make the target instance inaccessible.

Role required: admin

1. On the source instance, navigate to **System Clone > Preserve Data > Core Instance Properties.**
2. Make sure that the following SAML SSO-related properties are preserved using conditions, as shown:

- glide.authenticate
- glide.security
- glide.entry
- glide.script
- glide.session
- glide.saml2
- com.glide.communications
- com.snc.integration.saml_esig
3. On the source instance, navigate to **System Clone > Preserve Data** to preserve SAML certificates on sys_certificate and SAML users on sys_user related to SAML/SSO/Multi SSO. If you need them, export them into XML, then manually import them on the target.

**Warning:** Do not try to clone the SAML/SSO/Multi SSO setup from one system to another. Most transfers of SAML/SSO or Multi SSO settings do NOT work because they must be configured on the identity provider. If you overwrite a working setup, the target instance will fail to authenticate so your target instance will become inaccessible. Also, do not change the sys_id of your Multi SSO provider record; doing that will force your users to flush their cookies. For more information about cloning precautions, see Checklist before cloning an instance.

4. Exclude the Multi SSO tables sso_properties, digest_properties and saml2_update1_properties.

5. Manually create the SAML/SSO/Multi SSO records on each instance independently and set up the records on your identity provider as well.

6. Make sure that you manually create a LOCAL admin account on sys_user (not in LDAP or SAML) record on the target instance and with a sys_id that does not exist on the source instance.

7. Click **Update**.

**Identity Provider (IdP) system properties**

An IdP generally offers an XML document containing their authentication and logout metadata.

For example, SSOCircle publishes their metadata online.

Browse the IdP metadata to find these entries:

- The **SingleSignOnService** element with a **Binding** attribute that contains a value of **HTTP-Redirect**. The **Location** attribute lists the URL the integration requires for the AuthnRequest service.
- The **SingleLogoutService** element with a **Binding** attribute that contains a value of **HTTP-Redirect**. The **Location** attribute lists the URL the integration requires for the SingleLogoutRequest service.

**Note:** The SAML 2.0 integration only supports binding to IdP services by HTTP-Redirect.

For example:

```
```

```
```
IdP properties

Set the IdP issuer URL

Provide the URL to the IdP's who will issue the security token.

Role required: admin

The integration verifies that each SAML response contains the same URL listed in this system property as the URL listed in the `Issuer` element. For example:

```
<snmp:Response xmlns:snmp="urn:oasis:names:tc:SAML:2.0:protocol"
   Destination="https://demo12.service-now.com/navpage.do"
   ID="s28da6774c88ae1a292bf25fe625db81919d8e1e"
   InResponseTo="SNC841720c227c81948cf68cadcad235c6"
   IssueInstant="2012-01-30T20:07:10Z" Version="2.0"><snmp:Issuer
   ...
   <snmp:Assertion xmlns:snmp="urn:oasis:names:tc:SAML:2.0:assertion"
      ID="s2f347f973c63836cf70ea38302d94976f9c5b851"
   ...
</saml:Assertion></snmp:Response>
```

1. Navigate to SAML 2 Single Sign-on > Properties.
2. In the property **The Identity Provider URL which will issue the SAML2 security token with user info.**, enter the URL to your IdP. Each IdP URL must be unique.

   By default, the integration contains the URL to SSOCircle http://idp.ssocircle.com.

Set the AuthnRequest service URL

   Using the IdP's metadata, set the request service URLs for the integration's IdP.

   Role required: admin

   1. In the property **The base URL to the Identity Provider's AuthnRequest service. The AuthnRequest will be posted to this URL as the SAMLRequest parameter**, enter the URL to the HTTP-Redirect binding obtained from the SingleSignOnService element.

   2. Select the check box next to **Sign AuthnRequest** to enable the Identity Provider's single-sign on service to receive a signed AuthnRequest.

   3. In the property **When SAML 2.0 single sign-on fails because the session is not authenticated, or this is the first login, redirect to this URL. This is the base URL where the initial SAML 2.0 AuthnRequest is sent using the SAMLRequest parameter**, enter the URL to the HTTP-Redirect binding obtained from the SingleSignOnService element.

   By default, the integration contains the URL to the SSOCircle service.

Set the SingleLogoutRequest service URL

   Using the IdP's metadata, set the request service URLs for the integration's IdP.

   Role required: admin

   1. In the property **The base URL to the Identity Provider's SingleLogoutRequest service. The LogoutRequest will be posted to this URL as the SAMLRequest parameter**, enter the URL obtained from the SingleLogoutService element.

   By default, the integration contains the URL to the SSOCircle service.

   2. In the property **URL to redirect users after logout, typically back to the portal that enabled the SSO (e.g. http://portal.companya.com/logout)**, enter the URL where you want to redirect users after they successfully logout. If your IdP uses form-based authentication, enter the URL to your IdP's login form. If your IdP uses a non-form-based authentication method such as Kerberos, you should set the URL to a static logout page. This way, users who log out do not get immediately get redirected to the IdP and login again.

   By default, the integration contains the URL to the static UI page external_logout_complete.do.

(Optional) Enable signed logout requests

   Some IdPs require the Service Provider to sign logout requests with a certificate.

   Role required: admin

   If your IdP requires signed logout requests, use the IdP's metadata to set the following system properties.

   1. From the property **Sign LogoutRequest. Set this property to true if the Identity Provider's SingleLogoutRequest service requires signed LogoutRequest**, select Yes to specify that your IdP requires a signed logout request, or select No to use unsigned logout requests.

   2. If you selected Yes to Sign LogoutRequest, then in The protocol binding for the Identity Provider's SingleLogoutRequest service. (Value can be either "urn:oasis:names:tc:SAML:2.0:bindings:HTTP-Redirect" or "urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST") property, enter the one of the supported values listed in Binding attribute from the SingleLogoutService element.

   By default, the integration uses an HTTP-Redirect binding.

3. Click Update.

4. Install a Service Provider (SP) key store.
Service Provider (SP) system properties
These system properties define how the instance interacts with the IdP as a Service Provider.

Service Provider (SP) properties

The URL to the ServiceNow instance homepage.
https://yourinstance.servicenow.com/navpage.do

The entity identifier, or the issuer.
https://yourinstance.servicenow.com

The audience URI that accepts SAML2 token. (Normally, it is your instance URL. For example: https://demo.servicenow.com)
https://yourinstance.servicenow.com

The User table field to match with the Subject’s NameID element in the SAMLResponse

email

The NameID policy to use for returning the Subject’s NameID in the SAMLResponse. Your SAML identity provider will have to support this by declaring the policy in its metadata. The NameID value is used to match with the specified field in the User table to lookup the user.

urn:oasis:names:tc:SAML:1.1:nameid-format:emailAddress

Create an AuthnContextClass request in the AuthnRequest statement. This tells the IdP that ServiceNow requires that they present a specific login mechanism such as a form, Kerberos, etc. If the AuthnRequest doesn’t specify an AuthnContextClass, the IdP will choose the most appropriate method.

Yes | No

The AuthnContextClassRef method that we will be included in our SAML 2.0 AuthnRequest to the Identity Provider

urn:oasis:names:tc:SAML:2.0:ac:classes:PasswordProtectedTransport

The alias of key entry stored in SAML 2.0 SP Keystore used to sign SAML 2 requests.

saml2sp

The password of key entry stored in SAML 2.0 SP Keystore used to sign SAML 2 requests.

********

Service Provider properties

Set the instance URL for SAML
Set the instance-specific URLs so the IdP can authenticate users.

Role required: admin

1. In the property **The URL to the Service-now instance (usually this instance)**, enter the URL (including login page) of the instance for which the IdP authenticates. For example: https://yourinstance.service-now.com/navpage.do

2. In the property **The entity identification, or the issuer**, enter the base URL (excluding login page) of the instance for which the IdP authenticates. For example: https://yourinstance.service-now.com/

Set the audience URL for SAML
The Audience system property allows your instance to verify that it is the intended recipient of a SAML response.

Role required: admin

The integration verifies that each SAML response contains the same URL listed in this system property as the URL listed in the **Audience** element. For example:

```
<samlp:Response xmlns:samlp="urn:oasis:names:tc:SAML:2.0:protocol"
ID="s2cdcc74f37f923e26f1e4e4c42b0a9324230334f"
InResponseTo="90AA6073F01567BF80DF1945B96314E2" Version="2.0"
IssueInstant="2010-04-29T23:21:51Z" Destination="https://dloomac.service-
now.com/navpage.do">
...
<saml:Conditions NotBefore="2012-01-30T19:57:10Z"
demoi2.service-now.com</saml:Audience><saml:AudienceRestriction></saml:Audience></saml:Conditions>
...
</samlp:Response>
```

1. Navigate to **SAML 2 Single Sign-on > Properties**.
2. In the property **The audience uri that accepts SAML2 token. (Normally, it is your instance URL. For example: https://<instance name>.service-now.com.)**, enter the URL of your instance. For example, https://demoi2.service-now.com. This URL must match the value of the **Audience** element in the SAML Response.
3. Click **Update**.

Set up a NameID policy for SAML
SAML 2.0 requires the Idp to exchange a NameID token with the service provider.

Role required: admin

For the SAML 2.0 integration the NameID token must map to a particular field in the User table. The integration uses the NameID token’s value to determine what user the IdP authenticates.

1. Browse the IdP metadata to find the **NameIDFormat** element that contains a value of emailAddress. The value of this element is the default format that the integration uses.
2. Review other **NameIDFormat** elements to determine if there are formats that match other fields in the User table.

Determine what User table field matches the NameID token
Identity providers specify what format the NameID token has.

Role required: admin

Setting up SAML 2.0 requires selecting a field from the User table that matches the format of the NameID token. Typically, IdPs offer the option to use an email address as the NameID token. Since the User table contains an email field, this field is a logical choice for use as a NameID token. To use another field from the User table as the NameID
token, first verify that the IdP offers a NameID format that matches the value of a User table field. This may require adding the field to the User table.

1. Compare the available formats in the IdP's NameIDFormat element to fields in the User table.
2. Select a NameID format where there is a matching value in the User table.
3. In the The User table field to match with the Subject's NameID element in the SAMLResponse field, enter the name of the User table field to search for matching values in the NameID token.

By default, the integration uses the email field.

Set the IdP NameID policy
Specify what format the IdP uses for the NameID token.
Role required: admin
This format is listed as part of the IdP's metadata.

1. In the property The NameID policy to use for returning the Subject's NameID in the SAMLResponse. Your SAML identity provider will have to support this by declaring the policy in its metadata. The NameID value is used to match with the specified field in the User table to lookup the user., enter the value of the NameIDFormat element the integration uses.

By default, the integration uses the SSOCircle NameIDFormat for email addresses.
2. Click Save.

Values in the User table field for SAML
Ensure that the integration's User table field contains appropriate matching values.

For example, if the integration uses the email field as the NameID token, ensure that the instance lists the same email address as the IdP. The integration fails to authenticate any user who does not have a matching value for the NameID token.

(Optional) Enable providing an authentication context class for SAML
You can enable the instance to send an authentication context class request to the IdP containing your instance's preferred authentication request format.
Role required: admin
If you enable creating an AuthContextClass message, then you must also specify an authentication context class reference format.

Note: Some IdP's do not allow the Service Provider to set the authentication context class. Disabling this setting allows the IdP to choose the authentication context class.

1. From the property Create an AuthnContextClass request in the AuthnRequest statement, select Yes to specify a particular context class such as Password Protected Transport, or select No to have the IdP select the most appropriate context class.
2. If you selected Yes to Create an AuthnContextClass request in the AuthnRequest statement, then in The AuthnContextClassRef method that we will request in our SAML 2.0 AuthnRequest to the Identity Provider property, enter the URN of the context class you want to use for authentication (see table).

AuthnContextClass URN options

<table>
<thead>
<tr>
<th>Authentication type</th>
<th>Authentication context class URN</th>
</tr>
</thead>
<tbody>
<tr>
<td>Forms-based authentication</td>
<td>urn:oasis:names:tc:SAML:2.0:ac:classes:PasswordProtectedTransport</td>
</tr>
</tbody>
</table>
By default, the integration uses a Password Protected Transport authentication method.

3. Click **Update**.

(Optional) Set keystore properties for signing logout requests for SAML
The keystore properties allow the integration to sign logout requests using your signed server and signed CA certificates.

Role required: admin

1. In the property **The alias of key entry stored in SAML 2.0 SP Keystore used to sign SAML 2 requests**, enter the alias name you created for the SAML 2.0 Keystore. By default, the integration looks for the alias `saml2sp`.
2. In the property **The password of key entry stored in SAML 2.0 SP Keystore used to sign SAML 2 requests**, enter the password to your SAML 2.0 Keystore. By default, the password is the same as the default alias name.
3. Click **Update**.
4. Regenerate your SP metadata.

Install a service provider keystore for signing SAML requests
Use the following steps to remove the existing example key store and install your own Service Provider key store containing your public and private key pair.

Role required: admin

1. Create a Service Provider key store.
2. Navigate to **SAML 2 Single Sign-on > Certificate**.
3. Click **SAML 2.0 SP Keystore**.
4. Click the Manage Attachments link.
5. Select the Delete checkbox next to `saml2sp_keystore`.
6. Click **Remove**.
7. Click **Choose Files** and select the Keystore containing your signed certificates.
8. Click **Attach**.
9. Close the Attachments popup.
10. In **Key store password**, enter the password to access the SAML 2 alias.
11. Click **Update**.

Create a service provider keystore for SAML
In order for your instance to sign logout requests, you must create a Java Key store containing the following items.

- Signed server certificate for the instance
- Signed CA certificate
- Public and private key pair

You may create your own signed certificate with a private certificate authority or purchase one from a public certificate authority.

The following steps illustrate how to generate a new Java Keytool keystore file, create a certificate signing request (CSR), and import certificates. Any root or intermediate certificates need to be imported before importing the primary certificate for your domain. Type these commands in a command line interface.
Note: These instructions are not specific to the platform and require technical knowledge of security certificates to complete. Technical Support cannot assist in creating the certificates.

1. Generate a Java keystore and key pair.
   
   ```bash
   keytool -genkey -alias mydomain -keyalg RSA -keystore my.keystore
   ```

2. Generate a CSR for an existing Java keystore.
   
   ```bash
   keytool -certreq -alias mydomain -keystore my.keystore -file mydomain.csr
   ```

3. Import a root or intermediate certificate authority CA certificate to an existing Java keystore.
   
   ```bash
   keytool -import -trustcacerts -alias root -file Thawte.crt -keystore my.keystore
   ```

4. Import a signed primary certificate to an existing Java keystore.
   
   ```bash
   keytool -import -trustcacerts -alias mydomain -file mydomain.crt -keystore my.keystore
   ```

(Optional) Advanced SAML properties

The following advanced settings allow you to further increase security and debug the integration.

Advanced settings

<table>
<thead>
<tr>
<th>Advanced settings</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>The number in seconds before &quot;notBefore&quot; constraint, or after &quot;notOnOrAfter&quot; constraint, to consider still valid.</td>
<td>60</td>
</tr>
<tr>
<td>Turn on debug logging for SAML 2.0 Authentication</td>
<td>Select Yes to enable additional logging information for SAML 2.0 events.</td>
</tr>
</tbody>
</table>

Advanced system properties table

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>The number of seconds &quot;notBefore&quot; constraint, or after &quot;notOnOrAfter&quot; constraint, to consider still valid</td>
<td>Enter the number of seconds to add to the NotBefore and NotOnOrAfter constraints to account for time differences between the IdP clock and SP clock. These constraints prevent against replay attacks by denying requests that are not made within the specified time frame. If the IdP clock and SP clock are significantly different, network latency may result in the SAML request being unauthorized. This property adds a grace period during which SAML requests and responses are still considered valid.</td>
</tr>

<td>Select Yes to enable additional logging information for SAML 2.0 events.</td>
</tr>
</tbody>
</table>
Install the identity provider certificate
You can paste a PEM certificate into a X.509 Certificate form so the identity provider can verify communications with the service provider.

Role required: admin

The IdP’s certificate is located within the IdP’s metadata. The IdP developer determines where the certificate metadata resides when creating the local IdP.

Note: Certificates for single-sign on should always be in PEM format to work with SAML certificates.

1. Navigate to SAML Single Sign-on > Certificate.
2. Fill in the form fields (see table).
3. Click **Save**.

Click **Validate Stores/Certificates** to test the trust store and certificate.

Replacing a missing certificate for SAML
If the **Certificate** module displays a blank page, the SAML 2.0 certificate record has been deleted. You can replace the missing certificate by manually creating a certificate record.

**Role required:** admin

1. Navigate to **System Definition > Certificates**.
2. Create a new record called **SAML 2.0**.

   **Important:** You MUST use this name. This requirement is only true if you are not using External single sign-on (SSO).

3. Click **SAML 2 Single Sign-on > Certificate**.
4. In the **PEM Certificate** field, enter the value of the `ds:X509Certificate` element from your IdP's metadata.
5. Click **Save**.

Add a Java keystore for SAML

You can add Java keystores to the SAML application if you want another repository for your SAML security certificates.

**Role required:** admin

By default, SAML 2 Single Sign-on provides a default keystore named **SAML 2.0 SP Keystore** which uses 1024 bits and is SHA1. This keystore is active by default. If you need to use a key with 2048 bit key and SHA256, you need to activate this certificate before you generate your metadata with the x509 certificate. You can add keystores as needed and specify which one to use by default with a property.

1. Navigate to **System Definition > Certificates**.
2. Fill in the fields on the form (see table).
3. Click **Submit**.

![X.509 Certificate form](image)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a descriptive name.</td>
</tr>
<tr>
<td>Active</td>
<td>Select <strong>Active</strong> to keep the key store available.</td>
</tr>
<tr>
<td>Short description</td>
<td>Enter a description for the key store.</td>
</tr>
<tr>
<td>Type</td>
<td>Select <strong>Java Key Store</strong>.</td>
</tr>
<tr>
<td>Key store password</td>
<td>Enter the password for the key store.</td>
</tr>
</tbody>
</table>

4. To set the default key store, navigate to **System Properties > All Properties** and find and open the following property: `glideauthenticate.sso.saml2.keystore`

The Value field shows a default Sys ID (b88267271b012000f1129141be071393). If you have a custom keystore, you need to update this value to the newly created SAML 2.0 Keystore value. You might also need to do this after an upgrade from an earlier release.

5. Paste the Sys ID of the key store record that you created into the **Value** field.

6. Click **Update**.

*Install a service provider keystore for signing SAML requests*

Use the following steps to remove the existing example key store and install your own Service Provider key store containing your public and private key pair.

Role required: admin

1. Create a Service Provider key store.
2. Navigate to SAML 2 Single Sign-on > Certificate.
3. Click SAML 2.0 SP Keystore.
4. Click the Manage Attachments link.
5. Select the Delete checkbox next to saml2sp_keystore.
6. Click Remove.
7. Click Choose Files and select the Keystore containing your signed certificates.
8. Click Attach.
9. Close the Attachments popup.
10. In Key store password, enter the password to access the SAML 2 alias.
11. Click Update.

Test the SAML integration
After completing all other setup tasks, test the integration.

Role required: admin

1. Log in to the instance as a user with the admin role.
3. In the property Enable external authentication, select Yes.

Note:
Enabling external authentication requires all users to use SAML 2.0 single sign-on. Thus, if anyone tries to access the application in an unauthenticated state, the instance automatically sends an authentication request to the (IdP) and redirects the user to the SAML IdP Authentication page.

4. Click Save.
5. Log out of the instance.
6. Browse to the instance URL. If the integration is functioning properly, the IdP should ask for the users credentials.

### Common login and IdP errors

<table>
<thead>
<tr>
<th>Error or Symptom</th>
<th>Diagnosis</th>
<th>Fix</th>
</tr>
</thead>
</table>
| Login requests generate an infinite loop between the system and the IdP when High Security is active. | • Typically the URL endpoint is an error page or logout page.  
• The logout_redirect.do might create this loop when you define glide.security.url.whitelist without adding the IdP host name to the property value. | Set (or create) the system property glide.authenticate.failed_redirect to redirect failed authentication requests to this URL. |

**Note:** To learn more about this property, see URL allow list for logout redirects (instance security hardening) in Instance Security Hardening Settings.

The token used to authenticate the user or the request is signed with the signature algorithm http://www.w3.org/2001/04/xmldsig-more#rsa-sha256 which is not the expected signature algorithm http://www.w3.org/2000/09/xmldsig#rsa-sha1.

Check the Alert Context tab for event details.

Navigate to the Advanced tab of the Relying Party Trust configuration dialog and verify that the algorithm is set to SHA-1 and not SHA-256.

---

### Redirect single sign-on (SSO) logins

When SSO is enabled, you can redirect users to specific pages or direct users to login locally.

For example, if a user attempts to go to https://customerX.service-now.com, an internal company portal can display instead of the default login page. Or, when a user logs out of an application, the browser can redirect them to a specific internal page. You can set redirection properties within the instance to ensure that users see an SSO login page rather than the default login page.

**Note:** The following properties do not force SSO. The login.do page is still accessible and users can login to the system if they have a local password set.

###Redirection properties

When a user logs out, or if there is a failed attempt to sign on using SSO, you can define where the user is taken next, such as a main portal page or a knowledge base article with SSO login information. Use the following properties to specify the URLs. If one of these properties does not exist in your instance, you can create the property.

**glide.authenticate.failed_requirement_redirect**

URL to redirect users when they attempt to access a page that is private (for example, to view an incident) and do not provide SSO credentials. The property is typically set to a customer's login portal (for example, http://portal.companya.com/).

**glide.authenticate.failed_redirect**

URL to redirect users after a failed SSO attempt. You can redirect to a public knowledge article that describes the error and has helpful links (for example, http://portal.companya.com/error).
**glide.authenticate.external.logout_redirect**

URL to redirect users after logging out, typically back to the portal that enabled the single sign-on log in (for example, http://portal.companya.com/logout).

**glide.authentication.external.disable_local_login**

When set to true, requires SSO credentials for the main login page. Defaults to false. This property needs to be used in conjunction with the `glide.authenticate.failed_requirement_redirect` property.

The following table shows the relationship between the Installation Exit return values, the properties, and the expected behavior.

<table>
<thead>
<tr>
<th>Return value</th>
<th>Property</th>
<th>Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>failed_missing_requirement</td>
<td>glide.authenticate.failed_requirement_redirect</td>
<td>When this value is returned, it indicates that the required SSO credentials are not present in the session. Login fails and the session is redirected to the URL specified by the property. This is usually the URL for the SSO provider where login is challenged and credentials are collected.</td>
</tr>
<tr>
<td>failed_authentication</td>
<td>glide.authenticate.failed_redirect</td>
<td>When this value is returned, it indicates that the supplied SSO credentials failed authentication, the user does not exist, or the user is locked out. Login fails and the session is redirected to the URL specified by the property. This is usually the URL for the SSO provider where login is challenged and credentials are collected.</td>
</tr>
<tr>
<td>&lt;user_id&gt;</td>
<td>N/A</td>
<td>Login authorized for the user specified by &lt;user_id&gt;. This value matches with the field name defined in the SSO property <code>glide.authenticate.header.value</code> (&quot;the instance’s field name to match against the incoming header&quot;)</td>
</tr>
</tbody>
</table>

### Restricting local login

As a security precaution, you should do more than rely on redirection properties to prohibit logging in locally. If a user should never log in locally and will always be authenticated by your internal single sign-on system, then a random password should be assigned to each user that is imported into the instance. The random password is most easily set at the time of the user import. If the user data is imported into your system through an import set, you can create an `onBefore` transform script using the following code.

```java
var r = new Packages. java. util. Random () ;
var str1 = Packages. java. lang. Long. toString (Packages. java. lang. Long. random()) ;
```

© 2021 ServiceNow, Inc. All rights reserved.
Math.abs(r.nextLong(), 36); var str2 = Packages.java.lang.Long.toString(Packages.java.lang.Math.abs(r.nextLong()), 36);

var newPass = str1 + str2;
target.user_password = newPass;

//password now set to a random string like this:
//qvm81zdrn7cwwylpvw94eebk
SAML 2.0 concepts

Familiarize yourself with these SAML concepts.

Typical SAML process flow (diagram)

A typical SSO logic flow involves looking for an active session, checking user credentials, and creating the necessary token.

SSO Standard

Login (AuthnRequest) process flow

SAML 2.0 specifies a Web Browser SSO Profile that involves exchanging information among an identity provider (IdP), a service provider (SP), and a principal (user) on a web browser.

The identity provider can be any SSO service offering SAML authentication services (for example SSOCircle). The service provider is always an instance. The message flow begins with a request for a secured resource at the service provider.
Request the target resource at the SP

The principal requests a target resource at the service provider:

https://instance.service-now.com/

The instance checks the request to see if the SAMLRequest and RelayState URL parameters are present. If they exist, the user has already validated with the IdP and can skip steps 2–6.

Issue AuthnRequest to Identity Provider

The instance constructs an AuthnRequest to be sent to the IdP using the SAMLRequest value. The instance also constructs and sends a RelayState URL parameter value.

The RelayState token is an opaque reference to state information maintained at the service provider. The value of the SAMLRequest parameter is the deflated and base64 encoded value of the <samlp:AuthnRequest> element:

```
```

The integration then URL-encodes the <samlp:AuthnRequest> element and sends it as the SAMLRequest URL parameter.

The SSO service processes the <samlp:AuthnRequest> element by URL-decoding, base64-decoding and inflating the request, in that order. It then performs a security check. If the user does not have a valid security context, the IdP identifies the user by prompting for login credentials. If the user is already logged in, the IdP simply responds with the SAMLResponse and RelayState URL parameters (see step 3).

Respond with an SAMLResponse and RelayState

After collecting the required login credentials, the SSO service validates the request and responds with a document containing an XHTML form:

```
<form method="post" action="https://instance.service-now.com/navpage.do" ...><input type="hidden" name="SAMLResponse" value="response ..." /><input type="hidden" name="RelayState" value="token ..." />
...<input type="submit" value="Submit" /></form>
```

The value of the RelayState parameter comes from this step. The value of the SAMLResponse parameter is the base64 encoding of the following <samlp:Response> element:

```
<samlp:Response xmlns:samlp="urn:oasis:names:tc:SAML:2.0:protocol"
```
Validate SAMLResponse

The SAMLResponse value is base64 decoded and inflated to reveal the XML document in step 3. The login script extracts the XML value from the //Subject/NameID element and uses it to look up an existing user in the User table.

The login script also extracts the session ID from the //AuthnStatement/@SessionIndex element and stores it for the LogoutRequest.

Logout (LogoutRequest) process flow
During logout, the instance issues the SAML 2.0 LogoutRequest service call to the IdP.

This service logs the user out and then redirects back to the specified logout URL.
SAML 2 Logout

User Clicks the Logout Button

The user clicks the **Logout** button and the instance executes the logout script.
LogoutRequest issued

The logout script constructs a SAML 2.0 LogoutRequest and posts it to the preconfigured SingleLogoutRequest SAML 2.0 service at the IdP. The IdP deflates the request and then base64 encodes it. An example LogoutRequest looks like this:

```xml
<saml2p:LogoutRequest xmlns:saml2p="urn:oasis:names:tc:SAML:2.0:protocol"
  ID="21B78E9C6C8ECF16F01E4A0F15AB2D46"
  IssueInstant="2010-04-28T21:36:11.230Z"  Version="2.0">
  <saml2:Issuer
  <saml2:NameID
    xmlns:saml2="urn:oasis:names:tc:SAML:2.0:assertion"
    Format="urn:oasis:names:tc:SAML:1.1:nameid-format:emailAddress"
    NameQualifier="http://idp.ssocircle.com"
    SPNameQualifier="https://dloomac.service-now.com/navpage.do">david.loo@service-now.com</saml2:NameID>
  <saml2p:SessionIndex>s211b2f811485b2a1d2cc4db2b271933c286771104</saml2p:SessionIndex>
</saml2p:LogoutRequest>
```

User Logs Out

The user logs out of the IdP. The IdP redirects back to the instance, which in turns redirects back to the IdP since the user is not logged in.
URL information for an SSO provider

During a login challenge resulting from a URL link into the instance that requires an SSO session, the referring URL might need to be supplied to the SSO provider so that after authentication, the URL can be passed back to the instance and linked to the correct resource.

SSO Logic Flow w/ Target Redirect Feature

SSO Target Redirect
Installation exit return values have been enhanced to pass a URL instead of, or in addition to the URL defined by the properties. Usually, you would return a username or a predefined string value to control authorize or challenge the SSO session. The following examples show the extended behavior of passing a URL.

```
```

The example above passes the URL https://instance.service-now.com/nav_to.do?uri=incident.do?sys_id=12345 to the SSO provider in the form of a URL parameter named TARGET.

**Note:** It is assumed that the SSO provider will use that information in the TARGET parameter to redirect back to the instance when the user credentials have been collected and authentication passed.

A colon : demarcates the two return values and an encoded & (%26amp;) concatenates the URL defined in the property `glide.authenticate.failed_missing_requirement` and the TARGET parameter.

### SAML 2.0 Single Sign-On — Update 1

The **SAML 2.0 Single Sign-On - Update 1: security enhancements** plugin improves integration security by requiring additional checks against the SAMLResponse URL parameter.

The integration explicitly checks the SAML response for the proper Identity Provider (IdP) and intended audience URLs.

#### Additional SAML response validations

With Update 1, the integration validates these elements in the SAMLResponse.

- An **Issuer** element that matches the value listed in the issuer system property
- The **SubjectConfirmation** and **SubjectConfirmationData** elements with a **Recipient** attribute
- The **AudienceRestriction** and **Audience** elements that match the value listed in the audience system property

#### Support for Signed SingleLogoutRequest

With Update 1, the SAML 2.0 integration has the option to sign SingleLogoutRequest elements. Some IdPs, such as Microsoft ADFS, require a signed SingleLogoutRequest.

#### Support for AuthnContextClass

With Update 1, the SAML 2.0 integration has the option to specify the method by which the IdP authenticates the user in the AuthnContextClass element. For example, the integration can now specify contexts such as form-based Password Protected Transport or Kerberos. See [Optional] Enable Providing an Authentication Context Class for instructions on setting an authentication context class.

#### No support for mobile iOS and Android apps

You cannot use the SAML 2 Update 1 plugin or the single sign-on (SSO) configuration provided by Okta for the iOS and Android apps. You must use the ServiceNow multi-provider SSO plugin.
### Properties

The SAML 2.0 Update 1 plugin includes the following system properties.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Identity Provider URL which will issue the SAML2</td>
<td>Enter the value of the <strong>Issuer</strong> element that the integration uses to validate the IdP URL. Each IdP URL must be unique.</td>
</tr>
<tr>
<td>security token with user info.</td>
<td>glide.authenticate.sso.saml2.idp</td>
</tr>
<tr>
<td>Sign LogoutRequest. Set this property to true if the Identity Provider's</td>
<td>Select whether the IdP requires a signed logout request.</td>
</tr>
<tr>
<td>SingleLogoutRequest service requires signed LogoutRequest.</td>
<td>glide.authenticate.sso.saml2.require_signed_logoutrequest</td>
</tr>
<tr>
<td>Select whether the IdP requires a signed logout request.</td>
<td>glide.authenticate.external.logout_redirect</td>
</tr>
<tr>
<td>The audience URI that accepts SAML2 token. (Normally, it is your instance</td>
<td>Enter the URL where the integration redirects users after they log out. Typically, you set this property to a UI page if you are using Kerberos authentication to prevent users from being redirected back to the IdP and logging in again after a logout request.</td>
</tr>
<tr>
<td>URL. For example: https://&lt;instance name&gt;.service-now.com.)</td>
<td>glide.authenticate.sso.saml2.audience</td>
</tr>
<tr>
<td>Create an AuthnContextClass request in the AuthnRequest statement.</td>
<td>Select whether to create an AuthnContextClass element in the SAMLRequest that specifies the login mechanism the IdP should use to authenticate the user. Not all IdPs support a AuthnContextClass element in the SAMLRequest. If you select <strong>Yes</strong>, you must specify the URN of the context class with the glide.authenticate.sso.saml2.authncontextclassref property.</td>
</tr>
<tr>
<td>glide.authenticate.sso.saml2.createrequestedauthncontext</td>
<td></td>
</tr>
<tr>
<td>The AuthnContextClassRef method that we will request in our SAML 2.0</td>
<td>Enter the URN of the login mechanism you want the IdP to use to authenticate users. For example, by default the system uses the forms-based Password Protected Transport authentication context urn:oasis:names:tc:SAML:2.0:ac:classes:PasswordProtectedTransport.</td>
</tr>
<tr>
<td>AutnRequest to the Identity Provider</td>
<td>glide.authenticate.sso.saml2.authncontextclassref</td>
</tr>
<tr>
<td>The alias of key entry stored in SAML 2.0 SP Keystore used to sign SAML 2</td>
<td>Enter the alias of the key that signs SAML 2 logout requests. You will have to create a Java Keystore for the alias.</td>
</tr>
<tr>
<td>requests.</td>
<td>glide.authenticate.sso.saml2.signing_key_alias</td>
</tr>
<tr>
<td>The password of key entry stored in SAML 2.0 SP Keystore used to sign SAML 2</td>
<td>Enter the password for the key that signs SAML 2 logout requests.</td>
</tr>
<tr>
<td>requests.</td>
<td>glide.authenticate.sso.saml2.signing_key_password</td>
</tr>
<tr>
<td>The number in seconds before “notBefore” constraint, or after “notOnOrAfter” constraint, to consider still valid.</td>
<td>Enter the number of seconds between the two attributes that make up the SAMLResponse nonce. A valid SAMLResponse must fall between the <strong>notBefore</strong> and <strong>notOnOrAfter</strong> date-time values.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>AuthnRequest URL for eSignature Authentication.</td>
<td>com.snc.integration.saml_esig.idp_authnrequest_url</td>
</tr>
<tr>
<td>The SAML 2.0 Assertion Consumer URL for eSignature authentication.</td>
<td>com.snc.integration.saml_esig.approval_consumer_url</td>
</tr>
<tr>
<td>The SAML 2.0 Assertion Consumer Index for eSignature authentication.</td>
<td>com.snc.integration.saml_esig.assertion_consumer_service_index</td>
</tr>
<tr>
<td>Authentication Pop-up Dialog Width.</td>
<td>com.snc.integration.saml_esig.popup_dlg_width</td>
</tr>
<tr>
<td>Authentication Pop-up Dialog Height.</td>
<td>com.snc.integration.saml_esig.popup_dlg_height</td>
</tr>
</tbody>
</table>

**SAML 2.0 update 1 requirements**

The SAML 2.0 update requires:

- Activating the SAML 2.0 Update 1 plugin
- Additional metadata from the SAML 2.0 Identity Provider (IdP)
  - SAML Request can include an `AuthnContextClass` element to specify the Service Provider's preferred login mechanism such as form-based authentication or Kerberos. If this element is not specified, the IdP chooses the login method.
  - SAML Response must include an `Issuer` element that matches the value listed in the issuer system property
  - SAML Response must include `SubjectConfirmation` and `SubjectConfirmationData` elements with a `Recipient` attribute
  - SAML Response must include `AudienceRestriction` and `Audience` elements that match the value listed in the audience system property

**SAML 2.0 integration requirements**

The SAML 2.0 integration requires several items, such as an IdP that provides a certificate and a single logout service.

- Activating the latest SAML 2.0 plugin
• Access to a SAML 2.0 Identity Provider (IdP)
  • Must provide an authentication request service
  • Must provide a single logout service
  • Must have a valid certificate
  • Must accept Service Provider (SP) metadata
  • Must use the NameID element in the SAMLResponse

Upgrade from previous versions

The following table lists the actions to take if you are running a previous versions of SAML.

<table>
<thead>
<tr>
<th>Previous SAML version</th>
<th>Action required</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAML 1.1</td>
<td>Contact Customer Service and Support to migrate your instance to SAML 2.0 Update 1.</td>
</tr>
<tr>
<td>SAML 2.0</td>
<td>Update to SAML 2.0 Update 1.</td>
</tr>
</tbody>
</table>

Integrating SAML 2.0 with other features

You can integration your SAML 2.0 solution with other features like E-Signature, deep linking, and ADFS.

Add E-Signature support for SAML

Configure the following properties for E-Signature with SAML 2.0 update 1.

When E-signature is active with Multi-SSO, SAML properties are not used. The system adds E-signature properties to the SAML2 Update1 Properties [saml2_update1_properties] table:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Assertion Consumer Index for eSignature authentication</td>
<td>An index number that identifies the endpoint.</td>
<td>1</td>
</tr>
<tr>
<td>Assertion Consumer URL for eSignature authentication</td>
<td>The URL that identifies the consumer.</td>
<td><a href="https://yourinstance.service-now.com/consumer.do">https://yourinstance.service-now.com/consumer.do</a></td>
</tr>
<tr>
<td>AuthnRequest URL for eSignature Authentication</td>
<td>The URL for authentication</td>
<td>none</td>
</tr>
</tbody>
</table>

If you are using E-Signature with SAML 1.0 or SAML 2.0 (not including update 1), see the special configuration instructions: Using E-Signature with Single Sign-On (SSO).

Note: If you are a Life Science Customer using E-Signature, deactivate the User self-lockout prevention business rule.

Add deep linking support for SAML

Deep linking allows instances to support direct email links to a particular record in the system.

With the SAML 2.0 integration enabled, deep-linking URLs must pass an authentication check before the IdP redirects the user to the originally requested URL. For example, consider an email that contains this URL: https://<instance name>.service-now.com/nav_to.do?url=incident.do?sys_id=46c88ac1a9fe1981014de1c831fbcf6d
The instance sends an authentication request to the IdP and uses the `RelayState` URL parameter to preserve the originally requested resource (in this case, `uri=incident.do?sys_id=46c88a1a9fe1981014d1c831fbc6d`). After the IdP authenticates the user, the instance reads the value of the `RelayState` URL parameter and redirects the user to the requested resource (if it exists in the instance).

To add support for deep linking verify that the identity provider supports the `RelayState` URL parameter.

**ADFS integration with SAML 2.0**

The ServiceNow Multi-Provider SSO plugin supports a SAML 2.0 single sign-on (SSO) integration with Microsoft Active Directory Federation Services (ADFS).

For information about installing and configuring ADFS, see Active Directory Federation Services Overview. The Multi-Provider SSO plugin has been configured and tested with a SAML 2.0 SSO integration with ADFS 2.0, 3.0, and 4.0. An integration with ADFS 5.0 might also be compatible.

**Note:** Multi-line attributes are not supported in the SAML Response in ServiceNow for ADFS.

**Set up ADFS for SAML**

This procedure uses ADFS 2.0 and shows samportal.example.com as the ADFS website. Replace this with your ADFS website address.

Role required: admin

1. Log into the ADFS 3.0 server and open the management console.
2. Right-click **Service** and choose **Edit Federation Service Properties**.
3. Confirm that the General settings match your DNS entries and certificate names.

4. Browse to the certificates and export the Token-Signing certificate.
   a) Right-click the certificate and select **View Certificate**.
   b) Select the **Details** tab.
   c) Click **Copy to File**. The Certificate Export Wizard opens.
   d) Select **Next**.
   e) Ensure the **No, do not export the private key** option is selected, and then click **Next**.
   f) Select **DER encoded binary X.509 (.cer)**, and then click **Next**.
   g) Select where you want to save the file and give it a name. Click **Next**.
   h) Select **Finish**. The instance requires that this certificate be in PEM format. You can convert this certificate using client tools or even online tools such as: SSL Shopper.
5. Use the DER/Binary certificate that you just created, and export it in Standard PEM format.

Set up the instance for ADFS
Once you have set up ADFS for SAML, you can configure your instance and SAML 2.0 settings to work with ADFS.
Role required: admin

1. If not already active, activate the Integration - Multiple Provider Single Sign-On Installer plugin.
2. Configure Authentication with SAML, but when you install the IdP certificate, attach the PEM certificate you created when you Set up ADFS for SAML.
3. Click Save.
4. Verify that the Issuer and Subject fields have values and that there are no errors. If an error occurs, open the saved PEM formatted certificate in Notepad and copy and paste the certificate into the PEM Certificate field.
5. Verify that the SAML2SingleSignon_update1 installation exit is active.
6. Continue the SAML 2.0 configuration.

**Note:** When a certificate is updated on the ADFS server, you also need to upload an updated certificate to the instance.

Configure an ADFS relying party
At this point you can take the instance metadata and import it into your ADFS server. However, manual configuration of the relying party appears to be easier to implement.
Role required: admin

1. Navigate to Multi-Provider SSO > Identity Providers > SAML2 Update1 > Encryption And Signing and verify that the SAML property Sign AuthnRequest (glide.authenticate.sso.saml2.require_signed_authnrequest) is not active. Only keep this property active if your ADFS administrator can verify that you require signed requests.
2. Copy the metadata that you generated through the SAML 2 metadata link and save it to a file.
3. Log into the ADFS server and open the management console.
5. Select Add Relying Party Trust from the top right corner of the window.
   The add wizard appears.
6. Click Start to begin.
7. Use the Import File option to import the metadata file.
8. Give it a display name such as ServiceNow and enter any notes you want.
9. Select ADFS 3.0 Profile.
10. Do not select a token encryption certificate. It will use the certificate that is defined on the service that has already been exported. Defining a certificate here will prevent proper communication with the instance.
11. Do not enable any settings on the Configure URL.
12. Enter the instance site to which you connected as the Relying Party trust identifier. In this case use https://company.service-now.com and click Add.
13. Permit all users to access this relying party.
14. Click Next and clear the Open the Claims when this finishes check box.
15. Close this page. The new relying party trust appears in the window.
16. Right-click on the relying party trust and select Properties.
17. Browse to the Advanced tab and set the Secure hash algorithm. You can choose SHA-256 or SHA-1.

Configure ADFS relying party claim rules
Edit the Claim rules to enable proper communication with the instance.

Role required: admin

1. Log into the ADFS server and open the management console.
2. Right-click the relying party trust and select **Edit Claim Rules**.
3. Click the **Issuance Transform Rules** tab.
4. Select **Add Rules**.
5. Select **Send LDAP Attribute as Claims** as the claim rule template to use.
6. Give the claim a name such as **Get LDAP Attributes**.
7. Set the **Attribute store** to Active Directory, the **LDAP Attribute** to E-Mail-Addresses, and the **Outgoing Claim Type** to E-mail Address.

```
c:[Type == "http://schemas.microsoft.com/ws/2008/06/identity/claims/windowsaccountname", Issuer == "AD AUTHORITY"]
```
8. Select Finish.
9. Select Add Rules.
10. Select Transform an Incoming Claim as the claim rule template to use.
11. Give the Claim a name such as Email to Name ID.
12. Set the Incoming claim type to the Outgoing Claim Type in the previous rule. For example, E-Mail Address.
13. Set the Outgoing claim type to Name ID and the Outgoing name ID format to Email.

Note: These values must match the Name ID policy you define during SAML 2.0 configuration.
14. Select **Pass through all claim values**.

This claim rule should look similar to the following rule language.

```c
[Type == "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/emailaddress"]
```
Create a SAML logout endpoint
Create a SAML logout endpoint to allow single logout.
Role required: admin
See this article on ADFS signout for more information.

Note: An IdP initiated logout is not supported.

1. Go to ADFS manager > Trust Relationships > Relying Party Trusts > properties.
2. Under the Endpoints tab, click Add SAML.
3. Configure the settings:
   - Endpoint Type: SAML Logout
   - Binding: POST
   - Trusted URL: The URL of your ADFS server. For example,
     https://myadfsserver.domain.net/adfs/ls/?wa=wsignout1.0
   - Response URL: The application logout URL. For example,
     https://{instancename}.service-now.com/external_logout_complete.do

Test the ADFS configuration
Test your ADFS configuration to verify that it is properly functioning as an identity provider.
Role required: admin
1. Open an Internet Explorer browser.
   This page contains a drop down list of all configured Relying Party Trusts.
3. Select the relying party associated with your instance.
4. Click Continue to Sign In.
   If you have configured the SAML 2.0 external authentication properly, you should be automatically logged into the instance.

(Workaround) Enable service provider-initiated authentication
A workaround is available if authentication fails because you do not have SAML 2.0 Update 1. This can happen if users attempt to skip IdP authentication and navigate directly to the instance.
Role required: admin
This is an error with the instance not providing ADFS with the needed definition and semantics for the SPNameQualifier attribute in the SAMLResponse.
To enable service provider-initiated authentication, do one of the following

- Upgrade to SAML 2.0 Update 1 and clear the option to create an AuthnContextClass request. See Activate and set up SAML 2.0.
- Modify the SAML2 script include to comment out the definitions of the SPNameQualifier attribute when you have SAML 2.0 active (not SAML 2.0 Update 1).

Comment out these lines in the createNameID and createNameIDPolicy functions:

```java
//nid.setSPNameQualifier (serviceURL ) ;
//nameIdPolicy. setSPNameQualifier (serviceURLStr ) ;
```

If you do not want the login prompt from your ADFS server to appear when you access the instance, set the following SAML 2.0 Update 1 property to false: Create an AuthnContextClass request in the AuthnRequest statement (`glide.authenticate.sso.saml2.createrequestedauthncontext`).

(Workaround) Support Kerberos authentication

A workaround is available for the SAML 2.0 integration that changes the authentication context from forms-based authentication to Windows-based authentication.

Role required: admin

Currently, the SAML 2 integration uses a PasswordProtectedTransport or "forms-based authentication" authentication context. This authentication context requires the IdP to present users with a form for authentication credentials. With Kerberos, a SAML session is already active through an established Windows login, so the user does not need to authenticate with the IdP.

1. Navigate to Multi-Provider SSO > Identity Providers.
2. Open the SAML2 Update1 IdP record.
3. Set the The AuthnContextClassRef method that we will be included in our SAML 2.0 AuthnRequest to the Identity Provider to one of the following:

```
AuthnContextClassRef method values

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>urn:oasis:names:tc:SAML:2.0:ac:classes:PasswordProtectedTransport</td>
<td>(Default)</td>
</tr>
<tr>
<td>urn:federation:authentication:windows</td>
<td></td>
</tr>
</tbody>
</table>
```

4. Click Update.

Email links with external authentication

You can use email links when using the digestive token external authentication, however, you must establish how to handle links in email notifications.

The default links contain a URL that directs you to a specific location in the instance, like an Incident or Change Request, without incorporating SSO credentials. Below are examples for directing the user to the location in the instance without logging in on the instance login page.

- Unencrypted HTTP technique to connect to the /demo instance (it does not navigate to specific record):

  ```
  https://<instance name>.service-now.com/?
  SM_USER=user_name&DE_USER=1QjIVp7aRJtyPx5+2O/vgU24tbE=
  ```

© 2021 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
• Link (in an email notification) to a specific record, so that the user first goes to the company's own login portal:

```
https://login.company_portal_page.com/nav_to.do?uri=incident.do?
sys_id=009f8eda0a0b2b01ab4eb094223466%26sysparm_stack=incident_list.do
%3Psparm_query=active=true
```

You must set the `glide.email.override.url` property in your instance to contain the URL of the company portal page. If this property does not exist, you can create it.

• The company portal must then take that URL and construct the redirect URL to the instance preserving the segment necessary to access the specific record, and adding the SSO credentials to the end of the URL:

```
https://<instance name>.service-now.com/nav_to.do?uri=incident.do?
sys_id=009f8eda0a0b2b01ab4eb094223466%26sysparm_stack=incident_list.do
%3Psparm_query=active=true&SM_USER=user_name&DE_USER=1QjIVp7aRJtyPx5+2O/ 
vGU24tbE=
```

Migrating an existing SAML 1.1 integration to SAML 2.0

To migrate from a SAML 1.1 integration to a SAML 2.0 integration, contact customer support.

Update existing SAML 2.0 integration

Perform these steps to update your existing SAML 2.0 integration.

Role required: admin

Request the SAML 2.0 Update 1 Plugin

Contact Customer Service and Support to request the `SAML 2.0 Single Sign-On - Update 1: security enhancements` plugin. The plugin applies updated versions of the `SAML2SingleSignon` installation exit (login script), `SAML2Logout` installation exit (logout script), and `SAML2` script include (script object).

Merge Customizations from Existing Installation Exit Scripts into New Scripts

The update saves an inactive copy of the integration's original installation exit scripts. You can use these copies to merge any customizations you made to the login and logout scripts to the new versions of these installation exits.

```
<table>
<thead>
<tr>
<th>Original Installation Exit Script Name</th>
<th>Original Script Status</th>
<th>New Installation Exit Script Name</th>
<th>New Script Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAML2SingleSignon</td>
<td>Inactive</td>
<td>SAML2SingleSignon_update</td>
<td>Active</td>
</tr>
<tr>
<td>SAML2</td>
<td>Inactive</td>
<td>SAML2_update1</td>
<td>Active</td>
</tr>
<tr>
<td>SAML2Logout</td>
<td>Inactive</td>
<td>SAML2Logout_update1</td>
<td>Active</td>
</tr>
</tbody>
</table>
```

You can navigate to the SAML 2.0 login and logout installation exit scripts using these paths.

• **SAML 2 Single Sign-on > Login script.**
• **SAML 2 Single Sign-on > Logout script.**
• **System Definition > Installation Exits.**

You can navigate to the SAML 2.0 update 1 script include using these paths.

• **SAML 2 Single Sign-on > Script object.**
• **System Definition > Script Includes.**

Test the Update
Perform these steps to troubleshoot your integration update.

1. Add a system property called `glide.authenticate.sso.saml2.debug` with a value of `true`.
2. Attempt SAML 2.0 login.
3. Review the system log. SAML2 validation errors begin with the text `SAML2ValidationError`.
4. Identify and fix typical login errors. See Multi-SSO (SAML 2.0) errors and fixes.

Sample SAML 2 responses after the update

The following sections illustrate the new required elements and attributes that the IdP should provide in the SAML Response.

Sample SAML 2 Response with Issuer Element

The following SAML 2 response uses the `Issuer` element.

```xml
<samlp:Response xmlns:samlp="urn:oasis:names:tc:SAML:2.0:protocol"
    Destination="https://demoi2.service-now.com/navpage.do"
    ID="s28da6774c88ae1eab292bf25fe625db81919d8e"e"
    InResponseTo="SNC841720c227c81948cf6d68cad6235c6"
    IssueInstant="2012-01-30T20:07:10Z"
    Version="2.0">
    <saml:Issuer xmlns:saml="urn:oasis:names:tc:SAML:2.0:assertion">
        http://idp.ssocircle.com
    </saml:Issuer>
    ...
    <saml:Assertion xmlns:saml="urn:oasis:names:tc:SAML:2.0:assertion"
        ID="s2f347f973c0633836cf700a38302d94976f9c5b851"
        IssueInstant="2012-01-30T20:07:10Z"
        Version="2.0">
        http://idp.ssocircle.com</saml:Issuer>
    ...
</saml:Assertion>
</samlp:Response>
```

Sample SAML 2 Response with the SubjectConfirmation and SubjectConfirmationData Elements

The following SAML 2 response uses the `SubjectConfirmation` and `SubjectConfirmationData` elements with the `NotOnOrAfter` and `Recipient` attributes.

```xml
<saml:SubjectConfirmationMethod="urn:oasis:names:tc:SAML:2.0:cm:bearer">
    <saml:SubjectConfirmation
        InResponseTo="SNC841720c227c81948cf6d68cad6235c6"
        NotOnOrAfter="2012-01-30T20:17:10Z"
        Recipient="https://demoi2.service-now.com/navpage.do"/>
</saml:SubjectConfirmation>
```

Sample SAML 2 Response with the AudienceRestrictions and Audience Elements

The following SAML 2 response uses the `AudienceRestrictions` and `Audience` elements with the `NotBefore` and `NotOnOrAfter` attributes.

```xml
<saml:ConditionsNotBefore="2012-01-30T19:57:10Z"
    NotOnOrAfter="2012-01-30T20:17:10Z">
    <saml:AudienceRestriction>
        https://demoi2.service-now.com/navpage.do</saml:AudienceRestriction>
</saml:Conditions>
```
SAML user provisioning

If users exist in your IdP but are not in your instance, SAML user provisioning can automatically create the users in your instance’s User [sys_user] table.

SAML user provisioning is supported for SAML 2.0 Update 1 when Multi-SSO is enabled.

How SAML user provisioning works

When SAML user provisioning is enabled and the system encounters a new user that is not in the instance, the instance automatically creates a record in a temporary table with the name u_imp_saml_user_<suffix>, where <suffix> is an automatically generated text identifier. The system also creates transform map that specifies the data relationships between the import table and the User table. Each IdP in identified in the system has its own transform map. The transform map is created once for each IdP. Administrators can update it as necessary.

When the user logs in, they access an IdP to log in.

- The system presents a list of all IdPs that are able to use SAML user provisioning. If there is only one IdP that can use SAML user provisioning, that one is used automatically.
- If none of the above conditions are true, the system uses the Auto Redirect IdP.

Administer SAML user provisioning

To update the User table with the users in your IdP, you must first set up field mapping and then enable user provisioning through Multi-SSO IdP settings.

Set up your IdP mapping to identify what fields in the IdP are mapped to the correct fields in the User table.

Role required: admin

1. Navigate to Multi-Provider SSO > Properties.
2. Select Enable Auto Importing of users from all identity providers into the user table (glide.authenticate.multisso.user.autoprovision) to activate this feature.
3. Click Save.
5. Open the SAML2 Update1 record.
6. To create a record in the User table when the user does not already exist, select Auto-provision Users. If you upgraded to this release, you need to configure the form and add this field.
7. To enable user records to be updated when users log in to the IdP and the information on the IdP is out of date with the information on the User table, select Update User Record Upon Each Login. If you upgraded to this release, you need to configure the form and add this field.
8. Click User Provisioning Transform Map to see the map that the system automatically creates.
9. Make changes to the map as needed.

When the first unknown user tries to log in, the system creates the fields in the import set table from the metadata.xml file.

Note: You cannot map the fields from the IdP table until this first user logs in.

SAML 2.0 troubleshooting

Before contacting support, try the troubleshooting solutions available in the knowledge base on Hi.

Note: The instance does not support solutions provided by external sites.

See the following knowledge base article: KB0540617 "SAML Error Matrix".
### Other Common Issues

<table>
<thead>
<tr>
<th>Error or Symptom</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error message: &quot;is not a function.&quot;</td>
<td>This error occurs because the plugin was not active and did not load the .jar file. Therefore, the code appears to be missing. Contact Technical Support to restart nodes that are missing the plugin.</td>
</tr>
<tr>
<td>SAML does not authenticate users accessing CMS pages.</td>
<td>By default, CMS pages are public and therefore do not require authentication. If you want SAML to authenticate CMS pages, change the <code>view_content.do</code> public page from <code>active=true</code> to <code>active=false</code>.</td>
</tr>
<tr>
<td>Cannot redirect a user back to a CMS page after SAML authentication.</td>
<td>By default, the SSO integration uses a URL parameter called <code>URI</code> to control where the user is directed after authentication at the IdP. SSO ignores relative URLs. For example, SSO cannot redirect users to a <code>/ess</code> relative URL. Instead, the user has to navigate to a URL such as <code>/nav_to.do?uri=/ess</code>, which uses deep linking syntax. However, this puts the ESS portal inside the main navigation content IFrame. In other words, the site does not take up the full page, but rather loads as a page in your instance. For more information, see CMS Sites and Single Sign-On. If you change the CMS entry page to make it private by setting <code>view_content.do</code> to <code>active=false</code>, deep linking behavior then requires a customization to the Installation Exit login script. Create a script that looks for the <code>URI</code> portion of the URL and constructs a <code>RelayState</code> URL parameter containing the relative URL path to redirect users after authenticating at the IdP.</td>
</tr>
<tr>
<td>SAML does not redirect users to the appropriate page after authentication.</td>
<td>Determine if the relay state is passed out to the IdP and then passed back during authentication. You can do this with a browser capable of saving HTTP request headers and POST info, such as Chrome with its built-in developer tools, or Firefox with the add-on called HTTPfox. For Internet Explorer, use a third-party application such as Fiddler. The goal is to watch the requests pass from the client (browser) to the instance, and from the client to the IdP.</td>
</tr>
</tbody>
</table>

**Monitor the event queue for login activities**

Every single sign-on integration creates events for login activities.

You can use these events to monitor for login failures and determine if there are any security concerns to address.

**Monitoring the event queue for login failures**

**Certificate-based authentication**

Certificate-based authentication lets you mutually authenticate user logins or inbound API requests using certificates from a trusted Certificate Authority (CA).

**Certificate-based authentication for user interface logins**
Enable end users to use PIV (Personal Identity Verification) or CAC (Common Access Card) cards to log in to the Now Platform or Service Portal instead of using a user name and password. To set up mutual authentication for user interface logins, see Set up Certificate-based authentication.

After Certificate-based authentication is set up, end users can finalize their setup and log in. See Log in using Certificate-based authentication.

Certificate-based authentication for Inbound web services

Authenticate inbound requests to ServiceNow SOAP and REST APIs. To set up mutual authentication for inbound web services, see Set up Certificate-based authentication.

Set up Certificate-based authentication

Set up mutual authentication for either user interface-based logins or inbound web services.

Role required: admin

Check that your instance is using an ADCv2 load balancer. For more information, see the ADCv2 Migration knowledge article. If your instance is not using the ADCv2 load balancer, contact Now Support.

Set up Certificate-based authentication in order to:

• Allow end users to securely log in to the Now Platform or Service Portal using PIV or CAC cards. After certificate-based authentication is enabled, you can self-register the PEM certificate or an administrator can map the certificate for you. See Log in using Certificate-based authentication.

• Enable mutual authentication for inbound web services. Once certificate-based authentication is set up, the system uses the provided certificates to mutually authenticate requests to access ServiceNow REST and SOAP APIs.

Activate Certificate-based authentication

You can activate the Certificate based authentication plugin (com.glide.auth.mutual) for Now Platform if you have the admin role.

Role required: admin

The following items are installed with Certificate based authentication:

• Scheduled jobs: Poll LB For Certificate Status
• Tables: sys_user_certificate, sys_ca_certificate, sys_ca_certificate_api_track

1. Navigate to System Applications > All Available Applications > All.
2. Find the Certificate based authentication plugin (com.glide.auth.mutual) using the filter criteria and search bar.
   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel. For more information, see Request a plugin.
3. Click Install, and then in the Activate Plugin dialog box, click Activate.

   Note: When domain separation and delegated admin are enabled in an instance, the administrative user must be in the global domain. Otherwise, the following error appears:
   Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.

Register CA certificate

Register root certificates or intermediate certificates to make them available for authentication.

Role required: admin

1. Navigate to Certificate Based Authentication > CA Certificate Chain.
2. Click New.
3. On the form, fill in the fields:

**Mutual Auth CA Certificate form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name to identify the certificate.</td>
</tr>
<tr>
<td>Expiration notification</td>
<td>Option to warn users when a certificate is about to expire.</td>
</tr>
<tr>
<td>Notify on expiration</td>
<td>List of users to be notified when the certificate expires.</td>
</tr>
<tr>
<td>Warn in days to expire</td>
<td>Number of days when a notification is sent to users before a certificate expires.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to make the client certificate active.</td>
</tr>
<tr>
<td>Format</td>
<td>PEM</td>
</tr>
<tr>
<td>Type</td>
<td>Type of certificate. Options include:</td>
</tr>
<tr>
<td></td>
<td>• CA Cert: The root CA certificate. Can also include intermediate certificates in the chain. CA certificates are automatically sync with the load balancer. Use this option when possible to avoid missing a required certificate in the chain.</td>
</tr>
<tr>
<td></td>
<td>• Intermediate Cert: An intermediate certificate in the certificate chain. This certificate remains on the instance only and is not sync with the load balancer. Only use this option if you need to add an intermediate certificate to an existing chain.</td>
</tr>
<tr>
<td>Short description</td>
<td>Short description of the user client certificate.</td>
</tr>
</tbody>
</table>

**Note:** During the certificate upload, the read-only fields, **Valid from, Expires, Expires in days, Issuer, and Subject, Certificate Chain, and PEM Certificate** are extracted and auto-populated.

4. Click **Submit**.

5. Optional: Click Validate Stores/Certificates to validate the certificate.

**Map PEM certificate to user**

Map PEM certificates to users to enable them to log in using PIV or CAC cards or to authenticate inbound requests. You can map multiple PEM certificates to a user.

- Role required: admin
- Make sure that you have the Privacy Enhanced Mail (PEM) certificate of the user.

1. Navigate to **Certificate Based Authentication > User to Certificate Mapping**, and click **New**.
2. On the form, fill in these fields:

**User Client Certificate form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the user client certificate.</td>
</tr>
<tr>
<td>Expiration notification</td>
<td>Option to warn users when a certificate is about to expire.</td>
</tr>
<tr>
<td>Warn in days to expire</td>
<td>Number of days when a notification is sent to users before a certificate expires.</td>
</tr>
<tr>
<td>Notify on expiration</td>
<td>List of users to be notified when the certificate expires.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to make the client certificate active.</td>
</tr>
</tbody>
</table>
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>User</td>
<td>User who is mapped to the client certificate. The system receives the client certificate from either the inbound request or certificate registration, and then uses the user designated in this field to initiate a session to execute the request.</td>
</tr>
<tr>
<td>Short description</td>
<td>Short description of the user client certificate.</td>
</tr>
<tr>
<td>Format</td>
<td>PEM. Privacy Enhanced Mail (PEM) format is a base-64 encoded Distinguished Encoding Rules (DER) certificate.</td>
</tr>
<tr>
<td>Type</td>
<td>Client cert. This field is read only.</td>
</tr>
</tbody>
</table>

**Note:** During the certificate upload, the read-only fields, **Valid from**, **Expires**, **Expires in days**, **Issuer**, and **Subject** are extracted and auto-populated.

3. Click the attachments icon and upload the certificate.
4. Click **Submit**. The certificate is validated and mapped to the specified user if the certificate is from a trusted Certificate Authority (CA).

Configure Certificate-based authentication properties
Configure Certificate-based authentication properties.

Role required: **admin**

1. Navigate to **Certificate Based Authentication > Properties**.
2. On the form, fill in the fields:

#### Certificate Based Authentication Properties form

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable certificate based authentication</td>
<td>Option to enable to certificate-based authentication for both user interface logins and inbound web services. Default: true</td>
</tr>
<tr>
<td>Show 'Log in with PIV/CAC' option in login screen</td>
<td>Displays the <strong>Log in with PIV/CAC card</strong> option on the login screen. Allows users to log in using certificate-based authentication using the user interface. Default: false</td>
</tr>
</tbody>
</table>

**Log in using Certificate-based authentication**

After your administrator sets up Certificate-based authentication, you can register the client certificate and log in using your PIV (Personal Identity Verification) or CAC (Common Access Card) card.

**Register client certificate for your PIV or CAC card**

Before you log in to Now Platform using your PIV or CAC card, you must register the client certificate of your PIV or CAC card. If you are not able to register the client certificate, contact your administrator. Your administrator can also register the client certificate of your PIV or CAC card.

- Make sure that certificate-based authentication is enabled.
- Make sure that a card reader is connected to your computer and your PIV or CAC card is inserted.
• Role required: none

1. Log in to Now Platform using your user name and password.
2. Click your name from the User Menu and select Profile.
3. From the Related Links, click Register client certificate. If a valid is certificate is available, the following message displays:

![PIV/CAC Certificate Found dialog box]

Register your PIV/CAC certificate to use it for future login

Certificate

PIVKey

[Cancel] [Register]
4. Click **Register**.

After the registration is successful, the following message displays:

The PIV/CAC certificate has been successfully registered and linked to the user account.

**Note:** If a certificate is already registered to you or other users, you cannot register the same certificate again to yourself.
The next time you log in to your Now Platform, you can log in using your PIV or CAC card. For more information, see Log in to Now Platform using PIV or CAC card.
Log in to Now Platform using PIV or CAC card

You can log in with your PIV or CAC card instead of user name and password when certificate-based authentication is enabled on Now Platform.

- Role required: none
- Make sure that certificate-based authentication is enabled.
- Make sure that a PIV or CAC card reader is connected to your computer.
- Make sure that a client certificate of your PIV or CAC card is mapped to you. For more information, see Register CA certificate.

1. Insert your PIV or CAC card into the card reader.
2. Navigate to your instance in a browser.
   Browser prompts for a PIN for your PIV or CAC card.
3. Enter the PIN of your PIV or CAC card in the browser prompt.
   
   **Note:** If you forget your PIN, contact your administrator.

4. If you enter a correct PIN, the browser displays a prompt to select a certificate.
5. Select a certificate from the browser prompt.
   If the certificate is valid and mapped to you, you are redirected to the login page.

6. Click **Log in with PIV/CAC card** button.
   To log out of the Now Platform, you must remove the PIV or CAC from the card reader and then close the browser.

**Limit concurrent sessions**

You can limit the number of concurrent interactive sessions for a user or role on an instance across all nodes.

Concurrent interactive sessions refer to the number of sessions a user can have active per ServiceNow instance. An active instance session occurs with every new login to a specific ServiceNow instance. By default, there are no limitations on the number of active instance sessions a user can have.

With the Jakarta release, you can limit the number of active concurrent sessions per user. When the user logs in after hitting the maximum number of sessions active, the oldest active session terminates and a new interactive session becomes active. If a user tries to access a closed session through a browser, the user is redirected to the login page.

**Note:** The **Limit concurrent sessions** plugin must be active to enable a maximum session limit. Limits are set through the glide.authenticate.max.concurrent.interactive.sessions property. A maximum limit value applies to any user or role that has the limit property active. A user or a role connected to the user must have...
A typical use case if a maximum concurrent session of 1 is set:

1. The user accesses the initial ServiceNow instance through Chrome.
2. After the user successfully logs in, ServiceNow creates session 1 (S1) for the user.
3. The user decides to initiate another access to the ServiceNow instance through Firefox.
4. After the user successfully logs in, ServiceNow creates session 2 (S2) for the user.
5. Since the user has a maximum concurrent session limit of 1, the S1 session invalidates when S2 is created.
6. When the user goes back through Chrome to access the S1 ServiceNow instance, the user is redirected to the login page as S1 is invalid.

Concurrent session limits work with all the ServiceNow authentication mechanisms: SAML, LDAP, and local database authentication. It also works with Multi-factor authentication and all interactive ServiceNow authentication mechanisms. The source of the session is viewable through the `sys_user_session` table, under the column `Type`. The values can be:

- Web Browser
- Mobile Browser
- ServiceNow Mobile App
- Non-interactive (SOAP, WSDL, OAuth)

**Activate and configure limit concurrent sessions plugin**

You can activate the Limit Concurrent Sessions plugin (com.glide.limit.concurrent.sessions) if you have the admin role.

Role required: admin

1. Navigate to **System Definition > Plugins**.
2. Find and click the Limit Concurrent Sessions plugin.
3. On the System Plugin form, review the plugin details and then click the **Activate/Upgrade** related link.
4. Click **Activate**.
5. To enable this feature and set a maximum limit of concurrent sessions, go to the Plugin Files tab, find the following properties, and change the setting values:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>glide.authenticate.limit.concurrent.interactive.sessions</code></td>
<td>You can enable the ability to limit concurrent sessions by setting the value to <strong>True</strong>. By default, this property is set to <strong>False</strong>, which means there is no limit on the number of interactive sessions a user can have active.</td>
</tr>
<tr>
<td><code>Note:</code></td>
<td><strong>To disable this feature, set this property back to False.</strong></td>
</tr>
<tr>
<td><code>glide.authenticate.max.concurrent.interactive.sessions</code></td>
<td>You can set the maximum number of concurrent active interactive sessions a user can have on the instance across all nodes.</td>
</tr>
</tbody>
</table>
6. Optional: You can also amend the following properties, if necessary:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| glide.authenticate.session.types.to.limit.concurrency | This property limits session types. By default, only the web browser sessions have a limit. Session types include:  
    • Web Browser (1)  
    • Mobile Browser (2)  
    • ServiceNow Mobile App (3)  
    • Non-interactive (10)  

You can configure and set the value to '1' for web browser, '2' for mobile browser, or '1,2' for both.

| glide.authenticate.limit.concurrent.sessions.across.all.nodes | This property restricts the limit of concurrent sessions per node instead of restricting them across all nodes of a ServiceNow instance. By default, the value is set to true, which limits user sessions across all nodes. If the property is set to false, only the sessions on that node and not the ones on the other nodes are subject to the limit. |

7. Click Update to have the settings take effect.

Set a concurrent session limit by user or role

You can set a concurrent session limit on a specific user or on a particular role.

Role required: admin

1. Navigate to User Administration > Users or User Administration > Roles.
2. Select a user or role that you want to set a concurrent session limit, check the Limit Concurrent Sessions check box, and click Update.
   The user or role has a limit of how many concurrent sessions can be open at one time.

Disable a concurrent session limit by user or role

You can disable a concurrent session limit on a specific user or on a particular role.

Role required: admin

1. Navigate to User Administration > Users or User Administration > Roles.
2. Select a user or role that you want to disable a concurrent session limit, uncheck the Limit Concurrent Sessions check box, and click Update.
   The user or role is not subject to a limit of how many concurrent sessions can be open at one time.
OAuth 2.0

OAuth 2.0 lets users access instance resources through external clients by obtaining a token rather than by entering login credentials with each resource request.

You must have the security_admin role to manage the OAuth integration. Configure OAuth 2.0 for the following scenarios:

- **OAuth external client scenario**: Your instance provides an endpoint for third-party clients to pull data from the instance.
- **OAuth provider scenario**: Your instance pulls data from a third-party provider.

Both the simple security and high security frameworks support OAuth 2.0. High Security is recommended. See for information about which versions have high security already active and how to activate high security.

### Key concepts of the OAuth 2.0 implementation

<table>
<thead>
<tr>
<th>Concept</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resource Owner</td>
<td>An entity capable of granting access to a protected resource. A resource owner who is a person is called an <em>end user</em>. The resource owner is always a user account.</td>
</tr>
<tr>
<td>Client</td>
<td>An application that, with the authorization of the resource owner, makes requests for protected resources on behalf of the resource owner.</td>
</tr>
<tr>
<td>Resource Server</td>
<td>The server that hosts the protected resources, capable of accepting and responding to requests for protected resources.</td>
</tr>
<tr>
<td>Authorization Server</td>
<td>The server that issues access tokens to the client after successfully authenticating the resource owner and obtaining authorization.</td>
</tr>
<tr>
<td>Authorization Request</td>
<td>The permission that a client requires to access a protected resource. The authorization request is always an HTTP POST message that contains the ID of the client that is acting on behalf of the resource owner and credentials that authorize the request.</td>
</tr>
<tr>
<td>Authorization Grant</td>
<td>A credential that represents the authorization from the resource owner to access a resource. The authorization grant is either user login credentials or a refresh token.</td>
</tr>
<tr>
<td>Access Token</td>
<td>A secure string that a client uses to access protected resources. An instance issues access tokens to clients that have a valid authorization grant. Each access token has a specific scope, lifespan, and other attributes. By default, an instance issues access tokens with a 30-minute lifespan in the scenario where the instance is the OAuth provider. For third-party tokens, 30 days.</td>
</tr>
</tbody>
</table>
### ServiceNow DocVersion Now Platform administration

<table>
<thead>
<tr>
<th>Concept</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Refresh Token</td>
<td>A credential that a client uses to obtain new access tokens without requiring additional user authorization. An instance issues a refresh token to a client when it is first authorized to have an access token. By default, an instance issues refresh tokens with a 100-day lifespan in the scenario where the instance is the OAuth provider. For third-party tokens, 365 days.</td>
</tr>
<tr>
<td>Self-signed certificates</td>
<td>The Now Platform does not support self-signed certificates. The OAuth client does not utilize the certificate trust store or allow connection to OAuth endpoints that incorporate a self-signed certificate.</td>
</tr>
<tr>
<td>User agent</td>
<td>The user who delegates access rights to a client application, which is often a website. The access rights permit the client application or website to access data in the instance that the user has access rights to. The user agent is used in the scenario.</td>
</tr>
</tbody>
</table>

### OAuth grant types

A **grant type** is the way that the client obtains the access token. The following grant types are supported:

- **Authorization code:** The consumer first gets an authorization code and then uses it to get an access token. You can Specify an OAuth profile and specify this grant type. The process that uses the authorization code is also referred to as **auth code flow** or **authorization code flow**.

- **Resource owner password credentials:** The consumer of the resource already has the user credentials to get the access token. This process is also referred to as **password flow**.

- **Client credentials:** The consumer of the resource uses the client ID and client secret that is already configured in the application registry.

### Storage of authentication credentials

The OAuth client secret is stored as a **password2** type field, which is encrypted in Triple DES. User passwords, which are used to check incoming endpoint requests, are stored as a hash value in the User table in a **password** type field (SHA 256).

### Set up OAuth

Set up and activate OAuth, enable the OAuth system property, create an OAuth application endpoint for external client applications to access the instance, and set OAuth parameters.

Role required: admin

1. Make sure the **OAuth plugin** is active and the **OAuth activation property** is set to true.
2. Create an OAuth application registry using one of the following methods:
   • Create an endpoint for external clients that want to access your instance. This creates an OAuth client application record and generates a client ID and client secret that the client needs to access the restricted resources on the instance.
   • Use a third-party OAuth provider that provides the authorization for access to your instance.
     Specify an OAuth profile and Specify an OAuth scope when you are connecting to another OAuth provider.

3. Configure your client applications to create an HTTP POST that requests an OAuth token. The application must also be able to parse the JSON response to use the returned access token and refresh token.

**Activate OAuth**
By default, the OAuth 2.0 (com.snc.platform.security.oauth) plugin is active on new and upgraded instances. If the plugin is not active on your instance, you can activate it.

Role required: admin
1. Navigate to System Applications > All Available Applications > All.
2. Find the plugin using the filter criteria and search bar.
   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel. For more information, see Request a plugin.
3. Click Install, and then in the Activate Plugin dialog box, click Activate.

**Note:** When domain separation and delegated admin are enabled in an instance, the administrative user must be in the global domain. Otherwise, the following error appears: Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.

**Set the OAuth property**
To generate OAuth 2.0 tokens to registered applications, the com.snc.platform.security.oauth.is.active property must be active for the instance.

Role required: admin
1. To use OAuth 2.0, enter sys_properties.list in the Workspace filter navigator and click New.
2. Fill out the form with the following settings:
   • Name: com.snc.platform.security.oauth.is.active
   • Type: true | false
   • Value: true

**Create an endpoint for clients to access the instance**
Create an OAuth application endpoint for external client applications to access the ServiceNow instance.

Role required: admin
1. Navigate to System OAuth > Application Registry and then click New.
2. On the interceptor page, click Create an OAuth API endpoint for external clients and then fill in the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Client ID</td>
<td>[Read-Only] The auto-generated unique ID of the application. The instance uses the client ID when requesting an access token.</td>
</tr>
<tr>
<td>Client Secret</td>
<td>[Required] The shared secret string that both the instance and the client application or website use to authorize communications with one another. The instance uses the client secret when requesting an access token. Leave this field blank to have the instance auto-generate a client secret. To display existing client secrets, click the lock icon.</td>
</tr>
<tr>
<td>Redirect URL</td>
<td>The callback URL that the authorization server redirects to. Enter the full URLs of the clients requesting access to the resource, appended by /oauth_redirect.do. For example, http://token_consumer:port/oauth_redirect.do. Enter as many URLs as needed for all possible token consumers. The instance matches the URL of the incoming request to one of the redirect URLs. If no match is made, the instance uses the first redirect URL.</td>
</tr>
<tr>
<td>Logo URL</td>
<td>The URL that contains an image to use as the application logo. The logo appears on the approval page when the user receives a request to grant a client application access to a restricted resource on the instance.</td>
</tr>
<tr>
<td>Active</td>
<td>Select the check box to make the application registry active.</td>
</tr>
<tr>
<td>Refresh Token Lifespan</td>
<td>The number of seconds that a refresh token is valid. The instance uses the lifespan value when requesting a refresh token. By default, refresh tokens expire in 100 days (8640000 seconds).</td>
</tr>
<tr>
<td>Access Token Lifespan</td>
<td>The number of seconds that an access token is valid. The instance uses the lifespan value when requesting an access token. By default, access tokens expire in 30 minutes (1800 seconds).</td>
</tr>
<tr>
<td>Comments</td>
<td>Additional information to associate with the application.</td>
</tr>
</tbody>
</table>

3. Click **Submit**. The record is saved in the Application Registries [oauth_entity] table.

The system creates a record in the Application Registries [oauth_entity] table with of type **OAuth Client**. When the instance actually issues tokens and authorization codes, they are stored in the table. See for more information.

**Configure an OAuth OIDC provider on the Now Platform**

You can configure an OAuth OIDC provider to accept identity tokens generated by a third-party OIDC provider using inbound API calls or our Single Sign-On option (Multi-Provider SSO).

Role required: admin
The Now Platform supports OIDC through our external Single Sign-On (SSO) implementation in addition to inbound API calls. For an example of an OIDC provider configuration, see setting up Azure AD. For an SSO-specific example of an OIDC provider configuration, see Create an OpenID Connect (OIDC) configuration for Single Sign-On (SSO).

1. Navigate to **System OAuth > Application Registry**
   - Click **New**, click **Configure an OIDC provider to verify ID tokens**, and then fill in the form.
   - Select an existing template for an OIDC provider (ADFS, Auth0, Azure AD, Google, Okta), and then fill in the form.

**Note:** OIDC provider templates are available after loading demo data with the OAuth 2.0 plugin.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name that identifies the OAuth OIDC entity.</td>
</tr>
<tr>
<td>Client ID</td>
<td>The client ID of the application registered in the third-party OAuth OIDC server. The instance uses the client ID when requesting an access token.</td>
</tr>
<tr>
<td>Client Secret</td>
<td>The client secret of the application registered in the third-party OAuth OIDC server.</td>
</tr>
<tr>
<td>OAuth API Script</td>
<td>A script you can use to customize requests and responses to an external OAuth provider.</td>
</tr>
<tr>
<td>OAuth OIDC Provider Configuration</td>
<td>The OIDC provider (ADFS, Auth0, Azure AD, Google, Okta) you can use to validate the JWT token. Click the record of your OIDC provider configuration to validate the <strong>User Claim</strong> and <strong>User Field</strong> are set appropriately. If you check <strong>Enable JTI claim verification</strong>, the ServiceNow JWT token validation also validates the JTI sent by the provider.</td>
</tr>
<tr>
<td>Clock Skew</td>
<td>The number, in seconds, for the constraint to be considered valid. The default is 300.</td>
</tr>
<tr>
<td>Comments</td>
<td>Additional information to associate with the application.</td>
</tr>
<tr>
<td>Application</td>
<td>The name of the application containing this entity.</td>
</tr>
<tr>
<td>Accessible from</td>
<td>Select an option to make it accessible from all application scopes, or this application scope only.</td>
</tr>
<tr>
<td>Active</td>
<td>Select the check box to make the OAuth application active.</td>
</tr>
<tr>
<td>Redirect URL</td>
<td>The URL of the OAuth application for receiving the authorization code.</td>
</tr>
<tr>
<td>End Session Endpoint URL</td>
<td>The URL endpoint which enables after a session ends.</td>
</tr>
<tr>
<td>Enable force authentication</td>
<td>Option to enable force authentication for users.</td>
</tr>
</tbody>
</table>
2. Click **Submit**. The record is saved in the Application Registries [oauth_entity] table. The system creates a record in the Application Registries [oauth_entity] table with type **External OIDC Provider**. When the instance actually issues tokens and authorization codes, they are stored in the table. See for more information.

3. Optional: Go to the related list on the record OAuth Entity Profiles to validate a system generated default profile for the new OAuth provider without any scope. You can change or add an OAuth provider profile including the name, grant type, and OAuth Scope.

4. Optional: Go to the related list on the record OAuth Entity Scopes to define all available OAuth scopes for this OAuth provider. The scopes defined can be selected when you create or update a profile. Each OAuth scope defined contains a name and a scope that you must get from the provider specification, such as a read-scope or a write-scope. Each scope must be defined separately.

5. Optional: Go to the related list on the record User Provisioning to enable automatic user provisioning.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Automatically provision users</strong></td>
<td>Option to enable force authentication for users.</td>
</tr>
<tr>
<td><strong>Provision data source</strong></td>
<td>The data source to use to transform an OIDC token to a ServiceNow user. Use the <strong>Lookup list</strong> to select the pre-defined data source template, then open the record to configure the Transforms table mapping. When configuring the Transform mapping, the source fields are from the <strong>JWT token</strong>, the target fields are from the <strong>sys_user</strong> table.</td>
</tr>
<tr>
<td><strong>User roles applied to provisioned users</strong></td>
<td>The user roles applied to the newly provisioned ServiceNow users.</td>
</tr>
</tbody>
</table>

**Connect to a third-party OAuth provider**

Configure how the client ID and secret are sent to your OAuth provider.

Role required: admin

1. Navigate to System OAuth > Application Registry and then click **New**.
2. On the interceptor page, click **Connect to a third-party OAuth provider** and then fill in the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Unique name for the third-party OAuth connection.</td>
</tr>
<tr>
<td>Client ID</td>
<td>The client ID of application registered in the third-party OAuth server.</td>
</tr>
<tr>
<td>Client Secret</td>
<td>The client secret of the application registered in the third-party OAuth server.</td>
</tr>
<tr>
<td>OAuth API Script</td>
<td>The script used to customize request and response to the external OAuth provider.</td>
</tr>
<tr>
<td>Logo URL</td>
<td>The OAuth application logo URL.</td>

</tr>
<tr>
<td></td>
<td>•  Basic Authorization header</td>
</tr>
</tbody>
</table>

The system creates a record in the Application Registries [oauth_entity] table with type **OAuth Provider**.

3. Optional: Go to the related list on the record OAuth Entity Profiles to validate a system-generated default profile for the new OAuth provider without any scope.
   You can change or add an OAuth provider profile including the name, grant type, and OAuth Scope.

4. Optional: Go to the related list on the record OAuth Entity Scopes to define all available OAuth scopes for this OAuth provider. You can select the scopes when you create or update a profile.
   Each OAuth scope contains a name and a scope that you must get from the provider's specification, such as a read scope or a write scope. Each scope must be defined separately.

*Change OAuth password parameter*

Use this property to insure only POST body parameters are accepted as input for all supported grant types.

Sending sensitive information over URI query parameters might lead to sensitive information disclosure by clients, the server, or any host between the requests. Starting with the Madrid release, this new property insures only the POST body parameters are accepted as input for all supported grant types. Supported grant types include:

- authorization code
• password
• client credential
• refresh token

**OAuth password parameter property**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.oauth.allow.parameters.in.post.body.only</td>
<td>This property is set to true for zBoots only, as part of the OAuth 2.0 plugin. If you need this setting for your instance, create and set the property to true.</td>
</tr>
</tbody>
</table>

**OAuth parameters for default profile support**

The default profile feature requires a set of parameters that you can use with the `setParameter()` API to specify the OAuth requestor, a context for the request, and the provider profile.

In the OAuth provider scenario, you must set three parameters that tell the OAuth provider which OAuth profile to use by default. When these three parameters are set, the access token is saved in the instance database. Use the parameters with `GlideOAuthClientRequest`.

**OAuth parameters for default profile support**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oauth_requestor</td>
<td>The sys_id of the object, which can be a user record or an email account.</td>
</tr>
<tr>
<td>oauth_requestor_context</td>
<td>Descriptor that provides context for the OAuth requestor. As a good practice, use the name of the table where the <code>oauth_requestor</code> object is saved.</td>
</tr>
<tr>
<td>oauth_provider_profile</td>
<td>The sys_id of the OAuth profile record that is the default (see Specify an OAuth profile).</td>
</tr>
</tbody>
</table>

You do not need to use parameters to set the grant type and scope because the values are configured in the OAuth profile record. If you do not use the parameters, you can use the `GlideOAuthClientRequest` methods `setScope` and `setGrantType`. For additional information, see `setScope` and `setGrantType`.

**OAuth API request parameters**

Access token requests use the following request parameters.

**Note:** The content-type of the OAuth API should be application/x-www-form-urlencoded. A content-type of application/json results in an unspecified error.
### Access token request parameters

<table>
<thead>
<tr>
<th>Request parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| grant_type        | [Required] The type of credentials authorizing the request for an access token. This parameter must have one of the following values:  
> • **password**: A set of user credentials authorize the access token request. Specify the user credentials in the username and password parameters.  
> • **refresh_token**: An existing refresh token authorizes the access token request. Specify the refresh token in the refresh_token parameter. |
| client_id         | [Required] Auto-generated unique ID of the client application requesting the access token. |
| client_secret     | [Required] Shared secret string that the instance and the OAuth application use to authorize communications with one another. |
| username          | User account name that authorizes the access token request. This parameter is required for access token requests with a grant_type of password. |
| password          | Password for the user account that authorizes the access token request. This parameter is required for access token requests with a grant_type of password. |
| refresh_token     | Existing refresh token that authorizes the access token request. This parameter is required for access token requests with a grant_type of refresh_token. |

### Requests Using User Credentials

The instance requires clients to provide user login credentials when first authorizing the client or when authorizing the creation of a new refresh token. This type of request always returns two tokens:  
- An access token  
- A refresh token

The instance verifies that the user is active, not currently locked out, and has an interactive session. If any of these conditions are false, the instance does not produce an access token. Access requests made within the expiration time of the access token always return the current access token.

**Note:** This type of authorization grant relies on TLS encryption to protect the user credentials during transmission.

The following example illustrates requesting an access token with a set of user credentials. (Spaces have been added to improve readability.)

```
$ curl -d"grant_type=password&client_id=be3aeb583ace210011c15b24a43e25d8&client_secret=client_password&username=admin&password=admin"
```
Requests Using a Refresh Token

The instance can use an existing refresh token to create a new access token. This type of request returns only an access token. The instance confirms that the refresh token has not expired before generating a new access token. Access requests made within the refresh token expiration time always return the current refresh token. Transmitting refresh tokens is generally more secure than transmitting user credentials. The following example illustrates requesting an access token with an existing refresh token. (Spaces have been added to improve readability.)

```
$ curl -d "grant_type=refresh_token&client_id=be3aeb583ace210011c15b24a43e25d8 &client_secret=client_password &refresh_token=w599voG89897rGVDmdp12WA681r9E5948c1CJTPi8q4HGc4NWaz62k6k1K0FMxHW40H8y0O3Hoe"
https://instancename.service-now.com/oauth_token.do
```

OAuth API response parameters

The OAuth 2.0 API produces a JSON response containing the following parameters as name:value pairs.

### Access token response parameters

<table>
<thead>
<tr>
<th>Response parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scope</td>
<td>Amount of access granted by the access token. The scope is always <strong>useraccount</strong>, meaning that the access token has the same rights as the user account that authorized the token. For example, if Abel Tuter authorizes an application by providing his login credentials, then the resulting access token grants the token bearer the same access privileges as Abel Tuter.</td>
</tr>
<tr>
<td>token_type</td>
<td>Type of token issued by the request as defined in the OAuth RFC. The token type is always <strong>Bearer</strong>, meaning that anyone in possession of the access token can access a protected resource without providing a cryptographic key. See RFC6750 for more information about how OAuth 2.0 uses bearer tokens.</td>
</tr>
<tr>
<td>expires_in</td>
<td>Lifespan of the access token in seconds.</td>
</tr>
<tr>
<td>refresh_token</td>
<td>String value of the refresh token.</td>
</tr>
<tr>
<td>access_token</td>
<td>String value of the access token. Access requests made within the access token expiration time always return the current access token.</td>
</tr>
<tr>
<td>format</td>
<td>[Optional] Output format of the response. This value is always JSON.</td>
</tr>
</tbody>
</table>

The following example illustrates the JSON string returned by an access token request. (Spaces have been added to improve readability.)

```
{"scope":"useraccount","token_type":"Bearer","expires_in":1800,"refresh_token":"w599voG89897rGVDmdp12WA681r9E5948c1CJTPi8q4HGc4NWaz62k6k1K0FMxHW40H8y0O3Hoe"}
```
OAuth authorization code grant flow

Authorization code grant flow allows a user to access a resource by authenticating directly with an OAuth server that trusts the resource, in contrast with authenticating with username/password credentials.

This implementation of OAuth authorization code flow allows access to a resource via REST. The authorization code framework gets the access token through the authorized URL that the user configures rather than requiring the user to enter a username/password. The username/password are never exposed to the client that is requesting access to the resource.

A ServiceNow instance as the authorization server

The OAuth server is typically a third-party authorization server. You can also specify a ServiceNow instance as the authorization server that issues the tokens for authorization code flow.

The user who owns the restricted resource must authorize access. The user can also revoke the issued access token at any time to terminate access.

Authorization code grant flow process

The Authorization code grant flow process consists of these three steps:

1. **Initial token request**
   - The client application or website initiates a REST API call in the form of a GET request to the instance via the user agent. Typically, the REST call is initiated when the end user clicks a button or a link on the client application or website to request an access token. In the client application, the end user also has to specify the authorization URL, token URL, client ID, and client secret. For an explanation of these items, see the field descriptions in this topic: Use a third-party OAuth provider. If the client asks for a grant type, the end user must select **Authorization Code**.
   
   Example GET request from the client application to the instance:
   
   ```
   https://myinstance.servicenow.com/oauth_auth.do?
   response_type=code&redirect_uri={the_redirect_url}&client_id={the_client_identifier}
   ```
Note: The response_type must be code to use the standard OAuth code grant flow.

The end user must manually allow access to the restricted resource on the instance. In the ServiceNow implementation, the end user must be logged into the instance. The instance prompts the end user with a UI page that has Allow and Deny buttons. See for instructions.

The item that the client application is actually requesting the token from is the OAuth provider application registry record that you created, also known as the authorization endpoint (see Use a third-party OAuth provider). The auth code is sent from the authorization endpoint to the client. It does not go to the client directly but to the Redirect URL that you specify on the authorization endpoint form. This URL is also known as a callback URL. You can obtain this URL from the client application or website.

Example response from the instance to the client application, providing an authorization code:

```
https/http://{callbackURL}?code={the actual auth code}
```

Now that the client application has the authorization code, the client uses the code to request the access token. The authorization code proves that the user has consented in step 1.

Example POST request from the client application to the ServiceNow instance that provides the auth code and requests the access token:

```
https://myinstance.servicenow.com/oauth_token.do?grant_type=authorization_code&code={the auth code}&redirect_uri={the_same_redirect_url}&client_id={the_same_client_identifier}&client_secret={client_secret_value}
```

The endpoint on the instance returns an access token and a refresh token. The refresh token can be used to request additional access tokens.

You can manage the tokens, including revoking the token, in the instance. See .
The client application uses the access token to authenticate to the REST API. After authenticating the client application, the REST API returns the requested data in a JSON payload.

Example GET request for the JSON payload of data for the Incident [incident] table:

```
https://myinstance.service-now.com/api/now/table/incident?
access_token={the_token}
```

**Note:** The system also supports, also known as implicit grant code flow.

### Integration support

Authorization code flow supports the following integrations on the instance:

- Multi-S SO
- SAML 2.0 Update 1
- Multifactor authentication

The mobile interface is also supported.

**OAuth implicit grants**

ServiceNow instances support the implicit grant of an access token.

The implicit grant type, also known as *implicit grant code flow*, allows the access token to be given directly to the client application via the user agent, which is typically the web browser or mobile device. No refresh tokens are granted. The end user must still grant access to the protected resource on the instance, just as with standard.

**OAuth implicit grant flow process**

Just as with the standard authorization code flow process, the client application makes a request to use the restricted resource on the instance and the end user approves it. The request is in the form of a URL sent to the instance. The URL must include the following parameters:

- `client_id=(the necessary client ID)`. This is **mandatory** to identify which protected resource the client application wants access to.
- `response_type=token`. This is **mandatory** to request the access token directly (as opposed to asking for an authorization code). The value must be `token` for implicit grants. In the standard authorization code flow example, the response type is `code`.
- `redirect_uri=[a URL]`: The location where the token is sent.
The authorization server sends the access token, rather than an authorization code, to client application via the user agent.

Here is an example GET request to receive the JSON payload of data for the Incident [incident] table:

```
https://myinstance.servicenow.com/oauth_auth.do?
response_type=token&redirect_uri={the_redirect_url}&client_id={the_client_identifier}
```

If the user grants access, the token is included in the redirect (callback) URL:

```
https/http://{callbackURL}?access_token={the_token}
```

**Authorize access to an OAuth endpoint using auth code flow**

End users who own a protected resource on the ServiceNow instance must authorize access to the resource before the instance can provide the access token.

You must already be logged in to the instance that holds the protected resource. Alternatively, you can log in using the authentication method (such as multi-factor authentication or SAML) that your ServiceNow administrator already set up.

1. Click the link or button on the client application where you are requesting access to the protected resource on the instance. This kicks off the token request.
   If you are making a REST call from one instance to another, this link is **Get OAuth Token** on the REST Message form.
2. If you are not logged in, log in now. If you are not the same user as the user specified in the upper-right corner, click **Not You?** and log in.
3. Click account permissions to open the list of access tokens that you have already issued. is the same as the **Self-Service > My connected apps** token list.
4. Click **Allow** to allow access and have the instance issue the authorization code (if using auth code flow) or the access token (if using implicit grant type). If you click **Deny**, the authorization is not allowed, but you are not logged out of the instance.

A message that confirms access should appear. If you are requesting access from the REST Message form on an instance, the following message appears at the top of the form: **OAuth Refresh token is available and will expire at {date}**.
Authorization code flow state parameter requirement
The glide.oauth.state.parameter.required system property enables the State parameter to be required in an OAuth request for authorization code flow.

State parameter
Beginning in the Madrid release, the system property glide.oauth.state.parameter.required adds a State parameter for an OAuth request. For zbooted instances, the property is true. For upgraded instances, the property is not present, so the State parameter is not enabled. The State parameter is a string value, and should not contain special characters. The State parameter cannot be empty or “”.

Validating the state parameter
Create an endpoint for clients to access the instance. Initiate an authorization code flow for oauth_auth.do. For example:

```plaintext
http://10.11.95.5:16001/oauth_auth.do?grant_type=authorization_code&client_id=e9dba45b380d1300e676ccc91cef468f&response_type=code
```
If you do not specify the state parameter in the request, you get an error and the authorization code is not returned. Missing State parameter in request.

Adding the State parameter to the request:

```plaintext
http://10.11.95.5:16001/oauth_auth.do?grant_type=authorization_code&client_id=e9dba45b380d1300e676ccc91cef468f&response_type=code&state=123
```
Adding the State parameter redirects you to the login screen and the regular authorization code flow returns the authorization code.

Note: The response URL contains the state parameter passed in the request. In the example, the added parameter is state=123.

If the authorization code flow starts from oauth_initiator.do:

```plaintext
http://10.11.95.5:16001/oauth_initiator.do?oauth_requestor_context=sys_rest_message&oauth_requestor=eab8341fec0d1300964f214a2c2fcf67&oauth_provider_profile=dfa8f01fec0d1300964f214a2c2fcf51&response_type=code
```
The State parameter is automatically added when redirected by oauth_auth.do.

```plaintext
http://10.11.95.5:16001/oauth_auth.do?response_type=code&state=-790938844&redirect_uri=http://10.11.95.5:16001/oauth_redirect.do&client_id=e9dba45b380d1300e676ccc91cef468f
```

Authorization code flow example: ServiceNow instance as authorization server
You can use an instance as an authorization server to issue tokens to a client using authorization code flow. This example uses two instances: one as the authorization server and the other as the client. One instance uses a REST call to request tokens from another instance.

You must Activate OAuth on both instances.

1. On the authorization server instance (running the Istanbul or later release), navigate to System OAuth > Application Registry and then click New.
2. Click Create an OAuth API endpoint for external clients.
3. Fill out the form fields for the OAuth application record as described in Create an endpoint for clients to access the instance.
Completing these steps sets up an authorization server. Follow the next steps to set up the client server.

4. On the client instance, navigate to System OAuth > Application Registry and then click New.

5. Click Connect to a third party OAuth Provider.

6. Fill out the form fields for the OAuth application record as described in Use a third-party OAuth provider.
Note the following field values:
- **Client ID**: Client ID of the application registry record that you created for the authorization server.
- **Default Grant type**: Select Authorization code.
- **Authorization URL**: URL of the instance that is the authorization server. Remember to append oauth_auth.do at the end of the URL.
- **Token URL**: URL of the instance that is the authorization server. Remember to append oauth_token.do at the end of the URL.
- **Redirect URL**: URL of this instance: the client server instance. Remember to append oauth_redirect.do at the end of the URL.

7. Create a profile for the record with the Authorization code grant type.
The client server is setup. You can now create an outbound REST message and get an OAuth token.

8. Navigate to System Web Services > Outbound > REST Message and then click New.

9. Fill out the form fields for the OAuth application record as described in .
Note the following field values:
- **Endpoint**: URL of the instance that is the authorization server.
- **Authentication type**: OAuth 2.0.
- **OAuth profile**: OAuth profile that you created for the client server.

10. On the REST message record, click Get OAuth Token.

11. Authenticate with the instance that provides the token—the method depends on the single-sign on integration. You might use:
- Your username and password that you use to authenticate to the instance.
- The username and password for the IdP if is enabled. Click Use External Login to access the IdP login screen.

    **Note**: In order to automatically get redirected to the IdP login page, you must set the glide.authenticate.external system property.
- Your code, if MFA is enabled.

12. Click Allow or Deny to complete the authorization and issue the tokens.
The process that follows is outlined in OAuth authorization code grant flow.

**Manage OAuth tokens**

Open OAuth tokens to provide access to restricted resources.

Role required: any user or admin

Only the tokens that the instance issues are available, not the tokens that the instance can receive to access third-party resources.

1. Navigate to one of the following menu options:
   - **Self-Service > My Connected Apps** to see the tokens that the instance created when you granted access to a resource on the instance.
• **System OAuth > Manage Tokens** to see all tokens. Only administrators can access this module.

2. Click the **Name** to open the token.
3. Click **Revoke Access** to prevent access to the restricted resource.
4. You can also view other information about the token, including the scope it allows access to and the expiration date.

**Revoke an OAuth token**

You might want to revoke an OAuth access or refresh token for security reasons.

Role required: admin

Revoking the token pertains to the situation where your instance acts as the OAuth resource server. You can revoke the token through a URL or by:

- Access your instance using `oauth_revoke_token.do` and append the access or refresh token.

  For example: `https://[Your_ServiceNow_Instance]:[port]/oauth_revoke_token.do?token=[access or refresh token] without the brackets [ ]`.

This endpoint access does not require authentication. The token in this request is marked as expired.

**Set up OAuth provider with JWT Bearer grant type**

JSON Web Tokens (JWTs) enable the capability to configure server-to-server API interactions between ServiceNow and external API providers without requiring any user intervention. This support enables IntegrationHub or other automated tasks using JWTs to configure API and Service integrations with different providers.

Role required: admin

The following tasks show how ServiceNow can be set up to use JWTs for OAuth 2.0 client authentication and authorization grants. ServiceNow is the OAuth client, and you can configure an OAuth provider, such as Box or Docusign.

1. **Upload Java Key Store certificate**
   - Attach a JKS certificate to your instance to use to enable the JWT client authentication.
2. **Configure a JWT signing key**
   - Create a JWT signing key to assign to your Java KeyStore (JKS) certificate.
3. **Create a JWT provider with a JWT signing key**
   - Add a JWT provider to your ServiceNow instance.
4. **Connect to a third-party OAuth provider**
   - Create a third-party OAuth provider with a JWT Bearer as the default grant type in the ServiceNow Application Registry.
5. **Specify an OAuth profile**
   - Open the OAuth entity profile of the OAuth provider and assign a JWT provider.

**Upload Java Key Store certificate**

You can attach a Java KeyStore (JKS) certificate to your instance to use to enable the JWT client authentication.

Role required: admin

1. Navigate to Multi-Provider SSO > x509 Certificate.
2. Fill in the form and click **Submit**:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name for your certificate.</td>
</tr>
<tr>
<td>Notify on expiration</td>
<td>Designate whom to notify when the certificate expires.</td>
</tr>
</tbody>
</table>
### Configure a JWT signing key

Create a JSON Web Token (JWT) signing key to assign to your Java KeyStore (JKS) certificate,

Role required: admin

1. Navigate to **System OAuth > JWT Keys**.
2. Fill in the form and click **Submit**:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name for your JWT Key signing configuration.</td>
</tr>
<tr>
<td>Signing Keystore</td>
<td>The keystore designated when signing the JWT.</td>
</tr>
<tr>
<td>Key ID</td>
<td>The Key ID (kid) helps identify which key is used when multiple keys are used to sign tokens.</td>
</tr>
</tbody>
</table>

**Note:** If you configure this field, the Key ID claim is included in the JWT. If you do not configure this field, your JWT will not have a Key ID claim.

<table>
<thead>
<tr>
<th>Signing Algorithm</th>
<th>The algorithm to use to sign with the JWT key. RSA 256 is the only algorithm available.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Signing Key Password</td>
<td>The password associated with the signing key.</td>
</tr>
<tr>
<td>Active</td>
<td>Designate that the JWT key alias is actively referenced from a JWT provider.</td>
</tr>
</tbody>
</table>

### Create a JWT provider with a JWT signing key

Add a JSON Web Token (JWT) provider to your ServiceNow instance.

Role required: admin

1. Navigate to **System OAuth > JWT Provider**.
2. Fill in the form and click **Submit**:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name for your JWT provider configuration.</td>
</tr>
<tr>
<td>Expiry Interval (sec)</td>
<td>The lifespan of the tokens, in seconds, generated by the JWT provider.</td>
</tr>
<tr>
<td>Signing Configuration</td>
<td>The ServiceNow JWT signing key configuration to apply.</td>
</tr>
</tbody>
</table>

### Generate a JSON Web Token (JWT)

Create a JSON Web Token (JWT) for representing claims securely between two parties on the Now Platform.
The GlideJWT API is a scoped, scriptable API which generates a JWT. There are three arguments necessary before generating the JWT:

- **Sys_id of JWT Provider**
- **JSON serialized header**
- **JSON serialized payload**

There are two JWT API scripts, JWTTokenInternal and JWTTokenRestricted, that you can use when configuring a JWT Provider. The JWTTokenRestricted script enables administrators to configure who can generate a JWT. The JWTTokenInternal script is read-only and enables only logged in users to generate a JWT.

To generate a JWT:

- **Create a JWT Key with a shared key (HMAC) or a signing keystore (RSA)**
- **Associate a JWT provider with the signing configuration referring a JWT key**

You can use the API to create your token. You can use standard and custom claims when configuring a JWT provider. You can pass dynamic header and payload claims as part of the generateJWT API signature.

Sample script to test API:

```javascript
var jwtAPI = new sn_auth.GlideJWTAPI();
var headerJSON = {  "kid": "a1234"  };
var header = JSON.stringify(headerJSON);

var payloadJSON = {  "jti": "testjti",  "iss": "testiss",  "sub": "testsub"  };
var payload = JSON.stringify(payloadJSON);

var jwtProviderSysId = "7a40dde2d5303300964fb7c8f3c14ab5";
var jwt = jwtAPI.generateJWT(jwtProviderSysId, header, payload);

gs.info("JWT:" + jwt);
```

**OAuth client APIs**

The OAuth client API provides methods to request and revoke OAuth tokens. The OAuth client provides these classes:

- **GlideOAuthClient**: Methods for requesting and revoking the refresh and access tokens.
- **GlideOAuthClientRequest**: Methods for handling client requests.
- **GlideOAuthClientResponse**: Methods for handling client responses.
- **GlideOAuthToken**: Methods for retrieving the access token and information about the access token.

You can also customize the OAuthUtil script include to intercept the request parameters and also parse the responses from external OAuth providers.

When using OAuth classes in a scoped script, use the `sn_auth` namespace identifier.

**Scoped OAuth APIs**

OAuth supports application scoping by providing access to all OAuth methods in the available OAuth classes using the `sn_auth` namespace identifier.

For example, the following code accesses the requestToken:
var OAuthClient = new sn_auth.GlideOAuthClient();
var tokenResponse = OAuthClient.requestTokenByRequest('TestClient', text);

When using these methods in the global scope, omit the `sn_auth` namespace identifier.

**Digest token authentication**

The digest token authentication passes user credentials and a digest token within an unencrypted HTTP header.

The instance reads the HTTP header value and compares its computed hash value of the digest token. If the computed hash value matches the digest token value, then the instance searches for a matching value in the User table. If there is a matching value in the User table, the instance considers the user pre-authenticated and logs the user in.

Digest token authentication is more secure than simple unencrypted HTTP headers because any accidental or intentional change to the unencrypted HTTP header produces a different hash value. If the hash value fails to match, the instance denies the user access to the requested instance. This prevents users from attempting to login with another user's credentials.

**Integration requirements**

A Digest Token Authentication integration requires:

- A web server
- SiteMinder or another single sign-on application to pre-authenticate the user on the local network
- A web page or portal that passes user credentials to the target instance in one of these formats
  - HTTP Header
  - URL parameter
  - Cookie
- A web page or portal that creates and passes a digest token to the target instance using one of these encoding techniques
  - SHA1
  - MD5

**Set up Digest Token Authentication**

Setting up digest token authentication involves generating an unencrypted HTTP header and token, then enabling an installation exit and configuring properties.

*Generate an unencrypted HTTP header*

The first step in setting up digest token authentication is to generate an unencrypted HTTP header.

Role required: admin

The system only accepts one HTTP header as the source of pre-authentication.

1. Choose an HTTP header that matches data from the User (sys_user) table.
2. Configure your single sign-on software or authentication portal to generate the desired HTTP header.

For example, here are some sample SiteMinder HTTP headers.

**Sample SiteMinder HTTP headers**

<table>
<thead>
<tr>
<th>User credential</th>
<th>Sample HTTP header</th>
<th>Matching sys_user field</th>
</tr>
</thead>
<tbody>
<tr>
<td>username</td>
<td>SM_USER</td>
<td>user_name</td>
</tr>
</tbody>
</table>
Generate a digest token
After generating an unencrypted HTTP header, generate a digest token for authentication.

Role required: admin

The system only accepts one HTTP header as the source of pre-authentication.

Configure your single sign-on software or authentication portal to generate an HTTP header to contain the digest token.

For example, here is a sample SiteMinder HTTP header.

```
Sample SiteMinder HTTP headers

<table>
<thead>
<tr>
<th>Sample HTTP header</th>
<th>Sample digest HTTP header</th>
<th>Sample HTTP headers with digest</th>
</tr>
</thead>
<tbody>
<tr>
<td>SM_User</td>
<td>DE_USER</td>
<td>SM_USER=joe.employee;DE_USER=K1Nr4lht86b9gEfcoiT0dU/=YLM0=</td>
</tr>
</tbody>
</table>
```

Typically, the authentication portal or web page runs the code to generate a digest token from the unencrypted HTTP header and includes the digest token in the URL to the target instance. See SNC Guru for code samples of generating a digest token.

Enable digest installation exit script
After generating a digest token for authentication, enable a digest installation exist script.

Role required: admin

The system uses an installation exit to identify and decode incoming digest tokens. By default, the installation exit uses SHA1 to compute a hash value.

1. Navigate to System Definition > Installation Exits.
2. Click DigestSingleSignOn.
3. Set Active to true.
4. Click Update.
5. To use MD5 for computing the digest token hash value, change this line: `var MAC_ALG ="HmacSHA1";` to this: `var MAC_ALG ="HmacMD5";`

Enter single sign-on system properties
After enabling a digest installation exist script, configure properties for single sign-on.

Role required: admin

If you are configuring digest token for multi-provider SSO, skip this step and enter the digest properties for multi-provider single sign-on. Set these properties to enable single sign-on with an unencrypted HTTP header.

1. Navigate to System Properties > Single Sign-on.
2. For Enable external authentication, select Yes.
3. For HTTP header name to look for an externally authorized user (e.g. for SiteMinder), enter the HTTP header you generated. For example, SM_USER.
4. For **HTTP header name to look for an externally authorized user (e.g. for Digest Encryption)**, enter the HTTP header you generated. For example, `DE_USER`.

5. For **Service-now.com field name to match against the incoming header**, enter the `sys_user` field that contains matching data. For example, `user_name`.

6. For **Secret passphrase for single sign-on (SSO) encryption/decryption**, enter the secret key (password) to use for encoding digest keys. For example, `SecretKey123`.

7. Click **Save**.

---

**Enter the digest properties for multi-provider single sign-on (SSO)**

After enabling a digest installation exist script, configure properties for multi-provider SSO.

Role required: admin

If you are not using multi-provider single sign-on, configure standard single sign-on properties.

1. Navigate to **Multi-Provider SSO > Identity Providers**.
2. Fill in the fields of Digest Properties form.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter the name of the digest token.</td>
</tr>
<tr>
<td>User</td>
<td>Enter the <code>sys_user</code> field that contains the matching data for the incoming header.</td>
</tr>
<tr>
<td><strong>HTTP Digest header name</strong></td>
<td>Enter the HTTP header you generated. For example, <code>DE_USER</code>.</td>
</tr>
<tr>
<td><strong>HTTP header name</strong></td>
<td>Enter the HTTP header you generated for your created digested token. For example, <code>SM_USER</code>.</td>
</tr>
<tr>
<td><strong>Secret Passphrase</strong></td>
<td>Enter the secret key to use for encoding digest keys. For example, <code>SecretKey123</code>.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Failed SSO Redirect field</td>
<td>Enter the URL to redirect users after a failed authentication.</td>
</tr>
<tr>
<td>External logout redirect</td>
<td>Enter the URL to redirect users after a logout.</td>
</tr>
<tr>
<td>Single Sign-on Script</td>
<td>Select MultiSSO_DigestedToken.</td>
</tr>
</tbody>
</table>

3. Click **Update**.

4. Set your Digest Token default to true.

When you set the default to true, this overwrites the system default digest token record associated to SSO. Once the first multi-provider SSO related IdP record activates, only records associated to multi-provider SSO will be used.

Digest token records which exist in digest properties table can be individually called by appending the `Sys_ID` of the IdP. For example, a digest token record in the following authentication URL:

```plaintext
```

**Test the integration**

This single sign-on method allows pre-authentication from URL parameters, HTTP headers, or cookies.

Role required: admin

- Verify users can sign-on from all methods.

For example:

- **URL Format**: `https://<instance_name>.service-now.com?SM_USER=joe.employee&DE_USER=KfNr4nlt86b9EfcoiT0dU/YLM0=
- **HTTP Header Format**: `SM_USER=joe.employee;DE_USER=KfNr4nlt86b9EfcoiT0dU/YLM0=
- **Cookie Format**: `'SM_USER=joe.employee; DE_USER=KfNr4nlt86b9EfcoiT0dU/YLM0="; expires=Fri, 27 Jul 2012 02:47:11 UTC; path=/`

**Create links for digest authentication**

After you set up digest token authentication, construct URLs to take users to a particular page or resource.

Role required: admin

- Create a URL to your instance and append the appropriate user (SM_USER) and digest (DE_USER) request parameters.

Example URLs are as follows:

```
https://demo.service-now.com/nav_to.do?uri=ess&SM_USER=itil&DE_USER=nqQ82LONE=YQnXpmqddxnsvsArrQ=
```

```
https://demo.service-now.com/nav_to.do?uri=incident.do?sys_id=9d385017c611228701d22104cc95c371&SM_USER=itil&DE_USER=Uj/HopjjPczCNPnN2xcCX17kQty4=```

```
http://demo.service-now.com/nav_to.do?uri=incident_list.do?sysparm_userpref_module=4dedbac7d0bbf538017a7f13c4a1f257%26sysparm_query=caller_id=javascript:gs.getUserID()^active=true^EQ&SM_USER=itil&DE_USER=Uj/HopjjPczCNPnN2xcCX17kQty4=
```

Note: If you are using request parameters inside a URI (nav_to.do?uri=), ampersands (&) are encoded as %26.

Sample digest token implementations

Here are several samples of creating a digest token.

Sample digest authentication implementations

<table>
<thead>
<tr>
<th>Digest built with</th>
<th>Secret key value</th>
<th>Hash method</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Java</td>
<td>abc123</td>
<td>SHA1</td>
<td>Sample Java Digest Algorithm for Encryption</td>
</tr>
<tr>
<td>C</td>
<td>Value of sharedKey parameter</td>
<td>Value of strEncryptionMethod parameter (SHA1 or MD5)</td>
<td>Sample C</td>
</tr>
</tbody>
</table>

Sample Java digest algorithm for encryption

This Java algorithm illustrates creating a digest token from an HTTP header.

This sample assumes:

- The web server supports Java
- The hash computation method is SHA1
- The secret key value is abc123
- The unencrypted HTTP header name is user_name

Change the Java code to use another hash computation mechanism (such as MD5), change the secret key value, or HTTP header name.

```java
import javax.crypto.Mac;
import javax.crypto.spec.SecretKeySpec;
import sun.misc.BASE64Encoder;

public class DigestTest {
    private static final String MAC_ALG = "HmacSHA1";
    public byte[] getDigest(String acct) {
        try {
            byte[] bkey = fKey.getBytes();
            byte[] data = acct.getBytes();
            Mac mac = null;
            try {
                mac = Mac.getInstance(MAC_ALG);
                mac.init(new SecretKeySpec(bkey, MAC_ALG));
            } catch (Exception e) {
                e.printStackTrace();
            }
            byte[] sig = mac.doFinal(data);
            String signature = new String(sig);
            System.out.println("value:" + acct);
            System.out.println("digested value: " + signature);
            return sig;
        } catch (IllegalArgumentException e) {
            e.printStackTrace();
        }
        return null;
    }
}
```
Sample C

This C class illustrates creating a digest token from three input parameters.

- `strEncryptionMethod` – lists the hash computation method (SHA1 or MD5)
- `message` – lists the value to be converted into a digest token
- `sharedKey` – lists the secret key

This sample assumes:

- The web server supports C
- Other code calls this class and passes the expected parameters

Sample Code

```c
private string digestData(string strEncryptionMethod, string message, string sharedKey ) {
    UnicodeEncoding myUnicodeEncoding = new UnicodeEncoding();
    byte[] messageBytes = System.Text.Encoding.ASCII.GetBytes(message);
    byte[] sharedKeyBytes = System.Text.Encoding.ASCII.GetBytes(sharedKey);
    byte[] hashedMessage;
    string b64SHA1Message;
    if (this.DEBUG) {
        TextBoxMessage.Text = message;
        TextBoxSecret.Text = sharedKey;
    }
    switch ((strEncryptionMethod)) {
        case "SHA1":
            HMACSHA1 hmacsha1 = new HMACSHA1();
            hmacsha1.Key = sharedKeyBytes;
            hashedMessage = hmacsha1.ComputeHash(messageBytes);
            b64SHA1Message = Convert.ToBase64String(hashedMessage);
            if (this.DEBUG) TextBoxDigest.Text = Convert.ToString(hashedMessage);
            break;
        case "MD5":
            HMACMD5 hmacmd5 = new HMACMD5(sharedKeyBytes);
            hashedMessage = hmacmd5.ComputeHash(messageBytes);
            b64SHA1Message = Convert.ToBase64String(hashedMessage);
            if (this.DEBUG) TextBoxDigest.Text = Convert.ToString(hashedMessage);
            break;
    }
    return b64SHA1Message;
}
```
default :
    b64SHA1Message = "Unknown Encryption Method"; break;
}

TextBoxBase64.Text = b64SHA1Message; return b64SHA1Message;

**REST API access policies**

REST API access policies allow you to restrict access to inbound ServiceNow REST APIs based on the authentication type and the specified filter criteria of the access policy. Filter criteria contains filter conditions or queries that are used as policy inputs for an authentication policy. You can configure the default Global Blocking Policy or create a custom API access policy according to your security requirements.

For example, you can create a custom API access policy that allows only OAuth 2.0 authentication type from a specified range of IP addresses. Authentication requests of other authentication types and access requests from IP addresses other than the specified IP addresses are denied.

**Activate REST API access policy**

You can activate the REST API Access Policy plugin (com.glide.rest.policy) if you have the admin role. The application includes demo data and installs related ServiceNow® Store applications and plugins if they are not already installed.

Role required: admin

The following items are installed with REST API Access Policy:

- Plugins: com.glide.auth.profile, com.snc.adaptive_authentication, com.snc.platform.security.oauth
- Tables: sys_api_access_policy, sys_auth_profile_mapping, auth_policy_mapping, inbound_auth_profile, std_http_auth.

For more information, see Adaptive authentication.

1. Navigate to **System Applications > All Available Applications > All**.
2. Find the REST API Access Policy plugin (com.glide.rest.policy) using the filter criteria and search bar.
   - You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel. For more information, see Request a plugin.
3. Click **Install**, and then in the Activate Plugin dialog box, click **Activate**.

   **Note:** When domain separation and delegated admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.

**Create an authentication profile**

Create an authentication profile and add one or more authentication policies to the profile. You can also configure the **ID Token** and **OAuth Token** authentication profiles that are available by default.

Role required: admin

1. Navigate to **System Web Services > API Access Policies > Inbound Authentication Profiles**.
2. Click **New**.
The system displays the message "What kind of authentication profile?"

3. Select **Create standard http authentication profiles**.
4. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name to identify the authentication policy.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the authentication policy.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to make the authentication policy active.</td>
</tr>
<tr>
<td>Application</td>
<td>Scope of the authentication policy.</td>
</tr>
<tr>
<td>Type</td>
<td>Type of the authentications available. You can select Basic Auth, ID Token, or OAuth.</td>
</tr>
<tr>
<td>OAuth Entity</td>
<td>OAuth Entity profile. This field appears only when ID Token or OAuth is selected from Type.</td>
</tr>
</tbody>
</table>

5. Double-click **Insert a new row**.
6. Select an authentication policy from the list and click the save icon.

**Note:** Do not select Allow Access Policy or Deny Access Policy. These policies are meant only for user logins.

You can add one or more authentication policies for an authentication profile.

**Create REST API access policy**

Create an API access policy and map an authentication profile to restrict the authentication type for a REST API. For example, you can create an API access policy that allows only ID token authentication for a REST API.

- Role required: admin
- Make sure that an authentication profile is created. For more information, see Create an authentication profile.

1. Navigate to **System Web Services > API Access Policies**.
2. Click **New**.
3. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Unique name of the API access policy.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Active</td>
<td>Option to make the API access policy active.</td>
</tr>
<tr>
<td>REST API</td>
<td>The REST API to which the access policy is applied. For example, Attachment API.</td>
</tr>
<tr>
<td>REST API PATH</td>
<td>API path of the REST API. This field is auto-populated based on the selected REST API. For example, now/attachment.</td>
</tr>
<tr>
<td>HTTP Method</td>
<td>Method used for interacting with the API. This field is auto-populated based on the selected REST API.</td>
</tr>
</tbody>
</table>
| Version        | Version of the API. For example, v1. This field is auto-populated based on the selected REST API.  
                  | **Note:** If you want to create an authentication policy for all versions of a REST API, you must create individual policies for each version. |
| Resource       | Child resource of the REST API. This field is auto-populated based on the selected REST API. For example, /now/attachment |
| Application    | Scope of the application.                                                   |

4. Double-click **Insert a new row**.
5. Select an inbound authentication profile from the list and click the save icon

You can add one or more inbound authentication profiles.

**Filter criteria for APIs**

Filter criteria contains filter conditions or queries that are used as policy inputs for an authentication policy. Policy inputs are used to group one or more filter criteria and define the policy conditions of an authentication policy. For example, an IP Filter Criteria define an IP address in the Classless Inter-Domain Routing (CIDR) format or a range of IP addresses.

You can create filter criteria based on the user's IP address, role, and the user group to which they belong.

**Note:** You also use the filter criteria created from the **Adaptive Authentication** module. For more information, see Adaptive authentication.

**Create IP filter criteria for APIs**

IP filter criteria allows you filter users based on their IP addresses. You can configure an authentication policy to grant or block access to a specific address or range of addresses.

Role required: admin

1. Navigate to **System Web Services > API Access Policies > Filter criteria**.
2. Click **New**.
   - The system displays the message **What kind of Policy Input (Filter Criteria) do you want to create?**
3. Select **IP Filter Criteria**.
4. On the form, fill in these fields.
### IP Filter Criteria form

<table>
<thead>
<tr>
<th>Filed</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name to identify the IP network.</td>
</tr>
<tr>
<td>Description</td>
<td>Short description of the IP network.</td>
</tr>
<tr>
<td>Application</td>
<td>Scope of the application.</td>
</tr>
</tbody>
</table>

5. Right-click the form header and click **Save**.
6. From the IP Collections tab, click **New**.
The system displays the message **What kind of IP collection do you want to create?**.
7. Select an IP collection.

<table>
<thead>
<tr>
<th>IP Collection</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP Range</td>
<td>A range of IPv4 addresses. For example, 192.0.2.0 - 192.0.2.255.</td>
</tr>
<tr>
<td>Subnet</td>
<td>Subnet or subnet mask of an IP network. For example, 255.255.255.0.</td>
</tr>
<tr>
<td>IP Address List</td>
<td>A list of individual IPv4 addresses.</td>
</tr>
</tbody>
</table>

Create an IP collection for APIs
An IP collection can be a range of IP addresses, list of IP addresses or a subnet.
Role required: admin

1. Navigate to **System Web Services > API Access Policies > Filter Criteria**.
2. Open an IP Filter Criteria record.
3. From the **IP Collections** tab, click **New**.
4. Select an IP collection.

<table>
<thead>
<tr>
<th>IP Collection</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP Range</td>
<td>A range of IPv4 addresses.</td>
</tr>
<tr>
<td>Subnet</td>
<td>Subnetwork of an IP network.</td>
</tr>
<tr>
<td>IP Address List</td>
<td>A list of individual IPv4 addresses.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>IP Range</strong></th>
<th><strong>IP Address List</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Field</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>Name</td>
<td>Name to identify the IP range.</td>
</tr>
<tr>
<td>Description</td>
<td>Short description of the IP range.</td>
</tr>
<tr>
<td>Start IP</td>
<td>Starting IP address in a range of addresses. For example, 192.168.0.0</td>
</tr>
<tr>
<td>End IP</td>
<td>Ending IP address for a range of addresses. For example, 192.168.0.24</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Subnet form</strong></th>
<th><strong>IP Address List</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Field</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>Name</td>
<td>Name to identify the subnet.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>Description</td>
<td>Short description of the subnet.</td>
</tr>
<tr>
<td>Network IP</td>
<td>Network IP of the subnet.</td>
</tr>
<tr>
<td>Netmask</td>
<td>Subnet mask or netmask of the subnet.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name to identify the IP address list.</td>
</tr>
<tr>
<td>Description</td>
<td>Short description of the IP address list.</td>
</tr>
</tbody>
</table>

Create role filter criteria for APIs

Role filter criteria allows you to filter users based on roles. You can configure an authentication policy to grant or block access to a list of user roles.

Role required: admin

2. Click New.
   - The system displays the message What kind of Policy Input (Filter Criteria) do you want to create?
3. Select Role Filter Criteria.
4. On the form, fill in these fields.

   **Role Filter Criteria form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name to identify the role.</td>
</tr>
<tr>
<td>Application</td>
<td>Scope of the application.</td>
</tr>
<tr>
<td>Description</td>
<td>Short description of the role.</td>
</tr>
</tbody>
</table>

5. From the Roles for criteria, double-click Insert a new row.
6. Click the search icon
   - look up, and select a role.
7. Click the save icon
   - You can add one or more roles similarly.
8. Add a condition. For more information, see Create a condition statement using the condition

Create group filter criteria for APIs
Group filter criteria allows or denies user access based on the user group to which the user belongs.

Role required: admin

2. Click New.
   The system displays the message What kind of Policy Input (Filter Criteria) do you want to create?
4. On the form, fill in these fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name to identify the group.</td>
</tr>
<tr>
<td>Description</td>
<td>Short description of the group.</td>
</tr>
<tr>
<td>Application</td>
<td>Scope of the application.</td>
</tr>
</tbody>
</table>

5. From the Groups for criteria tab, double-click Insert a new row.
6. Click the search icon

look up, and select a user group.

7. Click the save icon

API Authentication Policies

Authentication policies evaluate authentication requests based on the specified policy conditions and either allows or denies access depending on the matching criteria.

You can use the built-in Global Blocking Policy or create an authentication policy according to your security requirements. Global Blocking Policy denies the authentication requests of users and APIs based on the specified filter criteria.

Note: Do not use or modify Allow Access Policy and Deny Access Policy. These policies are meant only for user logins.

Create an API authentication policy

Authentication policies allow you to enforce access restrictions on the APIs based on the specified filter criteria.

Role required: admin

1. Navigate to **System Web Services > API Authentication Policy**.
2. Click **New**
3. On the form, fill in these fields.

<table>
<thead>
<tr>
<th>Policy form</th>
</tr>
</thead>
<tbody>
<tr>
<td>Field</td>
</tr>
<tr>
<td>Name</td>
</tr>
<tr>
<td>Description</td>
</tr>
<tr>
<td>Application</td>
</tr>
</tbody>
</table>

4. Right-click the form header and select **Save**.
5. From the Policy Inputs tab, select **Edit** to add the existing Filter Criteria.
   You can also create a new Policy Input. For more information, see **Create policy inputs**.
6. Move one or more filter criteria from the Collections list to the Policy Inputs

- Add Filter
- Run filter

-- choose field -- ▼  -- oper -- ▼  -- value --

**Collection**

- Blocked IPs

</tr>
</tbody>
</table>
10. Select **Submit**.

**Configure global blocking policy for APIs**
Global blocking policy denies the authentication requests of users and APIs based on the specified policy conditions. This policy can be used as an alternative to the IP Address Access Control.

Role required: admin

1. Navigate to **System Web Services > API Access Policies > Global Blocking Policy**.
2. From the **Policy Inputs** tab, click **Edit**.
3. Select one or more filter criteria from the **Collection** list and move them to **Global Blocking Policy** list. You can also add additional filters.
4. From the **Policy Conditions** tab, click **New**.
5. On the form, fill these fields:

<table>
<thead>
<tr>
<th>Condition Form</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Field</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>Label</td>
<td>Name to identify the condition.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the condition.</td>
</tr>
<tr>
<td>Condition</td>
<td>Logical combination of multiple policy inputs(filter criteria) that is used to evaluate authentication requests. For example, you can create conditions that allow only contractors from a list of trusted IP addresses.</td>
</tr>
</tbody>
</table>

**Multifactor authentication (MFA)**
MFA, also known as two-step verification, is a security requirement that asserts a user enter more than one set of credentials to authenticate to an instance.

The basic level of authentication to an instance is local database authentication where a user enters a username and password combination. MFA gives administrators and users the ability to require a second level of authentication where a user must enter a passcode or token in addition to the password. A mobile application on a user mobile device generates the passcode.

- Users can require MFA for their own login credentials.
- Administrators can require MFA for any user login credentials or specific roles.

**Supported authentication methods**

- You can use MFA with the following authentication methods:
  - Local Database Authentication (native ServiceNow authentication)
  - LDAP integration
Authentication methods that are not supported

- MFA does not support with the following authentication methods:
  - SSO SAML
  - SSO Digest

Administrator MFA authentication flow

**Note:** If a user performs a password change while MFA is enabled on the user profile, the user does not need to enter the authorization code.

1. The administrator goes to a user profile or role in the instances and initiates MFA.
2. The instance displays a QR code and a QC code number.
3. Using a compatible authenticator, scan the QR code with the authenticator, or manually enter the QC code number in the MFA registration screen.
4. A Time-based One-time Password (TOTP) code generates and displays within the authenticator application along with your associated ServiceNow instance name and username.
5. For every subsequent login, enter the TOTP code generated from your authenticator application in the MFA challenge screen that displays after you enter your username and password.
6. If the challenge is correct, the user authenticates to the instance.

You can also skip the MFA challenge screen and directly logon to the instance:

1. You can also append your TOTP code to your password from the initial login screen. If your password is 'XXX' and your TOTP code is '123', you can enter 'XXX123' as your password to skip the MFA challenge screen.
2. If the username, password, and passcode combination are correct, the MFA challenge screen does not appear and the user directly logs into the instance.

MFA FAQs

<table>
<thead>
<tr>
<th>Questions</th>
<th>Answers</th>
</tr>
</thead>
<tbody>
<tr>
<td>What if I do not own a smart phone?</td>
<td>If you do not have access to a smart phone, you can use the Chrome browser Authy extension to set up and use MFA. Download and add the extension to your Chrome browser. Then, set up an Authy account and password with the Chrome extension before you set up MFA with it.</td>
</tr>
</tbody>
</table>
### Questions

<table>
<thead>
<tr>
<th>Questions</th>
<th>Answers</th>
</tr>
</thead>
</table>
| I use Firefox instead of Chrome. Is there an Authy plug-in for Firefox that I can use? | Currently, Firefox does not support the browser-based Authy plug-in. However, you can install the Authy plug-in through the Chrome browser. You can use the Authy app standalone (without using the Chrome browser) for generating the code to use in Firefox to log on to ServiceNow MFA-enabled applications.  

**Note:** After you install Authy, you must select the Multi-Device option from the Devices section. |
| What if I do not have a smart phone while logging in?                     | After the initial pairing, if you do not have your smart phone available, you can email yourself a code to log in.  

| Can I enter the code and my password in one login screen instead of two different screens? | Yes. After initial setup, you can enter your password followed by the 6-digit code in the first login screen to log in. |
| What if I must change devices and re-pair or reenter the code into a different mobile device? | Go to your user profile in the ServiceNow instance under My Profile and click multi-factor authentication to get access to the code to reenter and pair your device. |
| What should I do if my authenticator code obtained from Authy is not working on my computer? | Update the preference on your computer to set the time automatically to generate the correct code. If you manually set the time on your laptop, a time difference could cause the codes to fail. After you sync the time on your laptop, the app confirms that the time syncs and you can use your verification codes to sign in.  

**Note:** The sync only affects the internal time of your authenticator app and does not change the date and time settings on your device. |
| Can I turn it off?                                                        | No, when an administrator enables MFA, a user cannot disable it. |

For help or questions with MFA, contact your ServiceNow administrator.

### Activate the MFA plugin

The Integration - Multifactor Authentication plugin is active by default.

Role required: admin

1. Navigate to **System Applications > All Available Applications > All**.
2. Find the Integration - Multifactor Authentication plugin plugin () using the filter criteria and search bar.
   
   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel. For more information, see Request a plugin.
3. Click **Install**, and then in the Activate Plugin dialog box, click **Activate**.

**Note:** When domain separation and delegated admin are enabled in an instance, the administrative user must be in the global domain. Otherwise, the following error appears: Application...
Configure multifactor authentication (MFA)

You can enable and customize MFA to meet your security requirements.

To learn more about MFA, see Enable multi-factor authentication (MFA) (instance security hardening) in Instance Security Hardening Settings.

Role required: admin

1. Navigate to **Multi-factor Authentication > Properties**.
2. Configure these properties:

**Multifactor authentication properties**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable Multifactor authentication (glide.authenticate.multifactor)</td>
<td>Option that enables users and administrators to use this feature. The default is enabled. To learn more about this property, see Enable multi-factor authentication (MFA) (instance security hardening) in Instance Security Hardening Settings.</td>
</tr>
<tr>
<td>Number of times a user can bypass multi-factor authentication (glide.authenticate.multifactor.setup.bypass.count)</td>
<td>Number of times that a user can choose to skip the setup of MFA. Your users can still log in to your instance even if they don't have their mobile device with them. If you disable this feature and then reenable it, the counter starts over again. The default is 3.</td>
</tr>
<tr>
<td>The time in minutes the one-time code sent to user's email address is valid for (glide.multifactor.onetime.code.validity)</td>
<td>Number of minutes that the reset code is valid. See Log on with multifactor authentication. The default is 10.</td>
</tr>
<tr>
<td>Additional time in seconds for which the code will be valid to accommodate for the clock skew. The maximum value is 60 seconds. (glide.authenticate.multifactor.clock_skew)</td>
<td>Number of additional seconds that the reset code is valid. The maximum is 60. The default is 10. The instance validates the code entered by the user against the single app-generated code that is generated at the current time. You can skew the time window with this property and allow one or more codes to be generated during a time window to be considered valid. The property’s value is used in the following calculation: current time - x/2 and current time + x/2, where x is the value of this property. If you use the value of 10, for example, the instance considers any codes that are generated by the app between the time range [current time - 5 seconds] and [current time + 5 seconds] to be valid. Use this property to prevent login issues where the user is unable to enter the correct code in the default time allotted.</td>
</tr>
<tr>
<td>Enable remember browser feature for multi-factor authentication.</td>
<td>Set your instance to prompt a user for MFA when they log in from a new device or browser. The default is yes.</td>
</tr>
</tbody>
</table>
3. Click **Save**.

**Tested third-party authenticators with MFA**

Users must install and use an authenticator that supports Time-based One-time Password (TOTP) to generate a temporary MFA passcode.

**Tested third-party authenticators**

Users should install the recommended authenticator to their mobile devices. MFA has been tested with the following authenticators:

- Google Authenticator
- Microsoft Authenticator
- LastPass Authenticator
- Authy
- FreeOTP
- Duo
- Okta Verify

**Note:** Other authenticators not listed might also be compatible.

**Logging into your instance using MFA**

You can log into your instance with your credentials and a generated passcode.

1. Go to your instance login screen and enter credentials.  
   An MFA registration screen displays with a QR code and a QC code number.
2. Using a compatible authenticator, scan the QR code with the authenticator, or manually enter the QC code number in the authenticator application.  
   A TOTP code generates and displays within the authenticator application associated to your ServiceNow instance.
3. For every subsequent login, enter the TOTP code generated from your authenticator application in the MFA challenge screen that displays after you enter your username and password.

**Note:** You can also append your TOTP code to your password from the initial login screen. If your password is ‘XXX’ and your TOTP code is ‘123’, you can enter ‘XXX123’ as your password to skip the MFA challenge screen.

If you properly enter your credentials and current passcode, you should authenticate to the instance.

**Require MFA for a user**

Enable MFA for any user record in the system that you have access to.
Role required: admin

1. Navigate to User Administration > Users.
2. Configure the list to show the Enable Multifactor Authentication column.
3. Change the values of the Enable Multifactor Authentication column for the selected users to true.

When the user logs in with their username and password, they are prompted to set up multifactor authentication.

Enable MFA for high privileged roles

Automatically enable and enforce MFA for users who have high privileged roles that you have access to.

Role required: admin

All users designated with a high privileged role go through MFA before authenticating into the instance. This functionality also makes it easier to administrate MFA for many users based on their roles instead of enabling MFA for them at a per user level.

2. Select Role based multi-factor authentication.
3. Check the Active box.
4. Click Update to save.

When the user with the designated role logs in with their user name and password, they are prompted to set up MFA.
Set up multifactor authentication upon initial login

If your administrator enabled multifactor authentication on your profile but you have not yet set up the application, you can set it up upon login.

Role required: none

1. Log into your instance using your username and password. The multifactor authentication setup screen intercepts your login.

Enable multi-factor authentication

1. Download the Authenticator app for your mobile device
2. Open the app and scan the QR code below to pair your mobile device
3. Enter the code generated by the Authenticator app below

- Apple iTunes
- Google Play
- Windows store

6-digit code

Pair device and Login
2. If you want to skip the authentication setup at this time, click **Bypass Setup**. You can bypass multifactor authentication for a limited number of times that your administrator allows. Eventually you need to configure multifactor authentication.

3. If you do not yet have the Google Authenticator application in your mobile device, you can download it from one of the links provided under **Download the app**.

4. Take a photo of the QC code with the Google Authenticator application or enter the string in the application manually.

5. Enter the code and click **Pair device and log in**.

   The application responds with a six digit code that refreshes every 30 seconds. If you entered the correct code, a message appears telling you that Multifactor Authentication is set up. If you entered an invalid code, look for the code on your mobile device again as it may have refreshed, and enter the code that you see.

   **Note:** For the code to work properly, the system time on your computer must be in the same time zone as the time on your mobile device.

---

Log on with multifactor authentication

After multifactor authentication is enabled for your User profile, you can log in with the addition of the passcode that the Google Authenticator app gives you.

You must have multifactor authentication enabled for your profile. You can enable it yourself on your user profile or your administrator can enable it for you.

Role required: none

1. Go to the URL of your instance to open the log in screen.

2. Open the Google Authenticator application on your mobile device and make note of the number. The number refreshes every 30 seconds.

3. Enter your username and password, and append the passcode that you currently see on your mobile device to your password without any extra spaces. For example, if your password is **12345** and the current passcode is **424 058**, enter **12345424058**.

   If you forget to enter the code and you only enter the password, you are prompted to enter the code in a new window.

4. Enter the code and click **Login**.

5. If you do not remember the passcode, click the **Click to send one-time passcode** link.

   The temporary passcode is sent to your email address. You can append this passcode to your password as you would the original passcode. You can only use this temporary passcode once and it is only valid for 10 minutes.
Note: You must have an email address configured in your user profile on the instance to receive this email message.

Set up multifactor authentication on your own profile

You can set up multifactor authentication on your own User profile.

Role required: none

Note: If you are trying to reset multi-factor authentication, log in to the instance first by requesting the temporary code via email, and then follow the steps below.

1. Navigate to Self-Service > My Profile.
2. Click the Multifactor Authentication related link on your User record.

The multifactor authentication window appears.

Complete the steps below to enable multifactor authentication

1. Download the app
   - Apple iTunes
   - Google Play
   - Windows Store

2. Scan the QR Code:

3. Type in the App’s response:
   - 6 digit response
   - Validate Response
3. If you do not yet have the Google Authenticator application in your mobile device, you can download it from one of the links provided under **Download the app**.

4. Take a photo of the QC code with the Google Authenticator application or enter the string in the application manually.

5. Enter the code and click **Validate Response**.

   The application responds with a six digit code that refreshes every 30 seconds. If you entered the correct code, a message appears telling you that Multifactor Authentication is set up. If you entered an invalid code, look for the code on your mobile device again as it may have refreshed, and enter the code that you see.

   **Note:** For the code to work properly, the system time on your computer must be in the same time zone as the time on your mobile device.

### Disable multifactor authentication on an admin user profile

Only admins can disable multifactor authentication on their own user profile, as long as MFA is not required for the admin role.

**Role required:** admin

1. Log in the instance using your multifactor authentication code appended to your password.
2. Navigate to **Self-Service > My Profile**.
3. Click the **Multifactor Authentication** related link on your User record.
4. Click **Disable Multifactor Authentication**.
5. Confirm the action.

   You return to the user record. The setting is automatically saved. You do not need to save your User record again.

### Disable multifactor authentication on the User table

You can disable multifactor authentication for the users that you have access to on the User table.

**Role required:** admin

1. Log in the instance.
2. Open the User [sys_user] table.
3. Configure the list to show the **Enable Multifactor Authentication** column.
4. Change the values of the **Enable Multifactor Authentication** column for the selected users to **false**.

   These users will no longer need the passcode. However, each user can still enable multifactor authentication for their own user profile. To disable the ability for any user to enable multifactor authentication, **disable the system property**.

### Enable external authentication

You can enable external authentication on your instance.

1. Navigate to **System Definition > Installation Exits**.
2. Activate the **ExternalAuthentication** installation exit.

   **Note:** If you are using the Digest authentication method, you must also enable the **DigestSingleSignOn** installation exit.

3. Navigate to **System Properties > Single Sign-on**.
4. Select **Enable external authentication** and click **Save**.
You can also navigate to the **sys_properties.list** and search for the `glide.authenticate.external` property and set it to True.

Administrators might need to bypass external authentication when testing an SSO integration. Use the following URL to bypass external authentication and log in with a local user: `http://<your-instance>.service-now.com/side_door.do`

- A logged-in user cannot access the page
- Attempting to access the page while logged in produces a 'page not found' error

**Associating custom URLs to your instance**

You can enable your ServiceNow instance to be accessible from a company-branded or custom URL.

**Custom URL overview**

You can configure one or multiple custom URLs to your instance, and configure your custom URL to Service Portal mapping.

**Note:** Custom URLs are not available for on-premise customers or developer instances. Also, the URL must be public-facing.

Only the owner of the top-level domain (TLD) or any subdomain can configure the custom URL to a DNS subdomain. For example, your instance might have the following designated URL and additional custom URLs:

**Custom URL example**

<table>
<thead>
<tr>
<th>Example URLs</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="https://acme.service-now.com">https://acme.service-now.com</a></td>
<td>The initial domain name for Acme that came with the ServiceNow instance.</td>
</tr>
<tr>
<td><a href="https://support.acme.com">https://support.acme.com</a></td>
<td>A custom URL that associates to your ServiceNow instance. This URL is referred to as an alias (CNAME) of the initial domain name.</td>
</tr>
<tr>
<td><a href="https://US-support.acme.com">https://US-support.acme.com</a></td>
<td>A secondary custom URL that associates to a service portal on your instance. Your instance can support multiple custom URLs to the same service portal.</td>
</tr>
</tbody>
</table>

**Custom URL considerations outside of your instance**

Before you can associate a custom URL, you must own (or purchase) a URL through a domain provider. There are also specific configurations necessary before you can create and associate a custom URL on your instance.

**Custom URL configurations**

<table>
<thead>
<tr>
<th>Configuration items</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set the CNAME with the provider</td>
<td>The CNAME record must be set as the ServiceNow instance URL.</td>
</tr>
</tbody>
</table>
### Configuration items

<table>
<thead>
<tr>
<th>Configuration items</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Determine your dedicated VIP status</td>
<td>Your ServiceNow instance must be on a dedicated Virtual IP (VIP) address. Most are. To confirm if your instance uses a VIP, contact Customer Service and Support.</td>
</tr>
</tbody>
</table>

**Note:** When deleting or updating CNAME records which point to your instance, you must follow this sequence to avoid dangling records in the instance. First, delete the CNAME records from your instance and then remove or update the CNAME setting at your DNS provider.

### Activate custom URLs

Enable custom URLs to be set up on your ServiceNow instance. You can activate the Custom URL plugin (com.snc.customurl) if you have the admin role.

Role required: admin

1. Navigate to **System Definition > Plugins**.
2. Find and click the **Custom URL** plugin.
   
   **Note:** Do not select the **Custom URL - Internal** plugin, which is an internal component for scripted custom URL APIs.

3. On the Custom URL record, click the **Activate/Repair** related link.
4. In the Plugin Activation window, click **Activate**.
   
   When the Plugin Activation window reopens with a message that the plugin is activated, click **Close & Reload Form** to stay on this form.

5. In the Plugin Files related list, find the following property, and change the setting value:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.customurl.enabled</td>
<td>To enable custom URLs, set the value to <strong>True</strong>. By default, this property is set to <strong>False</strong>, which means that you cannot associate a custom URL.</td>
</tr>
</tbody>
</table>
   
   **Note:** To disable this feature, set this property back to **False**.

6. Click **Update**.

### Set a custom URL as the instance URL

Add a custom URL to your instance configuration to use instead of your ServiceNow URL.

Role required: admin

You must activate the custom URL plugin and have purchased or registered a URL before adding the custom URL to your instance.

1. Navigate to **Custom URL > Custom URLs**. You should either:
   
   - Click **New** to associate a new domain name that is new to your instance.
   - Select a custom URL already set up to set as your instance URL.
2. Fill in the appropriate fields:

### Custom URL fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Domain Name</td>
<td>Fully qualified domain name (FQDN) of the custom URL. The FQDN is a CNAME redirect created in the name server record for the custom domain.</td>
</tr>
<tr>
<td>Is Instance URL</td>
<td>Check box to enable this custom URL for all outbound URLs. Only one active custom URL can be the instance URL. To enable this setting for a custom URL, click Set as Instance URL on the URL record. Any previous custom URLs are then removed.</td>
</tr>
<tr>
<td>Status</td>
<td>Status of the custom URL record. If the status is Active, the custom URL is provisioned and ready to use.</td>
</tr>
<tr>
<td>Service Portal</td>
<td>Service portal that you want to use when you redirect users to your instance using the custom URL.</td>
</tr>
</tbody>
</table>

A custom URL should activate within six hours on your instance. A background job polls for custom URL job completion every 30 minutes.

### Custom URL datacenter job information

Every custom URL that is associated to your instance has a corresponding ServiceNow datacenter job which runs and shows URL information that is pertinent to your instance as described in the table.

<table>
<thead>
<tr>
<th>Job field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Job ID</td>
<td>Unique ID of the job that checks the domain of the custom URL.</td>
</tr>
<tr>
<td>Last Run At</td>
<td>Date and time when the job last ran.</td>
</tr>
<tr>
<td>Payload</td>
<td>List of domains or custom URLs that were sent to the datacenter for CERT provisioning.</td>
</tr>
<tr>
<td>Poll Count</td>
<td>Number of times that the results have polled for this job.</td>
</tr>
<tr>
<td>Result</td>
<td>Verifies and validates each domain or custom URL sent in a payload.</td>
</tr>
<tr>
<td>Status</td>
<td>Status of the datacenter job.</td>
</tr>
</tbody>
</table>

### Generate SP metadata for SAML/SSO custom URL installations

A SAML or SSO installation needs the SP metadata generated for the IdP before the custom URL instance generates.
Role required: admin

The IdP needs SP metadata for the instance to authenticate and forward requests.

**Note:** Adding the Assertion Consumer Service URL (SP login URL) might be different for each IdP (Azure, ADFS, or Okta).

1. Choose your installed SSO plugin:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Multi-Provider SSO</td>
<td>Navigate to Multi-Provider SSO &gt; Identity Providers. Choose an IdP and click the Generate Metadata button. The integration automatically generates the instance's SP metadata from the system property settings.</td>
</tr>
<tr>
<td>SAML 2 SSO</td>
<td>Navigate to SAML 2 Single Sign-on &gt; Metadata. The integration automatically generates the instance's SP metadata from the system property settings.</td>
</tr>
</tbody>
</table>

2. Copy the SP metadata in the text box.

For example:

```xml
<entityDescriptor xmlns="urn:oasis:names:tc:SAML:2.0:metadata" entityID="https://yourinstance.service-now.com">
  <SPSSODescriptor AuthnRequestsSigned="false"
    WantAssertionsSigned="true"
    protocolSupportEnumeration="urn:oasis:names:tc:SAML:2.0:protocol">
    <SingleLogoutService
      Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-Redirect"
      Location="https://yourinstance.service-now.com/navpage.do" />
    <NameIDFormat>urn:oasis:names:tc:SAML:1.1:nameid-format:emailAddress</NameIDFormat>
    <AssertionConsumerService isDefault="true" index="0"
      Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST"
      Location="https://yourinstance.service-now.com/navpage.do" />
    <AssertionConsumerService index="1"
      Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST"
      Location="https://yourinstance.service-now.com/consumer.do"/>
  </SPSSODescriptor>
</entityDescriptor>
```

3. Provide the instance SP metadata to the IdP.

For example, SSOCircle allows a user to provide the SP metadata online.

4. Optional: To set up custom URLs in Azure:
   a) Go to **App Registrations**
   b) Select **All apps** from the dropdown menu
   c) Select the **ServiceNow App** and click settings

5. Optional: To use OAuth authentication, set up the redirect URL as all the registered custom URLs in the OAuth application endpoint configuration for the external client applications.

The redirect URL is synonymous with the callback URL that the authorization server redirects to.

6. Optional: To use Google reCAPTCHA service, set up an API key pair.
Custom URL errors and fixes

A list of common errors and associated fixes for a custom URL setup and configuration.

## Errors during setup

<table>
<thead>
<tr>
<th>Error message</th>
<th>Fix</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unable to create a Custom URL. Try again later.</td>
<td>There might be an issue outside of your control interfering with the custom URL creation. Run at a different time before contacting support.</td>
</tr>
<tr>
<td>Unable to submit your new Custom URL request because another Custom URL request for your instance is still in progress.</td>
<td>Check the status on your Custom URL Jobs before you submit a new request.</td>
</tr>
<tr>
<td>You must clear the following properties before the instance URL can be set: Glide Proxy, Glide Servlet.</td>
<td></td>
</tr>
<tr>
<td>The provisioning of <code>&lt;custom_domain&gt;</code> is still in progress. This process can take up to X hours. Your instance administrator will receive a notification when this process completes.</td>
<td>After the provisioning on an instance starts for a custom URL, you must wait for the process to complete before the status changes.</td>
</tr>
<tr>
<td><code>&lt;custom_domain&gt;</code> is now set as the new instance URL. <code>&lt;base.service-now.com&gt;</code> is still in service, but all new URLs, such as in notifications, will use <code>&lt;custom_domain&gt;</code>.</td>
<td>Only one URL can be designated as the instance URL. The other URLs that are associated with your instance can be active, but only the instance URL can use notifications.</td>
</tr>
<tr>
<td>The Custom URL <code>&lt;custom_domain&gt;</code> is set to be immediately removed from the instance configuration and revert back to <code>&lt;base.service-now.com&gt;</code>. <code>&lt;custom_domain&gt;</code> continues an association to this instance as long as the CNAME record in your DNS is set.</td>
<td>This message confirms that you intend to change your custom URL. By accepting this confirmation, you initiate the change of the URL to your instance. Any URL that is on your Domain Name list, as a custom URL, can be active unless you remove it from the CNAME record on your provider.</td>
</tr>
<tr>
<td>You cannot modify glide.servlet.uri. This property is set by Custom URL.</td>
<td></td>
</tr>
<tr>
<td>You cannot modify glide.proxy.host. This property is set by Custom URL.</td>
<td></td>
</tr>
<tr>
<td>The CNAME record for <code>&lt;custom_domain&gt;</code> does not point to <code>&lt;base.service-now.com&gt;</code>.</td>
<td>The configuration on the URL provider side is not correct. Check your configuration on the CNAME record.</td>
</tr>
<tr>
<td>Missing CNAME record for <code>&lt;custom_domain&gt;</code>.</td>
<td>The CNAME record must be configured from your URL provider before the custom URL can be set for your instance.</td>
</tr>
</tbody>
</table>

**Note:** It usually takes 30 minutes to create a custom URL. If it is taking longer, contact https://support.servicenow.com/now?draw=case.
Enable password policies on your instance

Implement password policy controls at login to force users to change their password if the password does not meet the password policy criteria.

Role required: admin

The Password Policy [com.glide.password_policy] plugin is enabled by default. It goes into effect when a user changes or resets their password. If you customized your instance, via the ValidatePasswordStronger installation exit or your Password Reset credential store [pwd_cred_store], see password policy properties.

1. Navigate to Password Policy > Password Policies.
2. Click the available password strength preset that is initially set as Default.
   
   The password strength preset is the password policy that you apply to your instance. You can leave default as your instance password policy or you can select other options as described in the next step.

3. To customize your password policy, choose the password strength preset that applies to your organization:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>Default password policy that is applied to your instance.</td>
</tr>
<tr>
<td>Medium</td>
<td>Password policy preset that minimizes the minimum character options to apply to your password policy criteria.</td>
</tr>
<tr>
<td>High</td>
<td>Password policy preset that increases some of the minimum character options to apply your password policy criteria.</td>
</tr>
<tr>
<td>Custom</td>
<td>Password policy preset that enables you to edit all of your password policy criteria.</td>
</tr>
</tbody>
</table>

4. On the form, fill in the fields.

   **Password Policy form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Password Length</td>
<td>Minimum length of the password. The password cannot have fewer than 8 characters.</td>
</tr>
<tr>
<td>Maximum Password Length</td>
<td>Maximum length of the password. The default is 40 characters.</td>
</tr>
<tr>
<td>Minimum Uppercase Character(s)</td>
<td>Minimum number of uppercase characters in the password, from 0 to 10.</td>
</tr>
<tr>
<td>Minimum Lowercase Character(s)</td>
<td>Minimum lowercase characters in the password, from 0 to 10.</td>
</tr>
<tr>
<td>Minimum Numeric Character(s)</td>
<td>Minimum numeric of characters in the password, from 0 to 10.</td>
</tr>
<tr>
<td>Minimum Special Character(s)</td>
<td>Minimum number of special characters in the password, from 0 to 10.</td>
</tr>
<tr>
<td>Include Special Characters</td>
<td>Restricted set of characters. If you must allow a restricted set of special characters, delimit the restricted set by commas. For example, if you enter &quot;$,!” users can only use &quot;$&quot; and &quot;!” as special characters in their password. No other special characters can be used, and a password with other special characters is not allowable.</td>
</tr>
</tbody>
</table>

5. Optional: To test that a password meets the policy criteria, enter a password and click Test Your Password.
   
   The password comes back as valid or invalid. If a password is invalid, error messages display the criteria rules that are not met.
6. Click **Update**.

**Password policy properties**

The password policy properties enable you to administrate password policies, exclude list passwords, and apply a password policy upon login.

Go to **System Property > All Properties** to view and edit the password policy properties.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.enable.password_policy</td>
<td>This property enables a password policy for your instance which goes into effect when a user changes their password or resets their password. The default is true.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> If your instance has been customized, via the ValidatePasswordStronger installation exit or your Password Reset credential store [pwd_cred_store], you must create this property and add to your system properties.</td>
</tr>
<tr>
<td>glide.enable.blacklist_password</td>
<td>This property prohibits using specific passwords. The administrator can insert passwords into the Excluded Password table. The default is true.</td>
</tr>
<tr>
<td>glide.apply.password_policy.on_login</td>
<td>This property forces users to change their passwords during their next login, if their existing passwords are not in compliance with the current password policy. The default is false. Setting the value to true enforces a password policy upon login.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Enabling this property might force a significant number of users to change passwords that are not in compliance with a new password policy.</td>
</tr>
</tbody>
</table>

**Exclude passwords through password policies on your instance**

You can add passwords to the Excluded Password table to prohibit specific passwords from being used by users on your instance.

Role required: admin

1. Navigate to **Password Policy > Excluded Passwords**.
2. Click **New** and enter the password to add to your exclude list.

You can add as many passwords to your list as necessary.

**Enable external users to self-register to your ServiceNow instance**

Use external user self-registration to on-board a large volume of external users to your instance. This feature enhances identity verification to improve customer experiences and supports commonly used registration flows.

External user self-registration enables a large group of users to register to a ServiceNow app without the help of an administrator. For example, a university with a large group of students needing on-campus parking could register...
themselves to the campus parking app. Each student would be given a limited set of privileges specific to parking, and would complete an automated registration process. This system could generate a parking number, unique to each student, and insure they had a parking space.

A self-registration flow consists of a custom ServiceNow app, in this case, a campus parking app. After configuring an app with necessary tables, an administrator would configure the registration, including a pre-registration flow, field mapping, post registration mapping, captcha, role mapping and post registration flow.

**Activate External User Self-Registration**

You can activate the External User Registration plugin (com.snc.external_user_self_registration) if you have the admin role.

Role required: admin

1. Navigate to **System Applications > All Available Applications > All.**
2. Find the plugin using the filter criteria and search bar.
   - You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel. For more information, see Request a plugin.
3. Click **Install**, and then in the Activate Plugin dialog box, click **Activate**.

**Note:** When domain separation and delegated admin are enabled in an instance, the administrative user must be in the global domain. Otherwise, the following error appears: Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.

**External roles in self-registration**

To prevent inadvertently providing access to external users, you can assign the snc_external role to all external users.

External users that self-register must be assigned the snc_external role, which has the least privileges. The snc_external role indicates that the user is external to your organization and should not have any access to resources unless explicitly allowed through ACLs for the snc_external role or additional roles that inherit the snc_external role.

By default, users with the snc_external role cannot access:

- Scripted REST API resources that are not marked external.
- Tables without the role that inherits the snc_external role or the public role.
- Non-record type resources, such as processors and UI pages without the snc_external role or a role that inherits the snc_external role.
- Now Intelligence dashboards.

Beginning with the Paris release, you must enable an exclude-list property to enforce the explicit assignment of snc_external roles. For information about enabling the property, see Prevent future internal role assignments for external users.

**Create a user registration configuration for external users**

Create a user registration configuration record to bootstrap the onboarding process of external users to custom ServiceNow applications. This form guides the external users through the self-registration process.

- Role required: admin
- Activate External User Self-Registration

1. Navigate to **External User Self-Registration > User Registration Configurations** and click **New**.
2. On the form, fill in the fields.
## User registration configuration form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the registration form. For example, a student parking registration might be Parking Management Students.</td>
</tr>
<tr>
<td>Roles assigned to provisioned users</td>
<td>Roles assigned to the provisioned users. The specified roles have to extend or contain the <code>snc_external</code> role. The specified role can also be <code>snc_external</code> role. For external users, each role must have an <code>snc_external</code> to note an external user. If you have pre-configured roles, the roles should be accessible when you unlock the roles and search for users.</td>
</tr>
<tr>
<td>Enable terms and conditions</td>
<td>Option to add a terms and conditions URL to the registration page.</td>
</tr>
<tr>
<td>Terms and conditions URL</td>
<td>The publicly accessible URL which contains the terms and conditions of the registration form. This field appears only when Enable terms and conditions is selected.</td>
</tr>
<tr>
<td>Description</td>
<td>The description of the registration form. This field appears only when you save or submit the configuration. You can add more information about the registration form in this field.</td>
</tr>
<tr>
<td>Note:</td>
<td>You can only add a description after you save or update a user registration configuration.</td>
</tr>
<tr>
<td>Application</td>
<td>Application containing this record. The application is automatically set to Global.</td>
</tr>
<tr>
<td>Active</td>
<td>Option which makes the user registration configuration active. This option is selected by default.</td>
</tr>
<tr>
<td>Enable CAPTCHA</td>
<td>Option to add a CAPTCHA to the registration form. The default CAPTCHA provider is Google reCAPTCHA.</td>
</tr>
<tr>
<td>Note:</td>
<td>To enable CAPTCHA for user registration, follow the steps in Configure Google reCAPTCHA for external user self-registration.</td>
</tr>
</tbody>
</table>
3. **Click Submit.**

A user registration configuration with the default settings is created.

<table>
<thead>
<tr>
<th>Name</th>
<th>Parking Management Students</th>
<th>Application</th>
<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>Roles assigned to provisioned users</td>
<td>snc_external</td>
<td>Active</td>
<td>✓</td>
</tr>
<tr>
<td>Enable CAPTCHA</td>
<td>✓</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Terms and condition URL</td>
<td>example.com</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Description</td>
<td>Parking Management for Students</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
4. Optional: Configure the **Registration** tab to show fields and the order that they appear:

### Registration Form Fields

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display in Registration Form</td>
<td>Set any field you want to display as True.</td>
</tr>
<tr>
<td>Order</td>
<td>Set an order number to display fields on your form.</td>
</tr>
<tr>
<td>Mandatory</td>
<td>Set any field you want to make it mandatory as True.</td>
</tr>
<tr>
<td>Validation only field</td>
<td>Set any field you want to use only for validation. For example, registration code.</td>
</tr>
</tbody>
</table>

You can choose to display the default form fields or you can add custom form fields to the Registration Form. For more information, see **Default registration form fields**.

---

**Registration tab**

You can also add custom registration form fields. For more information, see **Add a custom registration form field**.
5. Optional: Configure the **Verification** tab to verify the identity of the registered users. When the user verification flow triggers, an activation link is sent to the user’s registered email address.

**Verification tab fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Requires user verification</td>
<td>Option to trigger a user verification subflow which runs after user registration. The subflow is for user identity verification.</td>
</tr>
</tbody>
</table>
| User verification flow               | The subflow used to verify the identity of the user. The subflow triggers only when you enable user verification.  

The **External User Verification** subflow is available by default. You can create a copy of the default subflow in Flow Designer and modify it according to your requirements. For more information, see [Flow Designer](#).  

**Note:** To preview the **External User Verification** subflow in a new tab use the following shortcuts:  
- Macintosh: Command + Click  
- Windows: Control + Click

| Activation link expiry time (in hours) | The number of hours after which an activation link expires. The default value is 24. |

6. Optional: Configure the **Transformation** tab to map self-registered users and activated users.  

There are two transformation maps (u_reg_xmap_[number]) which automatically map the registered users from the User Acti Req [number] table to the Self Registered User [number] table. You can create a copy of these
default transformation maps and modify the map according to your requirements. For more information, see Transform maps.

<table>
<thead>
<tr>
<th>Transformation Maps</th>
<th>SourceTable</th>
<th>TargetTable</th>
<th>Run Business Rules</th>
<th>RowA</th>
<th>RowB</th>
<th>Updated</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Registration</td>
<td>User Add Req 801776 [s_user_add_reg_801776]</td>
<td>User [sys_user]</td>
<td>true</td>
<td>100</td>
<td>true</td>
<td>2020-08-20 03:21:43</td>
</tr>
<tr>
<td>User Registration</td>
<td>User Add Req 801776 [s_user_add_reg_801776]</td>
<td>Self Reg User Profile 801776 [s_self_reg_user_profile_801776]</td>
<td>true</td>
<td>100</td>
<td>true</td>
<td>2020-08-20 03:21:44</td>
</tr>
</tbody>
</table>

Transformation tab
7. Configure the **Onboarding** tab to trigger subflows for onboarding activated users.

The default **External User Onboarding** subflow sends an email to the user that contains a link to reset their password. You can create a copy of the default subflow and modify it according to your requirements.

**Note:** When the **External User Onboarding** subflow triggers, the subflow sends an email to the user that contains a link to reset the password.

<table>
<thead>
<tr>
<th>Registration</th>
<th>Verification</th>
<th>Transformation</th>
<th>Onboarding</th>
<th>Advanced</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Flow triggered after user account creation</strong></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>✗ User onboarding flow</td>
<td>External User Onboarding</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Onboarding tab
8. Optional: Configure the **Advanced** tab to map user tables and redirection pages of the registration form.
## Advanced tab

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Registration table</td>
<td>Name of the table where registration form information is saved.</td>
</tr>
<tr>
<td>Registration form field configuration</td>
<td>The record associated to the registration form in the Record Producer.</td>
</tr>
<tr>
<td>Activation table</td>
<td>Label and name of the table used for user activation. The activation table contains records of the users who have completed verification.</td>
</tr>
<tr>
<td>User table</td>
<td>Label and name of the user profile table.</td>
</tr>
<tr>
<td>Activation success page</td>
<td>The page to which a user redirects after the activation is successful.</td>
</tr>
<tr>
<td>Activation error page</td>
<td>The page to which a user redirects when the activation fails.</td>
</tr>
<tr>
<td>Post registration redirect page</td>
<td>The page to which user is redirected after registration.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Registration link label</td>
<td>The button name used for registration from the service portal. The default value is Register.</td>
</tr>
</tbody>
</table>

While making changes or after completing all changes in the user registration configuration, you can use the **Preview Registration Form** button to preview changes in the registration form.
# Parking Management Students

**Required Information**

---

**Registration Form Preview**
Configure Google reCAPTCHA for external user self-registration

To use the Google reCAPTCHA service, you must request an API key pair from Google and then configure the related system properties.

- Request an API key pair (a site key and a secret) from Google at https://www.google.com/recaptcha.
- Role required: admin

1. Navigate to System Properties > All Properties.
2. Search for the following properties and set the values:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.user.registration.google.recaptcha.secret</td>
<td>The secret authorizes communication between the application and the reCAPTCHA server. Type: password2</td>
</tr>
<tr>
<td>glide.user.registration.google.recaptcha.site_key</td>
<td>The site key is used to invoke reCAPTCHA service on your registration page. Type: string</td>
</tr>
</tbody>
</table>

Default registration form fields

You can use the default registration form fields or create custom registration form fields.

Registration form fields

The following form fields are added in the Registration form by default.

<table>
<thead>
<tr>
<th>Field Label</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Business Phone</td>
<td>Single line text</td>
</tr>
<tr>
<td>City</td>
<td>Single line text</td>
</tr>
<tr>
<td>Country</td>
<td>Select Box</td>
</tr>
<tr>
<td>EDU Status</td>
<td>Select Box</td>
</tr>
<tr>
<td>Email</td>
<td>Email</td>
</tr>
<tr>
<td>First name</td>
<td>Single line text</td>
</tr>
<tr>
<td>Gender</td>
<td>Single line text</td>
</tr>
<tr>
<td>Home phone</td>
<td>Single line text</td>
</tr>
<tr>
<td>Language</td>
<td>Select Box</td>
</tr>
<tr>
<td>Last name</td>
<td>Single line text</td>
</tr>
<tr>
<td>Middle name</td>
<td>Single line text</td>
</tr>
</tbody>
</table>

Note: This field is useful when the registration form is for an educational institution.
<table>
<thead>
<tr>
<th>Field Label</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mobile phone</td>
<td>Single line text</td>
</tr>
<tr>
<td>Name</td>
<td>Single line text</td>
</tr>
<tr>
<td>Prefix</td>
<td>Select Box</td>
</tr>
<tr>
<td>Title of the user. For example, Mr., Dr., and so on.</td>
<td>Select Box</td>
</tr>
<tr>
<td>State / Province</td>
<td>Single line text</td>
</tr>
<tr>
<td>Street</td>
<td>Wide Single Line Text</td>
</tr>
<tr>
<td>Title - Job title</td>
<td>Select Box</td>
</tr>
<tr>
<td>Zip / Postal code</td>
<td>Single line text</td>
</tr>
</tbody>
</table>

**Note:** You cannot delete the default registration form fields.

**Add a custom registration form field**
You can add custom fields in the user self-registration form.

Role required: admin

1. Navigate to **External User Self-Registration > User Registration Configurations**.
2. Open the record for the required user registration configuration.
3. Navigate to the end of the Registration Form Fields section and click **Insert a new row**.
4. Enter the field name under the **Label** column and click check mark.

A new row is added with the default values. You can configure the custom registration form field based on your requirements.

**Registration Form Field Columns**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Label</td>
<td>The field name which appears on the registration form.</td>
</tr>
<tr>
<td>Type</td>
<td>The type of the user interface element. Following are the supported types:</td>
</tr>
<tr>
<td></td>
<td>- Single line text</td>
</tr>
<tr>
<td></td>
<td>- Email</td>
</tr>
<tr>
<td></td>
<td>- Date</td>
</tr>
<tr>
<td></td>
<td>- Date/time</td>
</tr>
<tr>
<td></td>
<td>- Yes/No</td>
</tr>
<tr>
<td></td>
<td>- Wide Single Line Text</td>
</tr>
<tr>
<td></td>
<td>- Multiple Choice</td>
</tr>
<tr>
<td></td>
<td>- Select Box</td>
</tr>
<tr>
<td>Display in Registration Form</td>
<td>Option to display the field in the registration form.</td>
</tr>
<tr>
<td>Order</td>
<td>The sequence in which the form fields appear on the registration form.</td>
</tr>
<tr>
<td></td>
<td>The field with the lowest order value appears first and the field with the highest order value appears last. The default value is 10,000.</td>
</tr>
<tr>
<td>Mandatory</td>
<td>Option to make a field mandatory on the registration form.</td>
</tr>
</tbody>
</table>
### Validation only field

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Validation only field</td>
<td>Option to use a field only for validation purposes. For example, registration code. When set to true, this field is not saved in the User Table (sys_user).</td>
</tr>
</tbody>
</table>

5. Save or Update the changes.

---

**Enable external user self-registration for Service Portal**

Enable external users to register to an app through Service Portal.

Role required: admin

1. Navigate to **Service Portal > Portals**.
2. Open a portal record.
3. On the form, fill in the **External user registration configuration** field.
   - Select a user registration configuration.
4. Click **Update**.

The login widget includes a link to the registration form that you previously configured.
Verify user self-registration requests

After a user registers from the Service Portal, a user record is added to the Registration Requests module. You can view the list of registered users who have successfully registered in the Service Portal.

Role required: admin

1. Navigate to **External User Self-Registration > Registration Requests**.
   The list of user records are displayed.

2. (Optional) Review the individual user records and modify according to your requirements. For example, you can change the status of a user record form **Pending** to **Processed**.
Normalization Data Services

The Normalization Data Services plugin helps maintain consistency for table fields that refer to a company name. Tables related to configuration items and assets usually contain columns referring to a company name, such as a vendor or manufacturer. Often, these tables refer to the same company by several different names. This situation can happen for many reasons. For example, vendors sometimes use different company names depending on the device. This inconsistency creates problems, especially for reports that rely on these company names.

The Normalization Data Services plugin helps alleviate this problem.

When you enable and configure the Normalization Data Services plugin, the system downloads a list of standard company names that ServiceNow has compiled. It also downloads a list of common variants of that name. Any time the plugin finds a company-name field with one of those variants, it substitutes the standard name in its place.

**Note:** The Normalization Data Services plugin refers to a standard name as a normalized name and to a variant name as a discovered name.

While the Normalization Data Services plugin provides services similar to the field normalization feature, this plugin does not require you to manually set up the mappings from one name to another. If you like, you can add your own mappings to the set. However, you automatically start with extensive lists of common company names (normalized names) and their variants (discovered names).

The Normalization Data Services plugin stores data in two tables. The Normalized Company Names table contains the list of normalized company names. The Normalized Mappings table contains the mappings between each discovered name and its normalized name.

**CAUTION:** If you edit a field whose value is a normalized name, you change the normalized name for ALL discovered names that map to it. These types of updates occur regardless of the table in which you edit the field.

Using guided setup to implement Normalization Data Services

Normalization Data Services guided setup provides a sequence of tasks that help you configure the Normalization Data Services plugin on your ServiceNow instance. To open Normalization Data Services guided setup, navigate to Normalization Data Services > Guided Setup. For more information about using the guided setup interface, see Using guided setup.

**Note:** Because the Normalization Data Services feature requires an internet connection to download mapping information, this feature is not supported for on-premise instances.

Normalized Company Names table

The Normalization Data Services plugin stores the normalized company names in the Normalized Company Names table.

**Normalized company names fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The normalized name for this company.</td>
</tr>
<tr>
<td>Table</td>
<td>The table in which this name is stored.</td>
</tr>
<tr>
<td>Description</td>
<td>[optional] A description with further information about this company or record.</td>
</tr>
</tbody>
</table>
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Field</td>
<td>The field in which this name is stored.</td>
</tr>
<tr>
<td>Customer override</td>
<td>True, if the customer has an override in place for this name. Otherwise, false.</td>
</tr>
</tbody>
</table>

### Normalized company names related lists

<table>
<thead>
<tr>
<th>List</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normalized mappings</td>
<td>A list of all the discovered names that map to this normalized name.</td>
</tr>
</tbody>
</table>

### Normalized Mappings table

The Normalized Mappings table lists all the discovered names and the normalized name to which each maps.

#### Normalized mappings fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discovered name</td>
<td>A variant of a normalized name in the database.</td>
</tr>
<tr>
<td>Normalized name</td>
<td>The normalized name to which the discovered name maps.</td>
</tr>
<tr>
<td>Table</td>
<td>The table in which this name is stored.</td>
</tr>
<tr>
<td>Field</td>
<td>The field in which this name is stored.</td>
</tr>
</tbody>
</table>

### Normalized company names related lists

<table>
<thead>
<tr>
<th>List</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Related mappings</td>
<td>A list of all the discovered names that map to the same normalized name as the selected record.</td>
</tr>
</tbody>
</table>

### Actions

<table>
<thead>
<tr>
<th>List</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Promote discovered name</td>
<td>Replaces the normalized name with the discovered name for the selected record and for all the records in its related mappings list.</td>
</tr>
</tbody>
</table>
Normalization Properties

On the Normalization Properties form, you can see and change the configurable properties for the Normalization Data Services plugin.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reference qualifiers on all tables that reference Company will be updated to use the Normalized field.</td>
<td>If Yes, any reference field for Company – for any table across the platform – uses the Normalized name. This service only works if you have run the Update Reference Qualifiers task in the Guided Setup.</td>
</tr>
<tr>
<td>Enable business rule that automatically normalizes manufacturer names for configuration items.</td>
<td>If Yes, the system normalizes company names when you add or update configuration items by a mechanism other than Discovery (such as by manual import sets).</td>
</tr>
<tr>
<td>Enable Discovery to use the normalization service for manufacturer name.</td>
<td>To have Discovery use the normalized company name for the manufacturer name, click Yes.</td>
</tr>
<tr>
<td>This property is to enable or disable the Normalization API.</td>
<td>To enable the Normalization Data Service API, click Yes. To disable, click No. For details, see Normalization Data Services.</td>
</tr>
</tbody>
</table>

Changing normalized company names

You can change a normalized company name several different ways. In all cases, that change affects all normalized fields referring to that company.

You have several options for changing a normalized company name:

• Edit the Normalized Name field in the Normalized Mappings table. This method is preferred.
• Edit the Normalized Company name table.
• Edit the Company Name field on any table that refers to the Company [core_company] table.

CAUTION: If you edit a field whose value is a normalized name, you change the normalized name for ALL discovered names that map to it.

Change a normalized company name

You can change normalized company names by editing records in the Normalized Company Name table.

Role required: admin

You can edit records in the Normalized Company Names tables, but you cannot add records to it.

1. Navigate to User Administration > Normalization Data Services > Normalized Mappings.
2. Find the record with the name you want to replace and edit the Normalized name field.

The system changes the Normalized Company name for every discovered name that maps to that normalized name.
Metrics

A metric measures and evaluates the effectiveness of IT service management processes.

For example, a metric could measure the effectiveness of the incident resolution process by calculating how long it takes to resolve an incident.

A metric can often be easily obtained from the data. To find the number of incidents created today, a report counts the number of incidents in the incident table with a Created date of today. However, metrics must be gathered as data is updated. For example, determining how long an incident was assigned to a certain group requires collecting information about assignment changes and calculating the duration of each assignment.

The Metric plugin provides an easy, declarative way of defining metrics. Once defined, the data for the metric is gathered, and instances of the metric are calculated and stored. For example, the "Assigned to Duration" metric measures the amount of time an incident is assigned to an individual. To define this metric, you create a metric definition of the type "Field value duration" and select the "Assigned to" field from the Incident table. A metric instance is created for each incident assignment showing its duration. Reporting on the duration of incident assignments becomes easy.

You can report on a metric by using a database view that links the metric to the table on which it is defined.

To install the Metric Definition plugin (com.glide.metrics), navigate to System Definition > Plugins, search for Metric Definition, and click Install.

Create a metric

Create a metric definition for a task table.

Role required: metric_admin

1. Navigate to Metrics > Definitions.
2. Click New.
3. Complete the Metric definition form then click Submit.

New metric definitions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The system generates a unique record number for the metric definition.</td>
</tr>
<tr>
<td>Name</td>
<td>Enter a unique name to describe what metrics are collected.</td>
</tr>
</tbody>
</table>
| Table | Select the table that you want to collect metrics for. A metric can only apply to one table.  
**Note:** The list shows only tables and database views that are in the same scope as the metric definition |
| Field | Select the table column you want to monitor for changes. Metrics only work on audited fields. Creating a metric for non-audited field produces unreliable metrics.  
**Note:** Fields starting with 'sys_' will not work for a metric definition, with the exception of 'sys_domain'. |
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>Script</td>
<td>Enter the script you want the metric to run to either calculate a duration</td>
</tr>
<tr>
<td></td>
<td>or perform some calculation on the metric_instance table.</td>
</tr>
</tbody>
</table>

**Note:** In the base system, metrics are configured to work on the task table only. To apply metrics to cmdb_ci tables, duplicate the metric events business rule that currently runs on the task table for the cmdb_ci table. Without the events created, no metric processing can occur.

**Sample field value duration script**

Review the existing Incident Open metric definition to see how you can create your own custom metric.

This script either provides a duration value or stops processing durations (sets the answer variable to `false`) when an incident is closed.

```java
// script can set answer to false to terminate processing of the metric
// mi - MetricInstance
// answer
if (!current.active) {
    answer = false;
    mi.endDuration();
    gs.log("Closing field durations");
    closeDurations(mi.current);
}
```
function closeDurations(current) {
    var now_GR = new GlideRecord('metric_instance');
    gr.addQuery('id', current.sys_id);
    gr.addQuery('calculation_complete', false);
    gr.addQuery('definition.type', 'field_value_duration');
    gr.query();
    while (gr.next()) {
        gs.log("closing: " + gr.definition.name + " for: " + current.number);
        var definition = new GlideRecord('metric_definition');
        definition.get(gr.definition);
        var mi = new MetricInstance(definition, current);
        mi.endDuration();
    }
}

**Metric instance**

A metric instance is a record in the metric_instance table. A record holds one instance of a metric.

Metric instance records get created and updated in one of two ways: 1) If the metric is a duration, the system automatically populates the metric instance table with duration values. 2) If the metric is calculated from a script, the script itself must populate the metric_instance table.
Some of the notable fields in the metric_instance table are:

- **Metric definition**: the metric definition for which this metric instance was gathered.
- **Value**: For a "Field value duration" metric this is the value of the table field for which duration is calculated. For example, for the "Assigned to Duration" metric, the Value is the name of the person assigned to the incident. For other metrics, the value can be any value calculated by the metric.
- **ID**: Identifies the specific record for which the metric is gathered. For example, the specific incident.
• **Duration**: Time duration for a Field value duration metric.

## Platform performance

Ensure system optimization through performance monitoring and diagnostics.

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application server response</td>
<td>Time for the application server to process a request and render the resultant page.</td>
</tr>
<tr>
<td>Network latency and throughput</td>
<td>Time for the network to pass your request to the server and the response back.</td>
</tr>
<tr>
<td>Browser rendering and parsing</td>
<td>Time for your browser to render the HTML and parse/execute Javascript.</td>
</tr>
<tr>
<td>Instance Cache</td>
<td>Amount of system resources available for processing.</td>
</tr>
</tbody>
</table>

## Instance cache effects on performance

There is a performance degradation whenever you purge and rebuild the instance cache. During core business hours, avoid or minimize any of the following actions that will cause a purge and rebuild of the instance cache.

- Adding or updating system properties
- Adding or updating dictionary entries
- Committing update sets
- Adding or updating translations

## Transaction log response times

The instance automatically logs the vital statistics of every transaction it processes, and that information is available to you as an administrator.

To look at the log, navigate to **System Logs > Transactions**.

To see the average response time of all listed transactions, right-click the column **Response time**. Select **Configure > List Calculations**, and then select the **Average value** check box.

It is a good practice to limit the list to those transactions that took place during the time period of interest. The default filter returns transactions from today.
Transaction log

For each completed transaction, the following information is available (times are in milliseconds):

- Date/time, User ID, IP address, and URL of the transaction.
- Total response time, which does not include the browser time because the server does not have that information.
- **Network time**: network transmission time, both from and to the user.
- **SQL time**: time spent executing SQL commands.
- **SQL count**: number of SQL commands executed.
- **Business rule time**: time spent processing business rules.
- **Business rule count**: number of business rules executed.
- **Output length**: how many bytes the transaction returned, after any compression.

Response time on forms

A response time indicator (clock) appears at the bottom right of many forms and lists.

This indicator provides the processing time for a completed transaction, including the total time and the time for each step. Click the icon to show and hide the response time details. Point to the icon to see a tooltip with the details. The following example shows the response time for retrieving a filtered list in a demo instance.

Response time

In this example, the transaction took the following amount of processing time:

- 1019 milliseconds total time
- 3 milliseconds moving data across the network
• 526 milliseconds on the server

**Note:** Server time is calculated using the following formula:

\[ \text{server time} = (\text{client response time} - \text{browser time} - \text{client network time}) \]

• 490 milliseconds in the browser, rendering the HTML and parsing and executing JavaScript

Response does not appear for simple operations, such as paging, changing a list sort order, or for the first transaction in a session.

To view a detailed breakdown of the browser processing time on forms, click **browser**.

Administrators can disable the response time by setting the `glide.ui.response_time` property to `false`.

When you review response times, look for the following issues.

1. A period where all transactions took an unusually long time. For example, transactions that normally took 1 second took 15 seconds between 11:00 AM and 11:20 AM. This issue can indicate that an unusual load, such as a large report, ran on that app server during that time.

2. A specific transaction which repeatedly took an unusually long time. For example, the list of closed incidents sorted by short description took 30 seconds each time it was displayed. This issue can indicate that a particular transaction put an unusual database load on the system, such as sorting 500,000 records on an unindexed field.

Try the following actions to improve performance.

1. Look for one or more transactions that span the entire window. For example, you observe that the response was slow for six minutes and one transaction ran the entire time. You can try adding additional indexing to the database to make the transaction faster. Certain types of queries are always going to run more slowly than others, regardless of indexing.

2. Ensure that a cache flush is not being run during business hours. Cache flushes are intended to prevent older data from interfering with changes and updates, and are performed automatically when using update sets. Scheduled cache flushes, using `cache.do`, can affect overall performance, and degrade system response times. Do not run cache flushes during business hours, and do not trigger cache flushes automatically.

3. If you cannot find any specific issues when experiencing slow response time, contact support to see if there are global issues with the application server hardware.
Client transaction timings

The Client Transaction Timings plugin provides extra information about the amount of time spent on both the client and server side, and by the browser and network. This feature not only helps find long-running processes, but also provides information about where in the process the performance issue is caused.

Network response times

Troubleshooting a poor network response time can be difficult, but there are certain quick tests you can perform.

One clear indicator of a network issue is when you find that users in one location have good performance, and users in another location have poor performance. That tells you that the server and application are fine. Assuming that browser settings are identical, the only meaningful difference is the network.

Ping times

The coarsest measure of network response time is a ping. A ping measures the total time for a packet to make it from the source machine to the target and back again.

To perform a ping in Windows, bring up a command window (DOS prompt) and type:

```bash
ping -t <yourinstancename>.service-now.com
```

```
Microsoft Windows [Version 6.0.6000]
Copyright (c) 2006 Microsoft Corporation. All rights reserved.
C:\Users\Admin>ping -t www.service-now.com
Pinging www.service-now.com [70.85.100.85] with 32 bytes of data:
  Reply from 70.85.100.85: bytes=32 time=37ms TTL=55
  Reply from 70.85.100.85: bytes=32 time=36ms TTL=55
  Reply from 70.85.100.85: bytes=32 time=57ms TTL=55
  Reply from 70.85.100.85: bytes=32 time=44ms TTL=55
  Reply from 70.85.100.85: bytes=32 time=37ms TTL=55
  Reply from 70.85.100.85: bytes=32 time=36ms TTL=55
  Reply from 70.85.100.85: bytes=32 time=36ms TTL=55
  Reply from 70.85.100.85: bytes=32 time=85ms TTL=55
  Reply from 70.85.100.85: bytes=32 time=36ms TTL=55
  Reply from 70.85.100.85: bytes=32 time=39ms TTL=55
  Reply from 70.85.100.85: bytes=32 time=49ms TTL=55
  Reply from 70.85.100.85: bytes=32 time=39ms TTL=55
  Reply from 70.85.100.85: bytes=32 time=36ms TTL=55
  Reply from 70.85.100.85: bytes=32 time=41ms TTL=55

Ping statistics for 70.85.100.85:
  Packets: Sent = 14, Received = 14, Lost = 0 (0% loss),
  Approximate round trip times in milli-seconds:
    Minimum = 36ms, Maximum = 85ms, Average = 43ms
```

Look for a time under 100 ms if you are in the U.S., or 150 ms if you are in Europe or Asia. In practice, anything less than 250 ms is not of concern as it is not generally a major component in your perceived response time.
Traceroute

If you are seeing slow ping times, you can run a traceroute. Some networks refuse to forward ICMP, and your traceroute request may not work. If it does work, it is a great tool for identifying network bottlenecks. To run a traceroute on Windows, bring up a command window and run the following command.

```
tracert <yourinstancename>.service-now.com
```

Sample output:

```
C:\dev\mysql5\bin>tracert mycompany.service-now.com
Tracing route to mycompany.service-now.com [70.87.98.130]
over a maximum of 30 hops:
1    1 ms    1 ms    1 ms  12.192.116.193
2    4 ms    4 ms    4 ms  12.116.227.37

11  31 ms   37 ms   31 ms  gi1-0-1.car16.dllstx4.theplanet.com [67.18.116.67]
12  32 ms   32 ms   32 ms  70.87.98.130
Trace complete.
```

Each line in the traceroute represents a network step between the source machine and the destination machine. In the sample traceroute, there were a total of 12 steps required to get the network traffic from the laptop to `<yourinstancename>.service-now.com`.

- The left column is the step number.
- The next three columns are latency estimates, performed three times to give an average.
- The last column is the machine you are hopping to.

For example, from rows #1 and #2 above, you can tell:

```
1    1 ms    1 ms    1 ms  12.192.116.193
2    4 ms    4 ms    4 ms  12.116.227.37
```

At the end of row 1, it was at 12.192.116.193. It then took 4 ms (on average) to get to 12.116.227.37.

Generally, with a traceroute, you are looking for individual steps that take a long time, like 500 ms for a particular hop. You are also looking for steps that show an asterisk (*) instead of a step time, for example:

```
1   100 ms  * 500ms  12.192.116.193
```

The asterisk indicates that a particular packet failed to arrive, which can indicate network problems on that particular hop. You also see an asterisk if that particular router is set to not forward ICMP. This outcome is potentially a false alarm if all three latency times for a step are asterisks.
Browser settings and performance

Depending on the browser you use, browser settings can affect the performance of your instance.

Web pages in your instance can be large, for example, over 500 kb for a long list of incidents with many columns. To speed performance, most browsers can accept compressed data from an application server so that the full 500 kb does not have to be sent over the wire. Instead, the browser indicates that it can accept compressed data if the server can send it. The app server then compresses the response, which transforms the 500 kb data to about 20 kb.

Compression is enabled by default on all ServiceNow application servers. The application server always sends compressed data if your browser accepts it. There are browser settings that control whether your browser accepts compressed responses.

In Microsoft Internet Explorer (IE), navigate to Tools > Internet Options. Ensure that the following two check boxes are selected in the Advanced tab.

- Use HTTP 1.1
- Use HTTP 1.1 through a proxy server

Frequently, a proxy or edge device in the environment disables gzip compression. Enabling gzip compression also speeds up the interactions.

Cache items from https locations

If you enforce an IE policy to never cache items from an https location, every interaction must refetch a large amount of JavaScript and images from the server, which affects performance. The IE option is Do not save encrypted pages to disk, and the default is off.

Diagnostics page

Administrators can use the system diagnostics page to look for root causes of platform performance issues. This page provides an overview of useful diagnostic information about a running instance and cluster nodes. Navigate to System Diagnostics > Diagnostics Page.
### System Diagnostics

#### Cluster Nodes Status
- **Name**: app124421.iad4.service-now.com:demo1nightlyhelsinki001
- **Status**: online
- **Logged in users**: 26
- **Last reported**: 0 seconds
- **Last reported (seconds ago)**: 0
- **JVM UP time**: 13 hours 1 minute
- **JVM CPU time**: 3 hours 8 minutes
- **Scheduler running**: true
- **Scheduler queue length**: 0
- **Memory (MB)**: 813.0 of 1880.0
- **JVM Classes**: 27229.0 toasted, 1503.0 unloaded
- **Transactions**: 82905
- **Errors**: 218
- **GC.ConcurrentMarkSweep.Count**: 329 (2 per 5 minutes)
- **GC.ConcurrentMarkSweep.TotalTime**: 202285 (4 minutes)
- **GC.ConcurrentMarkSweep.AvgTime**: 0.88840425
- **GC.ParNew.Count**: 7436 (47 per 5 minutes)
- **GC.ParNew.TotalTime**: 144463 (2 minutes)
- **GC.ParNew.AvgTime**: 0.019483676

#### System overview
- **Emails (recv) last 60 minutes**: 0
- **Emails (sent) last 60 minutes**: 0
- **Events pending**: 1
- **Log entries last 60 minutes**: 409
- **POP3 Status**: ?
- **SMTP Status**: There is currently no active SMTP account configured, cannot send email

#### Database overview
- **URL**: jdbc:mysql://db160144.iad4.service-now.com:3441/af5833df117db50a5
- **Name**: demo1nightlyhelsinki_1
- **Driver**: com.mysql.jdbc.Driver
- **Type**: com.mysql.jdbc.Driver
- **Version**: 5.6.16-log
- **JDBC**: 1.1
Memory

To see how much memory each node is using, you can use the 'stats' page for each node in System Diagnostics. Each 'stats' page lists the available and in-use memory. Bear in mind that memory use will fluctuate, and it's not uncommon for it to 'creep' up to beyond 95% usage before memory garbage collection reduces it back to normal levels.

Cluster Nodes

If you're running a multiple-node cluster, it's useful to know the status of each of the nodes. The nodes check in every 30 seconds and display their current status in the 'sys_cluster_state' table. You can see this information by clicking the 'Note States' module in the 'System Cluster' application.

Transactions

If you're looking for 'what was this user doing at this time', the transaction log is your friend. The transaction log lists all transactions, the user who performed it, and the URL the user was going to. You can get to the transaction log by going to System Logs > Transaction Log.

Email

The email log can help you determine whether emails are sending, who they're sending to, and the format of the message itself. The email log also shows all inbound email. You can get to the email log by going to System Logs > Email Log.

Configuring System Diagnostics Properties

Use properties to define when things appear red on the page.

Navigate to System Properties > System Diagnostics.
System Diagnostics

Please edit your changes and press Save

Customization Properties for System Diagnostics

Auto refresh the system_diagnostics_page after this many seconds:
60

Condition used to flag Emails Received value:

Condition used to flag Emails Sent value:

Condition used to flag Pending Events value:
> 1000

Condition used to flag number of log entries in last 24 hours value:

Condition used to flag a node’s Last Reporting Time value:
> 180

Condition used to flag a node’s Scheduler Is Running value:
!== 'true'

Condition used to flag a node’s Schedule Queue Length value:
> 10

Condition used to flag a node’s Status value:
!== 'online'

Condition used to flag POP3 Status value:
.indexOf('Connected') == -1

Condition used to flag SMTP Status value:
System Diagnostics Stats Tools

To aid in performance evaluation, the Stats Tools records statistics for system activities that affect performance such as the execution of queries, scripts, and transactions.

**Note:** The Stats Tools plugin is activated by default. It requires the admin role to activate or upgrade, and it requires the com.snc.jrobin.

Stats Tools adds modules under System Diagnostics > Stats, including Slow Queries, Slow Scripts, and Slow Transactions. Each module accesses a table of activity patterns [sys_query_pattern], [sys_script_pattern], and [sys_transaction_pattern]. Each pattern table represents a collection of unique activities. Each collection is an aggregation of executions of that unique activity over all time. Each record provides basic timing analysis with example identifiable details of the activity.

**Note:** To aid in debugging, you can filter most of these logs by application scope, limiting the transactions (for example, slow scripts or events) to only those transactions originating in specific scopes.

Activity patterns are immediately recorded to a cache and are later persisted to their pattern table. If you flush server caches, then recorded activities that have not been persisted are cleared. The following are examples of pattern records.

- Each time a query is executed that meets the recording and persistence threshold it is aggregated and stored as a query pattern record.
- Each time a particular business rule is executed it aggregates to a script pattern record.
- Each time a particular background job runs it aggregates into a unique transaction pattern record.
- Each click of the New button on the Incidents list counts as a list type transaction pattern with specific form action.

**Metrics**

Metrics include total and average times of interest per unique execution pattern over the total execution count. Metrics are aggregated with each new instance of the unique activity and persisted to the pattern record.

**Metadata**

Example data from specific executions are included on each pattern to identify execution details.

**Characterizations of each activity type**

<table>
<thead>
<tr>
<th>Transactions</th>
<th>Any transaction type includes server-side and related client-side transactions.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Metrics include Total server load time, which aggregates the total server-time excluding semaphore and session wait times. It also aggregates relevant server transaction times that are found on the syslog_transaction table.</td>
</tr>
<tr>
<td></td>
<td>Transaction types:</td>
</tr>
<tr>
<td></td>
<td>• An HTTP Request transaction is identified by a URL, transaction type, processor, form/list action, URL query (filters), and related table name.</td>
</tr>
</tbody>
</table>
Any other transaction is identified by its transaction URL/page/name, transaction type, and processor or thread name.

**Scripts**
Any script activity type includes scripts evaluated by GlideScopedEvaluator.

**Script Types:**
- A Jelly Script is identified by the sys_jelly_file table, jelly file path, line number, and script that was executed.
- Any other script is identified by the table and sys_id.

**Queries**
Any query activity includes prepared statements executed by GlideDBI

**Query Types:**
- All queries are identified by MongoDB query or insert, update, or select statements, as well as other components of the statement like selected columns, where clause, unions, column sets, and limits.

### Slow mutex locks record detail

Administrators can use slow mutex logs to gain insight into how mutex locks are affecting platform performance.

<table>
<thead>
<tr>
<th><strong>Field</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Mutex name</td>
<td>The name of the mutex lock for this record.</td>

<tr>
<td>Hash</td>
<td>Hash value for this record.</td>
</tr>
<tr>
<td>Month moving average (ms)</td>
<td>Average of the moving average values of execution time, calculated over periods of one month.</td>
</tr>
<tr>
<td>Label</td>
<td>Label for the event.</td>
</tr>
<tr>
<td>Example URL</td>
<td>URL for an individual event.</td>
</tr>
<tr>
<td>Example stack trace</td>
<td>Example stack trace for an individual event.</td>
</tr>
<tr>
<td>Total execution time</td>
<td>Total sum of the event execution times for the aggregated occurrences.</td>
</tr>
<tr>
<td>Event Execution Time / Event Count Trend graphs</td>
<td>Event Execution Time Trend graphs show the total execution time of these events over the most recent period of two hours, one day, or one month. Event Count Trend graphs show the event counts over the most recent period of two hours, one day, or one month.</td>
</tr>
</tbody>
</table>

**Slow scripts log record detail**

As an administrator, you can use Slow Scripts logs to gain insight into how events are affecting platform performance. To aid in debugging, you can filter a slow script log by application scope, limiting scripts to only those scripts originating in specific scopes.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Label</td>
<td>Label assigned to the script.</td>
</tr>
</tbody>
</table>
### Slow transactions log record detail

As an administrator, you can use Slow Transactions logs to gain insight into how transactions are affecting platform performance. To aid in debugging, you can filter transaction log detail by application scope, limiting transactions to only those transactions originating in specific scopes.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Average execution time (ms)</td>
<td>Average duration to execute the transaction, in a single occurrence, in milliseconds.</td>
</tr>
<tr>
<td>Execution count</td>
<td>Number of similar occurrences that are aggregated.</td>
</tr>
<tr>
<td>Total execution time</td>
<td>Total sum of the execution times for the aggregated executions of the transaction.</td>
</tr>
<tr>
<td>Average client time (ms)</td>
<td>Average duration to execute the transaction on the client, in a single occurrence, in milliseconds.</td>
</tr>
<tr>
<td>Total client time (ms)</td>
<td>Total sum of the transaction execution times for the aggregated occurrences on the client, in milliseconds.</td>
</tr>
<tr>
<td>Origin application</td>
<td>Application scope the transaction originated in. Global appears if the transaction originated in the global scope.</td>
</tr>
<tr>
<td>Example type</td>
<td>Example transaction type executed.</td>
</tr>
<tr>
<td>Example processor</td>
<td>Example processor for an individual transaction.</td>
</tr>
</tbody>
</table>

### Use a slow query log

Administrators can use slow query logs to gain insight into how queries are affecting platform performance. The Slow Queries log aggregates data for similar queries. Use slow query data to evaluate the need for new indexes, changes to existing indexes, or changes to frequent queries.

**Role required: admin**

Queries are similar when they select from the same table and query the same field in the where clause, but search for different values in the field. For example, these queries are aggregated as similar queries.

```
SELECT * FROM sys_user WHERE name="ITIL User"
SELECT * FROM sys_user WHERE name="System Administrator"
```
Aggregating similar query data allows administrators to monitor the performance impact of slow queries and of queries that occur frequently. The log reports data for similar queries where the total execution time exceeds 5 seconds.

1. Navigate to **System Diagnostics > Stats > Slow Queries**

   ![Slow Queries Table](image)

   **Query record fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example</td>
<td>An SQL statement for an individual query, before being canonicalized to aggregate it with similar queries.</td>
</tr>
<tr>
<td>Hash</td>
<td>The hash value for this record.</td>
</tr>
<tr>
<td>Example stack trace</td>
<td>A stack trace for an individual query. Lines referencing script code (includes both custom and base system code) appear in the following format: table_name.sys_id:line_number For example, this stack trace indicates a function call from line 119 of a script include. sys_script_include.105f70abc0a8010300d4d79ed1b93eb0:119 For more information, see stack traces.</td>
</tr>
</tbody>
</table>

2. Open a query record for more details.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Example URL</td>
<td>The URL for an individual query, depending on how the query was called.</td>
</tr>
<tr>
<td></td>
<td>• User transactions: lists the transaction parameters.</td>
</tr>
<tr>
<td></td>
<td>For example, if a user navigates to the incident list, the URL is</td>
</tr>
<tr>
<td></td>
<td><code>/incident_list.do sysparm_query=active=true</code></td>
</tr>
<tr>
<td></td>
<td>• Scheduled jobs: lists the name of the scheduled job.</td>
</tr>
<tr>
<td></td>
<td>• Any other method: lists an empty field.</td>
</tr>
<tr>
<td>First sighting</td>
<td>The first occurrence of a similar query.</td>
</tr>
<tr>
<td>Last sighting</td>
<td>The last occurrence of a similar query.</td>
</tr>
<tr>
<td>Total execution time</td>
<td>Total execution time.</td>
</tr>
<tr>
<td>Execution Count</td>
<td>The number of similar query occurrences that are aggregated.</td>
</tr>
<tr>
<td>Average execution time (ms)</td>
<td>The average duration to execute one of these similar queries.</td>
</tr>
</tbody>
</table>

3. To see what the database is doing to retrieve the data, click **Explain Plan**.
   The query plan is reported in the **MySQL Explain Plan** related list. Use the query plan to evaluate the need for new indexes or changes to existing indexes. For more information, see **MySQL explain plan documentation**.
   This feature works on other supported databases, including MongoDB and Oracle.

4. To generate an index suggestion for a slow query, click **Index Suggestion**. For details, see **Generate an index suggestion for a slow query**.

**Index suggestions for slow queries**

The Index Suggestion Engine (ISE) can generate an index suggestion for a selected slow query. When you request an index suggestion for a slow query, the ISE analyzes the query and recommends an index that can improve the query execution time.

If you choose to use the index suggestion and create the index, the ISE continues to review the effectiveness of that index during a 14-day evaluation period. The ISE provides details on the index during the evaluation, including recommendations for managing the index.

Administrators use the ISE to:
  • Generate an index suggestion for a slow query.
  • Review index suggestions for slow queries in your instance.
  • Export an index suggestion to a non-production instance for evaluation and testing.
  • Schedule an index for creation.
  • Monitor the effectiveness of an index during the index evaluation period.
  • Test index performance (this test is an immediate performance assessment of the index).
  • Drop an index that does not optimize query performance, as recommended by the ISE.

In new and upgraded instances, the Index Suggestion Engine plugin (com.glide.index_suggestion) is activated by default.
How index suggestions work

You start the index suggestion process by requesting an index suggestion for a selected slow query. The ISE runs a daily job that collects column statistics from tables in the slow query, gathering data such as cardinality (unique columns in a table) and null/not null count.

Next, the ISE aggregates and analyzes the information collected, applies a weighted column ranking algorithm to the slow query, and generates an index suggestion for the query.

After an index suggestion is generated, you review the suggestion and determine whether to create the index for the slow query. When you create the index, the ISE provides information on the index as it moves through its life cycle.

You can track the index suggestion through three main processing stages:

**Index suggestions to review**

During this initial stage, you can review index suggestions that the ISE generated for your slow queries. You can choose to ignore a suggestion, export the index suggestion to a non-production instance for further testing, or schedule the index for creation. If the ISE successfully generates an index suggestion and you choose to schedule the index for creation, the index suggestion moves to the next processing stage. However, if the database cannot use the suggestion or the suggestion degrades query performance, the ISE recommends that you drop the index suggestion.

**Index in progress**

In this stage, the ISE creates the index and the 14-day evaluation period begins. The ISE does an hourly evaluation to determine whether the index improves or degrades the query execution time. The ISE updates the index state, including recommended actions that you can take. For example, if the index does not improve the performance of the slow query, the ISE advises that you drop the index. You can then schedule the index to be dropped from the database. During this stage, you can also choose to test index performance or accept an index, even if the ISE recommends dropping it.

**Index done**

In the last processing stage, the ISE describes the final state of the index and related processing activity. If the index improved the slow query time, the ISE changes the index state to Created and the database continues to use the index. If the index did not improve the query time and you chose to drop the index, the ISE drops the index from the database and changes the index state to Dropped.

**Index suggestion life cycle**
Processing states for index suggestions

The Index Suggestions [sys_index_suggestion] table provides state information on your indexes as they move through the three main processing stages:

- Index Suggestions > To review
- Index Suggestions > In Progress
- Index Suggestions > Done

Index Suggestions table
The ISE uses the following states to describe the processing activity for an index.

**Index suggestion states**

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Index suggestions to review</td>
<td></td>
</tr>
<tr>
<td>Suggested</td>
<td>ISE generated an index suggestion for the slow query.</td>
</tr>
<tr>
<td>Drop Suggested—Unused</td>
<td>ISE recommends that you drop the index, since the database is not using the index for the slow query.</td>
</tr>
<tr>
<td>Drop Suggested—Performance Degradation</td>
<td>ISE recommends that you drop the index because the index did not improve the query time or made the performance worse.</td>
</tr>
<tr>
<td>Index in progress</td>
<td></td>
</tr>
<tr>
<td>Creation Scheduled</td>
<td>You scheduled the index for creation.</td>
</tr>
<tr>
<td>Creation in Progress</td>
<td>ISE is creating the index.</td>
</tr>
<tr>
<td>Creation Failed</td>
<td>ISE could not create the index.</td>
</tr>
<tr>
<td>Evaluating Effectiveness</td>
<td>ISE created the index and is assessing index performance during the 14-day index evaluation period.</td>
</tr>
<tr>
<td>Drop Suggested—Unused</td>
<td>ISE recommends that you drop the index from the table for which the index was created, since the database is not using the index for the slow query.</td>
</tr>
<tr>
<td>Drop Suggested—Performance Degradation</td>
<td>ISE recommends that you drop the index because the index did not improve the query time.</td>
</tr>
<tr>
<td>State</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Drop Scheduled</td>
<td>You scheduled the index to be dropped from the database.</td>
</tr>
<tr>
<td>Drop in Progress</td>
<td>ISE is dropping the index from the database.</td>
</tr>
<tr>
<td>Drop Failed</td>
<td>ISE could not drop the index. Contact Customer Service and Support for assistance.</td>
</tr>
<tr>
<td>Index done</td>
<td></td>
</tr>
<tr>
<td>Created</td>
<td>After the 14-day evaluation period, the ISE determined that the index improved query performance. Indicates that the database continues to use the index.</td>
</tr>
<tr>
<td>Ignored</td>
<td>You chose to ignore the index suggestion.</td>
</tr>
<tr>
<td>Dropped</td>
<td>ISE successfully dropped the index.</td>
</tr>
<tr>
<td>Accepted</td>
<td>You chose to keep the index even though the ISE recommended dropping it.</td>
</tr>
<tr>
<td>Superseded</td>
<td>A recent index suggestion replaced the index for the same table and slow query.</td>
</tr>
</tbody>
</table>

**Generate an index suggestion for a slow query**

Use the Index Suggestion Engine (ISE) to generate an index suggestion for a slow query.

Role required: admin

When the ISE generates an index suggestion for a slow query, it reviews query metrics and information from tables in the query. If the ISE does not have the information required to generate an index suggestion, the system displays messages informing you about the data needed. These messages typically provide links for obtaining more information, such as updated query metrics or gathering column statistics from tables in the query. Sometimes the ISE may be unable to suggest an index for the query and lets you know why the suggestion cannot be generated.

1. Navigate to **System Diagnostics > Stats > Slow Queries**.
2. In the Slow Queries table, click the query record for which the index suggestion is to be generated.
3. In the Slow Queries record, click **Suggest Index**.

If the ISE needs more information, the system may display one or more messages with details for obtaining that information. After you respond to each message, click **Suggest Index**. Repeat this process until the ISE has the information required to generate the index suggestion.

For example, the ISE may need:

- **Recent metrics**—If the system displays a message indicating that query metrics are outdated, the message provides a link for obtaining the most recent metrics.
  - Click the link to get the updated query metrics.
  - Click **Suggest Index**.

- **Column statistics**—If the column statistics do not exist for the query, the system displays a message asking you to schedule the Collect Column Stats job. You can choose to run the job at the default time when the system is less busy, or you can have the system collect the statistics immediately.
  - If you schedule the Column Stats job to run later, the ISE generates the index suggestion after it collects the column statistics. After the column stats job runs, return to the Slow Queries record and click **Suggest Index**.
  - If you choose to collect column stats immediately, the system displays the Collect Column Statistics progress indicator while it gathers column statistics. In the Slow Queries record, click **Suggest Index**.

When the ISE successfully generates an index suggestion, the Index Suggestion record for the query shows the index **State** as **Suggested**.

4. If you want to continue working with the index suggestion, select the next processing step:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Export</strong></td>
<td>Downloads the index suggestion as an .xml file so that you can export it to a non-production instance for testing and evaluation.</td>
</tr>
<tr>
<td><strong>Ignore</strong></td>
<td>Sets the index suggestion state to Ignore, which indicates that the index suggestion is not to be used. Index suggestions with an Ignore state are listed in the Index Suggestions &gt; Done view of the Index Suggestion table.</td>
</tr>
</tbody>
</table>
### Schedule creation
Opens the Schedule Index Creation window for scheduling index creation.

### Review index suggestions for slow queries
You can review index suggestions and indexes created by the Index Suggestion Engine (ISE). The ISE provides three main views of index suggestions as they move through their life cycle: index suggestions in review, index in progress, and index done.

Role required: admin

Access index suggestions from the Application Navigator or the Performance homepage.

1. Access the index suggestions for your instance:

<table>
<thead>
<tr>
<th>Location</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>From the Application Navigator</td>
<td>Navigate to System Diagnostics &gt; Index Suggestions &gt; Index Suggestions &gt; To review.</td>
</tr>
<tr>
<td>From the Performance homepage</td>
<td>If the suggestion icon indicates that one or more index suggestions are available, ( ), click it to open the Suggested Indexes window, and click View all suggested indexes.</td>
</tr>
</tbody>
</table>

**Note:** In the Suggested Indexes window, click View next to a specific table to open its index suggestion record in the Suggestion Details—Add Index form. This form is the same as the Index Suggestion form described later in this task.
2. In the Index Suggestions table, click the **Table Name** associated with the index suggestion you want to view.
3. Review the index suggestion for the selected table.

Index Suggestion fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Slow query</td>
<td>The slow query for which the index suggestion was generated.</td>
</tr>
<tr>
<td>Example</td>
<td>An actual SQL statement for an individual query, before being canonicalized to aggregate it with similar queries.</td>
</tr>
<tr>
<td>Table name</td>
<td>Name of the table used in the query.</td>
</tr>
<tr>
<td>Column names</td>
<td>Names of the columns used in the query.</td>
</tr>
<tr>
<td>Index name</td>
<td>Name of the index, assigned by the ISE after the index is created.</td>
</tr>
<tr>
<td>State</td>
<td>Processing state of the index. For details, see the Index suggestion states table.</td>
</tr>
<tr>
<td>Imported</td>
<td>This box, if checked, indicates that the index suggestion was imported from a different instance for evaluation and testing.</td>
</tr>
</tbody>
</table>
4. Choose the next processing step for the index suggestion.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Export</td>
<td>Downloads the index suggestion as an .xml file, which can be exported to a non-production instance for testing and evaluation.</td>
</tr>
<tr>
<td>Ignore</td>
<td>Changes the index suggestion state to ignore, which indicates the index suggestion is no longer active and available for index creation. Index suggestions with an Ignore state are listed in the <strong>Index Suggestions &gt; Done</strong> view of the Index Suggestion table.</td>
</tr>
<tr>
<td>Schedule creation</td>
<td>Opens the Schedule Index Creation window to schedule an index suggestion for creation.</td>
</tr>
</tbody>
</table>

**Export an index suggestion to a non-production instance**

You can export an index suggestion from a production instance to a non-production instance for evaluation and testing, before implementing the index on your production instance.

**Role required:** admin

This task involves exporting an index suggestion as an .xml file from your production instance and importing it to a non-production instance. You can then create the index and evaluate its performance on the non-production instance.

1. In your production instance, navigate to the Index Suggestion to be exported:
   a) Access the Index Suggestions table to review the index suggestions for slow queries.

<table>
<thead>
<tr>
<th>Location</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>From the Application Navigator</td>
<td>Navigate to <strong>System Diagnostics &gt; Index Suggestions &gt; Index Suggestions &gt; To review.</strong></td>
</tr>
<tr>
<td>From the Performance homepage</td>
<td>If the suggestion icon indicates that one or more index suggestions are available ( ), click it to open the Suggested Indexes window, and click <strong>View all suggested indexes.</strong></td>
</tr>
</tbody>
</table>

   **Note:** In the Suggested Indexes window, you can click **View** next to a specific table name to open its index suggestion record.

   b) In the Index Suggestions table, click the **Table Name** to open the index suggestion.

2. In the Index Suggestions form, click **Export**.

   The ISE downloads the index suggestion as an XML file with the file name `sys_index_suggestion_<alphanumeric identifier>.xml`. The file name has a unique alphanumeric string to differentiate it from other index suggestions.

3. In your non-production instance, navigate to **System Diagnostics > Index Suggestions > Index Suggestions > To review.**

4. In the Index Suggestions table under Related Links, click **Import Suggestions.**
5. In the Import XML form, choose the index suggestion file that you exported and click **Upload**.

After the import, the imported index suggestion appears in the Index Suggestions table on your non-production instance.

6. To continue the index evaluation process on your non-production instance, you can **schedule the index suggestion for creation** and **test index performance**.

**Schedule an index suggestion for creation**

Use the Index Suggestion Engine (ISE) to schedule an index suggestion for creation.

Role required: admin

1. Navigate to the index suggestion for the slow query:

   **Location** | **Description**
   --- | ---
   From the Application Navigator | Navigate to System Diagnostics > Index Suggestions > Index Suggestions > To review.

   From the Performance homepage | If the suggestion icon has a number ( ), click the icon to open the Suggested Indexes window, and click **View all suggested indexes**.

   **Note:** In the Suggested Indexes window, you can click **View** next to a specific table to open its index suggestion record.

2. In the Index Suggestion table, click the **Table Name** for which the index is to be created.

3. In the Index Suggestion form, click **Schedule Creation**.
4. In the Schedule Index Creation window, select the time that the index is to be created and click Create. You can schedule index creation later when your instance is less busy.

**Note:** If the index to be created involves large tables, such as the Incident or CMDB table, index creation may take up to one hour or longer.

- **Create now**—The Schedule Index Creation progress indicator window shows the progress of the index creation. When index creation is complete, click Close.
• **Create later**—If you select this option, the state changes to Create Scheduled, and the index is created at the scheduled time. After the index is created, the index state changes to Evaluating Effectiveness.

When the ISE creates the index at the selected time, it assigns an index name based on the tables used in the slow query.
5. Verify that the index was created by reviewing the index State in the Index Suggestion record or in the Index Suggestion table (System Diagnostics > Index Suggestions > Index Suggestions > In Progress). The Index Suggestion record shows the state, Evaluating Effectiveness. The ISE begins the 14-day index evaluation period.
6. During the evaluation period, you can monitor the index State in the Index Suggestion record or in the Index Suggestion table (System Diagnostics > Index Suggestions > Index Suggestions > In Progress).
Test index performance

After the Index Suggestion Engine (ISE) creates an index for a slow query, you can test the index to see if it improves the query time.

Role required: admin

This test is a quick assessment of the index and is not part of the 14-day index evaluation process. If you are evaluating an index suggestion on a non-production instance, you can run this test after creating the index to get immediate results on index performance.

Note: Index test results from your non-production instance may not necessarily predict similar performance results on your production instance.

1. Open the Index Suggestion record for the index to be tested:
   a) Navigate to System Diagnostics > Index Suggestion > Index Suggestions > In progress.
   b) In the Index Suggestions table, click the Table name for the index to be tested.

2. In the Index Suggestion record, click Test Performance to start the performance test.

3. When the Test Index Suggestion progress indicator shows that testing is complete, click Go to Result.

<table>
<thead>
<tr>
<th>Test Index Suggestion</th>
</tr>
</thead>
<tbody>
<tr>
<td>Query Execution Timer</td>
</tr>
<tr>
<td>Succeeded 100%</td>
</tr>
<tr>
<td>Go to result for final results - Succeeded in 0 Seconds</td>
</tr>
</tbody>
</table>

Go to Result Close
4. In the Query Performance Test Results form, compare the **Average with index** and **Average without index** fields to see if the index improved the query time.

In the following example, the index improved the query time. The **Forced** check box is unchecked, indicating that the database is using the index. If the check box is checked, the database was forced to use the index during the test but is not using the index outside of the test.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Index Suggestion</td>
<td>Name of the index suggestion.</td>
</tr>
<tr>
<td>Created</td>
<td>Date and time this performance test was run.</td>
</tr>
<tr>
<td>Average with Index (ms)</td>
<td>Query time using the index suggestion.</td>
</tr>
<tr>
<td>Average without Index (ms)</td>
<td>Query time before using the index suggestion.</td>
</tr>
<tr>
<td>Forced</td>
<td>Check box indicating whether the database is using the index. If this box is checked, the database was forced to use the index suggestion, but only for this test. If the box is unchecked, the database is using the index.</td>
</tr>
</tbody>
</table>

5. Click the back arrow to navigate back to the Index Suggestion record for the table. The result of this index performance test does not change the index state recorded in the Index Suggestion record.

**Schedule an index to be dropped**

You can drop an index for a slow query when the index is not used by the database or does not improve query performance.

Role required: admin
During the index evaluation period, the ISE may recommend that you drop the index when the database does not use the index or the ISE finds that the index does not improve the query time. You can drop the index immediately or schedule the drop for a later time.

**Note:** If you want to retain an index even though the ISE recommends dropping it, you can use the Accept option in the Index Suggestion record to continue using the index. Before using this option, contact Customer Service and Support for guidance.

1. Navigate to **System Diagnostics > Index Suggestions > Index Suggestions > In Progress**.
2. In the Index Suggestions table, click the Table Name for the index to be dropped.
3. In the Index Suggestion record, click **Schedule Drop**.
4. In the Schedule Index Drop window, select the time you want the index dropped and click **Drop**. You can schedule the index drop at a later time, when your instance is less busy.

**Note:** If the index you want dropped involves large tables, such as the Incident or CMDB table, dropping the index may take up to one hour or longer.

- **Drop now**—The Schedule Index Drop progress indicator window shows the progress of the index drop. When the index drop completes, click **Close**. If the drop is successful, the Index Suggestion record shows the index state as Dropped.
Schedule Index Drop

- **Drop later**—When you schedule the drop, the index state changes to Drop Scheduled. When the system drops the index at the scheduled time, the index state changes to Dropped.

5. Verify that the index was dropped by reviewing the index state in the Index Suggestion record or in the Index Suggestion table (System Diagnostics > Index Suggestions > Index Suggestions > Done).

transaction call chains

Identify and debug the root causes for a problematic transaction by recording, and then reviewing, its call chain. A call chain consists of the ordered series of scripts executed during the life cycle of a transaction.

Transaction Call Chain tracking enables an administrator to register the URL of a problematic transaction for recording of the call chain during the next URL occurrence. It is helpful for diagnosing transaction performance issues.
To enable transaction call chain tracking, perform the following tasks:

1. When you find a problematic transaction on the Transaction Log or Slow Transaction list that requires debugging, select it to view its detail record. To aid in debugging, filter and group these lists by application scope, limiting transactions that appear to only those transactions originating in specific scopes.

   **Note:** To learn more about these lists, see Transaction logs and Slow transactions log record detail.
2. In the record detail form, click **Record call chain of next occurrence**, located under Related Links.
   - It designates that the next occurrence of the transaction URL should be persisted with all of its call chain information.
   - You can optionally designate a user ID so call chain recording only takes place during the next transaction occurrence for a specific user.

3. The next time a user accesses the URL, the Transaction Call Chain Register record is updated to contain a listing of the script resources executed to service the request.

4. In Transaction Call Chains, review the recorded call chain for the transaction, and then take needed actions required to debug it.
Create a transaction call chain register

Create a call chain register to record call chain information for a problematic (or slow) transaction during the next occurrence of that URL. You specify that the next occurrence of the transaction URL should be persisted with all of its call chain information.

Role required: admin

1. Navigate to the Transaction Log or Slow Transactions list, select the problematic transaction, and enable recording of the call chain.

<table>
<thead>
<tr>
<th>Type of Log</th>
<th>Steps</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transaction Log</td>
<td>a. Navigate to System Logs &gt; Transactions</td>
</tr>
<tr>
<td></td>
<td>b. To aid in debugging, filter and group the Transaction Log by application scope, limiting transactions that appear to only those transactions originating in specific scopes.</td>
</tr>
<tr>
<td></td>
<td>c. Select the problematic transaction.</td>
</tr>
<tr>
<td></td>
<td>d. In the Transaction Log Entry form, click Open Record, then click Record call chain of next occurrence, located under Related Links.</td>
</tr>
</tbody>
</table>

| Slow Transactions | a. Navigate to System Diagnostics > Stats > Slow Transactions         |
|                   | b. To aid in debugging, filter and group the Slow Transactions list by application scope, limiting transactions that appear to only those transactions originating in specific scopes. |
|                   | c. Select the problematic transaction.                                |
|                   | d. In the Slow Transactions form, click Open Record, then click Record call chain of next occurrence, located under Related Links. |

2. When the Transaction Call Chain Register appears, optionally fill in the User field.

Transaction Call Chain Register form

<table>
<thead>
<tr>
<th>Control</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>URL</td>
<td>URL for the selected transaction.</td>
</tr>
<tr>
<td>Transaction Log</td>
<td>Transaction log ID created during the next occurrence of the URL. This field is empty when you first create the call chain register for a transaction.</td>
</tr>
<tr>
<td>Recorded</td>
<td>Check box that indicates if call chain recording has already taken place for this transaction.</td>
</tr>
<tr>
<td></td>
<td>• This field is empty (false) when you first create the call chain register for a transaction.</td>
</tr>
<tr>
<td></td>
<td>• true appears when the call chain is recorded during the next occurrence of the URL.</td>
</tr>
</tbody>
</table>
3. Click **Submit**.

A call chain register is created that designates that the next occurrence of the transaction URL should be persisted with all of its call chain information.

**Note:** Once the call chain is recorded (true appears in the **Recorded** field), you can view it in the Transaction Call Chain Register form itself. To learn more about transaction call chains, see Review a transaction call chain.

**Review a transaction call chain**

Use Transaction Call Chains to review the resulting call chain for a selected transaction.

Role required: admin

1. Navigate to **System Diagnostics > Transaction Call Chain > Transaction Call Chains**.
2. To view call chain detail, click the **Created** field for the selected call chain component or script.

**Note:** You can view transaction log detail by clicking the **Transaction Log** field for the selected call chain component or script. To learn more, see Transaction logs.

### Transaction Call Chain form

<table>
<thead>
<tr>
<th>Control</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source Table</td>
<td>Source table for the script resource executed in the call chain.</td>
</tr>
<tr>
<td>Source</td>
<td>Script resource executed in the call chain.</td>
</tr>
<tr>
<td>Persisted Sequence</td>
<td>Order in which the script executed in the call chain.</td>
</tr>
<tr>
<td>Call Depth</td>
<td>Depth of the executed call chain.</td>
</tr>
<tr>
<td>Trigger Table</td>
<td>Name of trigger table, if any, for the executed call chain component.</td>
</tr>
<tr>
<td>Duration(ms)</td>
<td>Observed duration for the script execution, in milliseconds.</td>
</tr>
<tr>
<td>Transaction Log</td>
<td>Transaction log ID created for the recorded call chain.</td>
</tr>
</tbody>
</table>
Transaction cancellation

A user can cancel a transaction that takes longer than expected to load.

Causes of slow-loading transactions include the following scenarios.

• Sorting a large number of records by an unindexed string field.
• Grouping a large table on a field that has predominantly distinct values.
• Exporting all rows from a large table.
• Testing a poorly scripted business rule that has an infinite JavaScript loop.

Note: You cannot cancel an import with these controls.

Transaction cancel timer

During a long-running transaction, a timer and a red cancellation button appear in the banner frame.

Cancel request

To cancel the transaction, click the cancellation button. The timer indicates that the transaction is being canceled. When it is finished, you see a message that the transaction was canceled.

If the transaction completes successfully, the timer indicates how long it took for the transaction to complete.

Canceled transaction logs

Canceled transactions appear in the transaction log with CANCELLED appended to the URL. Transactions canceled by a user are logged differently from transactions canceled by Transaction quotas.
Cancel transaction properties

Administrators can configure the behavior of the transaction cancel capability using the following properties.

<table>
<thead>
<tr>
<th>Property</th>
<th>Definition</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.glide.request_manager.active</td>
<td>Let users cancel long running transactions (enabled by default).</td>
<td>Open the sys_properties table.</td>
</tr>
<tr>
<td>glide.ui.transaction.long_response.time</td>
<td>Delay in seconds before the cancel transaction button appears for a long-running transaction.</td>
<td>Navigate to System Properties &gt; UI Properties</td>
</tr>
</tbody>
</table>

View and kill active transaction

Administrators can view active transactions and kill long-running transactions.

**Note:** Functionality described here requires the Admin role.

This action is intended to stop background processes, such as scheduled jobs, and not user-initiated transactions.

1. If high security is enabled, elevate privileges to security_admin.
2. Navigate to the appropriate Active Transactions module.
   - To view and kill transactions on the current node for your instance, navigate to User Administration > Active Transactions.
   - To view and kill transactions on all nodes for your instance, navigate to System Diagnostics > Active Transactions (All Nodes).
3. Select the transaction you want to stop.
4. Either right-click the record and select Kill, or select the check box next the to record and select Kill from the Actions on selected rows drop-down at the bottom of the list.

Canceled-transaction logging to a table

The system logs canceled-transactions to a table in addition to the transaction log.

Transactions canceled manually or by a quota rule are logged to the Transaction Cancellation Log [syslog_cancellation]. The Transaction Cancellation Log is an extra debugging feature, and will not contain information on all cancellations.

**Note:** There are safeguards in place to prevent infinite loops and issues related to synchronicity, which mean it is not always possible to log a cancellation to a database table.

You can find the Transaction Cancellation Log by clicking System Logs > System Log > Transaction Cancellations

You can turn off canceled-transaction logging to a table by changing a property.
Canceled-transaction log property

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.quota.manager.log.cancellation</td>
<td>Indicates whether canceled transactions are to be logged to the Transaction Cancellation Log table. Type: Boolean Default value: true Location: Add to the System Properties [sys_properties] table</td>
</tr>
</tbody>
</table>

Import set performance

The algorithm transforms import sets from their staging table into their final destination.

Importing data via an import set requires two phases:

1. The data is loaded from a data source into a staging table
2. The data is transformed from the staging table into a target table

The transform algorithm operates in "blocks" of 100 records at a time as opposed to the previous algorithm which transformed a single record at a time. The newer approach allows the application server to pre-fetch a variety of information relevant to each block of records, reducing the number of unique interactions with the database and improving throughput.

Who should expect to see a performance improvement?

Any customer using import sets should expect to see a performance improvement in large transformations.

What kinds of transformations benefit the most from these changes?

Transformations with a large number of reference or choice type columns see the largest improvement.

What kind of transformations benefit the least?

Transformations that with complex or unkeyed coalesce conditions see a proportionately smaller benefit.

Thread performance monitoring

The instance tracks the performance of individual threads, which administrators can view in the transaction log or System Overview graph in the Performance homepage.

Thread performance can be monitored in two places as described in the following sections.

Transaction log

The amount of time a thread waits for an available semaphore or session synchronization is included in the Response Time field in the transaction log. To view the transaction log, navigate to System Logs > Transactions.

Performance graph

Every second, the system looks at all active threads (both UI and background) and places them into one of the following categories.
• **CPU**: The thread is active, but is not executing any of the steps. This condition typically means non-business rule compute time, although in this case a few other internal wait states are categorized as CPU. Therefore a 1:1 correlation between threads in a CPU count and hardware CPU utilization is not expected.

• **Database**: Waiting for information from the database.

• **Business Rule**: The system is running a business rule (synchronous or asynchronous) and is not currently executing a query (which would be database).

• **Network**: Writing data out to the network or waiting for an outbound network buffer to flush.

• **Concurrency**: Cannot run because they are waiting on a semaphore or session synchronization.

Every minute, the system averages these transactions and records them in the database. These averages are displayed in the **System Overview** graph available in the ServiceNow Servlet metrics. For details, see ServiceNow Servlet.

The System Overview chart can be added to any homepage. For more information, see Add existing reports to a homepage.

### Platform performance metrics

You can view a wide range of platform performance metrics for your instance and for the machine on which your instance is running. The ServiceNow Performance homepage provides central access to different graph sets for monitoring the performance of your instance.

To open the ServiceNow Performance homepage:

1. Navigate to **Self-Service > Homepage**.
2. In the homepage list, select **Diagnostics**.
3. In the Diagnostics list, select **ServiceNow Performance Data**.

The ServiceNow Performance homepage features time series graphs for analyzing system behavior and patterns over selected time periods. The homepage interface provides:

- Aggregate summaries of time series graph data
- Graph overlay capability to compare two different data sources within a single graph
- Diagnostic event overlay on each graph to highlight performance anomalies
- Zoom controls to expand each graph and view time series details

**Note:** Users accessing a custom homepage or a dashboard must have an assigned pdb_user role to view performance metric graphs. For more information, see Add existing reports to a homepage and Customize your homepage content.

The graph sets provide performance data for the following functional areas:

- Asynchronous Message Bus (AMB)
- Database
- Instance View
- MySQL Global Status
- ServiceNow Servlet
- Slow Pattern

You can also filter the data in each graph by using different measurements, such as:

- Maximum and minimum values
- Means
- Medians
Customer Service and Support uses some of these graphs to troubleshoot performance issues or help you tune your system for maximum efficiency.

**ServiceNow Performance homepage features**

The ServiceNow Performance homepage provides the following graph and display controls.
ServiceNow Performance homepage elements

<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| 1      | Graph controls:  
  - **Graph set**: Graph collections for viewing performance in specific functional areas:  
    - AMB, Database  
    - Discovery  
    - MySQL Global Status  
    - ServiceNow Servlet  
    - Slow Pattern  
  - **Monitorable items**: Name of the instance under evaluation.  
  - **Timespan**: Period over which the data is captured: 1 hour, 2 hours, 1 day, 7 days, or 30 days  
  - **Compare with graph list**: Graph overlay feature that lets you select a graph from a different data source and compare it to the current graph set. |
| 2      | Suggestion icon: Opens the Suggested Indexes window, which provides links to index suggestions that have been created for slow queries. For details, see Review index suggestions for slow queries. |
| 3      | Display controls:  
  - **Information tooltip**: Provides details about the area on the graph you point to.  
  - **Documentation icon**: Opens the documentation page for the graph set. Appears when you point to the right corner of a graph. Opens the documentation page for the graph set.  
  - **Fullscreen icon**: Opens an enlarged view of the graph, which includes a legend that identifies the graph data. Appears when you point to the right corner of a graph. |
| 4      | Diagnostic Events widget: Lists system events that occurred during the selected timespan. Provides controls for displaying diagnostic events on graphs. |

**Display and zoom controls**

**Fullscreen graph view**

Click the fullscreen icon to open an enlarged view of a graph. The full screen view includes a legend with check boxes for controlling data displayed in the graph. To disable the display of a data item in a graph, clear its check box. On some graphs, you can also change the sort order of certain metrics in the legend.
Zoom in on a selected area of the graph

Click and drag across a portion of the graph area to zoom in on that area and view details over a smaller time interval. To return to the original view, click **Reset Zoom**.
Graph overlays

Use the graph overlay feature to look for trends or patterns between different data sets. For example, you can overlay the Database Response graph over the ServiceNow System Overview graph to determine possible correlations.

- In the **Compare with graph** list, select a performance graph to overlay the current graph set.
- To remove the graph overlay, select **None** in the **Compare with graph** list.
Diagnostic event overlays

Display controls for diagnostic events

Use the following features in the Diagnostic Events widget to control the diagnostic events overlaid on graphs:
• **Show on graphs** switch: Click to enable or disable the event overlay on the graph set. The event overlay is enabled when the switch is green. The following severity flags identify diagnostic events on the graphs:
  - I: Information
  - W: Warning
  - E: Error

• Filter: Click the filter icon to limit the events that appear on the graphs. Clear the check boxes for events you do not want displayed.

• **Clear filter**: Click to reset the filter to its default state (show all events).
Diagnostic event information

- If you enabled the diagnostic event display, point to an event in the graph to see its information.
• For quick access to details on a particular event, click the event listed in the Diagnostic Events widget to open the Event Details form.

### Event Details fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Type of event.</td>
</tr>
<tr>
<td>Reported on</td>
<td>Date and time of event.</td>
</tr>
<tr>
<td>Detail</td>
<td>Additional information on the event, such as type of plugin activated.</td>
</tr>
<tr>
<td>Severity</td>
<td>Type of diagnostic event:</td>
</tr>
<tr>
<td></td>
<td>• I: Information</td>
</tr>
<tr>

<td></td>
<td>• Open</td>
</tr>
<tr>
<td></td>
<td>• Closed</td>
</tr>
<tr>
<td>Configuration item</td>
<td>Infrastructure component, if applicable.</td>
</tr>
</tbody>
</table>
Asynchronous Message Bus (AMB)

Asynchronous Message Bus (AMB) graphs, available to view on the ServiceNow Performance homepage, use asynchronous communication to monitor the transaction count and response times, which provide a performance analysis.

If you have an admin role, you can review performance metrics. The AMB graphs are intended for use by Customer Service and Support to troubleshoot performance issues.

To view AMB graphs on the ServiceNow Performance homepage:

1. In the Graph Set list, select AMB.
2. In the Monitorable Items list, select an instance.
3. In the Timespan list, select a time period.

For details on using the graph and display controls on the Customer Service and Support Performance homepage, see Platform performance metrics.

The following graph displays the maximum, median, and minimum response times in milliseconds over a user-selected timespan. The second graph shows the number of AMB transactions over a user-selected timespan.
Database graphs, available to view on the ServiceNow Performance homepage, display metrics for various database operations, for example, insertions and deletions. They also display a current count of database connections for the selected ServiceNow instance.

If you are running on a single node, which is typical, the graphs show everything. All the traffic shown in the graphs is specific to your cluster node or instance. If you are looking at the database graph for your Discovery node, it does not include traffic for your UI node or vice versa.

If you have the admin role, you can review performance metrics. To view database metrics on the ServiceNow Performance homepage:
1. In the **Graph Set** list, select **Database**.

2. In the **Monitorable Items** list, select an instance.

3. In the **Timespan** list, select a time period.

For details on using the graph and display controls on the ServiceNow Performance homepage, see [Platform performance metrics](https://servicenow.com).
• **Database Throughput**: Displays the count (per minute) for each type of database operation (inserts, deletes, and so on) over time.

• **Database Response**: Displays the response time (in milliseconds) for each type of database operation.

• **DB Connection Use**: Shows how many connections this instance has open to the database. View the maximum, median, and minimum number of database connections in use by the selected node.

• **Replication Throughput**: Measures the difference in the data (delta) between the production instance and the replicated instance as user activity changes the database. Replication is the process whereby an entire instance is replicated on a second machine for failover protection.

    Customer Service and Support uses this information to monitor the progress of replicating a customer instance.

**Instance View**

Review data points across all near nodes (instances) using the Instance View graph set. In a single view, you can review how all active nodes are responding and identify which nodes are experiencing issues.

If you have the admin role, you can review performance metrics. Follow this procedure to view instance performance graphs on the ServiceNow Performance homepage:

1. In the **Graph Set** list, select **Instance View**.
   - The **Monitorable Items** list and **Compare With** selections are both disabled.
   - The **Monitorable Items** list has a value **-All-** for all near (active primary) instances, and excludes far (primary offline or active secondary) instances.
   - Each metric displays data across all active nodes. For example, if you have three instances, all three appear in each metric.

   **Note**: You can view performance metrics for up to 49 near nodes. If you have more than 49 nodes, no data appears for the 50th instance and above.

2. In the **Timespan** list, select a time period.

3. To overlay diagnostic events that have taken place during the time span you requested, toggle **Show on graphs, which appear** next to Diagnostic Events.

For details on using the graph and display controls on the ServiceNow Performance homepage, see **Platform performance metrics**.

Instance View
Transactions: Displays all UI transactions initiated by users. This graph can show large spikes in end-user traffic and identify when peak end-user activity occurs.
• **Response Time**: Displays the interval (in milliseconds) between the time the instance receives a transaction and the time the instance responds. Displays the time the server takes to complete a transaction, on average, during the given time span.

An increase in average response time might indicate that there is a systemic issue or an influx of generally slower transactions. To identify possible performance problems, you can correlate response time with other areas, such as memory, database, or a CPU.

• **Sessions**: Shows active sessions, including those sessions initiated by the MID Server and external integrations. Large numbers of stale but active sessions can lead to memory and performance issues. Session counts larger than 10,000 can typically result in performance degradation. Consider reviewing integration session guidelines and limiting session timeouts.

• **Session Wait Queue**: Displays the number of transactions that are waiting on another transaction for the same user. Waiting sessions occur when a user submits a duplicate request before the prior request completes. Can indicate a slow page or a transaction that requires further investigation.

To identify the transactions that are waiting, check the Transaction Log Entry [syslog_transaction] and view the Session wait time to find the transactions that are waiting. Next, find the transaction [Transaction Number?] that the user is waiting on.

• **Semaphore Use**: Shows the number of semaphores in use by the selected instance. Semaphores control the number of user transactions that can run in parallel.

Long-running transactions on a semaphore can back up all semaphores, causing transactions to wait. The platform manages semaphores, requiring no customer administration. The semaphore graph is used only for troubleshooting.

• **Semaphore Wait Queue**: Shows the wait queue for a semaphore. Use this graph with the **Semaphore Use** graph. A high wait queue indicates long-running transactions on the semaphore. A high and persistent semaphore queue can indicate that the instance node is overloaded with work.

Check the Transaction Log [syslog_transaction] to find the longest-running transactions during that time period and identify the problem. This graph is used only by the platform.

• **Scheduler Queue Length/ Scheduler Completed Jobs**: Displays all scheduler activity for the selected instance, including probes. You can determine the backlog of scheduled jobs in the queue for a particular time period. You can then compare that against the rate at which the jobs are being processed during the same period.

• **Errors**: Shows any severe errors printed to the localhost logs or syslog_ransactions. Multiple severe errors indicate a problem that requires further investigation.

• **Events Processed**: Shows the average number of events processed during the selected time period.

• **HTTP Transactions**: Displays all completed HTTP transactions, including UI, integration, and AMB traffic. This graph can show large spikes in HTTP traffic and can help identify when peak user activity occurs.

### Isolating data for specific instances

Using the Fullscreen View, you can isolate information for specific instances in a selected metric.
1. Select a metric, and then click the Fullscreen icon to open an enlarged view of the graph.
2. Clear the check box next to the instances you want to exclude.
   • For example, clear the check box next to Instance_8080 to exclude its data.
   • Only data for Instance_8081 and Instance_8082 appears.

**MySQL Global Status**

The MySQL Global Status graphs, available to view on the ServiceNow Performance homepage, provide an aggregate view of all traffic going to your database server. These graphs are distinct from the Database graph set, which monitor only queries originating at your particular application instance.

All the traffic shown in the MySQL Global Status graphs is specific to your cluster node and instance. If you have an admin role, you can review performance metrics.

The MySQL Global Status graphs are intended for use by Customer Service and Support to troubleshoot performance issues.

To view metrics for MySQL server status global variables on the ServiceNow Performance homepage:

1. In the **Graph Set** list, select **MySQL Global Status**.
2. In the **Monitorable Items** list, select an instance.
3. In the **Timespan** list, select a time period.

For details on using the graph and display controls on the ServiceNow Performance homepage, see Platform performance metrics.
**ServiceNow Servlet**

Each instance has a servlet, and you can monitor its performance using the Servlet graph set on the ServiceNow Performance homepage.

If you have the admin role, you can review performance metrics. To view servlet graphs on the ServiceNow Performance homepage:

1. In the **Graph Set** list, select ServiceNow Servlet.
2. In the **Monitorable Items** list, select an instance.
3. In the **Timespan** list, select a time period.

For details on using the graph and display controls on the ServiceNow Performance homepage, see Platform performance metrics.
• **System Overview**: Provides thread performance information. Every second, the system looks at all active threads (both UI and background) and places them into one of the following categories:

  • **CPU**: The thread is active, but is not executing any of the steps. This condition typically means non-business rule compute time, although in this case a few other internal wait states are categorized as CPU. Therefore a 1:1 correlation between threads in a CPU count and hardware CPU utilization is not expected.
  
  • **Database**: The thread is waiting for information from the database.
  
  • **Business Rule**: The system is running a business rule (synchronous or asynchronous) and is not currently executing a query (which would be database).
  
  • **Network**: The thread is writing data out to the network or waiting for an outbound network buffer to flush.
  
  • **Concurrency**: The threads cannot run because they are waiting on a semaphore or session synchronization.

The system averages these transactions every minute and records them in the database. The graph shows the averages for each category.

• **Transactions**: Displays all UI transactions initiated by users. This graph can show large spikes in end-user traffic and identify when peak end-user activity occurs.

• **Response Time**: Displays the interval (in milliseconds) between the time the instance receives a transaction and the time the instance responds. Displays the time the server takes to complete a transaction, on average, during the given time span.

An increase in average response time might indicate that there is a systemic issue or an influx of generally slower transactions. To identify possible performance problems, you can correlate response time with other areas, such as memory, database, or a CPU.

• **Sessions**: Shows active sessions, including those sessions initiated by the MID Server and external integrations. Large numbers of stale but active sessions can lead to memory and performance issues. Session counts larger than 10,000 can typically result in performance degradation. Consider reviewing integration session guidelines and limiting session timeouts.

• **Session Wait Queue**: Displays the number of transactions that are waiting on another transaction for the same user. Waiting sessions occur when a user submits a duplicate request before the prior request completes. Can indicate a slow page or a transaction that requires further investigation.

To identify the transactions that are waiting, check the Transaction Log Entry [syslog_transaction] and view the Session wait time to find the transactions that are waiting. Next, find the transaction [Transaction Number?] that the user is waiting on.

• **Semaphore Use**: Shows the number of semaphores in use by the selected instance. Semaphores control the number of user transactions that can run in parallel.

Long-running transactions on a semaphore can back up all semaphores, causing transactions to wait. The platform manages semaphores, requiring no customer administration. The semaphore graph is used only by for troubleshooting.

• **Semaphore Wait Queue**: Shows the wait queue for a semaphore. Use this graph with the Semaphore Use graph. A high wait queue indicates long-running transactions on the semaphore. A high and persistent semaphore queue can indicate that the instance node is overloaded with work.

Check the Transaction Log [syslog_transaction] to find the longest-running transactions during that time period and identify the problem. This graph is used only by .

• **Scheduler Queue Length/Scheduler Completed Jobs**: Displays all scheduler activity for the selected instance, including probes. You can determine the backlog of scheduled jobs in the queue for a particular time period. You can then compare that against the rate at which the jobs are being processed during the same period.

• **Errors**: Shows any severe errors printed to the localhost logs or syslog_ransactions. Multiple severe errors indicate a problem that requires further investigation.

• **Events Processed**: Shows the average number of events processed during the selected time period.

• **Events Logged**: Shows the average number of events queued and added to the event log in the selected time period.
- **HTTP Transactions**: Displays all completed HTTP transactions, including UI, integration, and AMB traffic. This graph can show large spikes in HTTP traffic and can help identify when peak user activity occurs.

### Slow Pattern

You can identify Slow Patterns (transactions, scripts, slow queries, events, mutexes, and cache) in your instance by using the Slow Pattern graph set on the ServiceNow Performance homepage.

If you have an admin role, you can review performance metrics. To view Slow Pattern graphs on the ServiceNow Performance homepage:

1. In the **Graph Set** list, select **Slow Pattern**.
2. In the **Monitorable Items** list, select an instance.
3. In the **Timespan** list, select a time period.

For details on using the graph and display controls on the ServiceNow Performance homepage, see [Platform performance metrics](#).

In the fullscreen view of each Slow Pattern graph, the legend provides links to the Slow Pattern records represented in the graph. For example, the legend in the Slow Query Time graph lists the slowest queries for the instance during the selected timespan.

- Clicking a slow query item in the legend opens the Slow Queries record for that item. You can review query details and determine what action to take on the slow query.
- For convenience, associated Slow Pattern graphs appears below the record so you can review and compare the graphs with details from the Slow Pattern record.
Table rotation

Table rotation preserves instance performance and averts risk associated with querying growing data sets. This feature uses the External Communication Channel (ECC) Queue and the `sys_created_on` field to separate data sets into multiple tables based on date.

**Functionality**

The administrator specifies the time parameter (duration) of the process and the number of tables (rotations) within. After the rotation writes the last table in a rotation, the rotation overwrites the first table in the rotation. Please contact ServiceNow Technical Support before applying table rotation to a custom table.

Examples:

- The query `Records created between 2015/12/10 08:49 and 2015/12/09 07/34 where topic=SystemCommand` is translated to a SQL query on a single table, because the clause on `sys_created_on` targets a single shard.

- The query `Records updated between 2015/12/10 08:49 and 2015/12/09 07/34 where topic=SystemCommand, or without a date range, needs to target all shards and therefore is translated as a union query on all shards.`

**Advantages**

- Allows deletion of old data without affecting current data (for example, to drop or truncate a table).
- Ensures tables only grow to a reasonable size.
- Reduces working set of data when date is known for query.

**Disadvantages**

Queries that do not use the table rotation date (for example, by using the `sys_created_on` field), force an inefficient union query to query time ranges that span multiple tables and can be extremely slow if the number of sub-tables is large.

To improve performance, it is recommended that the query includes a window of created dates.

You can use table rotation for sequentially-written tables or for insert-only tables. You cannot use table rotation for `sys_import` tables or tables that extend the Task `[task]` table.

**Apply table rotation**

You can apply a table rotation to preserve instance performance.

Role required: admin

1. Navigate to **System Definition > Table Rotations**.
2. Click **New**, or select the table rotation group to modify.
3. Fill in the fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter the name of the table.</td>
</tr>
<tr>
<td>Type</td>
<td>Choose Rotation, Extension, or Shard. Rotation and Extension are time-based, Shard is based on a document ID. See Database rotation for more information.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| Rotations             | Sets the number of tables to maintain through the duration.  
                                        | Applies to Rotation type.                                                    |
| Duration              | Set the overall duration for the action.  
                                        | Applies to Rotation and Extension type.                                      |
| Clean base rotation   | Sets the date to clean (truncate) the base table.  
                                        | Applies to Rotation type.                                                    |
4. Click **Submit** or **Update**.

**Note:** Deleting a rotation deletes the additional tables and all the data. Do not delete the rotation if you still need the data.

When you define a new rotation, a schedule creates and new data writes to one of the tables in the rotation group. The group includes the original table plus several additional tables.

</tbody>
</table>
Table flattening
Table flattening stores a hierarchy of related tables as one table in a relational database.

Extension models
Tables such as Task and Base Configuration Item [cmdb] have a hierarchy of related tables where one or more child tables extend from a parent table. The system offers these extension models to store a table hierarchy on a relational database.

<table>
<thead>
<tr>
<th>Available extension models</th>
</tr>
</thead>
<tbody>
<tr>
<td>Extension model</td>
</tr>
<tr>
<td>Table per class</td>
</tr>
<tr>
<td>Table per hierarchy</td>
</tr>
<tr>
<td>Table per partition</td>
</tr>
</tbody>
</table>

The extension model does not affect how the tables appear or function in the instance. All table functionality, including database views, remains unchanged by the extension model.

Table per class
The Table per class extension model stores each table of the hierarchy in its own physical table on the relational database. The physical table is named after the source table of the hierarchy and each stores a different class of records such as Change, Incident, Problem, or Task. The parent table of the hierarchy, such as Task, stores a copy of every record in its descendant tables such as Change, Incident, or Problem.

To find records in a table hierarchy, the system queries records from multiple tables and joins the results. For example, when searching for incidents that have a related problem, the system must join results from the Incident, Problem, and Task tables.

Table joins cause a performance bottleneck on relational databases. The more classes a query includes, the worse the query performance. Therefore any query for records from the top of the table hierarchy has the worst performance because it requires joining all descendant tables.

The system uses the Table per class extension model by default when creating tables. Most system tables also use the Table per class extension model as there is no performance benefit from flattening them.

Table per hierarchy
The Table per hierarchy extension model stores an entire table hierarchy in a single flat physical table on the relational database. The physical table is named after the parent table of the hierarchy, such as Task. The physical table contains all records of the table hierarchy and assigns a class name column value to each descendant table of the hierarchy. The system uses the name of the source table as the class name value. For example, Task records can have class names such as Change, Incident, or Problem.

To find records in a table hierarchy, the system queries the physical table and uses the class name column to constrain the results. Since such queries do not require joining results from multiple tables, the system provides better search performance.
The system uses the Table per hierarchy extension model for the Task table hierarchy on MySQL databases. Other tables use the Table per class extension model because there is no performance benefit to flattening them. To use Table per hierarchy on an Oracle database, contact Technical Support.

**Table per partition**

The Table per partition extension model stores an entire table hierarchy in a single flat logical table on the relational database. Each logical table can have multiple physical storage tables called partitions supporting it. Each partition optimizes the database resources available to a physical table such as the column count, index count, and row size. The system adds a partition whenever the logical table needs additional relational database resources.

Each logical table is named after the parent table of the hierarchy, and each supporting physical partition consists of the logical name plus a partition name. For example, the Base Configuration Item [cmdb] table starts as a logical table with no partitions. Suppose your hardware configuration items consume enough database resources that the system creates a partition called `cmdb$par1` to store them. Later, computer configuration items could consume enough database resources to warrant the system creating a second partition called `cmdb$par2` to store these records.

Within each logical table, the system assigns a class name column value to each descendant table of the hierarchy. For example, within the Base Configuration Item logical table there are records with class names for Application, Computer, and IP Router. The system also assigns a two-digit class path value to each descendant table of the hierarchy. The class path is based on the table location in the hierarchy. For example, the parent class Hardware might have a class path such as `/!!/ID` and the child class Computer might have a class path such as `/!!/ID/!!`.

To find records in a table hierarchy, the system queries the logical table and its partitions and uses the class path column to constrain the results. Since these queries do not require joining results from multiple tables, the system provides better search performance. In addition, the class path reduces the total number of records to search, which further improves search performance.

The system uses the Table per partition extension model for the Base Configuration Item [cmdb] table hierarchy on MySQL databases. To use Table per partition on an Oracle database, contact Technical Support.

**View a table hierarchy and the extension model**

The extension model used by a table is not immediately apparent. While a hierarchy can use a single physical table, the platform displays tables as if each logical table has a unique physical table. For example, when specifying a table for a workflow, you can select Change [change_request] or Incident [incident] even though the parent table, Task [task], uses a single physical table.

Role required: admin

Administrators can view the status of flattened table hierarchies, but cannot flatten additional hierarchies. You can configure the form to add the **Extension model** field if necessary.

1. Navigate to **System Definition > Tables**.
2. Select a table record.
3. Review the **Extension model** field value, which indicates whether the table hierarchy uses multiple unique tables or a single flat table.

- **None**: Indicates that the table uses the table per class model. Defines a unique physical table per logical table in a hierarchy. For example, there are separate physical tables for Task [task], Incident [incident], Problem [problem], and Change [change_request] on the MySQL database.

**Note:** If a table has an empty Extension Model field, it is not necessarily a Table Per Class table. If the table extends another table, it actually inherits the model from any parent tables it is extending, and only when none of the parents have a defined extension model is the table’s extension model Table Per Class. This can be seen on many tables that extend the Task table. Incident is a logical table that extends Task and is physically located on Task, but by default has a blank Extension Model value.
When a table that doesn’t extend anything at all, and has a blank Extension Model field, it is a Table Per Class table.

- **Table per hierarchy**: Defines a single physical table per logical table hierarchy. For example, there is a single Task [task] table on the MySQL database that contains all the Task, Incident, Problem and Change records. This single physical table is represented as separate logical tables.

### Add a module to test connection speed

A connection test can indicate the connection speed between your computer and your instance. A connection speed test (/connection_test.do) is available as a UI page.

Role required: admin

![Connection Test](image)

Connection test is used to determine the type of connect between the end computer and your Service-now.com instance.

To start the connection test, press this **button**:

**Start Connection Test**

Average time: 594ms (per 170k)
Estimated connection:T1/Cable (average download was 282K/s)

Connection Test page

1. Perform the appropriate action for your version of the UI:

| UI16 | a. Navigate to **System Definition > Application Menus**.  
| | b. Open the application menu to which you want to add the module, for example, **System Diagnostics**.  
| UI15 | Right-click an application menu, such as **System Diagnostics**, and select **Edit Application Menu** or click the pencil icon.  

2. Click **New** in the list of modules.
3. Complete the Module form using the following values:
   • **Title**: Unique name such as **Connection Test**
   • **Link type**: URL (from Arguments)
   • **Arguments**: `connection_test.do`

   ![Module form with filled values](image)

4. Click **Submit**.

**Transaction quotas**

Transaction quotas allow you to define a quota policy for different types of transactions. A transaction quota cancels any transaction in violation of the policy and notifies the user of the cancellation.

The Transaction Quotas plugin is active by default on all new and upgraded instances.
Transaction canceled

The transaction quota also writes the cancellation message to the log file as a warning.

Transaction canceled log

Typically, administrators set transaction quotas to prevent poorly performing queries and scripts from consuming system resources. This ensures that no transaction consumes enough resources to prevent other transactions from running. Administrators can also view cancellation log messages to identify transactions that might consume excessive resources.

How transaction quotas work

Transactions use the Quota Manager, which is a background thread that cancels transactions. The Quota Manager performs the following actions.

1. Obtains a list of active transactions, similar to the list under User Administration > Active Transactions.
2. Cycles through each transaction and checks all quota rules with conditions matching the transaction. The first occurrence that exceeds any of the quota limitations triggers a transaction cancellation. If a transaction changes or there is a new quota rule, the Quota Manager re-evaluates the transaction.

**Note:** The *Order* field on a quota rule affects the order in which the quota rules are checked. The Quota Manager checks lower-order rules first (for example, order 80 before order 90), but ultimately checks all rules. This might have marginal performance implications, depending on the conditions of the rules involved.

3. Cancels the transaction if it has been running longer than the specified quota maximum.

4. Logs the running transactions.

5. Sleeps until the next heartbeat, which is controlled by the `glide.quota.manager.heartbeat` system property.

**Transaction cancellation examples**

Transactions can be canceled for more than one reason. Look for the following indicators.

- **maximum execution time exceeded**: This message appears when the `glide.quota.manager` threads cancels the transaction.
- **canceled by other transaction**: This message appears when the transaction was canceled by the session thread that initially issued it, and not by the `glide.quota.manager` thread.
- **canceled by user request**: This message appears when the user clicked the red X button to cancel the running transaction.

If you are looking for transactions that were canceled by `glide.quota.manager`, search for the `[Message] [Contains] [maximum execution time exceeded]` combination. For example:

```
Cancelling transaction /home.do - Default-thread-11.0 (maximum execution time exceeded): Thread Default-thread-11.0 (Default-thread-11.0, F530DD111B11111111FC031767DA158E), after 30000ms
```

**Add variable information to the cancellation message**

You can use the following methods of the `jvar_transaction` variable to add information to the cancellation message.

### Adding Variable Information to the Cancellation Message

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getURL()</code></td>
<td>Returns the URL for the transaction.</td>
</tr>
<tr>
<td><code>getReason()</code></td>
<td>Returns the reason for page cancellation, localized to the user's language.</td>
</tr>
<tr>
<td><code>getQuotaId()</code></td>
<td>Returns the sys_id of the quota rule.</td>
</tr>
<tr>
<td><code>getQuotaName()</code></td>
<td>Returns the name of the quota rule.</td>
</tr>
<tr>
<td><code>getRunTime()</code></td>
<td>Returns the total run time for the page up to this point.</td>
</tr>
<tr>
<td><code>getType()</code></td>
<td>Returns the type of transaction, such as form, list, report, other.</td>
</tr>
<tr>
<td>Method</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>------------------------------------------------------------</td>
</tr>
<tr>
<td>getUser()</td>
<td>Returns the sys_id of the user.</td>
</tr>
<tr>
<td>getHomepage()</td>
<td>Returns the sys_id of the homepage.</td>
</tr>
<tr>
<td>getHomepageWidget()</td>
<td>Returns the name of the homepage widget.</td>
</tr>
</tbody>
</table>

## Transaction quota properties

An administrator can add the following system properties to manage transaction quotas.

### Configuring Transaction Quota Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.quota.manager.heartbeat</td>
<td>The number of seconds between the start of each Quota Manager heartbeat. This value determines how often the Quota Manager checks for transactions that exceed a quota and how often it writes status in the log file. Type: Integer Default value: 1 Location: Add to the [sys_properties] table</td>
</tr>
<tr>
<td>glide.quota.manager.minimum_transaction_time</td>
<td>The minimum number of seconds a transaction must run before the Quota Manager matches it to a transaction quota. ServiceNow recommends setting this value to at least 1 second to avoid performance issues. For optimal performance, set this value to the value of your most restrictive quota. For example, if your most restrictive quota cancels transactions longer than 1 minute, set the minimum transaction time to 60 seconds. Type: Integer Default value: 1 Location: Add to the [sys_properties] table</td>
</tr>
<tr>
<td>glide.quota.manager.debug</td>
<td>Controls whether to display (true) or hide (false) additional debugging information related to the Quota Manager. Debugging information includes running transactions, canceled transactions, and what quotas are matched to transactions. Type: True</td>
</tr>
</tbody>
</table>

### Enable transaction quota debugging

You can enable the logging of transaction quota debugging information by enabling the system property.

Role required: admin

1. Add the glide.quota.manager.debug system property, and set the value to true.
2. Navigate to System Diagnostics > Session Debug > Debug Quotas.
The Debug Quota script runs to enable debugging.

After setting the above system property to **true**, go to your system log to see messages from the Quota Manager.

**Default quota rules**

Various transaction quota rules are available in the base system.

**Fix Script Processor**

Allows the fix script processor to run for four hours.

**Presence**

Cancels presence requests quickly when the system is busy.

**REST Import Set API request timeout**

Prevents inbound REST Import Set API transactions from running for longer than 60 seconds.

**REST Table API request timeout**

Prevents inbound REST Table API transactions from running for longer than 60 seconds.

**AMB Transactions**

Cancels AMB transactions lasting longer than the specified maximum duration. Applies to all AMB transaction types: message send and message receive.

**Reference Completer**

 Stops the reference completer transaction after five seconds.

**REST Aggregate API request timeout**

Prevents inbound REST Aggregate API transactions from running for longer than 60 seconds.

**Homepage Widgets**

Prevents all homepage widgets from running longer than 30 seconds.

**REST Attachment API request timeout**

Prevents inbound REST Import Set API transactions from running for longer than 60 seconds.

**UA Count Persistor Quota**

Prevents UA count persistor scheduled jobs from running for more than one hour.

**UI Transactions**

Cancels UI transactions that are two seconds away from the 5-minute server disconnect. ServiceNow datacenter load balancers display an internal server error (HTTP Error 500) to users after five minutes. This quota rule returns a transaction canceled page instead of an error. This rule includes an exception to prevent the cancellation of background scripts.

**PA Diagnostics All**

Prevents any Diagnostics transaction that originates outside the scope of the Diagnostics application from running longer than 30 minutes. Diagnostics transactions refer to executing a diagnostic, opening a Diagnostics form, or opening a Diagnostics list.
Normal transaction activities

Before setting transaction quotas, navigate to User Administration > Active Transactions to review the normal transaction activities for your instance. You can view and terminate long-running transactions if necessary. Over time, you can determine the normal transaction load for your instance and set your quotas to match these norms.

Configure a transaction quota rule

Transaction quota rules allow you to define a quota policy for different types of transactions.

Role required: admin

Transaction quota rules allow you to specify the following conditions.

- The conditions under which the policy applies.
- The order in which transaction quotas apply.
- The maximum duration of a transaction before the quota manager cancels it.

**Warning:** Setting transaction quotas too low can severely impact your users and prevent normal instance operations. Test your transaction quotas rigorously before implementing them in production.

1. If necessary, activate the Transaction Quotas plugin.
2. Navigate to System Definition > Quota Rules.
3. Click New.
4. Complete the form.

### Transaction quota rule fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name to identify the rule.</td>
</tr>
<tr>
<td>Active</td>
<td>A check box that determines if this rule is active (selected).</td>
</tr>
<tr>
<td>Maximum Duration</td>
<td>The number of seconds a transaction has to complete before the quota cancels the transaction.</td>
</tr>
<tr>
<td>Maximum Business Rules</td>
<td>The number of business rules executions allowed.</td>
</tr>
<tr>
<td>Maximum Database Time</td>
<td>The total number of seconds for all SQL requests.</td>
</tr>
<tr>
<td>Maximum SQL Statement Time</td>
<td>The number of seconds a SQL statement can run.</td>
</tr>
<tr>
<td>Maximum Outbound Requests</td>
<td>The number of outbound HTTPs requests allowed.</td>
</tr>
<tr>
<td>Order</td>
<td>A number that represents the priority of the quota transaction in relation to other quotas. The transaction quota with the lowest timeout, the lowest order value, and matching conditions determines the applied quota policy.</td>
</tr>
<tr>
<td>Maximum Events</td>
<td>The number of sysevent inserts allowed.</td>
</tr>
<tr>
<td>Maximum Jobs</td>
<td>The number of sys_trigger inserts allowed.</td>
</tr>
<tr>
<td>Maximum SQL Queries</td>
<td>The number of SQL queries allowed.</td>
</tr>
<tr>
<td>Maximum Outbound Request Duration</td>
<td>The number of seconds for an outbound HTTP request.</td>
</tr>
<tr>
<td>Description</td>
<td>A description of the transaction quota rule.</td>
</tr>
</tbody>
</table>
5. Set a condition to specify when the transaction quota should take effect.

The transaction quota rule condition builder displays conditions that are only applicable to transactions as listed in the following table.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>URL</td>
<td>The URL of the page.</td>
</tr>
<tr>
<td>Thread Name</td>
<td>The name of the execution thread that is running the transaction. Foreground threads have names like http-bio-8080-exec-1. Background threads can have various names, and are useful where the URL is not sufficiently descriptive.</td>
</tr>
<tr>
<td>Foreground</td>
<td>Whether the transaction was completed in the foreground or background:</td>
</tr>
<tr>
<td></td>
<td>• True: a foreground transaction.</td>
</tr>
<tr>
<td></td>
<td>• False: a background transaction.</td>
</tr>
<tr>
<td>Type</td>
<td>The type of transaction:</td>
</tr>
<tr>
<td></td>
<td>• List: Any list transaction, such as incident_list.do.</td>
</tr>
<tr>
<td></td>
<td>• Form: All forms, UI pages, CMS pages, and so on.</td>
</tr>
<tr>
<td></td>
<td>• XMLHttp: Transactions that run through GlideAjax, where the URL is xmlhttp.do.</td>
</tr>
<tr>
<td></td>
<td>• Report: The page sys_report_template.do.</td>
</tr>
<tr>
<td></td>
<td>• SOAP: SOAP transactions.</td>
</tr>
<tr>
<td></td>
<td>• Export: When a list is exported in a format such as XML or Excel.</td>
</tr>
<tr>
<td></td>
<td>• Scheduler: When a scheduled job is performed.</td>
</tr>
<tr>
<td></td>
<td>• Text Search: The text search transaction or any of its related operations.</td>
</tr>
<tr>
<td></td>
<td>• Other: Any type that does not meet the qualities of another type.</td>
</tr>
<tr>
<td>User</td>
<td>The user performing the transaction.</td>
</tr>
<tr>
<td>Homepage</td>
<td>The homepage that is running. This condition is populated only if the URL is home.do.</td>
</tr>
<tr>
<td>Homepage Widget</td>
<td>The widget that is rendered in the transaction. When a homepage or non-responsive dashboard renders, each widget renders in parallel. When a responsive dashboard renders, each widget renders in sequence. When the quota is exceeded, users see the message: Widget cancelled – maximum execution time exceeded. Increase the quota value if you don’t want to show this message.</td>
</tr>
</tbody>
</table>

Note: Match the transaction quota Type to the transaction type listed in the Quota Manager log entry for the transaction.
6. Click Submit.

**View a canceled transaction**

The Quota Manager logs each canceled transaction as a warning message in the system log.

Role required: admin

Use the following procedure to search for transaction warnings in the system log.

1. Navigate to **System Logs > System Log > Warnings**.
2. Edit the filter to add the condition `[Message] [starts with] [Cancel].`
3. Click **Run**.

**Example system log messages**

An example of system log messages for transactions.

- At every heartbeat interval, which is one second by default, the Quota Manager prints the running transactions:

```
2012-02-13 12:34:08 (096) glide.quota.manager SYSTEM URL= /incident_list.do?
sysparm_userpref_module=b55fbec4c0a80090088e83d7ff500de&active=true&sysparm_query=active=true^EQ,
THREAD= http-bio-8080-exec-3, FG= true, TYPE= 1, STATE= 2, USER= null, TIME= 8,807, MEM= 0, ATTRIBUTES= {}
```

- Every time the Quota Manager matches a quota to a transaction, it prints a message similar to the following example:

```
2012-02-13 13:25:31 (900) glide.quota.manager SYSTEM QuotaFinder: Assigning quota "TEST PROBLEM FORM" with filter: type= form ^urlLIKEsys_id=46fb9e31a9fe198101492060c2a4f8cb^EQ to transaction: URL= /problem.do?sys_id=46fb9e31a9fe198101492060c2a4f8cb,
THREAD= http-bio-8080-exec-1, FG= true, TYPE= 1, STATE= 4, USER= null, TIME= 1,121, MEM= 0, ATTRIBUTES= {}
```
Every time the Quota Manager cancels a transaction, it prints a message similar to the following example:

```
2012-02-13 13:25:33 (930) glide.quota.manager SYSTEM WARNING *** WARNING ***
Transaction: Cancelling transaction /problem.do (maximum execution time exceeded):
Thread http-bio-8080-exec-1
```

**Modify the transaction cancellation page**

The Quota Manager uses a UI page to control the contents of the transaction cancellation message. 

Role required: admin

Knowledge of Apache Jelly is highly recommended when modifying the UI page. See Extensions to Jelly syntax for more information.

1. Navigate to System UI > UI Pages.
2. Open the UI page with the name `transaction_canceled_quota`.
3. In the HTML field, add or modify the new cancellation message.
   The following table describes available variables.

   **Cancellation message variables**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getURL()</td>
<td>Returns the URL for the transaction.</td>
</tr>
<tr>
<td>getReason()</td>
<td>Returns the reason for page cancellation, localized to the user's language.</td>
</tr>
<tr>
<td>getQuotaId()</td>
<td>Returns the sys_id of the quota rule.</td>
</tr>
<tr>
<td>getQuotaName()</td>
<td>Returns the name of the quota rule.</td>
</tr>
<tr>
<td>getRunTime()</td>
<td>Returns the total run time for the page up to this point.</td>
</tr>
<tr>
<td>getType()</td>
<td>Returns the type of transaction, such as form, list, report, other.</td>
</tr>
<tr>
<td>getUser()</td>
<td>Returns the sys_id of the user.</td>
</tr>
<tr>
<td>getHomepage()</td>
<td>Returns the sys_id of the homepage.</td>
</tr>
<tr>
<td>getHomepageWidget()</td>
<td>Returns the name of the homepage widget.</td>
</tr>
</tbody>
</table>

4. Click Update.

**Application quotas**

You can set a limit on the number of events or jobs that can run in an application’s scope within a specified time.

Application quota rules set application quotas. Each scoped application can have one application quota rule. When an application exceeds the quota limit, all transactions running in the application scope are canceled. New transactions are canceled when they start until the next update period. These actions effectively block transactions from an application scope from running for the update period.

An application quota rule applies to transactions created by all instances of an application and all transactions created by methods of the application called by other applications.
If two users are running the same application, the application quota rule does not distinguish between transactions for each instance of the application. If, together, they violate the quota, all transactions in the application's scope are canceled.

If you check the Log Only option, transactions are not canceled by a quota violation. Instead, entries are added to the local host log that indicate the transactions are running under violation.

Transaction and application quota rules are evaluated separately, by defining an application quota rule, you simply introduce another restriction. A transaction is canceled if it violates a transaction quota rule, or if collectively with other application transactions, it violates its application quota rule.

You cannot define an application quota rule for the global application.

### Application-quota property

An administrator can add a system property to specify how often application quota rules are evaluated.

#### Property

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| glide.quota.manager.cluster.update.seconds    | Indicates the application quota update period in seconds. If this value is less than the glide.quota.manager.heartbeat property, the glide.quota.manager.heartbeat value is used. Type: Number  
| Default value: 300 (5 minutes)                 | **Location:** [Add to the System Properties](#) [sys_properties] table                                                                                                                                 |

#### Configure an application-quota rule

You can configure an application-quota rule to limit the number of events or jobs that can run in an application's scope within a specified time.

Role required: admin

You must be in the application scope of the application for which you want to create a rule.

1. Navigate to System Definition > Application Quota Rules.
2. Click New.
   The Application Quota Rule form is shown.
3. Fill in the fields.

#### Configuring application quota rules

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name to identify the rule.</td>
</tr>
<tr>
<td>Application</td>
<td>The scoped application's name. To change this field, use the application picker to change the application. This field cannot be Global.</td>
</tr>
<tr>
<td>Order</td>
<td>A number that represents the priority of the quota transaction in relation to other quotas.</td>
</tr>
<tr>
<td>Active</td>
<td>A check box that determines if this rule is active (selected).</td>
</tr>
</tbody>
</table>
### Field | Description
--- | ---
Log only | When checked, transactions are not canceled by a quota violation, but entries are added to the local host log that indicate the transactions are violating the quota rule. An entry is added to the Transaction Cancellation Log where the log only field is set.
Maximum Events | The maximum number of events allowed during the update period.
Maximum Jobs | The maximum number of jobs allowed during the update period.
Condition | The conditions that determine when the transaction quota applies. The condition builder displays conditions that are only applicable to transactions. For example, Foreground is true.
Description | A description of the transaction quota.

4. Set a condition to specify when the application quota rule should take effect.

The application quota rule condition builder displays conditions that are only applicable to transactions as listed in the following table.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attributes</td>
<td>Miscellaneous attributes that are related to the transaction.</td>
</tr>
<tr>
<td>Created</td>
<td>When the transaction was created.</td>
</tr>
<tr>
<td>Created by</td>
<td>Who created the transaction.</td>
</tr>
<tr>
<td>Foreground</td>
<td>Whether the transaction was completed in the foreground or background:</td>
</tr>
<tr>
<td></td>
<td>• True: a foreground transaction.</td>
</tr>
<tr>
<td></td>
<td>• False: a background transaction.</td>
</tr>
<tr>
<td>Homepage</td>
<td>The homepage that is running. This value is populated only if the URL is <code>home.do</code>.</td>
</tr>
<tr>
<td>Homepage Widget</td>
<td>The homepage widget that is rendered in the transaction. When a homepage is rendered initially, each homepage widget is rendered in parallel.</td>
</tr>
<tr>
<td>Initial Scope Name</td>
<td>Scope where the method that created the transaction is defined. Setting this name to anything other than the selected application means that the rule is never used. The rule only looks at transactions of the selected application, and this value has the rule look for a different application, so the condition is never satisfied.</td>
</tr>
<tr>
<td>Scope Name</td>
<td>Scope of the application that called the method that created the transaction.</td>
</tr>
<tr>
<td>Sys ID</td>
<td>A sys_id of the transaction.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Thread Name</td>
<td>The name of the execution thread that is running the transaction. Foreground threads have names like http-bio-8080-exec-1. Background threads may have various names, and may be useful where the URL is not sufficiently descriptive.</td>
</tr>
</tbody>
</table>
| Type          | The type of transaction:
|               |   • List: Any list transaction, such as incident_list.do.  
|               |   • Form: All forms, UI pages, CMS pages, and so on.  
|               |   • XMLHttpRequest: Transactions that run through GlideAjax, where the URL is xmlhttp.do.  
|               |   • Report: The page sys_report_template.do.  
|               |   • SOAP: SOAP transactions.  
|               |   • Export: When a list is exported in a format such as XML, Excel.  
|               |   • Scheduler: When a scheduled job is performed.  
|               |   • Text Search: The text search transaction or any of its related operations.  
|               |   • Other: Any type that does not meet the qualities of another type.                                                                 |
| URL           | The URL of the page.                                                                                                                          |
| Updated       | When the transaction was updated.                                                                                                             |
| Updated by    | Who updated the transaction.                                                                                                                  |
| Updates       | What was updated.                                                                                                                             |
| User          | The user performing the transaction.                                                                                                          |

5. Click **Submit**.

**Use table extension**

This example shows you how to set the Table Extension parameter to a table rotation group.

Role required: admin

**Note:** Deploy this plugin in partnership with a ServiceNow representative.

Administrators typically specify the time parameter (duration) of the process, but may alternatively specify the number of tables (rotations). After the last table in a rotation is written, new tables are added and old tables are archived. Using table extension, tables are never overwritten.

An advantage of table extension is to partition data across tables. It also allows you to archive data while ensuring that tables stay reasonably-sized. The working set of data is reduced when a date is known for the query.

The disadvantage is that table extension requires a union query when you query for a time range that spans multiple tables. Union queries are less efficient than queries against a single table.
A good practice is to use table extension when you have sequentially-written tables or insert-only type tables (there are exceptions to this parameter). Table extension is also useful in tables where data is needed for long periods of time.

The following example describes how to set table extension for the [sys_audit] table.

1. Navigate to **System Definition > Table Rotations**.
2. Click **New**.
3. Enter the following information.

<table>
<thead>
<tr>
<th>Field</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter the name of the table to apply the action. In this example, the table is [sys_audit].</td>
</tr>
<tr>
<td>Duration</td>
<td>Enter the overall duration for the action. 30 days is the duration in this example.</td>
</tr>
<tr>
<td>Type</td>
<td>Select <strong>Extension</strong>.</td>
</tr>
</tbody>
</table>

4. Click **Submit**.
Platform security

Security is built into all levels of the Now Platform. Implement the security features that are appropriate for your organization, from managing failed logins and encrypted password protection, to access control rules and audit logs.

Platform security resources

<table>
<thead>
<tr>
<th>Resource</th>

**Instance Security Hardening Settings**

The Instance Security Hardening Settings content contains detailed descriptions and compliance values for the security-related system properties and plugins in the Now Platform. You can set most of these properties in the Hardening Compliance Configuration page in the Instance Security Center.

**Overview and purpose**

The Instance Security Center calculates a Daily Compliance Score, expressed as a percentage. It is based on how compliant your current instance security settings are with the compliance values in Instance Security Hardening Settings.
Using its Hardening Compliance Configuration page, you can manage the specific security configuration settings that may affect the score for your instance. To learn more about ensuring your instances meet hardening requirements, see:

- Instance Security Center
- Adjust instance security settings to increase compliance

Consult the Instance Security Hardening Settings whenever you set or update security-related properties, even if some of the compliance values may not be suitable for your instance. When you are updating these properties, ensure that the instance continues to behave as expected. Consult with the appropriate internal personnel who have the expertise to determine the security impacts.

Other resources

For user reference, the Now Platform maintains extensive configuration capabilities information in the product documentation. You access most of the security content using the links found in Platform security. Also, see the following:

- Available system properties
- General security settings properties
- High Security Settings

Access control (instance security hardening)

Access controls determine whether access to a particular resource should be granted or denied. It only allows access to resources to those users permitted to use them.

Authorization is not equivalent to authentication, as these terms and their definitions are frequently confused.

- Authentication is providing and validating identity.
- Authorization includes execution rules that determine what functionality and data the user (or principal) can access, ensuring the proper allocation of access rights after authentication is successful.

Authorization is a process that comes after a successful authentication. You can configure security properties that designate if, after determining that a user holds valid credentials associated with a well-defined set of roles and privileges, resource authorization occurs.

The following are some security controls that an administrator can configure to restrict unauthorized access to sensitive entities within the Now Platform.

- Access control list rules
- Create an ACL rule
- ServiceNow access control

Basic auth: JSONv2 requests (instance security hardening)

Use the `glide.basicauth.required.jsonv2` property to designate if incoming JSONv2 requests should require basic authorization.

**Check UI action conditions before execution (instance security hardening)**

Use the `glide.security.strict.actions` property to enable checking of UI actions conditions in forms and lists before they execute. When you set this property to `true`, it adds an extra layer of validation on the table UI actions before they are executed.

**More information**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td><code>glide.security.strict.actions</code></td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (<code>/sys_properties_list.do</code>)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>To ensure an extra layer of validation on the table UI actions before they are executed.</td>
</tr>
<tr>
<td>Recommended value</td>
<td><code>true</code></td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Low) This remediation only adds an extra layer of validation to check for UI actions on the target table/page on the instance. As long as the access controls are set appropriately on the customer instance, there should not be an impact here.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Medium) Access request is always checked when transactions happen between two zones. This operation validates any UI actions before the form renders for the end user.</td>
</tr>
<tr>
<td>References</td>
<td>High security plugin</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see Add a system property.
**Contextual Security: Role Management plugin (instance security hardening)**

Activate the Contextual Security: Role Management (`com.glide.role_management`) plugin to enable contextual security, which secures a record/information using create, read, write, and delete functionality.

After it is installed and activated, the dictionary roles (created by simple security manager) are no longer tested. Instead, the Now Platform looks for ACL rules on fields and tables. It secures the data with the help of ACL rules instead of traditional, role-based dictionary rules implemented by simple security manager. Even if you configure the dictionary form and add roles to a dictionary entry, no change in rights occurs.

**More information**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plugin ID</td>
<td><code>com.glide.role_management</code></td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Definition &gt; Plugins</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>Unlike the simple security manager, the contextual security manager is aware of the system table hierarchy. You can potentially have different security rules for a field based on where in the hierarchy it appears.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>Active (Plugin activated by default)</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Medium) This remediation enforces functional level of access controls, which would let application determine the access restrictions based on ACL table alone.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(High) Functional level access controls must be enforced from the server side prior to executing CRUD operations, ensuring the appropriate level of access to instance users.</td>
</tr>
<tr>
<td>References</td>
<td>Contextual Security Manager</td>
</tr>
</tbody>
</table>

To learn more about activating a plugin, see [Activate a plugin](#).

**CSV request authorization (instance security hardening)**

Use the `glide.basicauth.required.csv` property to designate if incoming CSV (Comma-Separated Values) requests should require basic authentication.

**More information**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td><code>glide.basicauth.required.csv</code></td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>To enforce basic authentication on CSV requests.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>true</td>
</tr>
</tbody>
</table>
### Functional impact

(Low) This remediation enforces a combination of authentication methods, in the form of basic authentication and system level access control.

- It performs this authentication while retrieving data from tables/pages in the form of CSV data on the instance.
- It restricts any guest users who are currently accessing this data. If applicable, you may need to create a new account for users who need access to this content, with necessary access control permissions.

To learn more, see [Retrieving data from a CSV formatted file](#).

### Security risk

(Medium) Without appropriate authorization configured on the incoming CSV requests, an unauthorized user can get access to sensitive content/data on the target instance.

### References

- [Web service security](#)
- [Add a system property](#)
- [Default deny (instance security hardening)](#)

### Default deny (instance security hardening)

Use the `glide.sm.default_mode` property to control the default behavior of security manager when it finds that existing ACL rules are a part of wildcard table ACL rules.

When the High Security Settings (`com.glide.high_security`) plugin is activated during initial instance installation, it creates this property, and wildcard ACL rules come into existence. To provide role-based access to system tables, these rules control a significant number of ACLs and most common record-based operations:

- Read
- Write
- Create
- Delete

Unless you use the High Security plugin with default deny option enabled, many tables are not protected. The Now Platform uses a default deny security model that prevents non-administrator users from accessing objects unless they meet a matching ACL rule. Using this model, it removes many attack vectors, such as insecure scripts.

### More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td><code>glide.sm.default_mode</code></td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (<code>/sys_properties_list.do</code>)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
</tbody>
</table>
### Attribute Description

**Purpose**
Best security practice would be to restrict an Access to the tables by an unauthorized user.
- If there are no ACL rules in place for tables, this property ensures that at least wildcard ACLs are validated for any CRUD operation performed on the table/field.
- These rules restrict the read, write, create, and delete operations on all tables, unless the user has the admin role or meets the requirements of another table ACL rule.

**Recommended value**
deny

**Functional impact**
(High) If you set this property to *Allow*, the wildcard table ACL rules allow CRUD operations on all tables unless there are specific table ACL rules in place to restrict such operations.

**Security risk**
(High) Non-administrator users can access objects that match the wildcard table ACL rules.

**References**
Default deny property

---

**Double check inbound transactions (instance security hardening)**

Use the `glide.security.strict.updates` property to enable double-checking of security on inbound transactions during form submission. When you set this property to *true*, it adds an extra layer of table validation before a form renders in the browser.

**More information**

<table>
<thead>
<tr>

</tr>
<tr>
<td>References</td>
<td>General security settings properties</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see Add a system property.

**Enable ACLs to control live profile details (instance security hardening)**

Use the `glide.live_profile.details` property to designate whether a user should be able to view all detail fields, such as company name and phone numbers, in a live profile.

Depending on the setting of the `glide.live_profile.details` property, the following occur:

- If the value is set to **Show**, access to the live profile information is granted, regardless of the ACLs created for the user profile.
- If the value is set to **ACL**, access to the live profile information is restricted, as per the ACLs created for the user profile.
- If the value is set to **Hide**, access to the live profile information is restricted, regardless of the ACLs created for the user profile.

**More information**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.live_profile.details</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>The purpose is to enable only authorized users to access the details of a Live Profile (such as Company name, Phone numbers)</td>
</tr>
<tr>
<td>Recommended value</td>
<td>ACL</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Medium) If property is not enabled, unauthorized users can access the Live profile details of all other users.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Medium) API requests should always honor table ACLs. Restriction must be applied to prevent unauthorized users accessing details of a Live Profile.</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see Add a system property.

**Enabling AJAXGlideRecord ACL checking (instance security hardening)**

Use the `glide.script.secure.ajaxgliderrecord` property to perform access control rule (ACL) validation when server-side records, such as tables, are accessed using GlideAjax APIs within a client script.

From client scripts, it is possible to query arbitrary data from the server using the AJAXGlideRecord (GlideAjax - Client) API, by using a syntax such as a server-side glide record. It is a powerful and useful tool in many deployments.
If you choose to apply, Access Control Lists (ACL) to GlideAjax API calls, you can only query data to which the currently connected user has access. For example, if an ESS user who has no rights to read the cmn_location table is logged in, any GlideAjax API call to that table would fail.

If the Now Platform is running without GlideAjax ACL call checking, an API can return information that the currently logged in user could not otherwise access.

More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.script.secure.ajaxgliderecord</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>Ensure security ACLs are checked and validated even when the records are accessed through Client Side APIs.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>true</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(High) This remediation enforces the ACL relationship with server-side records when the requests are made using the AJAXGlideRecord API calls. If the ACL configuration is not properly configured, then there is potential impact. For more details on its impact, and how to identify it, see Refer to the Audit and review client-side GlideRecord (AJAXGlideRecord) transactions [KB0550828] article in the HI Knowledge Base.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(High) Through client scripts, it is possible to query arbitrary data from the server through the GlideAjax API. Server-side resources can be accessed without proper authorization, so using ACL validation helps the application validate the request based on the configured authorization.</td>
</tr>
<tr>
<td>Workaround</td>
<td>Ensure that proper ACLs are created for script includes, processors, and other entities used by a GlideAjax (AJAXGlideRecord) API so that it executes under proper authorization. Implement methods like canRead(), canWrite(), canCreate(), and canDelete() to perform user authorization before accessing table records using GlideRecord. Another method is to use GlideRecordSecure. The class is inherited from the GlideRecord Server that performs the same functions as GlideRecord, and also enforces ACLs.</td>
</tr>
<tr>
<td>References</td>
<td>Apply ACLs to AJAXGlideRecord (client-side Glide record)</td>
</tr>
</tbody>
</table>

This property belongs to the same family of properties that secure and restrict execution of scripts originating from the client:

- glide.script.use.sandbox: See Client generated scripts sandbox.
- glide.script.allow.ajaxevaluate: See Enable AJAXEvaluate.

To learn more about adding or creating a system property, see Add a system property.
Excel request authorization (instance security hardening)

Use the `glide.basicauth.required.excel` property to designate if incoming Excel requests should require basic authentication.

More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.basicauth.required.excel</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>To enforce basic authentication on Excel requests.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>true</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Low) This remediation enforces a combination of authentication methods, in the form of basic authentication and system level access control.</td>
</tr>
<tr>
<td></td>
<td>• It performs this authentication while retrieving data from tables/pages in the form of Excel data on the instance.</td>
</tr>
<tr>
<td></td>
<td>• It restricts any guest users who are currently accessing this data. If applicable, you may need to create a new account for users who need access to this content, with necessary access control permissions.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Medium) Without appropriate authorization configured on the incoming Excel requests, an unauthorized user can get access to sensitive content/data on the target instance.</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see Add a system property.

Explicit Role plugin (instance security hardening)

Activate the Explicit Role (com.glide.explicit_roles) plugin to provide the instance with the new snc_internal and snc_external roles for B2B and B2C applications, preventing external users from accessing internal data. Enterprise users (employees) must have the internal role while non-enterprise users (non-employees) must have the external role.

When you install the explicit role plugin:

- It assigns all existing users with the new snc_internal role. It also assigns all tables without any role with the snc_internal role.
- When you create a user or table after activating the Explicit Role plugin, the Now Platform assigns the user or table with the snc_internal role.
- The Now Platform prevents the users with the snc_external role from accessing any table that is not explicitly assigned with the snc_external role.
- Any table with the public role are accessible by both internal or external users.

Role summary

snc_internal
This role is assigned to all internal users (employee or internal to an organization). Any new user that gets added also get this role during their first login/impersonation, provided the user doesn't have the snc_external role already assigned. All the existing ACLs without a role are patched with the 'snc_internal' role. For new ACLs, the Now Platform automatically adds this role if the ACL is saved without any role.

**snc_external**

This role indicates that the user is external to your organization and should not have any access to resources unless:

- You explicitly allow access through ACLs for the snc_external role, or
- You explicitly grant them additional roles.

By default, users with the snc_external role are unable to access non-record type resources as well, such as processors and UI pages.

**public**

Any entities with public role assigned to it are accessible by both snc_internal and snc_external users.

When using Explicit Role plugin:

1. Review and validate that any table with the public role doesn't contain any sensitive record to the external users, including unauthenticated public users.

2. If the table with the public role contains sensitive data, and you want to restrict the sensitive records from external users, either:
   - Remove the public role from the table or
   - Add additional scripted ACL to the table.

3. Review and validate that all endpoints, such as the Scripted REST APIs, use the **GlideRecordSecure** or explicitly check roles using `canRead()`, `canWrite()`, `canUpdate()`, and `canDelete()`.

### More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Plugin Name</strong></td>
<td>com.glide.explicit_roles</td>
</tr>
<tr>
<td><strong>Configuration type</strong></td>
<td>System Definition &gt; Plugin</td>

<td>No</td>
</tr>
<tr>
<td><strong>Purpose</strong></td>
<td>To prevent external users from accessing internal data.</td>
</tr>
<tr>
<td><strong>Recommended value</strong></td>
<td>Active</td>
</tr>
<tr>
<td><strong>Functional impact</strong></td>
<td>(Low) No significant impact as the plugin automatically assigns the snc_internal role to the table so the existing internal users still have the necessary access.</td>
</tr>
<tr>
<td><strong>Security risk</strong></td>
<td>(High) External Users (Non-employees) can access to many sensitive tables in the Now Platform that do not have any roles assigned to it. They are meant to be accessible by internal users (Employees) only.</td>
</tr>
<tr>
<td><strong>References</strong></td>
<td>Explicit Roles</td>
</tr>
</tbody>
</table>
Steps to configure

When creating feature or application with the explicit roles:

1. Create a role that inherits the snc_external role for your new feature or application.
2. When creating an external user, remove the snc_internal role and add the newly created role that inherits the snc_external role.
3. When adding the new role that inherits the snc_external role to the existing table, review and validate that the table doesn't contain any sensitive record.
4. When creating a table, validate that the table is accessible only by authorized internal and external user roles.
5. When creating endpoints such as the Scripted REST API, use GlideRecordSecure or explicitly check roles using `canRead()`, `canWrite()`, `canUpdate()`, and `canDelete()`.

When creating a table with the public role, make sure that the table doesn't contain any sensitive record to the external users including unauthenticated public users.

Import request authorization (instance security hardening)

Use the `glide.basicauth.required.importprocessor` property to designate if incoming import requests should require basic authentication.

More information

<table>
<thead>
<tr>

</tbody>
</table>
| Functional impact             | (Low) This remediation enforces a combination of authentication methods, in the form of basic authentication and system level access control.  
• It performs this authentication while retrieving data from tables/pages in the form of PDF data on the instance.  
• It restricts any guest users who are currently accessing this data.  
If applicable, you may need to create a new account for users who need access to this content, with necessary access control permissions.  
To learn more, see Web service import sets. |
| Security risk                 | (Medium) Without appropriate authorization configured on the incoming PDF requests, an unauthorized user can get access to sensitive content/data on the target instance. |

To learn more about adding or creating a system property, see Add a system property.

Performance monitoring (ACL) (instance security hardening)

Use the \texttt{glide.security.diag\_txns\_acl} property to control stats.do, threads.do, thread\_pool\_stats, and replication.do access from an unauthenticated connection.

When you set this property to \texttt{true}, the \texttt{glide.security.diag\_txns\_acl} property only allows access to the following by the administrator account:

• https://<instancename>.servicenow.com/stats.do
• https://<instancename>.servicenow.com/threads.do
• https://<instancename>.servicenow.com/replication.do
• https://<instancename>.servicenow.com/thread\_pool\_stats.do

Without enabling this setting, it is still possible to access these resources from an unauthenticated connection.
More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.security.diag_txns_acl</td>

<td>(Low) This remediation enforces only administrator account to get access to the application sensitive data for logging and troubleshooting purposes.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Low) Sensitive data such as server details, threads, and processes executed on the server should never be visible or accessible to the end user without appropriate privileges.</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see Add a system property.

Performance monitoring IP restriction (instance security hardening)

Use the **glide.custom.ip.authenticate.allow** property to enable only a specified comma-separated list or a range of IP addresses access to stats.do, threads.do, and replication.do pages. If this property is not enabled, it is possible to access those types of pages from any IP address.

**Note:** Based on some recent changes, IP Address Access Control must be used for all IP restriction. Refer to the Steps to Configure section in Restrict access to specific IP ranges.

More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.custom.ip.authenticate.allow</td>

<td>Comma-separated list of IP address.</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Low) Sensitive information pages can be accessed even from an untrusted IP address.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Low) Unnecessary exposure to the target instance on the internet should be restricted with the help of IP access controls functionality.</td>
</tr>
<tr>
<td>Reference</td>
<td>Available system properties</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see Add a system property.
Privacy on client-callable script includes (instance security hardening)

By default, client-callable script includes that do not explicitly set visibility, are public. If needed, add the `glide.script.ccsi.ispublic` property to enable privacy control over all client-callable script includes accessed by public pages.

When you add this property, you must set its value to `false`, which designates that all client-callable script includes are private, and changes their visibility in public pages.

Note: You cannot add the property with a value of `true`, or change its value from `false` to `true`. If you attempt to do so, an error message appears.

If needed, you can change the privacy setting for an individual client-callable script include by adding the `isPublic()` function.

- The `isPublic()` setting takes precedence over the `glide.script.ccsi.ispublic` property.
- For example, if you set `isPublic()` to `true` in an individual script, it makes it public, which overrides the `glide.script.ccsi.ispublic` property that makes all other client-callable script includes private.

More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td><code>glide.script.ccsi.ispublic</code></td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>Making client-callable script includes private means that guests who access public pages can't access the client-callable script include. A non-logged-in user can't execute a private script.</td>
</tr>
<tr>
<td>Recommended value</td>
<td><code>false</code></td>
</tr>
<tr>
<td>Functional impact</td>
<td>(High) If the client-callable script includes are designated as public (that is, this property is missing), then unauthenticated users can execute client scripts. Add the property restricts the execution of scripts by a non-logged-in user.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(High) If you do not add this property, client-side script includes circumvent ACLs, which may result in unintended public functionality. If the client script provides confidential information, it could have an adverse potential security risk.</td>
</tr>
<tr>
<td>Workaround</td>
<td>Setting the <code>glide.script.ccsi.ispublic</code> property to <code>false</code> makes all client-callable script includes private. You can change the privacy setting for an individual client-callable script include by adding the <code>isPublic()</code> function. The <code>isPublic</code> function takes precedence over the <code>glide.script.ccsi.ispublic</code> property. Add the following syntax to the script include: <code>isPublic:function(){return[true/false];}</code>,</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see Add a system property.
Restrict access to specific IP ranges (instance security hardening)

Use the `com.snc.ipauthenticator` property to restrict access to specific IP ranges. Unless public access is intended for the instance, administrators should limit access to their assigned IP net blocks.

**Prerequisites**

Before setting this property, you must activate the IP Range Based Authentication `com.snc.ipauthenticator` plugin. To learn more, see IP range based authentication and in the Steps to configure section (below).

**More information**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plugin Name</td>
<td>com.snc.ipauthenticator</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Security &gt; IP Address Access Control</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>To add the range of IP address that can or can't access the instance to the trusted and untrusted domain lists.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>Active</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Low) Customer-denied IP ranges are used for this remediation item. No impact as customer defines the target list.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Low) Unnecessary exposure to the target instance on the internet should be restricted with the help of IP access controls functionality.</td>
</tr>
<tr>
<td>References</td>
<td>IP range based authentication</td>
</tr>
</tbody>
</table>

**Steps to configure**

1. Ensure that the `com.snc.ipauthenticator` plugin is active.

2. Navigate to **System Security > IP Address Access Control**.

3. Click **New** to create an exclusion list (Deny) or an inclusion list (Allow) of IP addresses.
4. Click Submit.

![Image of a web interface for setting permissions]

**RSS request authorization (instance security hardening)**

Use the `glide.basicauth.required.rss` property to designate if incoming RSS requests should require basic authentication.

### More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td><code>glide.basicauth.required.rss</code></td>

SAML 2.0 web browser SSO profile (instance security hardening)

The `com.snc.integration.sso.saml20.update1` plugin ensures that the status of the SAML 2.0 Single Sign-On plugin is active.

Security Assertion Markup Language (SAML) is an XML-based standard for exchanging authentication and authorization data between security domains. SAML exchanges security information between an identity provider (a producer of assertions) and a Service Provider (a consumer of assertions).

The `com.snc.integration.sso.saml20.update1` plugin is a required plugin, but you do not need to manually activate it. The `sso.multi.installer` installs all required SAML-related plugins, and also contains saml2 implementation scripts that provide options for response validation. To learn more, see the topics in References in More Information.

**Security jump start (ACL rules) (instance security hardening)**

Activate the Security Jump Start (ACL Rules) (**com.snc.system_security**) plugin to create several important ACLs that validate the Access Controls on some of the key system tables within the Now Platform.

These rules provide a jump-start on securing many system tables, making it easier for an organization to get an instance into production. The Security Jump Start (ACL Rules) plugin is installed automatically on all new instances.

**More information**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plugin ID</td>
<td>com.snc.system_security</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Definition &gt; Plugins</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>Activate the Security Jump Start (ACL Rules) plugin to achieve proper security compliance.</td>
</tr>
<tr>
<td></td>
<td>It provides some basic ACLs that secure system tables in the first place instead of creating manually for each system table that comes with default provisioning of an instance. These ACLs are helpful when the newly created instance must quickly move into production.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>Active</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Medium) There is significant functional impact if this plugin is installed without auditing of the existing ACLs on the instance. Customer outreach and definitions are required before the remediation can occur.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(High) Access control should be enforced to lock down the unintended access to the instance. ACL jumpstart rules were created to provide a starting point on securing many system tables to make it easier for an organization to quickly get into production.</td>
</tr>
</tbody>
</table>
### Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>References</td>
<td>Security jump start - ACL rules</td>
</tr>
</tbody>
</table>

### Steps to configure

If this plugin is not activated on your instance, contact ServiceNow Support. Activating the plugin at this point might modify security access to tables already in use in a production environment. If an administrator is interested in the new ACL rules the plugin provides, you can manually create one or more of them in an existing instance if needed. This list of ACLs may be used as a guideline in that case.

To learn more about activating a plugin, see [Activate a plugin](#).

### SNC Access Control plugin (instance security hardening)

Activate the SNC Access Control ([com.snc.snc_access_control](#)) plugin to control access to your instances by Customer Service and Support personnel.

The default configuration for the Now Platform enables Customer Service and Support to access instances through an internal process that creates short-term support credentials. Although all access is audited, some customers prefer to control this access.

This plugin enables the Customer Administrator to prohibit Customer Service and Support employees from accessing the instance. This decision does have an impact on support SLAs because you must enable Now Platform access before support activities can begin. To learn more, see [ServiceNow access control](#).

### More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plugin Name</td>
<td>com.snc.snc_access_control</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Definition &gt; Plugins</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>Prohibits Customer Service and Support employees from accessing the instance</td>
</tr>
<tr>
<td>Recommended value</td>
<td>Active</td>
</tr>
<tr>
<td>Role required</td>
<td>The customer administrator can't activate this plugin. It must be explicitly requested because it requires elevated privileges to activate the plugin.</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Low) If this plugin is inactive, all Customer Service and Support employees can access the customer's instance. Enabling the plugin enables the customer to restrict access to authorized Customer Service and Support employees only.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Low) Unnecessary exposure of instance access to wider group of people</td>
</tr>
<tr>
<td>References</td>
<td>ServiceNow access control</td>
</tr>
</tbody>
</table>
Steps to configure

1. To request the plugin, follow the steps in Request ServiceNow access control. Customers must request the SNC Access Control plugin (com.snc.snc_access_control) from HI.

2. To enable SNC access control, follow the steps in Configure ServiceNow access control. Configure an access control record to specify one or more Customer Service and Support employees that have permission to log in your instance.

SOAP content type checking (instance security hardening)

Use the `glide.soap.require_content_type_xml` property to enable validation of a content type as text/xml and protect against invalid SOAP requests.

- When set to `true`, the Now Platform validates the content type as text/xml and protects against invalid SOAP requests.
- If set to `false`, any content-type value is allowed.

More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td><code>glide.soap.require_content_type_xml</code></td>
</tr>
<tr>
<td>Configuration type</td>

</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>Protect against invalid SOAP requests</td>
</tr>
<tr>
<td>Recommended value</td>
<td>true</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Low) This remediation enables validation of SOAP content type for all the inbound SOAP requests.</td>
</tr>
<tr>
<td></td>
<td>• If you are using a content type other than text/xml for inbound requests, it may cause potential failure of SOAP transactions.</td>
</tr>
<tr>
<td></td>
<td>• If you are not using the correct MIME type, it could disrupt third-party integrations.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(High) When accepting inbound SOAP requests, the appropriate validation is performed to ensure that the relevant content type is being defined as a part of the request. It restricts the invalid SOAP responses that can be viewed as a security risk.</td>
</tr>
<tr>
<td>Reference</td>
<td>Content types</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see Add a system property.
**Strict IP restriction (instance security hardening)**

Use the `glide.ip.authenticate.strict` property to enable a strict set of IP addresses, such as DC and secure VPN, to access this instance.

**More information**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.ip.authenticate.strict</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>Allows ServiceNow employees to access the instance only through secured set of IP ranges</td>
</tr>
<tr>
<td>Recommended value</td>
<td>true</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Low) If this property is not enabled, ServiceNow employees can access the customer’s instance through all the IP ranges. Enabling the property restricts access to a secure set of IP ranges (Secure VPN, DC).</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Low) Unnecessary exposure of instance access to wider group of people.</td>
</tr>
<tr>
<td>Reference</td>
<td>IP range based authentication</td>
</tr>
</tbody>
</table>

**Note:** If you set this property to true, the Now Platform uses a more restrictive `glide.ip.authenticate.allow.secured` property instead of the Performance Monitoring IP restriction `glide.ip.authenticate.allow.secured` property for a set of IP ranges that can access the instance.

To learn more about adding or creating a system property, see [Add a system property](#).

**Unload request authorization (instance security hardening)**

Use the `glide.basicauth.required.unl` (useUnloadFormat) property to designate if incoming unload requests should require basic authentication.

**More information**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

To learn more, see Non-interactive sessions. |
| Security risk        | (Medium) Without appropriate authorization configured on the incoming XSD requests, an unauthorized user can get access to sensitive content/data on the target instance.                                                                 |
| References           | Authentication                                                                                                                                                                                                |

To learn more about adding or creating a system property, see Add a system property.

**Attachments (instance security hardening)**

Many Now Platform business processes allow for the upload of data/information. It regularly checks the validity and security of text, but accepting these files can introduce even more risk.

To reduce the risk, you should validate for malicious files so that the Now Platform can correctly protect against attackers who send these files. You handle these files by including business logic that scans files during the upload process and rejects those files perceived as malicious.

**Internal References**

- Administering attachments
- Configure attachment system properties

**Downloadable MIME types (instance security hardening)**

Use the glide.ui.attachment.download_mime_types property to specify a list of comma-separated attachment MIME types that should be downloaded but not render inline in the browser.

To view a listing of existing MIME types, type /sys_attachment_icon_rule_list.do. You can enable any one of these MIME types to meet the security compliance requirements within the Now Platform.

**Note:** If you set the Force Download MIME Types property to true, it overrides the Downloadable MIME types property, which is a comma-delimited listing of downloadable MIME types. To learn more, see Force download MIME types.
### Attribute Description

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.ui.attachment.download_mime_types</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>To restrict the file types from being rendered in the browser to avoid any hidden malicious script execution.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>Some defined file types, for example, text/html, text/csv.</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Low) This remediation enforces performance of validation checks before performing an action when you click an attachment in a Now Platform application. There is no potential impact, but the user experience is altered.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Medium) Client-side scripting attack vectors come in different flavors and MIME type attachment abuse is no exception. Attackers can abuse MIME types and place unintended script content in the attachment on the victim's side to capture sensitive information. In the current context, populate the property with a list of comma-separated attachment mime types that should not render inline in the browser. Example: text/html</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see [Add a system property](#).

### Enable blacklist for attachments (instance security hardening)

Use the `glide.security.attachment_type.use_blacklist` property to designate if the Now Platform should validate the attachment against a specified exclusion list.

**Note:** Set this property before setting the `glide.attachment.blacklisted.extensions` and `glide.attachment.blacklisted.types` properties. To learn more, see [Specify excluded attachment extensions](#) (instance security hardening) and [Specify excluded attachment file types](#) (instance security hardening).

</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see Add a system property.

**Enable file download restrictions (instance security hardening)**

Use the *glide.ui.strict_customer_uploaded_static_content* property to enable restrictions on the file types that can be downloaded when they have been uploaded using the Upload File functionality.

You use this property with the *glide.ui.strict_customer_uploaded_content_types* property, which creates a comma-delimited list of restricted downloadable file types. To learn more, see Downloadable file types.

**More information**

<table>
<thead>
<tr>
<th>Attribute</th>

<td>true</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Low) This remediation enforces restriction of file downloads based on the values specified in the <em>glide.ui.strict_customer_uploaded_content_types</em> property. To learn more, see Downloadable file types.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Medium) File download restrictions should be applied to any untrusted user input sources.</td>
</tr>
</tbody>
</table>

**Enforce strict user image upload (instance security hardening)**

Use the *glide.security.strict.user_image_upload* property to enable Access Control for the upload/update of a profile picture when performed on a user record.

This setting opens the possibility of an unauthorized user uploading an image to another user's profile.

- When you set this property to true, the table ACLs are enforced when uploading photos, only allowing authorized users to upload an image.
• When you set it to false, ACLs are not enforced on image uploads to the Photo field.

More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>

</tr>
<tr>
<td>Functional impact</td>
<td>(Medium) This remediation enforces the download of all attachments. No functionality impact, but it results in altered user experience.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(High) To reduce the client-side scripting attacks, file attachments should be force downloaded as opposed to being rendered in the browser context.</td>
</tr>
</tbody>
</table>

References

Available system properties
To learn more about adding or creating a system property, see Add a system property.

**Restrict file extensions (instance security hardening)**

Use the `glide.attachment.extensions` property to create a comma-delimited list of restricted downloadable file extension types. The specified files extension types are the only ones that can be uploaded as attachments. Using this property improves security by preventing users from uploading harmful files, such as viruses, as attachments.

This functionality can also prevent the use of incompatible file types. For example, some browsers do not support icons in a .png format. This property doesn't restrict files based on the actual file type, but only based on the extension. If no extensions are specified, then all extensions are allowed. However, if any extensions are specified, all unlisted extensions are restricted.

**Note:** Set this property before setting the `glide.security.file.mime_type.validation` property. Only those extensions specified within this property are checked for MIME type during upload. To learn more, see Upload MIME type restriction.

**More information**

<table>
<thead>
<tr>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.attachment.extensions</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>To only enable acceptable file extensions to be uploaded during file attachment. It blocks an attempt to upload potentially malicious extensions.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>Some defined file extensions, such doc, docx, pdf, xls, xlsx</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Medium) This remediation restricts all the file extensions except the ones in the inclusion list. No functionality impact unless there is an attempt to upload any file other than extensions acceptable by organization.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Medium) As MIME type verification depends on this property, it is recommended to mitigate against the vulnerabilities related to malicious file upload.</td>
</tr>
</tbody>
</table>

**Steps to configure**

1. Navigate to `/sys_properties_list.do`.
2. Search for the `glide.attachment.extensions` property.
3. Specify the acceptable downloadable file extensions in a comma-separated list as shown, then click **Update**.

![System Property glide.attachment.extensions](image)

Specify excluded attachment extensions (instance security hardening)

When you enable exclusion list validation in the Now Platform, use the `glide.attachment.blacklisted.extensions` property to create a comma-delimited list of restricted uploadable file extension types. Uploading of the specified file extension types is restricted.

### Prerequisites

Before setting this property, set the `glide.security.attachment_type.use_blacklist` property to true. To learn more, see [Enable blacklist for attachments](#).

### More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>

<tr>
<td>Security risk</td>
<td>(Medium) A malicious user can upload malware infected attachment with common executable file types.</td>
</tr>
</tbody>
</table>
| Workaround         | Properties are available in base system functionality that address the same issue with inclusion listing rather than with exclusion listing. To learn more, see:  
                       • Restrict file extensions  
                       • Upload MIME type restriction |
To learn more about adding or creating a system property, see Add a system property.

**Downloadable file types (instance security hardening)**

Use the glide.ui.strict_customer_uploaded_content_types property to create a comma-delimited list of restricted downloadable file types. The specified files types are the only ones that can be downloaded as static content from an instance.

### More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.ui.strict_customer_uploaded_content_types</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>To ensure that only file types in inclusion lists are allowed to be downloaded.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>User Specified (Common: doc, docx, xls, xlsx, pdf, and the like)</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Medium) Only files that are in inclusion lists can be downloaded which might affect the organization policy. The comma-separated inclusion list must be modified to comply with organization's policy for acceptable downloadable file types.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Low) File download restrictions should be applied to any untrusted user input sources.</td>
</tr>
<tr>
<td>References</td>
<td>General security settings properties</td>
</tr>
<tr>
<td></td>
<td>Content types</td>
</tr>
</tbody>
</table>

### Steps to configure

1. Navigate to /sys_properties_list.do.
2. Search for the glide.ui.strict_customer_uploaded_content_types property.
3. Specify the acceptable downloadable file types in a comma-separated list as shown, then click **Update**.

![Upload MIME type restriction (instance security hardening)](image)

**Upload MIME type restriction (instance security hardening)**

Use the `glide.security.file.mime_type.validation` property to activate MIME type checking for uploads. You can enable (set the property to **true**) or disable (set it to **false**) MIME type validation for file attachments.

**Prerequisites**

Before setting this property, set the `glide.attachment.extensions` property. Only those extensions specified in `glide.attachment.extensions` are checked for MIME type during upload. To learn more, see **Restrict file extensions**.

**More information**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td><code>glide.security.file.mime_type.validation</code></td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>To enforce checking of MIME type / magic bytes during file uploads.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>true</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Medium) This remediation enables MIME type verification on the attachments to the application. No functionality impact, unless there is a malicious intent in uploading the files as this validation is merely checking for mis-sync between the MIME type and the data.</td>
</tr>
</tbody>
</table>
### Email security (instance security hardening)

This section contains security controls an administrator can configure to ensure that proper security policies are in place for all inbound emails.

**Convert inbound email HTML (instance security hardening)**

Use the `glide.email.inbound.convert_html_inline_attachment_references` property to specify whether to convert inbound email HTML so email images appear in the email HTML body preview.

In the Now Platform, broken cid (content ID) links appear in place of images received when you set this property to false. The format in which the email image appears depends on the property setting at the time the email is received, not the current property setting.

Whatever ‘malicious’ content is received in the attachment is not referenced in the HTML in the email. The attachment itself is stored in the `sys_attachment` table.

**Prerequisites**

Before setting this property, set the `glide.email.read.active` property to true. To learn more, see [Enable using your own POP3 server](#).

### More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td><code>glide.email.inbound.convert_html_inline_attachment_references</code></td>
</tr>

<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>To restrict image rendering in HTML body preview.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>false</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Medium) Once this property is configured, user are not able to see the image preview in the email body.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Medium) If the property is not enabled, an attacker might send malicious image containing malware.</td>
</tr>
<tr>
<td>References</td>
<td>Email properties</td>
</tr>
<tr>
<td></td>
<td>Inbound mail configuration</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see [Add a system property](#).
Email spam scoring and filtering (instance security hardening)

Install the Email Filter (`com.glide.email_filter`) plugin to install email filtering within the instance. This filtering identifies existing headers, which enables you to decide what to do with the email based on the associated header. Every message sent through Now Platform email servers is assessed for the likelihood of being spam.

**Note:** If an instance uses a private email server, this topic is not applicable. For more information, see Email Spam Scoring and Filtering.

**Prerequisites**

Before setting this property:

- Set the `glide.email.read.active` property to true. To learn more, see Enable using your own POP3 server.
- Create a comma-separated list, in the `glide.pop3.ignore_headers` property, of email headers that cause the instance to ignore an email message. To learn more, see Available system properties.

**More information**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Plugin Name</td>
<td><code>com.glide.email_filter</code></td>
</tr>
<tr>

To learn more about activating a plugin, see Activate a plugin.

Restrict access to emails with empty target table (instance security hardening)

Activate the `glide.email.email_with_no_target_visible_to_all` property to restrict user access to emails, unless they were the one who sent the email, or have an admin role.

Unauthorized users are able to access emails in the `sys_email_list` table that are missing a target record. Instead of enforcing ACLs on email entries, this property restricts access only to the email sender, and users with the admin role.
Note: Emails sent to and received by the instance and received appear in the sys_email_list table. However, only received emails that were marked with an Error and Ignored state should have an empty target table.

More information

<table>
<thead>
<tr>

<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>To block email client from showing emails when user doesn't authorize access.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>false</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Low) Users are no longer able to see emails where target table is empty unless they are an admin or were the sender of the email.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Medium) If the property is not enabled, unauthorized users are able to access any email where the target_table field is empty.</td>
</tr>
<tr>
<td>References</td>
<td>Advanced email properties <a href="https://support.servicenow.com/kb_view.do?sysparm_article=KB0690043">https://support.servicenow.com/kb_view.do?sysparm_article=KB0690043</a></td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see Add a system property.

Restrict emails by domain for user creation (instance security hardening)

Use the glide.user.trusted_domain property to specify the comma-separated list of trusted domains used in the creation of users from incoming emails.

By default, an asterisk (*) is used to trust all domains. Specific domains should be provided if it is not required to allow email from every domains. The instance ignores incoming email from other domains unless it is from an existing user's address. The instance doesn't create guest users from email from untrusted domains.

Prerequisites

Before setting this property:

- Set the glide.email.read.active property to true. To learn more, see Enable using your own POP3 server.
- Set the glide.pop3readerjob.create_caller property to true. To learn more, see Enable automatic user creation.

Note: Skip the glide.user.default_password property if the glide.pop3readerjob.create_caller property is set to false.
More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.user.trusted_domain</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>To restrict the inbound emails coming from domains that included are not in the trusted domain list.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>Comma-separated list of trusted domains [Ex. servicenow.com (a specific domain name)]</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Medium) Once this property is configured, the instance no longer accepts emails from untrusted domains. If you do not include the domain in the trusted list, there is an impact to guest users because accounts are created automatically.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Medium) If the property is not enabled, an attacker might use an email spoofing/spamming campaign to send multiple emails resulting in the creation of more unnecessary guest users.</td>
</tr>
<tr>
<td>References</td>
<td>Email properties</td>
</tr>
<tr>
<td></td>
<td>Inbound mail configuration</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see Add a system property.

Set complex default password (instance security hardening)

Use the glide.user.default_password property to specify the password for new users created from incoming email from trusted domains.

Although this password resets during login, a complex custom password must be applied instead of the default value 'password'. The instance ignores incoming email from other domains unless it is from an existing user's address. The instance doesn't create guest users from email from untrusted domains.

Prerequisites

Before setting this property:

- Set the glide.email.read.active property to true. To learn more, see Enable using your own POP3 server.
- Set the glide.pop3readerjob.create_caller property to true. To learn more, see Enable automatic user creation.

Note: Skip the glide.user.default_password property if the glide.pop3readerjob.create_caller property is set to false.

Input validation (instance security hardening)

The Now Platform performs input validation to prevent issues that result from the entry of malformed data. This section describes security controls within the Now Platform that an administrator can configure to minimize entry of malformed data, regardless of source. These sources include manual user entry, or from an infrastructure, external entities, or database systems.

Allow embedded HTML code (instance security hardening)

Use the glide.ui.security.allow_codetag property to disable support for embedding HTML code created using the [code] tag.

The Now Platform mitigates many injection and cross-site attacks by implementing escaping and encoding techniques. As a result, users can't write/submit HTML formatted inputs for journal fields. But journal fields can render text enclosed within code tags as HTML.

- However, there is an associated security risk. If set to true, malicious users can write harmful HTML JS code that may be executed on a different client browser after rendering of journal fields.
- Set this property to false so that administrators can prevent journal fields from rendering HTML code by disabling support for the [code] tag.

**Client generated scripts sandbox (instance security hardening)**

Use the `glide.script.use.sandbox` property to enable script sandboxing.

There are two cases in the Now Platform that enable the client to send scripts to the server for evaluation:

**Filters or queries**

It is legal to send a filter to the server such as `assigned_to=JavaScript:getMyGroups()`.

**System API**

API call enables the client to run arbitrary scripts on the server and receive a response.

If you enable script sandboxing, the script being evaluated at either of these two entry points runs in a sandbox with reduced rights, with the following characteristics:

- Only those business rules marked client callable are available within the sandbox.
- Only script includes marked client callable are available within the sandbox.
- Certain API calls (largely, but not entirely, limited to ones dealing with direct DB access are not allowed.
- You can't insert, update, or delete data from within the sandbox. For example, any calls to `current.update()`, are ignored. If you run the Now Platform without enabling script sandboxing, none of these restrictions apply.

**More information**

<table>

| References           | Script sandbox property

**glide.script.use.sandbox** belongs to the same family of properties that secure and restrict execution of scripts originating from the client:

- **glide.script.allow.ajaxevaluate**: See Enable AJAXEvaluate.
- **glide.script.secure.ajaxgidererecord**: See Enabling AJAXGlideRecord ACL checking (instance security hardening).

To learn more about adding or creating a system property, see Add a system property.

**Enable AJAXEvaluate (instance security hardening)**

Use the **glide.script.allow.ajaxevaluate** property to restrict arbitrary client script execution using the system API on the server side.

There are two cases in the Now Platform that enable the client to send scripts to the server for evaluation:

- **Filters and/or queries**
  It is legal to send a filter to the server such as: `assigned_to=javascript:getMyGroups()`

- **System API**
  The AJAXEvaluate API call allows the client to run arbitrary scripts on the server and receive a response.

When you set this property to **false**, the Now Platform doesn't enable the use of the AJAXEvaluate API call from the client script.

**More information**
### Attribute | Description
--- | ---
**Functional impact** | (Medium) This remediation forces the AJAEvaluate processor to be turned off. It could impact functionality if you are explicitly using the AJAX evaluate processor as part of any customized scripts. For more information, see GlideAjax.

**Security risk** | (High) AJAXEvaluate can allow arbitrary JavaScript code to execute on the client browser by applying the server-side objects.

### References

    - **glide.script.secure.ajaxgliderecord**: See Enabling AJAXGlideRecord ACL checking.

To learn more about adding or creating a system property, see [Add a system property](#).

### Escape Excel formula (instance security hardening)
Use the **glide.export.escape_formulas** property to prevent Excel Injection, also, known as formula injection.

Excel injection occurs when websites embed untrusted entries inside Excel files. When you use a spreadsheet application such as Microsoft Excel, or LibreOffice Calc, to open a file, any cells starting with +, -, =, or @ are interpreted as a formula. When you set the **glide.export.escape_formulas** property to **true**, string values starting with +, -, =, or @ are prepended with a single apostrophe when you export to CSV, XLS, or XLSX files.

### More information

<table>

</tr>
<tr>
<td>Purpose</td>
<td>To prevent application against the Excel or formula injection.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>true</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Low) Maliciously crafted formulas can be used for hijacking the user's computer by exploiting vulnerabilities in the spreadsheet software.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Medium) Malicious formulae pose a risk even when the embedding spreadsheet doesn't contain any sensitive information, as they can be used to compromise the viewer's computer.</td>
</tr>
<tr>
<td>Workaround</td>
<td>As an alternative consider stripping all trailing white spaces where possible, and limiting all client-supplied data to alpha-numeric characters.</td>
</tr>
</tbody>
</table>
To learn more about adding or creating a system property, see Add a system property.

Escape HTML (instance security hardening)

Use the glide.ui.escape_html_list_field property to force HTML escapes for HTML fields in a list view.

HTML is one of the types that can be assigned to the dictionary fields. Assigning HTML fields to any field type provides the functionality to format content using HTML codes (for example, `<p>`, `<a href>`, `<b>`, `<font>`, `<img>`). A malicious user can inject HTML code within the form field to execute unwanted scripts on different client/user sessions.

- Set this property to true to perform an HTML escaping before the records/fields are rendered in the browser when the table appears as a list view.
- If set to false, and you select that column in a list view when viewing a table or record listing, these HTML formatted fields may appear.

More information

To learn more about adding or creating a system property, see Add a system property.

Escape JavaScript (instance security hardening)

Use the glide.html.escape_script property to force escape from JavaScript (`<script>`</script>) tags in HTML fields during list views.

HTML is one of the types that can be assigned to the dictionary fields. Assigning HTML fields to any field type provides functionality to the user to format the content using HTML codes (for example, `<p>`, `<a href>`, `<b>`, `<font>`, `<img>`). If you set glide.html.escape_script to false, the (`<script>`</script>) tags may appear when you select that column in a list view while viewing a table or record listing.
A malicious attacker can insert JavaScript code by embedding it within the `<script></script>` tags. The attacker can take advantage by injecting a sophisticated JS vector that may execute when any user opens the table record.

To learn more about adding or creating a system property, see Add a system property.

**Escape Jelly (instance security hardening)**

Use the `glide.ui.escape_all_script` property to force escape of all scripts injected into Jelly.

It escapes all the JS and HTML strings included in `<j:jelly> ... </j:jelly>` before they are written to the output stream, preventing several XSS issues from occurring.

**More information**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.ui.escape_all_script</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
</tbody>
</table>
### Attribute Description

**Purpose**
If the property is not set to `true`, developers have to perform several steps on each custom Jelly script to prevent XSS issues. These steps include locating the Jelly variables being sent to output stream to render on web pages, and performing escaping on each of the following tags:

- `$$ {JS:expression}`
- `$$ {HTML:expression}`

OR
- `$$ {JS,HTML:expression}`

**Recommended value**
true

**Functional impact**
(Medium) This remediation enforces Jelly escaping at the parser level. It can have a functionality impact on user interaction with the resulting data.

**Security risk**
(High) Input validation has to occur on all the user input being entered on the application. By doing so, injection attacks against the platform can be defended and protected.

**Workaround**
The UI may be affected because some of the scripts and HTML tags designed for rendering on a web page may appear broken. This remediation sends the output encoded page to the browser to render. For example, instead of 'my string here', it might display `<u>my string here</u>` as the `<u>` tag was properly escaped. In this case, to prevent escaping, add the NOESC prefix to Jelly expression to prevent JS escaping. For example:

- Before: `($[jvar_context_menus]);`
- After: `($[NOESC:jvar_context_menus]);`
- Before: `[$[jvar_ui_policy_scripts]`
- After: `($[NOESC:jvar_ui_policy_scripts]`

**References**
- High Security Settings
- Jelly tags

To learn more about adding or creating a system property, see [Add a system property](#).

### Escape XML (instance security hardening)

Use the `glide.ui.escape_text` property to force escape of XML values at the parser level before transmitting them to the client's browser.

Cross-site scripting occurs when an attacker injects malicious JavaScript into an entry point. The platform/application fails to escape the malicious JavaScript before transmitting it to the victim's browser for execution. Escaping in this context means the following:

- `&` --> `&amp;`
- `<` --> `&lt;`
- `>` --> `&gt;`
- `"` --> `&quot;`
- `'` --> `&#x27;`
Example: `<script>alert('XSS Attack');</script>`

Escaping: `<script>alert('XSS Attack');</script>`

**More information**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.ui.escape_text</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>Escaping XML ensures that browsers do not parse the malicious JavaScript embedded in untrusted data, and execute it as JavaScript.</td>
</tr>
<tr>
<td></td>
<td>• A malicious user may try XSS attack to either hijack other users' session or redirect the user to a malicious website.</td>
</tr>
<tr>
<td></td>
<td>• The Now Platform contains code to secure cookies, but escaping it relies on this property being set to <code>true</code>.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>true</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Medium) This remediation enforces XML encoding at the XML parser level on the UI. It renders the encoded results for the user, which can have a functionality impact based on the instance user interaction with the resulted data.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(High) Input validation must occur on the application to defend against cross-site scripting attacks. These attacks enable foreign scripts to execute on user session in the logged in browser's context. Attackers can use it to steal session information and sensitive data.</td>
</tr>
<tr>
<td>Workaround</td>
<td>After you set this property to <code>true</code>, rendering stops on the HTML tags in the catalog item description or in the catalog item variable help text. You may not be able to use HTML formatting for some fields. However, if the <code>glide.ui.escape_text</code> property is turned off, all JEXL expressions would be prefixed with an output encoder:</td>
</tr>
</tbody>
</table>
|                                        |    ```jsp
|                                        |    ${JS:expression}
|                                        |    ${HTML:expression}
|                                        |    or
|                                        |    ${JS,HTML:expression}
| References                             | High Security Settings                                                                                                                       |

To learn more about adding or creating a system property, see Add a system property.
HTML sanitizer (instance security hardening)

Use the `glide.html.sanitize_all_fields` property to enable the HTMLSanitizer script include, which sanitizes HTML input based on exclusion listed and inclusion listed attributes configured in a script.

The field types available with dictionary/fields include HTML and Translated HTML. These HTML input fields enable users to write HTML formatted input, for example:

```html
<h1>Test</h1>, using the most basic HTML tags such as `<img>`, `<a href ...>`, and `<iframe>`.
```

It can open a door for a malicious attacker to inject malicious vector with HTML tags such as:

```html
[<IMG SRC=" &amp;#14; JavaScript:alert('XSS');">][<IMG onmouseover="alert('xss')">][a href="" onclick=alert(/xss/)].
```

### More information

</tbody>
</table>

To learn more about adding or creating a system property, see Add a system property.

Jelly/JS interpolation (instance security hardening)

Use the `glide.ui.jelly.js_interpolation.protect` property to ensure that any JavaScript about to be executed on a Jelly page is protected from injection with the help of Jelly interpolation.

When you set property to `true`, an application goes through a Jelly script tree (nested). It wraps potentially dangerous Jelly expressions with a filter that:

- Escapes their results to be safe, or
• If their safety can't be guaranteed, generates a SecurityException because the expression that was going to be evaluated represents a possible security issue.

More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.ui.jelly.js_interpolation.protect</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>To mitigate against malicious code execution attacks that can occur using Jelly Injection.</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(High) This property makes a best guess at whether an expression is quoted. It may wrongly quote legitimate expression. In that case manually marking an expression as safe may be necessary.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Medium) JEXL injection is a form of input injection unique to the Now Platform that can lead to both cross-site request forgery and code execution. Completely turning off the protection may potentially open many P1 security vulnerabilities.</td>
</tr>
<tr>
<td>Workaround</td>
<td>To manually mark an expression as safe add SAFE prefix to Jelly expression: $(SAFE:sysparm_input); Blindly adding SAFE to each expression is the wrong way to approach the problem, because it may open a security vulnerability.</td>
</tr>
<tr>
<td></td>
<td>• Only add SAFE to an expression if you can guarantee that the expression does not contain input from the client.</td>
</tr>
<tr>
<td></td>
<td>• If it does, it's possible for a malicious client to cause evaluation of privileged JavaScript.</td>
</tr>
</tbody>
</table>

**SOAP request strict security (Instance security hardening)**

Use the `glide.soap.strict_security` property to enforces web service security. This property uses a combination of:

• Basic authentication challenge/response over the HTTP protocol and
• System level access controls in the [Contextual Security: Role Management plugin](#).

If you set this property to `true`, it performs the following actions:

• If the user has appropriate role to perform the operation, it checks incoming SOAP request for role authorization to validate. It occurs during SOAP web service calls/requests made against Now Platform tables when performing CREATE, READ, UPDATE or DELETE operations.
• Checks the system-level ACLs while retrieving data in the form of SOAP data on the table.
• Checks the field-level ACLs for any CRUD operation performed against a field of table

Secure communications (instance security hardening)

The secure communication properties relate to the security of the transportation of HTTP traffic.

Certificate trust (instance security hardening)

By default, the com.glide.communications.trustmanager_trust_all property is set to false. The Now Platform only trusts certificates that it can verify against the JVM certificate store. Self-signed and enterprise-signed certificates are not trusted.

Note: For security purposes, do not change this property value. If you have further questions, contact Customer Service and Support.

Security best practices (instance security hardening)

In addition to security configurations, some extra manual effort is required to further secure Now Platform applications on a day-to-day basis. This section contains security tasks that an administrator should perform periodically, within a certain interval of time.

Cache-Control HTTP header value (instance security hardening)

Use the `glide.http.cache_control` property to set the default Cache-Control value in the HTTP response headers that the Now Platform sends when requesting static content data for a page. Examples of static content include images, CSS, and JavaScript rendered from within, for a page.

The `glide.http.cache_control` property sets the default Cache-Control value in HTTP response headers to **private** or **public**. The default is **private**.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>private</td>
<td>Static content can be cached at the browser (client) level, but not at the proxy server level.</td>
</tr>
<tr>
<td>public</td>
<td>Static content can be cached at the browser (client) level, and also at the proxy server level.</td>
</tr>
</tbody>
</table>

The Expires value in the HTTP response headers control when the static content expires, and has a default value of 369 days. To manually override the default value, use the `glide.http.expire.days` property.
Note: You can use the `glide.http.cache` property to designate whether to enable or disable setting of the Cache-Control and Expires values in HTTP response headers. Its default is `true`, which allows you to set the:
Cache-Control value default using the glide.http.cache_control property.
Expires value default using the glide.http.expire.days property.

To learn more about adding or creating a system property, see Add a system property.

High security plugin (instance security hardening)

When you activate the High Security plugin, it creates or updates hundreds of different configurations to control the level of security on your instance. These configurations mitigate many of the top OWASP attacks by enabling strict access control, input validation, and output encoding.

These configurations include:
• Access Control
• Business rules
• System properties
• UI policy action
• script actions
• script includes

Example

Refer to the examples for the following properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Topic</th>

To learn more about activating a plugin, see [Activate a plugin](#).

### Individual login IDs (instance security hardening)

Ensure that all users have individual user IDs, which enables auditing of all user activities.

**Note:** Local user accounts that are not being used should have the **Active** flag set to false.

- Setting the **Active** flag to **false** automatically sets the **Locked Out** flag to **true**. If the **Locked Out** flag is set to **true**, it doesn't allow that user account to authenticate to the instance.
- Setting the **Active** flag to **false** does not remove a user from the Now Platform, but does remove visibility to non-admin accounts.
- If **Active** flag is set to **false**, and **Locked Out** flag is also set to **false**, a user still is able to log in to this account.

To learn more about user accounts, see [User administration](#).
Mobile UI obfuscation (instance security hardening)

Use the `glide.ui.m.blur_ui_when_backgrounded` property to obfuscate all fields from the snapshot as the image is saved during the backgrounding process. To obfuscate.

On Android devices, the Android operating system takes a screenshot for usage in the recent task menu when the application is sent to background. Users can also take manual screenshots of the application, which are stored publicly on the device.

On iOS devices, the iOS operating system also allows applications to save an image file. This file represents the last screen seen by the user when the application is sent to the background. While the intent is to provide a better user experience, it also creates a security risk because the images are saved as PNG image files.

**Note:** This setting or configuration is per instance basis so the user must connect to the instance with the property configured.

To obfuscate all fields from the snapshot in the ServiceNow Classic app, see Configure the blur app option to improve security.

**Example**

When you set this property to **true**, Background application is obfuscated for iOS devices, and blacked out for Android iOS devices.

<td>(Low) If the <code>glide.ui.m.blur_ui_when_backgrounded</code> property is set to <code>true</code>, the native apps use the parameter defined on the server to blur the screen when the app enters the background.</td>
</tr>
<tr>
<td></td>
<td>• It blurs the screenshots taken by iOS and Android when the app enters the background.</td>
</tr>
<tr>
<td></td>
<td>• The user experience may be adversely affected because they would not be able to see the content when the app is sent to background.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Medium) A compromised (jailbroken) device would enable an attacker to have full access to the file system, with access those files/snapshots with sensitive information embedded in them.</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see [Add a system property](https://support.servicenow.com/kb_view.do?sysparm_article=KB0550107).

### Patches and updates (instance security hardening)

Ensure that the instance is running the most current patch level. Security fixes are routinely released for the Now Platform within many of the patches and hot fixes that accompany product feature updates. Upgrading when new patches and hot fixes are available reduces the risk of potential vulnerabilities.

The Now Platform undergoes two penetration tests per week on average.

- While most of these tests do not result in significant vulnerabilities, there are vulnerabilities found and fixed regularly.
- Information about Now Platform releases, patches, and hot fixes can be found in the Release Notes section of the product documentation.

### Remove demo data (instance security hardening)

Demo data, particularly demo accounts, are typically included when an instance is created. If so, all demo data should be removed prior to using the instance in non-production or production.

Open a request in HI. Make sure to create an administrative account prior to submitting the request.

### Internal resources

- [https://support.servicenow.com/kb_view.do?sysparm_article=KB0550107](https://support.servicenow.com/kb_view.do?sysparm_article=KB0550107)

### Removing demo data using the Service Catalog

Instead of submitting the request as an incident, certain users can request demo data removal on an instance using the Service Catalog. These users include internal users, and those users who have customer admin or partner admin roles,

1. Navigate to [https://support.servicenow.com/hisp](https://support.servicenow.com/hisp).
2. Click **Self-Service > Remove Demo Data >**.
3. Specify the instance from which to remove demo data.
   - If you are having trouble finding your instance, preface the instance name with * to perform a contains query.
4. Specify the date and time to remove demo data from the selected instance.
The date and time must be at least four hours later than the current time.

5. Click **Submit**.

A new change request is created and appears automatically. The **Planned end date** is automatically calculated based on the **Planned start date** plus five hours, which is how long the process takes. In the change request, use the Watch List to add any other members of your team who must be aware of the change request status.

### Security inclusion listing (instance security hardening)

A 'positive' security model (also known as an 'inclusion list') is one that defines what is allowed, and rejects everything else. This section contains security controls that an administrator can configure to restrict behavior to known inclusion lists.

### Check allow list member calls (instance security hardening)

Review and remove inclusion list member call entries as needed from the sys_whitelist_member table.

Member call entries can access the Java resources on the server-side to perform application-based operations without appropriate validation. Because it can cause unauthorized disclosures or alteration of customer data, it is a serious security concern.

### More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table Name</td>
<td>sys_whitelist_member</td>
</tr>
<tr>
<td><strong>Note:</strong> In recent releases, only ServiceNow employees can access this table; not even administrators are able to do so.</td>

</tr>
<tr>
<td>Configuration type</td>
<td>Table</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>To review and remove entries from this table.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>No record should exist in the table (the list must be empty).</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Low) There should be no impact as long as you review and approve the results generated when running the Packages call removal tool. To ensure proper functioning of the instance, test the changes in a non-production environment before deploying in the production environment. To learn more, see Packages call removal tool.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(High) client-side API calls that result in data retrieval or object access on server are deemed to be dangerous from a security standpoint. Validate these items for authorization and restriction of sensitive object access.</td>
</tr>
</tbody>
</table>

### Steps to configure

**Note:** The following steps are similar to the steps outlined in the Steps to Configure sections in:
• Packages call removal tool
• Check whitelist package calls

If you already completed them, you can skip these steps.

1. Activate the Packages Call Removal Tool plugin. To learn more, see Packages call removal tool.
2. Using filter navigator, navigate to **Packages Call Removal Utility**.
3. Click each script starting from (1) to (4). Wait for the output, then proceed to the next one.
4. Once you run the script (4), a listing of affected fields appears on the Packages Call Items page.

5. Resolve all the items in the Proposed and Error sections.

**Note:** This tool might report some package calls used in `sa_mapping_ext_commands` and `sa_custom_operation`. These package calls belong to the MID Server. Because there are no classes, the code runs in MID Server. If you find the following member calls under the Errors section, mark them as **Rejected** (Ignored). The tool doesn't report that member call again.

- Packages.com.snc.sw.util.JSONUtil.toJSONPlain(file_content);
- Packages.com.snc.sw.util.JSONUtil.toJSONPlain(file_name);
- Packages.com.snc.sw.commands.HttpCallHandler;
- Packages.com.snc.sw.dto.ProviderType.SSH

6. Contact ServiceNow Support for further remediation.

**Check allow list package calls (instance security hardening)**

Review and remove inclusion list package call entries as needed from the `sys_whitelist_package` table.

Package call entries can access Java resources on the server-side to perform application-based operations without appropriate validation. Because it can cause unauthorized disclosures or alteration of customer data, it is a serious security concern.

   - `Packages.com.snc.sw.dto.ProviderType.SSH`

6. Contact ServiceNow Support for further remediation.

---

**Enable URL allow list for cross-origin iframe communication (instance security hardening)**

Use the `glide.ui.concourse.onmessage_enforce_same_origin` property to enable cross-origin communication between iframes.

Openframe can only process messages from trusted domains that are specified in the `glide.ui.concourse.onmessage_enforce_same_origin_whitelist` property. To learn more, see Specify URL whitelist for cross-origin iframe communication.

**More information**

<table>
<thead>

<tr>
<td>Purpose</td>
<td>To enable inclusion listing of trusted domains, so they can communicate between iframes for openframe.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>true</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Medium) If you do not inclusion list intended domains, the ability to embed other pages within Now Platform instances may be limited.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(High) If a web page contains event handlers that do not perform proper origin validation, a web page, or script from any origin, can communicate with it. It can also initiate any functionality performed by the event handler.</td>
</tr>
<tr>
<td>References</td>
<td><a href="#">OpenFrame overview</a></td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see [Add a system property](#).

**Enforce relative links (instance security hardening)**

Use the `glide.cms.catalog_uri_relative` property to enforce relative links from the URI parameter on `/ess/catalog.do`. 
• If you set the property to **true**, only relative URLs are permitted through the `/ess/catalog.do` page using the `uri` parameter.

If you set it to **false**, all URLs are permitted, which may permit linking to external unauthorized content.

### More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>

<td><em>(Low)</em> This remediation enforces validation on Catalog page such that only Relative URLs are permitted. Existing links to external web applications become broken.</td>
</tr>
<tr>
<td>Security risk</td>
<td><em>(Medium)</em> Absolute URLs can pose a security risk when used as a part of parameter or a field value, thus redirecting the source page to an adversary-controlled website.</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see [Add a system property](#).

### Packages call removal tool (instance security hardening)

Activate and run the Packages Call Removal Tool (`com.glide.script.packages_call_removal`) plugin, and then consider whether each of the proposed changes should be completed or rejected.

The Packages Call Removal Tool is a plugin that:

- Scans scripts for package calls to Now Platform Java classes.
- Proposes changes to replace them with preferred GlideScriptable names.
- Facilitates the script changes.

**Note:** If this record is a base system record, using the recommendation from the tool causes the item to be marked as customer_update. That script may not take on further updates in the future. In later releases, the `sys_whitelist.xxx` tables are expected to be empty. However, it may still be useful to use this tool because it flags `Packages.xxx` calls.

The Packages Call Removal Tool might report some package calls used in `sa_mapping_ext_commands` and `sa_custom_operation`. These package calls belong to the MID Server. As there are no classes, the code runs in MID Server. If you find any of the following listed package calls in the Errors section, mark them as Rejected (Ignored). The tool doesn't report that package call again.

- `Packages.com.snc.sw.util.JSONUtil.toJSONPlain(file_content);`
- `Packages.com.snc.sw.util.JSONUtil.toJSONPlain(file_name);`
- `Packages.com.snc.sw.commands.HttpCallHandler;`
- `Packages.com.snc.sw.dto.ProviderType.SSH`
More information

<tr>
<td>Purpose</td>
<td>To remove/replace unauthorized package/member calls with Glide Acceptable (GlideScriptable) names that only allow authorized access to data.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>Active</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Low) This remediation would replace the package calls with GlideScriptable APIs, and can affect the customizations that include package calls. The tool doesn’t actually replace package calls automatically. Instead, it provides suggestions that are stored into the packages_call_item table. Your administrator can then decide whether to accept or reject the proposed change.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Medium) Client-side API calls that result in data retrieval or object access on server are deemed to be dangerous from a security standpoint. They should be validated for authorization and restriction for sensitive object access.</td>
</tr>
</tbody>
</table>

Steps to configure

1. Navigate to System Definition > Plugins
2. Search for the plugin ID = `com.glide.script.packages_call_removal`. 
3. Click **Activate/Upgrade** to activate the plugin.
4. To check inclusion list package calls and inclusion list member calls, complete the actions outlined in the Steps to Configure sections in the following topics:
   - Check whitelist member calls
   - Check whitelist package calls

**Specify URL allow list for cross-origin iframe communication (instance security hardening)**

Use the `glide.ui.concourse.onmessage_enforce_same_origin_whitelist` property to enable cross-origin communication between iframes from trusted domains you specify in an inclusion list.

**More information**

<table>
<thead>
<tr>

It can also initiate any functionality performed by the event handler. Communication with iframes from other domains is a security risk.</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see Add a system property.

**URL allow list for logout redirects (instance security hardening)**

Use the `glide.security.url.whitelist` property to add extra layer of validation to ensure whether any external URL introduced should be a part of inclusion listed URLs.

Open redirection occurs when a vulnerable web page is redirected to an untrusted and malicious page that may compromise the user. Open redirection attacks come with a phishing attack because the modified vulnerable link is identical to the original site, increasing the likelihood of success for the phishing attack.

This property is applicable in the following cases:
   - `/logout.do?sysparm_goto_url={External URL}`
   - `/cms_login_redirect.do?sysparm_goto_url={External URL}`

Users are directed to an external trusted site after they log out of the instance:
   - `/logout_redirect.do?sysparm_url={External URL}`
   - `/saml_redirector.do?sysparm_uri={External URL}`

When SAML is enabled, it invokes an identity provider (IDP) logout URL.

Virtual agent embedded client content security policy (instance security hardening)

Use the com.glide.cs.embed.csp_frame_ancestors property to enable the configuration of the frame-ancestors policy for only the https://<your-instance>.service-now.com/sn_va_web_client_app_embed.do page.

The Virtual Agent Plugin enables embedding of a client in an external web page. To enable the client page to be embedded in the web page, the Content Security Policy must allow the external page as a parent frame.

**Note:** Avoid using only '*' as the Content Security Policy because it would enable all domains and leave the application potentially vulnerable to clickjacking.

More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>com.glide.cs.embed.csp_frame_ancestors</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>No</td>
</tr>
<tr>
<td>Purpose</td>
<td>To enable creation of customized Content Security Policy for the embeddable Virtual Agent page.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>Set to trusted domains</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(High) Virtual Agent embeddable client doesn't allow itself to be embedded in external sites unless Content Security Policy is configured properly.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Medium) If configured improperly (allowing all parent frames), it may possibly leave the embeddable client page vulnerable to clickjacking.</td>
</tr>
<tr>
<td>References</td>
<td>Embed the Virtual Agent web client in an external web page</td>
</tr>
<tr>
<td></td>
<td>To learn more about creating a frame-ancestors Content Security Policy, see here.</td>
</tr>
</tbody>
</table>

**Steps to configure**

1. Navigate to `/sys_properties_list.do`.
2. Search for the `com.glide.cs.embed.csp_frame_ancestors` property.
3. Assign acceptable content security policy (allow only company or other accepted domains), then click **Update**.

Virtual agent embedded client X-Frame-Options (instance security hardening)

Use the `com.glide.cs.embed.xframe_options` property to enable the configuration of the X-Frame header for only the `https://<your-instance>.service-now.com/sn_va_web_client_app_embed.do` page.
The Virtual Agent Plugin enables embedding of a client in an external web page. To enable the client page to be embedded in the web page, the X-Frame-Options header must enable the iframe to be included in the parent frame.

**Note:** Avoid using allow-from * as the X-Frame-Options header value because it would enable all domains and leave the application potentially vulnerable to clickjacking.

### More information

<table>

</table>

To learn more about adding or creating a system property, see [Add a system property](#).

### X-Frame-Options: SAMEORIGIN (instance security hardening)

Use the `glide.set_x_frame_options` property to set the X-Frame-Options response header to SAMEORIGIN for all UI pages.

Use the X-Frame-Options HTTP response header to indicate whether browser should be allowed to render a page in a `<frame>` or `<iframe>`. Sites can use this function to avoid clickjacking attacks by ensuring that their content is not embedded into other sites.

### More information

<table>
<thead>
<tr>

### XML external entity processing validation

These properties enable entity expansion, and restrict any external entity (for example, URL) when included as a part of XML DOCTYPE reference. DTD is basically an XML schema. If you are looking for a solution for entity declarations that could have potential for XXE (external entity), enable an inclusion listed defense against XXE using system properties.

#### For XMLDocument and XMLUtil parsing

If your customizations use `XMLDocument` or `XMLUtil`, set the following system properties. They control entity expansion and enable the validation of external entities, which allow processing of only ones on inclusion lists.

**Setting entity expansion threshold (instance security hardening)**

Use the `glide.xmlutil.max_entity_expansion` property to change the maximum entity expansion limit to a smaller number.

The Now Platform doesn't process further entity expansions that are greater than the allowed limit specified in this property.

**Note:** 3000 is the default minimum imposed by the Now Platform, which is considered to be a safe threshold. Hence, platform considers this default minimum if the integer value you enter is below 3000.

To learn more about adding or creating a system property, see Add a system property.

XMLdoc/XMLUtil entity validation with allow list (instance security hardening)

Use the glide.xml.entity.whitelist.enabled property to enable the validation of external entity, and only allows processing of inclusion listed ones.

- If you set this property to **true**, it allows processing of only inclusion listed entities (recommended setting).
- If you set this property to **false**, it allows processing of all external entities.

**Prerequisites**

Before setting this property, define a listing of comma-delimited FQDN in the glide.xml.entity.whitelist property, which are the only URLs that can be reached using XML Entity processing. property. To learn more, see XML external entity processing - whitelist.

**More information**

<td>If you are not using external entity expansion, disable it. To learn more, see Disable entity expansion.</td>
</tr>
</tbody>
</table>
To learn more about adding or creating a system property, see Add a system property.

*For XMLDocument2 parsers*

If your customizations use a XMLDocument2 parser, use the following system properties to enable external entity validation.

Disable entity expansion (instance security hardening)

If customizations do not require entity expansion, use the `glide.stax.allow_entity_resolution` property to completely disable external entity expansion. The XML completes parsing but doesn't include any internal or external entities.

- If you set this property to `true`, all external entities attempt to resolve or expand subject entities, subject to the setting of the `glide.stax.whitelist_enabled` property.
- If you set that property to `true`, all entity resolution and expansion is blocked (recommended setting). To learn more, see XMLdoc2 entity validation with whitelist.

**Prerequisites**

Before setting this property:

- Set the `glide.xml.entity.whitelist.enabled` and `glide.stax.whitelist_enabled` properties to true. To learn more, see XMLdoc/XMLUtil entity validation with whitelist and XMLdoc2 entity validation with whitelist.
- Define a listing of comma-delimited FQDN in the `glide.xml.entity.whitelist` property, which are the only URLs that can be reached using XML Entity processing, property. To learn more, see XML external entity processing - whitelist.

**More information**

<table>

</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see Add a system property.

XMLdoc2 entity validation with allow list (instance security hardening)
Use the `glide.stax.whitelist_enabled` property to enable processing, using XMLDocument2, of external entities that are inclusion listed.

**Prerequisites**

Before setting this property:

- Set the `glide.xml.entity.whitelist_enabled` property to true. To learn more, see [XMLdoc/XMLUtil entity validation with whitelist](#).
- Define a listing of comma-delimited FQDN in the `glide.xml.entity.whitelist` property, which are the only URLs that can be reached using XML Entity processing. To learn more, see [XML external entity processing - whitelist](#).

**More information**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.stax.whitelist_enabled</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>This remediation control must be enabled to defend against XML External Entity attacks.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>true</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Low) If the customization is using an external entity that is not inclusion listed, the Now Platform might block further processing. To learn more, see <a href="#">XML external entity processing - whitelist</a>.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(High) An attacker can use the DTD may include arbitrary HTTP requests that the server may execute. Using the server's trust relationship with other entities, it could lead to other attacks.</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see [Add a system property](#).

**XML external entity processing - allow list (instance security hardening)**

Use the `glide.xml.entity.whitelist` property to enable access to a listing of comma-delimited FQDN, if needed. These URLs are the only ones that can be reached using XML Entity processing.

**Prerequisites**

Before setting this property, set the `glide.xml.entity.whitelist.enabled` property, which enables the validation of an external entity, and only allows processing of the inclusion list you specify in the `glide.xml.entity.whitelist` property. To learn more, see [XMLdoc/XMLUtil entity validation with whitelisting](#).

**More information**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.xml.entity.whitelist</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>To create an inclusion list of URLs that XML Entity processing can access.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>User Specified (for example, <a href="https://google.com">https://google.com</a>)</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Low) External entity processing might be blocked if not mentioned in the inclusion list. When the inclusion list is enabled, it requires the PUBLIC form of an external entity definition.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(High) An attacker can use the DTD may include arbitrary HTTP requests that the server may execute. This could lead to other attacks using the server's trust relationship with other entities</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see Add a system property.

**Session management (instance security hardening)**

Session management helps to properly identify traffic that belongs to a specific user. Take precautions to ensure no abuse of the trust relationship.

Web applications can create sessions to track anonymous users after the first user request. An example would be maintaining the user language preference, ensuring:

- Identification of the user on any subsequent requests.
- Application of security access controls.
- Authorization of access to the user private data.
- Increase of the usability of the application.

Therefore, current web applications can provide session capabilities both pre and post-authentication.

**Authentication and Session Management**

Authentication is the process of verifying that an individual, entity, or website is who it claims to be.

Authentication attempts to verify the digital identity of the sender of a communication. Testing the authentication schema means understanding how the authentication process works, and using that information to circumvent the authentication mechanism. A common example is the log in process. Authentication takes place after submission of a user name, user ID, and one or more items of private information that only the user would know.

Session management includes security-related properties that an administrator can configure to ensure that secure session management mechanisms are established in the Now Platform.

**Absolute session timeout (instance security hardening)**

Use the `glide.ui.user_cookie.max_life_span_in_days` property to set a maximum cap for a valid user session to expire before forcing a user to reauthenticate into the instance.

It enables the user cookie to be valid for the duration of specified days, starting when the cookie was first issued. The default value is 30 days, and the maximum cap is at 365 days.
More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.ui.user_cookie.max_life_span_in_days</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>To force the user to relogin after specific days.</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Medium) This property enforces mandatory relogin by avoiding any sort of cookie rotation after a given timeframe.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Medium) The user cookies being active for an indefinite amount of time is a security risk and should expire on a time-based configuration.</td>
</tr>
<tr>
<td>References</td>
<td>Available system properties</td>
</tr>
<tr>
<td></td>
<td>Change settings for the Remember me check box and cookie</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see [Add a system property](#).

**Anti-CSRF token (instance security hardening)**

Use the `glide.security.use_csrf_token` property to ensure the use of a secure token to identify and validates incoming requests, which in turn are used to prevent these attacks.

Cross-Site Request Forgery (CSRF) is an attack that forces an end user to execute unwanted actions on a web application in which they’re currently authenticated. CSRF attacks specifically target state-changing requests, not theft of data, since the attacker has no way to see the response to the forged request.

The following properties can be enabled for added controls over CSRF token:

- `glide.security.csrf_previous.time_limit`
- `glide.security.csrf_previous.allow`
- `glide.security.csrf.strict.validation.mode`

**More information**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.security.use_csrf_token</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>To protect the application from potential CSRF attack.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>true</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Low) This remediation enables an extra validation step before the instance user submits a write request to the instance. Every write request contains a CSRF token (i.e a validation/CSRF ID tied to the user session). When the user session expires, the secure token expires with it.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Security risk</td>
<td>(High) Cross Site Request Forgery is a significant security risk that violates the integrity of the instance data. An attacker can launch the CSRF attack by abusing the trust of an instance user. With the help of social engineering attacks, a user can submit a malformed request on behalf of the attacker on the instance.</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see Add a system property.

**Change default credentials (instance security hardening)**

Use the **Password needs reset** check box in Users and Groups to ensure that an illegitimate user can't take advantage of default data.

The Now Platform includes some default data when the instance is zbooited, or when you provision a new instance. It might contain the demo user accounts like default admin, ITIL, and employee. Setting the property makes it necessary to change the default admin, ITIL, and employee credentials when logging in to the application.

**Steps to configure**

1. Log in with the username `admin` and the password `admin`.
2. Navigate to **System Security > Users > Users and Groups**.
3. Search for the user under User ID `admin` and Name `administrator`. Click the `admin` User ID to modify the user’s settings.
4. Modify the **Email** field to reflect a valid email address for that user.
5. Select the **Password needs reset** check box.
6. Click **Update**.
7. Log out and log in again. You are prompted to set a new password.

8. Repeat steps 3 through 7 for ITIL and employee accounts.

Cookies HTTP only (instance security hardening)

Use the `glide.cookies.http_only` property to enable the HTTPOnly attribute for sensitive cookies.

Use the HTTPOnly attribute to prevent attacks, such as cross-site scripting, because it doesn't allow access to the cookie using a client-side script, such as JavaScript. It does not eliminate cross site scripting risks but does eliminate some exploitation vectors.
### More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.cookies.http_only</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>To mitigate the risk of client-side script accessing the protected cookie.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>true</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Low) This remediation adds an extra HTTPOnly flag in on session cookies, thus protecting them from being stolen.</td>
</tr>
<tr>
<td></td>
<td>• If you have custom functionality that requires JavaScript to access the user's cookie, it breaks that functionality. It should not be the case under normal circumstances.</td>
</tr>
<tr>
<td></td>
<td>• The Now Platform handles session management and there shouldn't be a reason for a custom script to access the user's cookies.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Medium) Session cookies in the application authenticate an end user and provide implicit access permissions on the application. That means there is a need to secure them from being stolen or exported. HTTP Only flags protect the session cookies from JavaScript injections or cross site scripting vulnerabilities stealing them.</td>
</tr>
<tr>
<td>References</td>
<td>Available system properties</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see Add a system property.

### CSRF strict validation (instance security hardening)

Use the `glide.security.csrf.strict.validation.mode` property to enable CSRF token strict validation. If the CSRF token doesn't match, it prevents resubmission of the request.

### More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.security.csrf.strict.validation.mode</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>To enforce strict validation of CSRF token, and prevents its reuse.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>true</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Medium) This remediation enables an extra validation step before the instance user submits a write request to the instance. It checks whether the current CSRF token has been used previously. If Yes, it prevents submission of further write requests.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Medium) Cross site Request Forgery is a significant security risk that violates the integrity of the instance data. An attacker can launch the CSRF attack on any instance user by abusing the trust of the instance user. With the help of social engineering attacks, a user can submit a malformed request to the instance on behalf of the attacker.</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see Add a system property.

**Disable password-less authentication (instance security hardening)**

Use the glide.login.no_blank_password property to prevent users from logging in to the Now Platform with blank passwords, or by leaving the Password field empty.

Even if the admin purposefully assigns an empty value or blank password in user records, a user can't log in without providing a value in the Password field.

**More information**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.login.no_blank_password</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>To ensure strong authentication as sometimes the username are easy to guess within an organization.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>true</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Low) Operations should not use blank passwords because it is viewed as a critical security risk. However, if there is a valid case for such usage, there is a possibility of an outage. Users with blank passwords wouldn't be able to log in to the instance.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(High) An attacker is able to log in to the instance with the default usernames, or by specific individual/group (usually firstname.lastname) without any password. Doing so is viewed as a critical security risk, because it would enable a public user to violate the confidentiality and integrity of the instance data.</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see Add a system property.

**Enable multi-factor authentication (MFA) (instance security hardening)**

Use the glide.authenticate.multifactor property to enable Multi-Factor Authentication (MFA) in the instance.

MFA is a security requirement that requires a user to enter more than one set of credentials to authenticate to an instance.

**More information**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.authenticate.multifactor</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>Strengthen instance security by introducing multi-factor authentication for interactive user logins.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>true</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Medium) Enabling this property improves the experience of the user. It acts as an extra layer of protection and security against compromised credentials.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Medium) If this property is not enabled, there is a risk of unauthorized access to sensitive data.</td>
</tr>
<tr>
<td>References</td>
<td>Configure multifactor authentication (MFA)</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see Add a system property.

**Enforce strong passwords (instance security hardening)**

Use the `glide.enable.password_policy` property to enable password policy checks whenever a user changes their password using the user interface.

To define which password policy to use once this property is enabled, see Enable password policies on your instance.

**Note:** The `glide.enable.password_policy` does not apply when an administrator changes a password or adds a user through script.

**More information**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.enable.password_policy</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Purpose</td>
<td>To apply password policy at time of password change.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>true (for higher strength passwords)</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Medium) Setting the property to true turns on password policy checks when a user resets their password.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Medium) Without a password policy, a user can create a weak password which increases the likelihood of an adversary gaining access to the instance.</td>
</tr>
</tbody>
</table>

**Steps to configure**

If you configure this setting in the Hardening Compliance Configuration page in the Instance Security Center:

1. Under **Medium**, Select **Session Management**.
2. In the **Enable Password Reset Policy Check** setting, select **Medium** for medium strength passwords, or **Strong** for more robust, higher strength passwords. Selecting one of these options sets the `glide.enable.password_policy` property to true and starts a workflow that automatically updates your password policy.

Additionally, you can set the `glide.apply.password_policy.on_login` system property to enable password policy checks at the time of log in.

**Managing failed login attempts (instance security hardening)**

Two script actions are available that enable a site administrator to manage the number of times a user can provide an incorrect password before being locked out from the Now Platform. You can enable either of these script actions to manage failed login attempts.

**More information**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property/Plugin Name</td>
<td>N/A</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Policy &gt; Script Actions</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>To enforce strict policy for failed login attempts to avoid brute forcing of credentials.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>Active</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Low) This remediation would enable administrator of the instance to monitor and report any malicious user access. No functionality impact, only User experience change.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Medium) Apply a defined logging and auditing strategy so that you can identify and act on suspicious activity in a timely manner.</td>
</tr>
</tbody>
</table>

**Steps to configure**

1. Navigate to **System Policy > Script Actions**.
2. Search for the name **SNC User**.
3. To enable management of failed login attempts, change the Active state of either the **SNC User Lockout Check with Auto Unlock** or **SNC User Lockout Check** scripts actions from **false** to **true**.

![Script Actions](image)

4. To reset the failed login counter after a successful login, you can activate the **SNC User Clear** script action.

**Password field auto-complete (instance security hardening)**

Use the **glide.login.autocomplete** property to enable browsers to use auto-complete on password fields in login forms.

**More information**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.login.autocomplete</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>To disable browser to attempt auto-complete for a password field.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>false</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Low) This remediation causes the Password field autocomplete flag to be turned off such that password history cache by browser is not shown in the field. There shouldn't be any functionality impact.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Low) User authentication fields should be validated and should never let the client-side caching to happen.</td>
</tr>
<tr>
<td>References</td>
<td><a href="https://support.servicenow.com/kb_view.do?sysparm_article=KB0563953">https://support.servicenow.com/kb_view.do?sysparm_article=KB0563953</a></td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see Add a system property.

**Remove credentials from welcome page (instance security hardening)**

Modify the default content on the Welcome page to remove the default credentials.

**Note:** Two How to Login records are part of the demo data for the CMS plugin. If you do not install the demo data for an instance, these records do not exist. In that case, the configuration is considered as Security Compliant as per the recommended security practices. To learn more, see Security best practices (instance security hardening).
Steps to configure

1. Navigate to System UI > Welcome Page Content >.
2. Find the two sections with a short description of How To login.
3. Change the Active state of each from true to false.

Remove remember me (instance security hardening)

Use the glide.ui.forgetme property to remove the Remember Me check box from the login page to prevent login information from being cached.

More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.ui.forgetme</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>To ensure that no authentication information is cached.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>true</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Low) This remediation would change the user experience by automatically logging them out of the instance when their session expires. The session expiration would solely depend on the value set in the system property as detailed in Manage user sessions.</td>
</tr>
</tbody>
</table>
| Security risk                    | (Medium) When you select the Remember me check box at login, an extra cookie is stored on the user's computer.  
  • Its purpose is to automatically re-establish the session for the subsequent visits of the logged-in user.  
  • It poses a security risk as it allows the user session to be active until they deliberately log out. The likelihood of an attack for this scenario increases when the end user has left the browser unattended, or if it is compromised from a different attack. |
| References                       | Remove the Remember me check box                                           |

To learn more about adding or creating a system property, see Add a system property.

Rotate HTTP session identifiers (instance security hardening)

Use the glide.ui.rotate_sessions property to enable rotation of the HTTP session identifiers to reduce security vulnerabilities.

If an unauthenticated user's session ID doesn't change after authentication, a web application is vulnerable to a session fixation attack. A malicious user could start an unauthenticated session and give the associated session ID to the victim. Once the victim authenticates, the malicious user now shares that authenticated session.

</tr>
<tr>
<td></td>
<td>• If you are using the SAML 2.0 plugin for Single Sign-on authentication, it might interfere with the session information sharing between the instance and the Identity Provider. In such case, you can set this property to false.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Late) SessionID is used to process and authenticate the instance user by maintaining the session state on the browser. Thus, SessionID is deemed as sensitive data and should be secure by default. Session Rotation is a security control that enforces the alteration of sessionID whenever the user navigates from unauthenticated pages to authenticate pages.</td>
</tr>
<tr>
<td>References</td>
<td>Authentication with SAML</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see [Add a system property](#).

**Secure session cookies (instance security hardening)**

Use the `glide.ui.secure_cookies` property to enforce the use of highly secure authentication cookies.

When you set the property to true, authentication cookies contain only a token, and have no embedded user information.

- On the service side, it looks up the token in the database, and associates it with a specific user. An authentication cookie can be used a single time only.
- Once used, the cookie is invalidated and removed from the database so that it can't be used again. The service then issues a new cookie.

More information

<table>

<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Recommended value</td>
<td>true</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Low) When the property is set to true, pre-existing, low-security authentication cookies are rejected. When such a cookie is rejected, the user must login again.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(High) If you set the property to false, an attacker can exploit low-security authentication cookies, in an attempt to compromise the Now Platform.</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see [Add a system property](#).

**Security referral policy (instance security hardening)**

Use the `com.glide.security.referrerpolicy` property to control what referrer data should be sent in HTTP response headers when Now Platform pages sends requests for data. The Referrer-Policy value in an HTTP header controls what referrer information should be included with data requests.

**Security referral policy values**

Set the `com.glide.security.referrerpolicy` property to one of the following values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>Now Platform instance manages the level of information sent in referrer headers that is appropriate for the specific Now Platform page request.</td>
</tr>
<tr>
<td>same-origin</td>
<td>Now Platform pages send a full referrer URL within the instance and same domain, and no referrer header to outside origin.</td>
</tr>
<tr>
<td></td>
<td>This setting ensures a good level of instance security.</td>
</tr>
<tr>
<td>origin</td>
<td>Now Platform pages send the base URL in the referrer header within the instance and same domain, and also externally.</td>
</tr>
<tr>
<td></td>
<td>This setting ensures a good level of instance security.</td>
</tr>
<tr>
<td>origin-when-cross-origin</td>
<td>Now Platform pages send the whole URL in the referrer header within the instance and same domain, and send only the base URL externally.</td>
</tr>
<tr>
<td></td>
<td>This setting ensures a good level of instance security.</td>
</tr>
<tr>
<td>no-referrer-when-downgrade</td>
<td>Now Platform pages send the origin, path, and querystring in the URL, as long as there is no downgrade in a security protocol.</td>
</tr>
</tbody>
</table>

**Note:** This setting does not ensure a good level of instance security in the Now Platform and should not be used.
Referrer Policy example and values summary

<tr>
<td>Configure in Instance Security Center</td>
<td>No</td>
</tr>
<tr>
<td>Purpose</td>
<td>Controls how much incoming data is sent via the &quot;referrer&quot; header when a Now Platform page sends a request for data.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>default</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Low) If set to 'default', the Now Platform instance manages the level of information sent in referrer headers.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(High) Setting this property value to 'no-referrer-when-downgrade' does not ensure a good level of security for your instance.</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see Add a system property.

Session activity timeout (instance security hardening)

Use the glide.ui.session_timeout property to designate, in minutes, activity timeout value.

There are several functional impacts from setting this property:

- The longer the specified session time-out, the greater the amount of memory is utilized during a processing session. The base system uses a default Apache Tomcat timeout duration of 30 minutes.
- The Now Platform still logs out users out with Remember Me. After 30 minutes of inactivity in the application, the platform logs the user out automatically, unless the Remember Me check box in the login page is selected. What’s different is that they don’t log in again to continue.
- If there are gauges or content on users' home pages that refresh automatically, then this timeout may never be reached.

More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>glide.ui.session_timeout</td>
</tr>
<tr>
<td>Configuration type</td>
<td>System Properties (/sys_properties_list.do)</td>
</tr>
<tr>
<td>Configure in Instance Security Center</td>
<td>Yes</td>
</tr>
<tr>
<td>Purpose</td>
<td>To enforce session timeout.</td>
</tr>
<tr>
<td>Recommended value</td>
<td>User specified timeout in minutes. 60 minutes is the recommended value, but this value may vary depending on functionality and security requirement. Do not set this value to more than one day.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Functional impact</td>
<td>(Medium) This remediation enforces timely expiration of user account. No functionality impact, however User experience is altered.</td>
</tr>
<tr>
<td>Security risk</td>
<td>(Medium) User sessions being active for indefinite amount of time is a security risk and should expire on a time-based configuration.</td>
</tr>
<tr>
<td>References</td>
<td>Manage user sessions</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see [Add a system property](#).

**Session window timeout (instance security hardening)**

Use the `glide.ui.user_cookie.life_span_in_days` property to set the expiration time period for the Remember Me cookie. The default value is 15 days and the maximum cap is at 30 days.

**More information**

<table>
<thead>
<tr>
<th>Attribute</th>

<td>Change settings for the Remember me check box and cookie</td>
</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see [Add a system property](#).

**Other settings and security resources**

This section contains security properties you set outside of the Instance Security Center, and also contains other security-related resources.

**Logging, auditing, and errors (instance security hardening)**

Apply a logging and auditing strategy so that you can identify and act on suspicious activity in a timely manner.

To learn more about what can be logged in the instance, see [System logs](#). Ensure that there is a schedule for monitoring system events such as login and failed logins by using **System Logs > Events**.

**Disabling SQL error messages (instance security hardening)**

Use the `glide.db.loguser` property to disable SQL error messages from rendering in a browser.
More information

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>

</tr>
</tbody>
</table>

To learn more about adding or creating a system property, see Add a system property.

**MID server secure deployment guide (instance security hardening)**

The ServiceNow Management, Integration, and Discovery (MID) server is a lightweight Java application that runs as a Windows service or UNIX daemon on standard hardware, including virtual machines.

![MID server diagram](image)

It securely authenticates to your instance in the ServiceNow Cloud using its own login credentials, and facilitates the data transmission with your applications, data sources, and services. Multiple MID servers can be deployed in different network segments to provide additional scalability.

Consider the following factors regarding security for your MID Server:
Physical security
It is important to secure the physical hardware that hosts the MID Server or the hypervisor for virtualized MID Servers.

- Place the hardware in a secure location that protects the hardware from unauthorized access.
- Protect access to this location with an electronic card reader and CCTV monitoring.
- Place the physical hardware in a locked cage or a rack with physical key access control.

Virtual infrastructure security
Virtualization offers the flexibility to install multiple MID Servers in virtualized operating systems and networks in shared physical hardware.

Access to the hypervisor and virtual infrastructure management consoles must be protected to prevent unauthorized cloning of the virtualized MID Server:

- Limit the access to the hypervisor and virtual infrastructure management consoles by the trusted few admins.
- Only allow connections to the internal trusted network for management console such as ESX Server and VirtualCenter.
- Use VLANs to prevent network attacks.
- Follow the security guidelines published in the virtualization hardening guides from the vendors.

Operating system security
The MID Server stores its Now Platform username and password in its configuration file, named config.xml, for secure authentication to the instance.

The MID Server must be deployed in a secure and hardened operating system for protection against unauthorized access to the credentials:

- Limit the access to the operating system to a few, trusted administrators.
- Monitor the operating system logs to detect any unauthorized access, particularly attempts to access the config.xml file, as this file contains important MID Server configuration information.
- Install operating system security patches regularly with the latest anti-virus software and update AV definitions regularly.
- The MID Server requires a current Java framework to run. Keep Java updated regularly.
- Remove or disable unnecessary services and applications.
- Install an OS firewall to limit access to unauthorized ports.
- Follow the security guidelines published in the operating system hardening guides from the vendors.

Network security
The MID Server communicates on port 443 using SSL to the instance and requires no inbound connections.

To properly secure your MID server in a network, do the following:

- Install the MID Server on a secured server behind a corporate firewall for protection against unauthorized access from the internet.
- Configure the firewall on the MID Server to accept no inbound connections other than the ones required for corporate management of the operating system and hardware.
- The system that hosts the MID Server must be able to access the ServiceNow download site at install.servicenow.com.

Note: This URL is to the ServiceNow download site, which is not accessible from this topic.

The MID Serve host machine must be able to access that site to download the installer package. It contacts install.servicenow.com every 60 minutes to see if a newer version is available and if so, it performs an automatic upgrade. A MID Server upgrade also takes place when you upgrade an instance.

Firewall
Configure your firewall to allow outbound network traffic from the MID Server to your instance and auto-upgrade server.

To configure your firewall, use the following example syntaxes:

- `<source IP> TO <instance_name>.service-now.com ON PORT 443`
- `<source IP> TO install.service-now.com ON PORT 443`

**Administration and Management**

This section describes the security practices and guidelines for administering and managing the MID Server in your environment.

**Create an account with a mid_server role**

Create a user account in the instance that contains a mid_server role.

When you create a user account, follow these guidelines:

- Do not use an administrative account in the instance for the MID Server.
- Use sufficient password length and complexity for the MID Server account.
- The password should be at least 12 characters with upper, lower, numerical, and special characters.
- Use different MID Server accounts with unique passwords for different MID Servers in an instance.
- Use strict SOAP security feature to protect all tables with access control lists (ACL) by enabling **Enforce strict security on incoming SOAP requests** in System Properties > Web Services.
- Change the MID Server passwords at frequency that meets your organization's password policy.

**Note:** The Incompatible MID Server user role business rule prevents setting the Web Service access only option. To learn more, see the Create the MID Server user and grant the role.

**Setting up a MID server on a Windows host**

When you install the MID Server on a Windows host, it creates a Windows service. By default, this service is running as the local Windows system account. After the installation completes, change the newly created Windows service to an account with the least number of privileges required to run the MID Server on the Windows host.

1. Navigate to **Computer Management > Services and Applications > Services**.
2. Right-click **ServiceNow MID Server**, then click **Properties**.
3. Click the log in tab in the pop-up window.
4. Click the radio button next to **This account**.
5. Enter in the appropriate username and password of the account that the service should be running as:

![ServiceNow MID Server properties](image)

6. Click **OK**.

7. In the Services window, right-click **ServiceNow MID Server**, then click **Restart**.

8. Ensure that the MID Server was able to restart successfully and connect to the instance.

**Windows Discovery and Orchestration credentials**

Set up a local Windows or Active Directory account on the target systems with the least number of privileges necessary. It may not be necessary to use domain admin credentials.

The following product documentation pages provide guidance on the type of account that should be used and what permissions are required.

- Windows credentials
- Windows probes and permissions
- Microsoft Just Enough Administration (JEA) for Discovery

**Linux Discovery and Orchestration credentials**

Use a non-root account with limited pseudo-privileges on target Linux systems when performing discovery and orchestration.

Use the following guidelines:

- Use sufficient password length and complexity for the Linux account. The password should be at least 12 characters with upper, lower, numerical, and special characters.
- When configuring sudo permissions, local paths to binary executable files may differ depending on what Linux distro you are running, see **MID Server privileged commands**.

Encrypt MID server login credentials
By default, the MID Server login credentials are encrypted in the config.xml file.

When editing the config.xml file and supplying the password, ensure that the encrypt="true" attribute exists, using the following syntax:

```
<parameter name="MID.instance.username" value="MIDsrvadmin" />
<parameter name="MID.instance.password" encrypt="true" value="$ECUREpassw0rd" />
```

**Note:** Encrypting MID Server login Credentials does not substitute insecure server host with poor physical and network security. The password stored in the config.xml file is encrypted when you first start the MID Server, or, if it is an existing MID Server, on restart.

Set the minimum size of DH Group to 2048 bits
The National Standard Institute of Technology (NIST) disallowed the use of Diffie-Hellman (DH) 1024 bits key after year 2013. Set the minimum size of DH group to 2048 bits instead.

1. In the instance, navigate to **MID Server > Servers**.
2. Click the MID Server name that you would like to disable this functionality on.
3. In the MID Server configuration, click the **New** button next to Configuration Parameters.
4. In MID Server Configuration Parameter, configure the following parameter settings:
   - **Parameter name** mid.ssh.dh_group_length_min
   - **Value** 2048

Disable outbound SSL
You can disable SSLv2 and SSLv3 in the Now Platform. Setting this property forces the MID Server to use TLS, taking advantage of its increased security, when making outbound connections, such as REST and SOAP requests.

1. In the instance, navigate to **MID Server > Properties**.
2. Add a configuration parameter and set its value as follows:
   - **Name** glide.outbound.sslv3.disabled
   - **Value** true

Disable weaker algorithms
You can disable the weaker algorithms so that requests to any non-TLS 1.2 compliant HTTP server would fail where it used to work.

Edit the jre/lib/security/java.security file in the agent folder, using the following syntax:

```
jdk.tls.disabledAlgorithms=SSLv3, TLSv1, TLSv1.1, [other weak algos...]
```

**Note:** Keep in mind that this file is overwritten on upgrade, so you should have to have a process in place to reupdate this file after every upgrade.

### Revertible behavior

There are system properties that are categorized as either 'safe_overrides' or 'no_db_override'.

**Safe override**
The values for these properties can't be altered once changed (they are non-revertible).
<table>
<thead>
<tr>
<th>Attribute</th>
<th>Category</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enabling AJAXGlideRecord ACL checking (instance security hardening)</td>
<td>Access Control</td>

<tr>
<td>Client generated scripts sandbox (instance security hardening)</td>
<td>Input validation (instance security hardening)</td>
</tr>
<tr>
<td>Collection mode override (deprecated)</td>
<td>Security inclusion listing (instance security hardening)</td>
</tr>
</tbody>
</table>

No DB override
The existing values for these properties can't be altered or overridden.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Category</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable file download restrictions (instance security hardening)</td>
<td>Attachments</td>
</tr>
</tbody>
</table>

Deprecated security properties
These security properties were deprecated in earlier releases.

Collection mode override (deprecated)
The `glide.whitelist.manager.collection_mode.override` property was designed to provide backwards compatibility for highly customized instances. It used package calls that were created on a version prior to Calgary and has since been deprecated.

More information

<table>
<thead>
<tr>
<th>Attribute</th>

**Instance Security Center**

Monitor the compliance level of instance security controls, view security event monitoring metrics, and configure and maintain instance security settings all from within the Instance Security Center. The Instance Security Center consolidates several key security components into a single control console that helps you detect, protect, and respond to instance-based security events.

From the Instance Security Center homepage, you can view the security compliance score for your instance and monitor its overall security health. You can then configure or update system properties that are related to your instance security so that they comply with security requirements.

**Note:** The Instance Security Center does not support domain separation.

### User roles

To use the Instance Security Center, you must have the admin or security_dashboard_user role.

<table>
<thead>
<tr>
<th>User</th>
<th>Required role</th>
<th>Benefits</th>
</tr>
</thead>
<tbody>
<tr>
<td>Security personnel in your organization who monitor security-related information for an instance and have authorization to change security hardening settings. They should be able to return to the Instance Security Center at any time to adjust settings and manage the overall security health of an instance.</td>
<td>admin</td>
<td>Continually monitor and manage instance security compliance.</td>
</tr>
<tr>
<td>Security personnel in your organization who monitor security-related information for an instance but do not have authorization to change security hardening settings. For example, a security analyst with this role can view instance security information. However, another user with an admin role would have to make actual security setting updates.</td>
<td>security_dashboard_user</td>
<td>Continually monitor instance security compliance to detect and respond to security threats.</td>
</tr>
</tbody>
</table>

**Warning:** To ensure that the Instance Security Center receives up-to-date security information with every upgrade, do not customize this module. If you change any security settings on your instance, make sure that you test them in a non-production environment first.

### Instance Security Center components

To access the Instance Security Center, navigate to System Security > Instance Security Center or the System Administration homepage.
Configure Security Notifications
Starting in Paris, ISC users can now subscribe to security email notifications. Begin updating by selecting

Hardening: Live Protection
Access restrictions help reduce the attack surface and the likelihood of malicious actions on your system. A new rule has been added to defend against unauthorised access.

Daily Compliance Score
83%
The Instance Security Center homepage contains the following security components:

- Administrator messages
- Rotating security banner
- Search
- Security event ribbon
- Daily compliance score
- Session Management
- Hardening
- Auditor
- Metrics (user, email, and antivirus)
- Resources
- Security notifications
- Tours
- Security testing portal
- Security center
- Help
- Virtual Agent access

**Administrator messages**

Messages and reminders, intended mostly for administrators, appear above the rotating security banner.

- For example, a Configure Security Notifications message appears that reminds administrators to configure preferences for security notifications if they have not done so already. It also points them to the proper page to do so.
- To learn more about security notifications and enabling notification preferences, see Security notifications.

**Note:** The administrator messages banner does not appear for non-admin users, or if there are no actionable items for admin users.

**Rotating security banner**

To assist you in monitoring the security health of your instance, critical instance security messages appear in the rotating banner.

- Two to three security messages normally rotate at a regular interval.
- The dots at the bottom of the banner show you the total number of current security messages.
- To navigate through them, click the dots, or click the arrows that appear on either side of the messages.

The banner background colors indicate the relative severity of the messages.

<table>
<thead>
<tr>
<th>Color</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Red</td>
<td>Critical security situation requiring a timely response, or a recommendation on how to protect or respond to critical security events.</td>
</tr>
<tr>
<td>Dark gray</td>
<td>Non-critical warning message.</td>
</tr>
<tr>
<td>Blue</td>
<td>General information message.</td>
</tr>
</tbody>
</table>
To collapse or minimize the text content in the banner, click [icon]. To maximize the text content, click it again.

- When you use the Instance Security Center again, the text content appeared as collapsed or expanded, depending on how you used it during your previous session.
- If the text content itself changes, it appears as maximized for all users.

**Search**

Use the search bar to search the entire Instance Security Center for security resources that assist you with understanding and resolving security issues. You can search the following security-related resources:

- Now Support Knowledge Base articles
- Instance Security Center pages
- External Now Support links
- PA security widgets, such as the Daily Compliance Score and External Incoming Emails
- Banner content

**Event ribbon**

Use the event ribbon to view key security event monitoring metrics for the current instance.

- To manually scroll through the metrics, click the right or left arrow keys.
- To configure the event ribbon, click **Edit**.

To learn more about the event ribbon and how to configure it, see Monitor security events and Configure the security event ribbon.

**Daily compliance score**

The Daily Compliance Score section contains the **Daily Compliance Score**, **Session Management**, **Hardening**, **Auditor**, and **Resources** tiles.

You use the Daily Compliance Score to gauge how healthy your instance is from a security standpoint.

The Daily Compliance Score is a percentage score. It is based on how compliant the current settings of your instance security properties are with the compliance values published in the Instance Security Hardening Settings.

- To learn more about Daily Compliance Score calculations, and how hardening settings impact it, see Check the daily compliance score and configure security property settings.
- The **Refresh** button enables an administrator to instantly recalculate the Daily Compliance Score. To learn more, see How Daily Compliance score, trend, and graph data is refreshed.

**Hardening**

Use this process to adjust the specific security configuration properties that affect the Daily Compliance Score:

1. To access the Hardening Compliance Configurations page and perform instance security hardening, click the **Daily Compliance Score** tile or the **Hardening** link.

2. Specify if you want to view all or only recommended security controls, and then select the category you want to work in.
3. Set each security configuration property in the selected category. Click More Info to view detailed information for a property.

To learn more about hardening and optimizing security configuration properties to further increase compliance, see Adjust instance security settings to increase compliance.

To learn more about how trend and graph data is refreshed, see How Daily Compliance score, trend, and graph data is refreshed.

**Auditor**

Run the Auditor to scan your instance and find incorrect security definitions. It provides findings you can correct to help improve the security posture of your instance.

To access the Auditor page, click the Auditor tile or the Auditor link. To learn more, see Scan for incorrect security definitions.

**Session management**

Use Session Management to:

- View and manage user login sessions.
- See all users who are currently logged in to the instance.
- See detailed information about each session, such as the user name and IP address.
- Isolate and lock out specific user sessions that pose security risks.

To access the Session Management page, click the Session Management tile or link.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| User  | Name of the user associated with this login session.  

- To locate a specific user session, click the spotlight search icon ( ) to search by user, user agent keyword, or IP address.  
For example, if you want to find all current logins from a specific type of browser, enter the browser name as a keyword into the User Agent field.  
- Click a user name to access the user profile record. You can modify the user profile only if you have an assigned admin role.  

**Note:** To learn more about user profiles, see Create a user. |
| MFA   | Check box indicating if Multifactor Authentication (MFA) is enabled for the logged in user. To learn more about MFA, see Multifactor authentication (MFA). |
| Active| Check box indicating if the logged in user is active or inactive. |
### Field

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Agent</td>
<td>Type of browser and the device operating system for the user login session.</td>
</tr>
<tr>
<td>IP Address</td>
<td>IP address of the logged in user.</td>
</tr>
<tr>
<td>Last Accessed</td>
<td>Date and time this user session last accessed the instance.</td>
</tr>
</tbody>
</table>

**Note:** To view detailed information for a particular login session, or to lock out the session itself, click the User Agent, IP Address, or Last Accessed fields.

### Metrics (user, email, and antivirus)

View detail for the following types of metrics:

<table>
<thead>
<tr>
<th>Type of metric</th>
<th>Description</th>
</tr>
</thead>
</table>
| User | Security metrics that are associated with user activity in the instance.  
To access the User Metrics page, click the Metrics link, and then select User Metrics. |
| Email | Security metrics that are associated with user activity in the instance.  
To access the User Metrics page, click the Metrics link, and then select User Metrics. |
| Antivirus | Security metrics that are associated with antivirus event activity in the instance.  
To access the Antivirus Metrics page, click the Antivirus tile or click the Metrics link, and then select Antivirus. |

**Note:** To learn more about monitoring each type of metric, see Monitor user, email, and antivirus metrics.

### Resources

Access Now Support Knowledge Base articles, resources, and blogs that are related to instance security. These resources include security settings, coding, compliance, fixes, and related topics. To access the Resources page:

1. Click the Resources tile or link.
2. In the Resources page, click a category:

<table>
<thead>
<tr>
<th>Category</th>
<th>Description</th>
</tr>
</thead>
</table>
Security notifications

A notifications bell icon appears in the Instance Security Center, with a count total of unread security notifications. Notifications persist and are included in this count until you mark them as read.

1. Click the bell icon to view the first five unread security notifications.

   A notification appears when Admin Login, Admin Unlocked, Failed Login, High Privilege Role, Impersonation, Security Elevation, and Weekly Digest events take place in your instance. To learn more about these security events, see Monitor security events.

2. To view detailed information for a specific security event, click the notification.

   For example, if you click a High Privilege Role notification, you can view the Roles (sys_user_role) table. Use this table to see which users were assigned privileged roles during the calendar day. Using this history helps you to determine if roles have been properly assigned.

3. If there are more than five unread notifications, click View All Notifications to access an All Notifications page with a listing of all unread notifications.

   • To view detailed information for a specific security event, click the notification.
   • To mark all listed notifications as read, click Mark All as Read.

Note: As an administrator, you can also configure preferences for sending specific types of notifications for each type of security event. To learn more, see Set preferences for security event notifications.

Tours

Click the Tours link to view a guided visual tour of the Instance Security Center.

• The guided tour includes only the security monitoring functions that are listed on the homepage.
• It does not include the security functions that you access when you click the tiles or links on the homepage.

Security testing portal, security center, and help

The Now Support Service Portal is a central resource that you use to manage instances, tasks, and accounts. You can also access useful resources you can use to diagnose and resolve security and technical issues in your instance.

To access these resources, click Learn More or Get Help in the following tiles:
### Security Testing Portal

### Security Center

### Help
Access to the following help resources in the Now Support Security Portal:
- Ask an expert to find answers to common questions.
- Report an issue or outage to ServiceNow Global Technical Support by opening a case.
- Self-Service Support Resources, including:
  - Videos
  - Documentation
  - Now Community
  - Knowledge Base
  - Known Error Portal
  - Security RFX Database
- Now Community questions that are recommended for your use.

### Virtual Agent access
The Virtual Agent is a platform for providing user assistance through conversations within a messaging interface.

If you have an assigned admin role and have activated the proper plugins, you can access the Virtual Agent and Natural Language Understanding (NLU) functions by clicking the Virtual Agent icon:

It enables you to perform the following tasks:
- Ask security-related questions, then get quick summary answers and reference links to learn more.
- Get answers related to the Instance Security Center, Platform Security, ServiceNow security policies, trust, governance, risk, and other processes.
- Search for security-related resources, such as Knowledge Base topics in the Now Support Security Portal.

**Note:** To learn more about how to use and activate the Virtual Agent, see:
- Virtual Agent
- Activate the ISC Virtual Agent interface

### Monitor security events
Analyze the event metrics in your instance so that you can identify and prevent potential security events.

In the event ribbon, which is on the Instance Security homepage, you can analyze these metrics and accompanying detail to identify potential security events in the instance.

- For each event metric, a real-time single score count appears, indicating how many times that the event occurred during the day in this instance. These single score reports are updated automatically as the corresponding events take place.
• Each event metric also contains compliance trend and graph information over a range of dates. This information updates on a daily basis when you run the performance analytics job. To learn more, see the Analyzing event trend detail section.

Event types

You can monitor at least six of the following types of events. For more than six events, use the left or right arrows below the event ribbon to scroll through them. To learn how to configure the event ribbon, see Configure the security event ribbon.

<table>
<thead>
<tr>
<th>Notification preference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Admin Logins</td>
<td>Number of login attempts in this instance, during the calendar day, by users who have an assigned admin role.</td>
</tr>
<tr>
<td>Admin Users Added</td>
<td>Number of users with an admin role that were added in this instance during the calendar day. For example, your instance may have a security issue if the count is 10, but 4 users are known to have an assigned admin role.</td>
</tr>
<tr>
<td>External Incoming Email</td>
<td>To learn more, see Email metrics.</td>
</tr>
<tr>
<td>External Logins</td>
<td>Number of users with an assigned snc_external role who logged into this instance during the calendar day. These logins typically occur for maintenance, support, consulting, or audit purposes. Monitoring this metric enables you to verify that the external login attempts are legitimate and not potential security issues. To learn more about assigning external user roles, see Explicit Roles.</td>
</tr>
<tr>
<td>Failed Logins</td>
<td>Number of attempted logins that failed in this instance during the calendar day. This metric may indicate that attempts are being made to log in and compromise your instance security.</td>
</tr>
<tr>
<td>Impersonations</td>
<td>Number of impersonation logins in this instance during the calendar day. To learn about impersonating users, see .</td>
</tr>
<tr>
<td>Quarantined Files</td>
<td>Number of files that were quarantined when you ran Antivirus Scanning in this instance during the calendar day. To learn more about quarantined files and Antivirus Scanning, see Antivirus metrics and Antivirus Scanning.</td>
</tr>
</tbody>
</table>
## Notification preference

<table>
<thead>
<tr>
<th>Notification preference</th>
<th>Description</th>
</tr>
</thead>
</table>
| Security Elevations     | Number of times that a security administrator has elevated security for standard users by changing their assigned user role to a high privilege security role during the calendar day. These high privilege security roles include oauth_admin, admin, security_admin, and impersonator.  
- This metric indicates that someone might have tried to elevate the security of an unauthorized user. Do not use this metric by itself to detect a specific security compromise. Instead, treat this metric as an indication that you should check another metric to see if a security compromise has occurred.  
- To learn more about elevating user security, see Elevate to a privileged role and Elevated privilege roles. |
| SNC Logins              | Number of Customer Service and Support personnel who logged into this instance using the hi-hopping technique during the calendar day. These logins typically occur for maintenance, support, consulting, or audit purposes.  
For information on how to control ServiceNow corporate employee access, see ServiceNow access control. |
| Spam                    | To learn more, see Email metrics. |
| Trusted Incoming Email   | To learn more, see Email metrics. |
| Untrusted Incoming Email | To learn more, see Email metrics. |
| Virus Types             | Number of different types of antivirus events that occurred in this instance during the calendar day. To learn more about antivirus event types, see . |

### Analyzing event trend detail

To view trend details for an event metric, click the event count to access the Analytics Hub page. The details that appear for the instance depend on the type of metric.

For example, to view a listing of each failed attempt on the Security Dashboard Event Logs page:

- Select the **Failed Logins** metric,
- In the Analytics Hub page, click **Show Records**.
- Click one of the failed login attempts.
- The detail includes the name of the user who attempted to log in, their IP address, and the table name that they tried to access.

You can set up event threshold triggers in the to provide alerts when a certain event occurs within a range of scores for an indicator. You can also set targets that enable you to visualize the difference between the desired score and the actual score of an event.
For example, you can set a threshold of 10 for the Failed Logins metric. When ten or more failed login attempts occur during the day, an alert is sent to specific security personnel. You can also set a similar target that provides a visual highlight in the Analytics Hub when 10 failed logins occur during a day.

Trend data and graphs that appear in Event ribbon tile and the Analytics Hub are updated after the performance analytics job executes at 02:00 local time. To learn more, see How Daily Compliance score, trend, and graph data is refreshed.

Configure the security event ribbon

Configure the security event ribbon on the Instance Security Center homepage to include only those events that are relevant for tracking instance security in your operations. You can also change the order in which the security event tiles appear on the ribbon.

Role required: security_dashboard_user or admin

The security event ribbon is initially populated with a full set of standard security events. You can customize it by removing the events that are not relevant to your organization.

- For example, if you suspect that security issues are due to the actions of internal personnel, include the Admin Logins, Admin Users added, and Security Elevations event indicators.
- These indicators monitor how many times users with admin roles attempted to log in and, if admin users were added, what attempts were made to elevate security roles.

Note: To learn about the types of security events that appear in the event ribbon, see Monitor security events.

2. In the event ribbon, click Edit

On the Edit Events form, the Selected column contains the events that are already listed.

3. To add security events to the event ribbon, move them from the Available column to the Selected column.
   To change the order the events appear on the ribbon, select an event, then click the up or down arrow to move it to its correct position.
   - Place the events in the same sequential order they should appear on the Instance Security Center event ribbon.
   - The events you place at the top of the Available column appear sequentially, beginning on the left side of the Instance Security Center event ribbon. The events placed towards the bottom of the column appear on to the right on the event ribbon.

4. To remove security events from the event ribbon:
   - In the Selected column, select the security events that you want to remove from the event ribbon.
   - Move them from the Selected column to the Available column.

5. Click Save.

Set preferences for security event notifications

Configure preferences for the types of notifications you want to receive for occurrences of specific security events. For each type, you designate whether to receive notifications by email, by push notification in Now Mobile, or in third party messaging applications such as Slack or Microsoft Teams.
To enable third party messaging applications to send security event notifications, you must activate the Messaging Notification (com.glide.notification.messaging) plugin. Individual users must configure their own settings. For details, see Notifications in messaging applications.

Role required: admin

1. In the Instance Security Center home page, click the profile menu, then click **Notification Preferences**.

<table>
<thead>
<tr>
<th>Notification preference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Admin Login</td>
<td>Send the selected type of notification whenever other users with assigned admin roles log into this instance from a different IP address.</td>
</tr>
<tr>
<td>Admin Unlock</td>
<td>Send the selected type of notification whenever an account for a high privilege user has been unlocked.</td>
</tr>
<tr>
<td>Failed Login</td>
<td>Send the selected type of notification whenever other users fail to log in into this instance in less than the number of attempts defined in the <code>glide.user.max_unlock_attempts</code> property. If you don't configure this property, the default value is 5. To learn more about this property, see Specify lockout for failed login attempts.</td>
</tr>
<tr>
<td>HP Role Added</td>
<td>Send the selected type of notification whenever a high privilege security role (including oauth_admin, admin, security_admin, and impersonator roles) is granted to another user. To learn more about elevating user security, see Elevate to a privileged role and Elevated privilege roles.</td>
</tr>
<tr>
<td>Impersonation</td>
<td>Send the selected type of notification whenever another user is impersonating you. To learn more about impersonating users, see Impersonate a user.</td>
</tr>
<tr>
<td>Security Elevation</td>
<td>Send the selected type of notification whenever other users are elevated to a security admin role in this instance.</td>
</tr>
</tbody>
</table>
| Weekly Digest | Send a weekly digest on the selected type of notification. It includes:  
  - A summary all security activities that took place in this instance throughout the week.  
  - The current daily compliance score for the instance. |

2. For each type of security event, select the appropriate check boxes to designate the type of notifications to send you. You can select multiple notification methods for each.

<table>
<thead>
<tr>
<th>Check box</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Email</td>
<td>Send an email for this type of security event.</td>
</tr>
<tr>
<td>Check box</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>Slack</td>
<td>Send notifications for this type of security event through Slack.</td>
</tr>
<tr>
<td><strong>Note</strong>: This column appears only if you have set up Slack integration to the Now Platform.</td>
<td></td>
</tr>
<tr>
<td>Teams</td>
<td>Send notifications for this security event through Microsoft Teams.</td>
</tr>
<tr>
<td><strong>Note</strong>: This column appears only if you have set up Microsoft Teams integration to the Now Platform.</td>
<td></td>
</tr>
<tr>
<td>Push</td>
<td>Send push notifications on Now Mobile for this type of security event.</td>
</tr>
<tr>
<td><strong>Note</strong>: This column appears only if you first log into Now Mobile.</td>
<td></td>
</tr>
<tr>
<td>Select All</td>
<td>Select a specific type of notification for all types security events. For example, click Select All located above Email if you want to receive email notifications for each security event type.</td>
</tr>
</tbody>
</table>

3. Click **Save**.

### Check the daily compliance score and configure security property settings

Review the Daily Compliance Score metric and security configuration properties to see if your instance complies with the suggested security requirements. You can affect the daily compliance score by updating non-compliant security properties in the Hardening Compliance Configurations page.

The Daily Compliance Score is a percentage score. It is based on how compliant the current settings of your instance security properties are with the compliance values published in the Instance Security Hardening Settings.

Review the daily compliance score of your instance regularly. Follow these guidelines when you are evaluating your daily compliance score:

- Greater than or equal to 90% indicates that the instance is compliant with critical security controls.
- Greater than or equal to 50% and less than 90% indicates a moderate level of security compliance.
- Less than 50% indicates a low level of security compliance.

### Adjust instance security settings to increase compliance

Using the Hardening Compliance Configuration page, harden and optimize non-compliant security properties that affect the daily compliance score of your instance. Its use ensures that your instance complies with the published security hardening standards, while fulfilling your company's security requirements.

Refer to the Instance Security Hardening Settings content for detailed descriptions, and compliance values, for the security-related system properties and plugins in the .

- Consult the Instance Security Hardening Settings whenever you set or update security-related properties, even if some of the compliance values may not be suitable for your instance.
When you are updating these properties, ensure that the instance continues to behave as expected. Consult with the appropriate internal personnel who have the expertise to determine the security impacts.

Role required: security_dashboard_user or admin

**Note:** If you have an admin role, you can view and edit security controls. If you have a security_dashboard_user role, you can view security controls, but you cannot edit them.

1. Navigate to **System Security > Instance Security Center**.
2. Click the **Daily Compliance Score** tile or the **Hardening** link to access the Hardening Compliance Configuration page.
3. In the Hardening Compliance chart, view the statistics for compliant and non-compliant security configuration properties.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compliant</td>
<td>Number of security configuration properties that comply with the compliance values in the Instance Security Hardening Settings.</td>
</tr>
</tbody>
</table>

**Note:** You cannot change the settings for compliant security properties in the Hardening Compliance Configuration. If you want to do so, you must update them in System Properties. To learn more, see Add a system property.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-Compliant</td>
<td>Number of security configuration properties that do not comply with the compliance values in the Instance Security Hardening Settings. You can update settings for non-compliant properties.</td>
</tr>
</tbody>
</table>

**Note:** To view the number of compliant or non-compliant security scores over a range of dates, move the blue dot on the slider below the Daily Compliance Score.

4. In **Show**, specify whether you want to access all security configuration properties, or only recommended ones.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>All</td>
<td>(Default) All compliant and non-compliant security configuration properties in each selected category.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Recommended</td>
<td>Only recommended security configuration properties appear in each selected category. These security configuration properties are a selected subset of the most critical ones used to secure the Now Platform. Consider these security configuration properties to be the bare minimum number of settings you must set to secure the Now Platform.</td>
</tr>
</tbody>
</table>

**Note:** To fully secure your instance, use the **All** option. It includes all recommended security configuration properties too.
5. In **Categories**, select the category that contains the security configuration properties you would like to access:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access Control</td>
<td>Access controls determine whether to grant or deny user access to a particular resource based on who is permitted to use those resources. To learn more, see <a href="instance_security_hardening">Access control (instance security hardening)</a> in the Instance Security Hardening Settings.</td>
</tr>
<tr>
<td>Attachments</td>
<td>Attachment security controls enable validation of incoming attachments to protect your instance against malicious files sent by attackers. To learn more, see <a href="instance_security_hardening">Attachments (instance security hardening)</a> in the Instance Security Hardening Settings.</td>
</tr>
<tr>
<td>Email Security</td>
<td>Email security encompasses security configuration properties an administrator can configure to ensure that proper security policies are in place for all inbound emails. To learn more, see <a href="instance_security_hardening">Email security (instance security hardening)</a> in the Instance Security Hardening Settings.</td>
</tr>
<tr>
<td>Input Validation</td>
<td>Input validation includes security-related properties that an administrator can configure to minimize entry of malformed data, regardless of source. To learn more, see <a href="instance_security_hardening">Input validation (instance security hardening)</a> in the Instance Security Hardening Settings.</td>
</tr>
<tr>
<td>Secure communications</td>
<td>Secure communications properties are those that an administrator can configure to secure the transportation of HTTP traffic. To learn more, see <a href="instance_security_hardening">Secure communications (instance security hardening)</a> in the Instance Security Hardening Settings.</td>
</tr>
<tr>
<td>Security Best Practices</td>
<td>Security best practices encompass security tasks that an administrator should perform periodically, within a certain interval of time, and include related configuration properties. To learn more, see <a href="instance_security_hardening">Security best practices (instance security hardening)</a> in the Instance Security Hardening Settings.</td>
</tr>
<tr>
<td>Security Inclusion Listing</td>
<td>Security inclusion listing includes security-related properties that an administrator can configure to restrict behavior to known inclusion listings. To learn more, see <a href="instance_security_hardening">Security inclusion listing (instance security hardening)</a> in the Instance Security Hardening Settings.</td>
</tr>
<tr>
<td>Session Management</td>
<td>Session management includes security-related properties that an administrator can configure to ensure secure session management in the . To learn more, see <a href="instance_security_hardening">Session management (instance security hardening)</a> in the Instance Security Hardening Settings.</td>
</tr>
</tbody>
</table>

6. Configure the non-compliant security properties in the selected category.

   - Unless otherwise specified, sliding the switch on sets a security property to its recommended setting. For example, you set most controls to true or false, but some require entry of a value, or values, such as a comma-separated value list.
   - To access the dedicated Instance Security Hardening Settings topic for the security control, and learn more about it, click **More Info**.

The Daily Compliance score increases or decreases depending on the changes that you make to the non-compliant security control settings.
How Daily Compliance score, trend, and graph data is refreshed

Trend and graph data in the Instance Security Center is updated after the performance analytics job executes at 02:00 local time. It appears in the Daily Compliance Score tile, in the Event ribbon tiles, and in the Analytics Hub page detail when you click one of the event tiles.

The [AppSec] Daily Data Management job is a regularly scheduled job that runs nightly and performs the following tasks:

1. Verifies if valid users have been assigned to the [AppSec] Daily Data Management and [PA AppSec] Daily Data Collection jobs when you first schedule them.
   - If you entered a valid user into the Run As field, the job continues processing. A valid user is one that is not locked out of the instance and has an assigned admin role.
   - If you entered an invalid user, an error message appears above the rotating security banner in the Instance Security Center.

   **Note:** To learn more about updating the assigned user when running scheduled jobs, see Create or schedule a data collection job.

2. Executes business logic to set the compliance state for the security properties you configure in the Hardening Compliance Configuration page. To learn more, see Check the daily compliance score and configure security property settings.

3. Runs the [PA AppSec] Daily Data Collection performance analytics job to collect compliance data and update the Daily Compliance Score.

Manually refreshing the Daily Compliance Score

Alternately, if you have an assigned admin role, you can refresh and recalculate the Daily Compliance Score at any time by clicking Refresh.

- The Refresh function performs the same tasks as the Daily Data Collection performance analytics job but does it in real time, rather than in a batch process.
- You typically use it when you want to perform updates to the Daily Compliance Score to immediately view the impact of instance security activities.
- There may be a slight delay before the updated score appears.

**Note:** The Refresh button does not appear for users with an assigned security_dashboard_user role.

**Note:** When you perform an upgrade (for example, from London to Quebec), the Instance Security Center (ISC) plugin is automatically activated. A ServiceNow-supplied fix script automatically assigns a custom user without any assigned roles.

Scan for incorrect security definitions

Run the Auditor to scan your instance and find incorrect security definitions. It provides findings you can correct to help improve the security posture of your instance.

The Auditor performs a “full-body” assessment of your instance health that analyzes your system configuration. For security scans, it compares your current security configuration to best practice definitions, and to security property compliance values.
From an instance security standpoint, it provides insights and recommendations into what you should continue doing, and where you might be able to improve. These insights and recommendations help you answer the following questions:

- Are the appropriate security-related properties set?
- Is the High Security plugin enabled?
- Do the right access control rules exist?

### Run the Auditor and analyze scan results

1. To run the Auditor, click **Audit** on the Instance Security Center home page.
2. When it completes, open Scan Results to review and analyze the security findings.
3. To review the detail for a specific scan result, double-click the result number. This information includes its status, scan type, execution time, and error messages.
4. Each of the Auditor findings contains resolution details, and a URL to product content about how to address them. Follow the documented guidelines to resolve the issues in each of the findings.

### Monitor user, email, and antivirus metrics

Monitor user, email, or antivirus metrics for your instance. For example, you can monitor your email security by checking metrics for spam, external emails, and inbound emails from untrusted and trusted domains for your instance. Analyze these metrics to look for anomalous security behaviors that are related to activities that take place in your instance.

### User metrics

Analyze user metrics to look for anomalous behaviors that are related to specific types of user activity in your instance.

#### Not Logged in Last Month / Last Six Months / Last Year

Indicates the number of users who have not logged into the instance within the last month, within the last six months, and within the last calendar year. To view user detail for a specific metric:

- Click the metric to view a listing of users that have not logged in to the instance during the indicated time period.
- Click a user name to view more details about that user.

#### Users with High Privilege Roles

Indicates the number of users with the following high privilege role types:

<table>
<thead>
<tr>
<th>User role</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>admin</td>
<td>Primary administrator role that has access to all system features, functions, and data, regardless of security constraints.</td>
</tr>
<tr>
<td>script_include_admin</td>
<td>Administrator role that also has access to script includes.</td>
</tr>
<tr>
<td>password_reset_admin</td>
<td>Administrator role that enables a user to view the status of password reset activities, identify potential security threats, and monitor for compliance with password security policies. To learn more, see Password Reset and Password Change reports and logs.</td>
</tr>
<tr>
<td>User role</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>security_admin</td>
<td>Elevated privilege role that enables a user to create and change access controls and High Security Settings. To learn more, see security_admin role</td>
</tr>
<tr>
<td>user_admin</td>
<td>Administrator role that can also manage users, roles, user groups, roles, and department assignments.</td>
</tr>
</tbody>
</table>

**Note:** To learn more about these administrative role types, see Special administrative roles.

To view user detail for a specific user role metric:
- Click the user count role metric to view a listing of users with that high privilege role type.
- Click a user name to view more details about that user. You can then determine if these security-critical roles are assigned to the proper personnel.

**Users Trend**

Shows count trend information over a time period for the following types of users:

<table>
<thead>
<tr>
<th>Count type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active Users</td>
<td>Number of users who are marked as Active in the instance.</td>
</tr>
<tr>
<td>Inactive Users</td>
<td>Number of users who are marked as Inactive in the instance.</td>
</tr>
<tr>
<td>Locked Out</td>
<td>Number of users who are locked out of the instance.</td>
</tr>
</tbody>
</table>

To view user detail for a specific user count (for example, Locked Out Users):
- Click the Locked out users metric.
- In the Analytics Hub page, click Show Records.
- Click a user name to view more details about that user. You can then determine if there is a reason this person is locked out and remedy the situation.

**Events Trend**

Shows count trend information for specific types of events, over a time period:

<table>
<thead>
<tr>
<th>Event type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Admin login</td>
<td>Number of users with high privilege administrator user roles who logged in on a specific day.</td>
</tr>
<tr>
<td>External login</td>
<td>Number of users with an assigned snc_external role who logged into this instance during the calendar day. These logins typically occur for maintenance, support, consulting, or audit purposes. Monitoring this metric enables you to verify that the external login attempts are legitimate and not potential security issues.</td>
</tr>
<tr>
<td>Failed login</td>
<td>Number of failed login attempts on a specific day.</td>
</tr>
<tr>
<td>Impersonation</td>
<td>Number of users logged in on a specific day who are impersonating other users.</td>
</tr>
<tr>
<td>Event type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Security elevation</td>
<td>Number of times that a security administrator has elevated security for standard users by changing their assigned user role to a high privilege security role during the calendar day. These high privilege security roles include oauth_admin, admin, security_admin, and impersonator.</td>
</tr>
<tr>
<td>SNC login</td>
<td>Number of Customer Service and Support who logged in to this instance using the hopping technique during a specific day.</td>
</tr>
</tbody>
</table>

To view user detail for a specific event count (for example, Impersonation):

- Click the user count metric. The Security Dashboard Event Logs page lists event logs for that type of event.
- Click a user name to view more details about that event.

### Email metrics

Analyze your email metrics to look for anomalous behaviors that are related to the incoming emails to your instance. For example, if the metrics indicate a spike in spam emails from specific domains, you can define inbound actions that prevent their delivery to the instance.

For each email metric, a count appears for each type of email that is delivered or sent to the instance during the calendar day.

<table>
<thead>
<tr>
<th>Notification preference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>External Incoming Email</td>
<td>Number of incoming emails for the calendar day that were delivered to the instance from external email domains.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> The external email domains are those domains that are not listed in the security.list.internal.domains system property, because this property tracks only your internal email domains. To learn more about this property, see Available system properties.</td>
</tr>
<tr>
<td>Spam</td>
<td>Number of incoming emails for the calendar day that were delivered to the instance and marked as spam. A number that is out of line with historical trends may indicate that attempts are being made to compromise your instance security.</td>
</tr>
<tr>
<td>Trusted Incoming Email</td>
<td>Number of incoming emails to the instance for the calendar day from email domains designated as trusted.</td>
</tr>
<tr>
<td>Untrusted Incoming Email</td>
<td>Number of incoming emails to the instance for the calendar day from email domains designated as untrusted.</td>
</tr>
<tr>
<td></td>
<td>You can designate untrusted or trusted email domains in the Untrusted And Trusted Domain form so that you can track your inbound emails that are sent from them. To learn how to designate untrusted or trusted email domains, see Designate email domains as untrusted or trusted.</td>
</tr>
</tbody>
</table>

After you click an email metric, you can learn about the possible email security issues in your instance by clicking one of the following:
### Command | Description
--- | ---
Chart | Incoming email counts and count trends over time for the selected email type (spam, incoming external, untrusted, or trusted).
Records | Individual email records that compromise the daily count for the selected email type.
More Info | Additional information for the selected email type.

**Note:** The email metrics apply only to your incoming emails to the instance. The metrics do not apply to the normal traffic that is processed through your enterprise-wide email servers. To learn about defining inbound actions and how they impact the processing of your inbound emails, see Inbound email actions.

#### Designate email domains as untrusted or trusted
Designate specific email domains as untrusted or trusted so that you can monitor the metrics for incoming emails from these sources in your instance.

Role required: security_dashboard_user or admin

When untrusted or trusted domains send emails to your instance, their daily counts appear on the **Untrusted Incoming Email** or **Trusted Incoming Email** metrics on the Email page. You can then track email activity from these domains and use email logs to view specific incoming emails. You can also specify a user, usually a manager, or a security analyst, to notify whenever activity occurs from the untrusted or trusted domain.

**Note:** Designating an email domain as untrusted is for security tracking purposes only. Administrators can also set up a system address filter to ignore emails from untrusted domains. To learn about filtering emails to block their delivery, see System address filters.

1. Navigate to **System Security > Instance Security Center**.
2. On the Instance Security Center homepage, click the **Email** tile, or click the **Email** link to access the Email page.
3. On the Email page, in the Untrusted And Trusted Domain section, click **New**.
4. On the form, fill in the fields.

#### Untrusted And Trusted Domain form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Domain</td>
<td>Name of the email domain that you are designating as untrusted or trusted. For example, enter servicenow.com to designate ServiceNow employees can send trusted emails to the instance.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Category</td>
<td>Category that indicates if the email domain is untrusted or trusted:</td>
</tr>
<tr>
<td></td>
<td><strong>Untrusted</strong></td>
</tr>
<tr>
<td></td>
<td>Designates that the email domain as untrusted. You use it to identify domains that send suspicious or emails that pose a potential security threat to the instance.</td>
</tr>
<tr>
<td></td>
<td><strong>Trusted</strong></td>
</tr>
<tr>
<td></td>
<td>Designates that the email domain as trusted. You use it to identify domains when your metrics indicate that the incoming emails from it pose no security threats. Designating the domain as trusted enables you to track its inbound email activity over time.</td>
</tr>
<tr>
<td>Active</td>
<td>Check box for enabling or disabling the designated untrusted or trusted status for the specified email domain.</td>
</tr>
<tr>
<td>Notify</td>
<td>Name of the user to notify by email when activity occurs in the untrusted or trusted domain. Click the spotlight search icon (</td>
</tr>
<tr>
<td></td>
<td>) to search for the name of the user. Leave the Notify field blank if you do not want notifications sent.</td>
</tr>
</tbody>
</table>

5. Click **Save**.

Untrusted or trusted email domain information is also added to the **Untrusted And Trusted Domains** listing on the Email page.

**Antivirus metrics**

If the Antivirus Scanning plugin is activated, Antivirus Scanning runs in your instance to help protect it against virus infections from attachments.

The following metrics appear for the last 60 days of activity, and enable you to assess the effectiveness of the Antivirus Scanning functions.

**Antivirus Events**

Antivirus Events indicate the number of antivirus events in your instance, by date. To access the antivirus events, navigate to **System Security > Instance Security Center** and select the Metrics tab. Color coded graph lines represent the following types of antivirus events:

<table>
<thead>
<tr>
<th>Color</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blue</td>
<td>Number of files quarantined by Antivirus Scanning in this instance for the indicated date.</td>
</tr>
<tr>
<td>Green</td>
<td>Number of infected files downloaded to the instance, and then quarantined for the indicated date. These files are primarily email attachments that contain a virus or rouge code.</td>
</tr>
<tr>
<td>Color</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>-------------</td>
</tr>
<tr>
<td>Yellow</td>
<td>Number of quarantined files in the instance that were deleted for the indicated date.</td>
</tr>
<tr>
<td>Orange</td>
<td>Number of quarantined files in the instance that were restored for the indicated date.</td>
</tr>
</tbody>
</table>

**Note:** After Antivirus Scanning runs and finds any false positives, you can restore a quarantined file and make it accessible in the instance.

- To access the Analytics Hub page and view the detailed score card and analytics information for a specific date, click a colored line in the Antivirus Events graph. For example, click the blue graphics line to view analytics information for files quarantined for a specific date.
- To view the following breakdowns in the Analytics Hub page, click

  ![icon]

  then click:

<table>
<thead>
<tr>
<th>Breakdown</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AppSec - Antivirus Event Source</td>
<td>Source of the antivirus event.</td>
</tr>
<tr>
<td>• On Upload: Occurred due to an upload of an infected file, usually an attachment.</td>
<td></td>
</tr>
<tr>
<td>• From Quarantine: Occurred due to the quarantine of an infected file, usually an attachment.</td>
<td></td>
</tr>
<tr>
<td>• On Download: Occurred due to a download of an infected file, usually an attachment.</td>
<td></td>
</tr>
<tr>
<td>• From Record: Occurred due to an infected record in a table.</td>
<td></td>
</tr>
<tr>
<td>AppSec - Antivirus Event Type</td>
<td>Type of antivirus event.</td>
</tr>
<tr>
<td>• Quarantined: Occurred due to the quarantine of a file, usually an attachment.</td>
<td></td>
</tr>
<tr>
<td>• Downloaded: Occurred due to a download of a file, usually an attachment.</td>
<td></td>
</tr>
<tr>
<td>• Restored: Occurred due to the restoration of a quarantined file.</td>
<td></td>
</tr>
<tr>
<td>• Deleted: Occurred due to the deletion of a quarantined file.</td>
<td></td>
</tr>
<tr>
<td>AppSec - Antivirus Uploader</td>
<td>Name of the logged in user who uploaded the files that were the source of virus infections detected by the Antivirus Scanning application.</td>
</tr>
</tbody>
</table>

### Quarantined Files

Lists the infected files in the instance quarantined by Antivirus Scanning:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>File name</td>
<td>Name of the infected file.</td>
</tr>
<tr>
<td>Content type</td>
<td>Type of content that was infected in the file. For example, application/x-dosexec is an infected application or DOS executable file, while text/plain is an infected .txt file.</td>
</tr>
</tbody>
</table>
### Field | Description
--- | ---
**Table** | Name of the table that contains the infected file. For example, *incident* appears for an incident file record.

**Virus** | Name of the file quarantined by Antivirus Scanning.

**Detected** | Date and time the infected file was detected.

**Created By** | Name of the user who quarantined the infected file.

**Created** | Date and time the quarantine file record was created.

**Table sys ID** | Table system identifier assigned to the quarantine file record.

---

**Note:** You can also add Quaranatined Files and Virus Types tiles to the Event ribbon. To learn more, see Monitor security events and Configure the security event ribbon.

### Activate the ISC Virtual Agent interface

If you have the admin role, you can activate the ISC Virtual Agent Conversations plugin (com.glide.isc_virtualagent). Activating this plugin installs the Virtual Agent and Natural Language Understanding (NLU) content packs, providing Virtual Agent access from the Instance Security Center.

The Virtual Agent interface in the Instance Security Center is only available for users with paid Virtual Agent subscriptions, and who have activated the Glide Virtual Agent (com.glide.cs.chatbot) plugin. To learn more, see Activate Virtual Agent.

Role required: admin

To learn more about the accessing the Virtual Agent from the Instance Security Center, see Virtual Agent access in the Instance Security Center.

#### Plugins for ISC Virtual Agent

<table>
<thead>
<tr>
<th>Plugin</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISC Virtual Agent Conversations [com.glide.isc_virtualagent]</td>
<td>Activates the ISC Virtual Agent Conversations content pack for the Instance Security Center.</td>
</tr>
</tbody>
</table>

**Note:** Activating the com.glide.isc_virtualagent plugin automatically activates com.glide.isc_nlu. However, if you activate the com.glide.isc_nlu plugin first, you must manually activate com.glide.isc_virtualagent as well.

1. Navigate to **System Applications > All Available Applications > All.**
2. Find the plugin using the filter criteria and search bar.

You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel. For more information, see Request a plugin.
3. Click **Install**, and then in the Activate Plugin dialog box, click **Activate**.

**Note:** When domain separation and delegated admin are enabled in an instance, the administrative user must be in the **global** domain. Otherwise, the following error appears: Application installation is unavailable because another operation is running: Plugin Activation for **<plugin name>**.

---

**General security settings properties**

Security settings provide several properties to control the level of security on your instance. There are several ways to set or change general security settings properties.

- **Navigate to** **System Properties > Security**.
  
  Options on the Security page are **Yes** or **No**.

- **Navigate to the** **sys_properties.list** and search for the property you want to set or change.
  
  Options in the System Properties table [sys_properties.list] are **true** or **false**.

- **Navigate to** **System Security > Instance Security Center**, then click **Hardening**.
  
  You can configure the settings for the most important and critical security properties. The Instance Security Hardening Settings content contains detailed descriptions, and compliance values, for the security-related system properties and plugins in the **. To learn more about each of these properties, see Instance Security Hardening Settings.**

**Warning:** When implementing any of these security features, you must thoroughly test the features before you deploy them in a production instance.

---

**Escaping and embedded script support**

**glide.ui.security.allow_codetag**

Supports embedding HTML code using the [code] tag.

- Default value: Yes
- Instance Security Hardening Settings: Allow embedded HTML code (instance security hardening)

**glide.ui.security.codetag.allow_script**

Allows embedded HTML (using [code] tags) to contain Javascript tags.

- Instance Security Hardening Settings: Allow JavaScript tags in embedded HTML (instance security hardening)

**glide.ui.escape_all_script**

Forces all expressions within Jelly JavaScript `<script type="text/javascript">` tags to be escaped by default. Enforces escaping only if the type attribute in the `<script>` tag is empty, or if the value is `text/javascript`, `text/ecmascript`, `application/javascript`, `application/ecmascript`, or `application/x-javascript`.

- Default value:
  - New/zbooted instances: Yes
  - Upgraded instances: No
• Recommended value: Yes
• Instance Security Hardening Settings: Escape Jelly (instance security hardening)

Attachment limits and behavior

**com.glide.attachment.max_size**
Sets the maximum file attachment size in megabytes.

**glide.attachment.role**
Lists the roles (comma-separated) that can create attachments.

**glide.attachment.extensions**
Lists the file extensions (comma-separated) that can be attached to documents via the attachment dialog. Extensions should not include the dot (.). For example, xls, xlsx, doc, docx. Leave blank to allow all extensions.
• Instance Security Hardening Settings: Restrict file extensions (instance security hardening)

**glide.ui.attachment.force_download_all_mime_types**
Forces download of all multipurpose internet mail extensions (MIME) type attachment files.
• Default value:
  • New/zbooted instances: Yes
  • Upgraded instances: No
  • Instance Security Hardening Settings: Force Download MIME types (instance security hardening)

**glide.security.file.mime_type.validation**
Enables (Yes) or disables (No) MIME type validation for file attachments. File extensions configured via **glide.attachment.extensions** are checked for MIME type during upload.
• Default value:
  • New/zbooted instances: Yes
  • Upgraded instances: No
  • Instance Security Hardening Settings: Upload MIME type restriction (instance security hardening)

Customer uploads

These properties affect customer uploads only. They do not affect attachments.

**glide.ui.strict_customer_uploaded_static_content**
When you set this property to Yes, turns on the ability to restrict the types of files that can be downloaded, when they have been uploaded using the Upload File functionality of the Now Platform. Used with **glide.ui.strict_customer_uploaded_content_types**
• Instance Security Hardening Settings: Enable file download restrictions (instance security hardening)

**glide.ui.strict_customer_uploaded_content_types**
When this parameter includes a list of comma-delimited file types, of the files that were uploaded using the Upload File functionality of the Now Platform, only these file types can be downloaded from the instance.

- **Instance Security Hardening Settings:** Downloadable file types (instance security hardening)

**Security Manager and options**

**glide.security.manager**
Security Manager.

**glide.sm.default_mode**
Security manager default behavior in the absence of any ACLs on a table.

**glide.security.strict.updates**
Double-checks security on inbound transactions during form submission. Rights are always checked on form generation.

- **Instance Security Hardening Settings:** Double check inbound transactions (instance security hardening)

**glide.security.strict.actions**
Checks conditions on UI actions before execution. Normally, conditions are checked only during form rendering.

- **Instance Security Hardening Settings:** Check UI action conditions before execution (instance security hardening)

**glide.security.granular.create**
Enforces the create rules on new records (as opposed to the write rules, which may include creating and updating).

**glide.security.explain.write.locks**
Displays an explanation on locked form elements.

**Cookies**

**glide.ui.forgetme**
Removes the Remember me check box from the login page when the instance is using either LDAP or DB logins. User’s active logged in sessions are timed out after X minutes of inactivity, where X is the value of the glide.ui.session_timeout system property.

- Default value:
  - New/zbooted instances: Yes

- **Instance Security Hardening Settings:** Remove remember me (instance security hardening)

**glide.ui.secure_cookies**
Enables secure session cookies to enforce additional cookie security. If Yes, strict session cookie validation is enforced. With version 3 cookies enabled, additional security requirements are also enforced.

- **Instance Security Hardening Settings:** Secure session cookies (instance security hardening)

**glide.secure_cookie.debug**
Secure session cookie debugging. Select to enable extensive debug logging of secure session cookie operations.

**Security restrictions for execution of scripts originating from the client**

**glide.script.use.sandbox**
Run client-generated scripts (AJAXEvaluate and query conditions) inside a reduced-rights sandbox. If enabled, only those business rules and script includes with the Client callable check box selected are available, and certain back-end application programming interface (API) calls are disallowed.

- Instance Security Hardening Settings: Client generated scripts sandbox (instance security hardening)

**glide.script.allow.ajaxevaluate**
Enables the AJAXEvaluate processor.

- Instance Security Hardening Settings: Enable AJAXEvaluate (instance security hardening)

**glide.script.secure.ajaxgliderecord**
Applies standard security access control lists (ACLs) to AJAXGlideRecord calls.

- Default value: Yes for new and upgraded instances. If Yes, cannot be changed to No.
- Instance Security Hardening Settings: Enabling AJAXGlideRecord ACL checking (instance security hardening)

**Miscellaneous**

**com.glide.communications.trustmanager_trust_all**
By default, the instance trusts a certificate's Certificate Authority (CA). Ensures that the instance accepts self-issued certificates. To validate a certificate's CA, set this property to No.

- Instance Security Hardening Settings: Certificate trust (instance security hardening)

**glide.outbound.sslv3.disabled**
When active, forces outbound connections from an instance to use the transport layer security (TLS) instead of the secure sockets layer (SSL).

- Instance Security Hardening Settings: Disabling SSLv2/SSLv3 (instance security hardening)

Additional properties are available for High Security Settings.

**High Security Settings**

High Security Settings refer to several security options available in your instance.

The High Security Settings module is activated with the High Security Settings plugin, which is active by default on new instances. If High Security Settings are not active on your instance, see Requesting High Security Settings activation. To learn more about this plugin, see High security plugin (instance security hardening) in Instance Security Hardening Settings. Properties for these types of high security settings are available:

- Default property values: To harden security on your platform by centralizing all critical security settings to one location for management and auditing.
• Default deny property: Provides a security manager property to control the default security behavior for table access.
• Security Administrator role: Provides a role to prevent modification of key security settings and resources. The Security Administrator role is not inherited by the admin role and must be explicitly assigned.
• Elevated privileges: Allows users with the security admin role to operate in the context of a normal user and elevate to higher security role when needed.
• Property access controls: Allows security administrators to set the roles required to read and write properties.
• Transaction and system logs: Are read only.
• Access control rules: Control what data users can access and how they can access it.

Note: High Security Settings also automatically activates the Contextual Security plugin, if it is not already active. In addition, Platform Security Settings - High delivers settings and features in the context of increasing the security of your instance.

Note:

Note: The Instance Security Hardening Settings content contains detailed descriptions, and compliance values, for the security-related system properties and plugins in the . To learn more about each of these properties, see Instance Security Hardening Settings.

There are two ways to set or change High Security Settings properties.

• Navigate to System Security > High Security Settings.
  Options on the High Security Properties page are Yes or No.
• Navigate to the sys_properties.list and search for the property you want to set or change.
  Options in the System Properties table [sys_properties.list] are true or false.

Property access control

Two additional columns are created in the Properties [sys_properties] table when High Security Settings are active:

• read_roles: A comma-separated list of role names that are allowed to read all fields of this property.
• write_roles: A comma-separated list of role names that are allowed to write/modify all fields of this property.

Properties listed in the Properties table have read_roles of admin, and write_roles of security_admin. Users with the admin role can view and read the property values, but must elevate to the security_admin role to modify them.

Notifications

Activation of high security settings also activates security warning messages. The following is an example of a message that appears after an approval.
Security Warning notification

High Security Settings properties

**glide.ui.escape_text**

Escape XML values at the parser level for the user interface. Prevents reflected and stored cross-site scripting attacks. This property is not applicable in Service Portal.

- Default value: Yes
- Instance Security Hardening Settings: Escape XML (instance security hardening)

**glide.ui.escape_all_script**

Forces all expressions within Jelly JavaScript `<script type="text/javascript">` tags to be escaped by default. Enforces escaping only if the type attribute in the `<script>` tag is empty, or if the value is `text/javascript`, `text/ecmascript`, `application/javascript`, or `application/x-javascript`.

- Default value: Yes in new instances
- Instance Security Hardening Settings: Escape Jelly (instance security hardening)

**glide.ui.rotate_sessions**

- Default value: Yes
  - If you are using the SAML 2.0 plugin for Single Sign-on authentication, set this property to No. Otherwise, it interferes with the session information sharing that takes place between the instance and the Identity Provider.
- Instance Security Hardening Settings: Rotate HTTP session identifiers (instance security hardening)

**glide.ui.secure_cookies**

Enable secure session cookies: Enable additional cookie security. If **Yes**, strict session cookie validation is enforced.

- Default value: Yes
• Instance Security Hardening Settings: Secure session cookies (instance security hardening)

**glide.security.password_reset.uri**

For mobile Password Reset, URL that the user is taken to when the user clicks the **Forgot password?** button.

**glide.security.strict.updates**

Double-check security on inbound transactions during form submission (rights are always checked on form generation).

- Default value: Yes
- Instance Security Hardening Settings: Double check inbound transactions (instance security hardening)

**glide.security.strict.actions**

Check conditions on UI actions before execution. Normally conditions are checked only during form rendering.

- Default value: Yes
- Instance Security Hardening Settings: Check UI action conditions before execution (instance security hardening)

**glide.security.use_csrf_token**

Enable usage of a secure token to identify and validate incoming requests. This token is used to prevent cross-site request forgery attacks.

- Default value: Yes
- Instance Security Hardening Settings: Anti-CSRF token (instance security hardening)

**glide.ui.escape_html_list_field**

Escape HTML for HTML fields in a list view.

- Default value: Yes
- Instance Security Hardening Settings: Escape HTML (instance security hardening)

**glide.html.escape_script**

Escape JavaScript tags in HTML fields.

- Default value: Yes
- Instance Security Hardening Settings: Escape JavaScript (instance security hardening)

**glide.ui.forgetme**

Remove the **Remember me** check box from the login page.

- Default value: Yes
- Instance Security Hardening Settings: Remove remember me (instance security hardening)

**glide.smtp.auth**

Authenticate with the SMTP server by the user name and password properties.

- Default value: Yes
- Instance Security Hardening Settings: SMTP authentication (deprecated)

**Note:** This property is deprecated.
glide.script.use.sandbox
Run client-generated scripts (AJAXEvaluate and query conditions) inside a reduced-rights sandbox. If Yes, only those business rules and script includes with the Client callable check box set to Yes are available, and certain back-end API calls are disallowed. For more information, see Script sandbox property.

- Default value: Yes
- Instance Security Hardening Settings: Client generated scripts sandbox (instance security hardening)

glide.soap.strict_security
Enforce strict security on incoming SOAP requests. Requires incoming SOAP requests to go through the security manager for table and field access and checks SOAP users for the correct roles for using the web service.

- Default value: Yes
- Instance Security Hardening Settings: SOAP request strict security (instance security hardening)

Note: If you choose not to require authorization for incoming WSDL requests, you must modify the Access Control (ACL) rules to allow guest users to access the WSDL content.

glide.basicauth.required.wsd
Require authorization for incoming WSDL requests.

- Default value: Yes
- Instance Security Hardening Settings: WSDL request authorization (instance security hardening)

Note: If you choose not to require authorization for incoming WSDL requests, you must modify the Access Control (ACL) rules to allow guest users to access the WSDL content.

glide.basicauth.required.csv
Require basic authorization for incoming CSV requests.

- Default value: Yes
- Instance Security Hardening Settings: CSV request authorization (instance security hardening)

glide.basicauth.required.excel
Require basic authorization for incoming Excel requests.

- Default value: Yes
- Instance Security Hardening Settings: Excel request authorization (instance security hardening)

glide.basicauth.required.importprocessor
Require basic authorization for incoming import requests.

- Default value: Yes
- Instance Security Hardening Settings: Import request authorization (instance security hardening)

glide.basicauth.required.pdf
Require basic authorization for incoming PDF requests.

- Default value: Yes
- Instance Security Hardening Settings: PDF request authorization (instance security hardening)

glide.basicauth.required.rss
Require basic authorization for incoming RSS requests.
• Default value: Yes
• Instance Security Hardening Settings: RSS request authorization (instance security hardening)

**glide.basicauth.required.scriptedprocessor**

Require basic authorization for incoming script requests.

• Default value: Yes
• Instance Security Hardening Settings: Script request authorization (instance security hardening)

**glide.basicauth.required.soap**

Require basic authorization for incoming SOAP requests.

• Default value: Yes
• Instance Security Hardening Settings: Basic auth: SOAP requests (instance security hardening)

**glide.basicauth.required.unl**

Require basic authorization for incoming unload requests.

• Default value: Yes
• Instance Security Hardening Settings: Unload request authorization (instance security hardening)

**glide.basicauth.required.xml**

Require basic authorization for incoming XML requests.

• Default value: Yes
• Instance Security Hardening Settings: XML request authorization (instance security hardening)

**glide.basicauth.required.xsd**

Require basic authorization for incoming XSD requests.

• Default value: Yes
• Instance Security Hardening Settings: XSD request authorization (instance security hardening)

**glide.cms.catalog_uri_relative**

Enforce relative links from the URI parameter on /ess/catalog.do. If **Yes**, only relative URLs are permitted through the /ess/catalog.do page using the **uri** parameter. If **No**, all URLs are permitted, which may permit linking to external unauthorized content.

• Default value: Yes
• Instance Security Hardening Settings: Enforce relative links (instance security hardening)

**glide.set_x_frame_options**

Enable this property to set the X-Frame-Options response header to SAMEORIGIN for all UI pages. The X-Frame-Options HTTP response header can be used to indicate whether a browser should be allowed to render a page in a <frame> or <iframe>. Sites can use this property to avoid clickjacking attacks by ensuring that their content is not embedded into other sites. [https://developer.mozilla.org/en/the_x-frame-options_response_header](https://developer.mozilla.org/en/the_x-frame-options_response_header)

• Default value: Yes
• Instance Security Hardening Settings: X-Frame-Options: SAMEORIGIN (instance security hardening)

**glide.ui.attachment.download_mime_types**
A list of comma-separated attachment mime types that do not render inline in the browser. Prevents cross-site scripting attacks. For example, `text/html` forces HTML files to be downloaded to the client as attachments rather than viewed inline in the browser.

- Default value: `text/html, image/svg, image/svg+xml`
- Instance Security Hardening Settings: Force Download MIME types (instance security hardening)

**glide.security.groupby_acl_check**

When this property is enabled, ACL checks for GroupBy operations are performed for the group names based on the actual data from the groups.

- Default value: Yes

**glide.security.diag_txns_acl**

If Yes, only the admin user or user from allowed IP address can access `stats.do`, `threads.do`, and `replication.do`.

- Default value: No
- Instance Security Hardening Settings: Performance monitoring (ACL) (instance security hardening)

**glide.ui.security.codetag.allow_script**

Allow embedded HTML (using `[code]` tags) to contain JavaScript tags.

- Default value: Yes
- Instance Security Hardening Settings: Allow embedded HTML code (instance security hardening)

**glide.script.allow.ajaxevaluate**

Enable the AJAXEvaluate processor. The AJAXEvaluate API call allows the client to send and execute arbitrary scripts on the server.

- Default value: No
- Instance Security Hardening Settings: Enable AJAXEvaluate (instance security hardening)

**glide.login.autocomplete**

Allow browsers to use auto-complete on password fields on login forms.

- Default value: No
- Instance Security Hardening Settings: Password field auto-complete (instance security hardening)

The following properties are defined in the `sys_properties` table, but are not visible on the High Security Settings page.

**com.glide.communications.httpclient.verify_hostname**

Verify the hostname and certificate chain presented by remote SSL hosts. Protect against Man-In-The-Middle (MITM) attacks.

- Default value: true
- Learn more: Set up Kubernetes spoke

**Note:** This property overrides the `com.glide.communications.trustmanager_trust_all` property.

**glide.basicauth.required.schema**
Require basic authentication for inbound table schema requests.

- Default value: true

**glide.security.csrf_previous.allow**
Allow usage of an expired secure token to identify and validate incoming requests. This token is used to prevent cross-site request forgery attacks.

- Default value: false

**glide.security.csrf_previous.time_limit**
Time in seconds for a secure token to expire. Allows control over the length of time that the previous CSRF token is valid. When the user session expires, the secure token expires with it unless the **glide.security.csrf_previous.allow** property is enabled and it is within the timeframe described by this property. This token is used to prevent cross-site request forgery attacks.

- Default value: 86400 seconds or 1 day

**glide.security.csrf.strict.validation.mode**
Enforces strict validation on CSRF tokens so that users cannot resubmit a request if the CSRF token does not match.

- Default value: false
- Instance Security Hardening Settings: CSRF strict validation (instance security hardening)

**com.glide.security.check.unsanitized.html**
Enforces sanitization behavior of translated_html fields on a global level for field assignments.

- Default value: enforce

### Script sandbox property
Enable the script sandbox property (**glide.script.use.sandbox**) to run client generated scripts inside a sandbox that has restricted rights.

There are two cases within the system that allow the client to send scripts to the server for evaluation.

- Filters and/or queries: It is legal to send a filter to the server such as:
  
  `assigned_to=javascript:getMyGroups()`.

- System API: The API call `AJAXEvaluate` allows the client to run arbitrary scripts on the server and receive a response.

If you enable the script sandbox property (**glide.script.use.sandbox**), the script being evaluated via either of these two entry points runs within a reduced rights sandbox with the following characteristics:

- Only those business rules marked **client callable** are available within the sandbox.
- Only script includes marked **client callable** are available within the sandbox.
- Certain API calls (largely but not entirely limited to those dealing with direct DB access) are not allowed.
- Data cannot be inserted, updated, or deleted from within the sandbox. Any calls to `current.update()` for example, are ignored.

**Note:** To learn more about this property, see Client generated scripts sandbox (instance security hardening) in Instance Security Hardening Settings.
These methods are not allowed in client scripts when script sandboxing is enabled.

### Restricted methods

<table>
<thead>
<tr>
<th>Class</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideRecord</td>
<td>deleteMultiple(), deleteRecord(), insert(), update(), updateMultiple()</td>
</tr>
<tr>
<td>GlideSystem (gs)</td>
<td>addErrorMessage(), addInfoMessage(), addMessage(), eventQueue(),</td>
</tr>
<tr>
<td></td>
<td>flushMessages(), getEscapedProperty(), getProperty(), setProperty(),</td>
</tr>
<tr>
<td></td>
<td>setRedirect(), setReturn(), workflowFlush()</td>
</tr>
<tr>
<td>ScopedGlideRecord</td>
<td>deleteMultiple(), deleteRecord(), insert(), update(), updateMultiple()</td>
</tr>
<tr>
<td>ScopedGlideSystem (gs)</td>
<td>addErrorMessage(), addInfoMessage(), eventQueue(), executeNow(),</td>
</tr>
<tr>
<td></td>
<td>getProperty(), getSessionToken(), setRedirect()</td>
</tr>
</tbody>
</table>

If you run the system without script sandboxing enabled, then none of these restrictions apply.

**Note:** This property is activated by default when you activate the High Security Settings plugin. Do not activate this property outside of the plugin.

<table>
<thead>
<tr>
<th>Property</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run client generated scripts (AJAXEvaluate and query conditions) inside a reduced rights &quot;sandbox.&quot;</td>
<td>Enabled (sandbox in use)</td>
</tr>
<tr>
<td>If enabled, only those business rules and script includes with the <strong>Client callable</strong> checkbox set to true are available and certain back-end API calls are disallowed.</td>
<td></td>
</tr>
</tbody>
</table>

### Request High Security Settings activation

The High Security Settings plugin is active by default on all new instances. If it is not active on your instance, you can request the plugin.

Before activating High Security Settings on an existing instance:

1. Review the following information to understand the new behavior:
   - Access control list rules
   - High Security Settings
   - Default deny property
2. Enable the plugin on a non-production instance. A recent clone of production is preferable.
3. Test the revised functionality, especially the added ACLs and default-deny functionality. Continue testing until the system performs as expected. If users cannot access expected resources, ensure they have appropriate roles and ACL rules to grant them the access.
4. Create update sets of any needed changes so you can apply them to production.
Role required: admin

1. Navigate to **System Applications > All Available Applications > All.**
2. On the All Applications page, click **Request Plugin** to open the Request form on HI.
3. On Now Support, select the redirect link to access the Now Support Service Portal Service Catalog.

<table>
<thead>
<tr>
<th>Activate Plugin</th>
</tr>
</thead>
<tbody>
<tr>
<td>In order to enhance the user experience, we have redesigned Activate a Plugin service catalog. Please use the new HI Service Portal ‘Activate a Plugin’ service catalog item. You can also use Manage Instances page on Service Portal to Activate a Plugin.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target Instance</td>
<td>Instance on which to activate the plugin.</td>
</tr>
<tr>
<td>Plugin Name</td>
<td>Name of the plugin to activate.</td>
</tr>
<tr>
<td>Specify the date and time you would like this plugin to be enabled</td>
<td>The date and time must be at least two business days from the current time.</td>
</tr>
</tbody>
</table>

**Note:** Plugins are activated in two batches, once in the morning and once in the evening, on every business day in the US Pacific time zone. If the plugin must be activated at a specific time, enter the request in the **Reason/Comments** field.

| Reason/Comments | Information that would be helpful for the ServiceNow personnel who are activating the plugin. For example, if you need the plugin activated at a specific time instead of during one of the default activation windows, specify that in the comments. |

5. Click Submit.

**ServiceNow access control**

This SNC Access Control plugin (com.snc.snc_access_control) enables you to control which Customer Service and Support employees can access your instance, and when.

When you first activate the plugin, Customer Service and Support employees cannot log into the instance. Any currently logged-in Customer Service and Support employees remain logged in. You create records in the SNC Access Control table that grant access to specific SNC employees or all employees.

The plugin prevents Customer Service and Support personnel from accessing the instances without your express permission. However, other authorized ServiceNow Operations personnel, in their capacity to support and manage the product, are required to perform administrative actions on the underlying infrastructure. This infrastructure includes servers and databases, among other infrastructure components that make up the SaaS solution. This access method is fully auditable and tracked.
This plugin enables you to restrict access to your instance without your express permission, so it may affect support service levels and the Availability SLA. Availability SLA is then measured from the time that Support staff personnel are granted access to your instance.

**Login security**

Security for authorized Customer Service and Support employee logins to instances employs encrypted tokens generated by a secure server. Only properly authenticated Customer Service and Support employees are granted access to an instance. Without the SNC Access Control plugin, the security server ensures that access rights are enforced on hi.service-now.com. When the plugin is enabled, the encrypted login tokens must match names in the plugin-provided access list, using the criteria defined in those records. This method of authentication enables you to determine precisely which Customer Service and Support employees may access their instances, and when these employees may do so.

The architecture chosen for this system has several features designed to enhance security for your instances:

**Security server**

The security server is a locked-down, Linux host that only ServiceNow security personnel can access. This server is the only system that has access to the critical private encryption key necessary to produce the login tokens. By using this compartmentalization (a standard security practice), the private key is protected, even in the unlikely event that an attacker compromises the HI instance.

**Synthetic user**

The facility on instances that enables authorized Customer Service and Support employees to log into their instance does not require an account to be provisioned on that instance. There is no user record provisioned, and no permanent or persisted credentials. Instead, a synthetic user is created for each Customer Service and Support employee logon. This user exists only in memory and provides no ongoing privileges. If the SNC Access Control plugin is enabled, you can deauthorize any Customer Service and Support employee at any time.

**Tokens**

The security tokens are specific to an instance and a particular Customer Service and Support employee. In addition, the mechanism that generates the tokens only works with actual Customer Service and Support employee logins to HI, not impersonated users. Once a security token is generated, only a specific Customer Service and Support employee can use it to log into an instance.

**Time limit**

Security tokens expire four hours after they are generated. This expiration limits the utility of hijacked tokens, which can only be used during this short window.

**Logging**

Logins by Customer Service and Support employees to instances are recorded as a login event.

- Every action taken by the logged-in Customer Service and Support employee is added to the transaction log in the database.
- It is also added to the instance log on the file system, which is inaccessible to most ServiceNow employees.
- Customer Service and Support employee logins and actions are readily identifiable, since the user names all end in @snc (like frodo.baggins@snc).

These actions provide you with easy-to-use, robust, and reliable security logging for non-employee access.
Security processing flow

When a Customer Service and Support employee wants to log into an instance, the security processing flow is as follows:

2. HI checks that the technician has the proper role authorizing access to instances.
3. If the user has the proper role, HI sends the request for access to the Security Server.
4. The Security Server verifies that the request came from the HI IP address, and evaluates the request (user, role, and IP address of the requester). If the request is valid, the Security Server approves it and constructs a token. This token contains the user name, roles, the instance ID, and the time (the start of the 4-hour token life span). Finally, the Security Server encrypts the token with the private encryption key.
5. The Security Server sends the encrypted token to HI.
6. Hi sends the token to the Support technician's browser.
7. The Support technician's browser initiates a login into the instance, using the special user name ending with @snc.
8. The instance uses the public key to decrypt the token. To verify the token, the instance matches it to the user name supplied in the previous step, the instance ID, and the authorized time window. If the SNC Access Control plugin is enabled, the instance verifies that the user is:
   - Listed
   - Active
   - Configured to access the instance in the current time window
9. If the user is authenticated, the instance creates a synthetic user in memory with the given roles. This user does not persist after the time limit expires, the user logs off, or the instance is restarted.
Audit logging

The following logging tracks logins and activity by Customer Service and Support employees:

- Event logs: The event logs show all Customer Service and Support logins to an instance.
- Transaction logs: The transaction logs show all activity on the instance, including any efforts to delete logs.

Note: To learn more about this plugin, see SNC Access Control plugin (instance security hardening) in Instance Security Hardening Settings.

Request ServiceNow access control

You request activation of the SNC Access Control plugin (com.snc.snc_access_control).

Role required: admin

There are two ways to request a plugin:

- Access the Now Support Service Catalog directly by clicking Service Catalog > Activate Plugin on Now Support.
- Access the Now Support Service Catalog through the All Applications page on your instance by following these steps.

1. Navigate to System Applications > All Available Applications > All.
2. On the All Applications page, click **Request Plugin** to open the Request form on HI.
3. On Now Support, select the redirect link to access the Now Support Service Portal Service Catalog.

<table>
<thead>
<tr>
<th>Activate Plugin</th>
</tr>
</thead>
<tbody>
<tr>
<td>In order to enhance the user experience, we have redesigned Activate a Plugin service catalog. Please use the new Hi Service Portal 'Activate a Plugin' service catalog item. You can also use Manage Instances page on Service Portal to Activate a Plugin.</td>
</tr>
</tbody>
</table>

4. On the form, fill in the fields.

**Activate Plugin request form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target Instance</td>
<td>Instance on which to activate the plugin.</td>
</tr>
<tr>
<td>Plugin Name</td>
<td>Name of the plugin to activate.</td>
</tr>
<tr>
<td>Specify the date and time you would like this plugin to be enabled</td>
<td>The date and time must be at least two business days from the current time.</td>
</tr>
</tbody>
</table>

**Note:** Plugins are activated in two batches, once in the morning and once in the evening, on every business day in the US Pacific time zone. If the plugin must be activated at a specific time, enter the request in the Reason/Comments field.

| Reason/Comments | Information that would be helpful for the ServiceNow personnel who are activating the plugin. For example, if you need the plugin activated at a specific time instead of during one of the default activation windows, specify that in the comments. |

5. Click **Submit**.

**Configure ServiceNow access control**

Configure an access control record to specify one or more Customer Service and Support employees who have permission to log in your instance.

Role required: admin

**Note:** The SNC Access Control (com.snc.snc_access_control) plugin prevents Customer Service and Support personnel from accessing the instances without your express permission. However, other authorized ServiceNow Operations personnel, in their capacity to support and manage the product, are required to perform administrative actions on the underlying infrastructure. This infrastructure includes servers and databases, among other infrastructure components that make up the SaaS solution. This access method is fully auditable and tracked.
This plugin enables you to restrict access to your instance without your express permission, so it may affect support service levels and the Availability SLA. Availability SLA is then measured from the time that Support staff personnel are granted access to your instance.

2. Click New.
3. Fill in the form fields (see table).
4. Click Submit.

### SNC Access Control

<table>
<thead>
<tr>
<th>Form fields</th>
<th>Description</th>
</tr>
</thead>
</table>
| Name        | Names each Customer Service and Support employee who has permission to log in this instance.  
  • Express the names as firstname.lastname in lower case letters, separated by a period (for example, john.smith). Each name must have a corresponding user record in hi.servicenow.com.  
  • If more than one Customer Service and Support employee has permission to log in this instance, enter multiple names and separate them by commas.  
  • To enable all Customer Service and Support employees login rights to access the instance, enter an asterisk (*) in place of the name.  
  • If you intend on restricting Customer Service and Support employee access to the instance, the values in the Name field must not have an asterisk (*) anywhere in the field. |
| Reason      | Human-readable field that describes why you are granting access permission. This field is optional. |
| Start       | Specifies the start date and time of the period during which the specified Customer Service and Support employees have login access. This field is mandatory. |
| End         | Specifies the ending date and time of the period during which the specified Customer Service and Support employees have login access. This field is mandatory. |
| Active      | Controls whether this permission record is active. The default is Active. |

### Audit logging

The following logging tracks logins and activity by ServiceNow employees.

<table>
<thead>
<tr>
<th>Event logs</th>
<th>The event logs show all ServiceNow logins to a customer instance.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transaction logs</td>
<td>The transaction logs show all activity on the instance, including any efforts to delete logs.</td>
</tr>
</tbody>
</table>
Access control list rules

Rules for access control lists (ACLs) restrict access to data by requiring users to pass a set of requirements before they can interact with it.

Components of ACLs

All access control list rules specify:

- The object and operation being secured
- The permissions required to access the object

The object is the target to which access needs to be controlled. Each object consists of a type and name that uniquely identifies a particular table, field, or record.

For example, all these entries specify an object:

<table>
<thead>
<tr>
<th>Type</th>
<th>Name</th>
<th>Object secured</th>
</tr>
</thead>
<tbody>
<tr>
<td>record</td>
<td>[incident].[-- None --]</td>
<td>The Incident table.</td>
</tr>
<tr>
<td>record</td>
<td>[incident].[active]</td>
<td>The Active field in the Incident table.</td>
</tr>
<tr>
<td>REST_Endpoint</td>
<td>user_role_inheritance</td>
<td>The record for the user_role_inheritance Scripted REST API.</td>
</tr>
</tbody>
</table>

Each operation describes a valid action the system can take on the specified object. Some objects, such as records, support multiple operations, while other objects, such as a REST_Endpoint, only support one operation.

For example, all these entries specify an operation:

<table>
<thead>
<tr>
<th>Type</th>
<th>Name</th>
<th>Operation</th>
<th>Operation secured</th>
</tr>
</thead>
<tbody>
<tr>
<td>record</td>
<td>[incident].[-- None --]</td>
<td>create</td>
<td>Creating records in the Incident table.</td>
</tr>
<tr>
<td>record</td>
<td>[incident].[active]</td>
<td>write</td>
<td>Updating the Active field in the Incident table.</td>
</tr>
<tr>
<td>REST_Endpoint</td>
<td>user_role_inheritance</td>
<td>execute</td>
<td>Running the user_role_inheritance scripted REST API.</td>
</tr>
</tbody>
</table>

The permissions specify when someone can access the named object and operation. Security administrators can specify permission requirements by adding:

- One or more user roles to the Requires role list.
- One or more conditions.
- A script that evaluates to true or false or sets the answer variable to true or false.

To gain access to an object and operation, a user must pass all permissions listed in an access control. For example, this access control restricts access to write operations on the incident table.
Access Control Rules allow access to the specified resource if all three of these checks evaluate to true:

1. The user has one of the roles specified in the Role list, or the list is empty.
2. Conditions in the Condition field evaluate to true, or conditions are empty.
3. The script in the Script field (advanced) evaluates to true, or sets the variable "answer" to true, or is empty.

The three checks are evaluated independently in the order displayed above.

More Info

Requires role

Role

Condition

30 records match condition

Add Filter Condition  Add "OR" Clauses

Incident state ▼ is not ▼ Closed ▼ AND OR ▼

Update  Delete
To update a record in the incident table, a user must have the listed role and the record must meet the condition.

<table>
<thead>
<tr>
<th>Permission type</th>
<th>Requirement</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Requires role</td>
<td>Requires role: itil</td>
<td>Only allow users with the itil role to update incidents.</td>
</tr>
<tr>
<td>Condition</td>
<td>[Incident state] [is not] [Closed]</td>
<td>Only allow updates to active incident records.</td>
</tr>
</tbody>
</table>

**ACL evaluation process**

An ACL rule only grants a user access to an object if the user meets all of the permissions required by the matching ACL rule.

- The condition must evaluate to **true**.
- The script must evaluate to **true** or return an answer variable with the value of **true**.
- The user must have one of the roles in the required roles list. If the list is empty, this condition evaluates to **true**.
- [Record ACL rules only] The matching table-level and field-level ACL rules must both evaluate to **true**.
ACL evaluate permissions
Whenever a session requests data, the system searches for access control rules that match the requested object and operation. If there is a matching access control rule, then the system evaluates if the user has the permissions required to access the object and operation. If an access control rule specifies more than one permission, then the user must meet all permissions to gain access to the object and operation. Failing any one permission check prevents the user from accessing the matching object and operation.

If a user does not meet the permissions of the first matching rule, the system evaluates the permissions of the next matching access control rule as specified by the access control processing order. If the user fails to meet the permissions of any matching access control rule, the system denies access to the requested object and operation.

Note: If there are no matching access control rules for the requested object and operation, then the system grants the user access to it. In practice, it is rare for the system to find no matching rules because the system has a set of default access control rules that protect all record operations.

The effects of being denied access to an object depend on the ACL rule that the user failed. For example, failing a read operation ACL rule prevents the user from seeing the object. Depending on the object secured, the ACL rule hides a field on a form, hides rows from a list, or prevents a user from accessing a UI page. The following table contains complete list of results of failing an ACL rule for a given operation and object type.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Results of failing an ACL rule on object</th>
</tr>
</thead>
<tbody>
<tr>
<td>execute</td>
<td>User cannot execute scripts on a record or UI page.</td>
</tr>
<tr>
<td>create</td>
<td>User cannot see the <strong>New</strong> UI action from forms. The user also cannot insert records into a table using API protocols such as web services. A <strong>create</strong> ACL with a condition requiring that a field contain a specific value always evaluates as false. Fields on new records are considered empty until the record is saved.</td>
</tr>
<tr>
<td>read</td>
<td>User cannot see the object in forms or lists. The user also cannot retrieve records using API protocols such as web services.</td>
</tr>
<tr>
<td>write</td>
<td>User sees a read-only field in forms and lists, and the user cannot update records using API protocols such as web services.</td>
</tr>
<tr>
<td>delete</td>
<td>User cannot see the <strong>Delete</strong> UI action from forms. The user also cannot remove records from a table using API protocols such as web services.</td>
</tr>
<tr>
<td>edit_task_relations</td>
<td>User cannot define relationships between task tables.</td>
</tr>
<tr>
<td>edit_ci_relations</td>
<td>User cannot define relationships between Configuration Item [cmdb_ci] tables.</td>
</tr>
<tr>
<td>save_as_template</td>
<td>Used to control the fields that should be saved when a template is created.</td>
</tr>
<tr>
<td>add_to_list</td>
<td>User cannot view or personalize specific columns in the list mechanic.</td>
</tr>
<tr>
<td>list_edit</td>
<td>User cannot update records (rows) from a list.</td>
</tr>
<tr>
<td>report_on</td>
<td>User cannot create a report on the ACL table. For more information, see Restrict report creation with an ACL rule.</td>
</tr>
<tr>
<td>Operation</td>
<td>Results of failing an ACL rule on object</td>
</tr>
<tr>
<td>-----------------------</td>
<td>--------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>report_view</td>
<td>User cannot view the content of a report on the ACL table or on the ACL field. For more information, see Restrict report creation with an ACL rule.</td>
</tr>
<tr>
<td>personalize_choices</td>
<td>User cannot right-click a choice list field and select Configure Choices.</td>
</tr>
</tbody>
</table>

### ACL matching requirements for objects

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Matching ACL Rules Required to Access Object</th>
<th>Existing Wildcard ACL Rules</th>
</tr>
</thead>
<tbody>
<tr>
<td>Client-callable script includes</td>
<td>Users must meet the permissions of two ACL rules:</td>
<td>By default, there are no wildcard (*) rules for these object types. If you create a wildcard ACL rule for one of these objects, then the ACL rule applies to all objects of this type.</td>
</tr>
<tr>
<td>Processors</td>
<td>1. All wildcard ACL rules for the object (if any ACL rule exists for the operation).</td>
<td></td>
</tr>
<tr>
<td></td>
<td>2. The first ACL rule that matches the object's name (if any ACL rule exists for the operation).</td>
<td></td>
</tr>
<tr>
<td>UI pages</td>
<td>Users must meet the permissions of two ACL rules:</td>
<td>By default, there are wildcard table rules (<em>) for the create, read, write, and delete operations and wildcard field rules (</em>.*) for the personalize_choices, create, and save_as_template operations. When you create a new table, create new ACL rules for the table unless you want to use the provided wildcard ACL rules.</td>
</tr>
<tr>
<td>Record</td>
<td>1. The first ACL rule that matches the record's field (if any ACL rule exists for the operation).</td>
<td></td>
</tr>
<tr>
<td></td>
<td>2. The first ACL rule that matches the record's table (if any ACL rule exists for the operation).</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** The Security manager default behavior (`glide.sm.default_mode`) property determines whether users can access objects that only match against wildcard table ACL rules. When this property is set to **Deny access**, only administrators can access objects that match the wildcard table ACL rules.

**Note:** The wildcard field ACL rule (".*") for the create operation reuses the same permissions as the write operation. This means that the create permissions are the same as the write permissions unless you define an explicit create operation ACL rule.

### Multiple ACL rules at the same point in the processing order

If two or more rules match at the same point in the processing order, the user must pass any one of the ACL rules permissions to access the object. For example, if you create two field ACL rules for `incident.number`, then a user who passes one rule has access to the number field regardless of whether the user failed any other field ACL rule at the same point in the processing order.
Required role

Normal admin users can view and debug access control rules. However, to create or update existing access control rules, administrators must elevate privileges to the security_admin role. See Elevate to a privileged role for instructions.

ACL rules in scoped applications

You can create ACL rules for objects in the same scope as the ACL rule and for tables with at least one field that is in the same scope as the ACL rule.

For tables that are in a different scope than the ACL rule record, the types of rules are limited.

- You can create an ACL rule for any table, UI page, or other object that is in the same scope as the ACL rule.
- You can create an ACL for a field that is in the same scope as the ACL rule.
  - If the table is in the same scope, you can use a script to evaluate permissions.
  - If the table is in a different scope, you cannot use a script to evaluate permissions.
- You cannot create or modify ACL rules for objects that are in a different scope than the application you have selected in the application picker, including adding a role to an ACL in a different scope.
- You can create wildcard table rules (*) only in the global scope.
- You can create wildcard field rules (*) only for tables in the same scope as the ACL rule.

ACL rule types

Create ACL rules on different components of the system.

Record ACL rules

Record ACL rules consist of table and field names.

- The table name is the table that you want to secure. If other tables extend from this table, then the table is considered a parent table. ACL rules for parent tables apply to any table that extends the parent table.
- The field name is the field that you want to secure. Some fields are part of multiple tables because of table extension. ACL rules for fields in a parent table apply to any table that extends the parent table.

ACL rules can secure the following record operations:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>create</td>
<td>Enables users to insert new records (rows) into a table.</td>
</tr>
<tr>
<td>read</td>
<td>Enables users to display records from a table.</td>
</tr>
<tr>
<td>write</td>
<td>Enables users to update records in a table.</td>
</tr>
<tr>
<td>delete</td>
<td>Enables users to remove records from a table or drop a table.</td>
</tr>
<tr>
<td>edit_task_relations</td>
<td>Enables users to extend the Task [task] table.</td>
</tr>
<tr>
<td>edit_ci_relations</td>
<td>Enables users to extend the Configuration Item [cmdb_ci] table.</td>
</tr>
<tr>
<td>save_as_template</td>
<td>Enables users to save a record as a template.</td>
</tr>
<tr>
<td>Operation</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>add_to_list</td>
<td>Prevents users from viewing or personalizing specific columns in the list mechanic.</td>
</tr>
<tr>
<td></td>
<td><img src="image" alt="Note: Conditions and scripts are not supported." /></td>
</tr>
<tr>
<td>list_edit</td>
<td>Enables users to update records (rows) from a list.</td>
</tr>
<tr>
<td>report_on</td>
<td>Enables users to report on tables. This operation is also valid for field ACL rules.</td>
</tr>
<tr>
<td>personalize_choices</td>
<td>Enables users to configure the table or field.</td>
</tr>
</tbody>
</table>

Record ACL rules are processed in the following order:

- Match the object against table ACL rules.
- Match the object against field ACL rules.

This processing order ensures that users gain access to more general objects before gaining access to more specific objects. A user must pass both table and field ACL rules to access a record object.

- If a user fails a table ACL rule, the user is denied access to all fields in the table, even if the user passes a field ACL rule.
- If a user passes a table ACL rule, but fails a field ACL rule, the user cannot access the field described by the field ACL rule.

End
Processor ACL rules

Processor ACL rules specify the processor you want to secure. For a list of available processors, navigate to System Definition > Processors.

By default, an ACL rule for the EmailClientProcessor is included to restrict the email client to users with the itil role. Processor ACL rules honor the STAR (*) rule if they cannot find a more specific ACL for those resources.

Table ACL rules

The user must first pass the table ACL rule. Since the base system includes STAR (*) table ACL rules that match every table, the user must always pass at least one table ACL rule. The base system provides additional table ACL rules to control access to specific tables.

Table ACL rules are processed in the following order:
1. Match the table name. For example, incident.
2. Match the parent table name. For example, task.
3. Match any table name (*). For example, *.

If a user fails all table ACL rules, the user cannot access the fields in any table. If a user passes a table ACL rule, the system then evaluates the field ACL rules.

Field ACL rules

After a user passes a table ACL rule, field ACL rules are processed in the following order:
1. Match the table and field name. For example, incident.number.
2. Match the parent table and field name. For example, task.number.
3. Match any table (*) and field name. For example, *.number.
4. Match the table and any field (*). For example, incident.*.
5. Match the parent table and any field (*). For example, task.*.
6. Match any table (*) and any field (*). For example, *.*.

A user must pass the table ACL rule to be granted access to the table's fields. For example, the user must first pass the table ACL rule for the incident table to access the Number field in the incident table.

The first successful field ACL evaluation stops ACL rule processing at the field level. When a user passes a field ACL rule, the system stops searching for other matching field ACL rules. For example, if a user passes the field ACL rule for incident.number, the system stops searching for other ACL rules that secure the Number field in the incident table.

UI page ACL rules

UI page ACL rules specify the UI page to be secured. For a list of available UI pages, navigate to System UI > UI Pages. When defining an ACL rule for a UI page, use the fully scoped page name. For example, x_myapp_mypage.
Note: You can use the STAR (*) character in the Name field on ui_page type ACLs to match any UI pages.

UI page ACL rules honor the STAR (*) rule if they cannot find a more specific ACL for those resources. For example, if you have a UI page named mysecretpage but do not define an ACL for this UI page, the STAR (*) rule for the UI page processor is used for access check.

ACL rules can secure the following UI page operation:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>read</td>
<td>Allows users to display the UI page.</td>
</tr>
</tbody>
</table>

Client-callable script include ACL rules

Script include ACL rules specify the client-callable script include to be secured. For a list of available script includes, navigate to System Definition > Script Includes. You can personalize the list to show the Client callable column.

The base system does not include any ACL rules for client-callable script includes.

Client-callable script include ACL rules honor the STAR (*) rule if they cannot find a more specific ACL for those resources.

ACL control of function fields

When evaluating access to a function field, in addition to checking access to the function field itself, the system also checks access to the function's contributing fields. Contributing fields are those used as the arguments in a given function definition.

For more information about function fields, see Function field.

In Paris and earlier, the system simply checks access to the function field itself (as with any other field). If the ACLs on that field allow access, the user receives the resulting value, regardless of whether the user has access to the contributing fields.

In Quebec, the system also requires access to all contributing fields in order to allow access to the function field. If one or more of the contributing field ACLs refuse access, the function field also refuses access.

The only operations affected by the new requirement are read and report_view. Report_view has its own additional requirements.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>read operation</td>
<td>A user has read access to a function field only if both of the following are true:</td>
</tr>
<tr>
<td></td>
<td>• The user has read access to the function field.</td>
</tr>
<tr>
<td></td>
<td>• The user has read access to all of the contributing fields used in the function.</td>
</tr>
</tbody>
</table>
### Operation Description

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
</table>
| report_view operation | A user has report_view access to a function field only if all of the following are true:  
  - The user has report_view access to the function field.  
  - The user has report_view access to each of the contributing fields.  
  - There is a role-only ACL without conditions and without a script, and the user has that role.  
  - The user has role-only read access to the contributing fields, such that only ACLs without condition or script can allow. |

### Examples

**Given:**
- Table: salary
- Columns: base, bonus, total (all are Integers in this example)
- Function field: The total column is marked as a function field, with function definition `glidefunction:add(base, bonus)`.
- Contributing fields: base and bonus, since they're used in the function definition
- Roles: salary_admin, bonus_admin

**Example 1: All fields allow access**

<table>
<thead>
<tr>
<th>ACLs</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>total, base, bonus: read and report_view for role salary_admin, with no conditions or scripts</td>
<td>A user with the salary_admin role is granted read and report_view access to total because they have the required role.</td>
</tr>
</tbody>
</table>

**Example 2: Contributing field refuses read access**

<table>
<thead>
<tr>
<th>ACLs</th>
<th>Result</th>
</tr>
</thead>
</table>
| total, base: read and report_view for role salary_admin, with no conditions or scripts  
  bonus: report_view for role salary_admin, with no conditions or scripts  
  bonus: read for role bonus_admin, with no conditions or scripts | A user with the salary_admin role is refused read and report_view access to total, because bonus refuses read access to their role. |
Example 3: Contributing field ACL has script

<table>
<thead>
<tr>
<th>ACLs</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>total, base: read and report_view for role salary_admin, with no conditions or scripts</td>
<td>A user with the salary_admin role is granted read access to total, because they have the required role for all fields. But the same user with the salary_admin is refused report_view access, because the read ACL with the script refuses access by default for this case, even though they have the required role.</td>
</tr>
<tr>
<td>bonus: report_view for role bonus_admin, with no conditions or scripts</td>
<td></td>
</tr>
<tr>
<td>bonus: read for role salary_admin, with a script (note that it doesn’t matter what’s in the script, only that it’s there)</td>
<td></td>
</tr>
</tbody>
</table>

Create an ACL rule

Create a custom ACL rule to secure access to new objects or to change the default security behavior.

Role required: security_admin

To create ACL rules, you must elevate privileges to the security_admin role. For tables that are in a different scope from the ACL rule record, the types of rules are limited.

1. Elevate privileges to the security_admin role.
3. Click New.
4. Complete the form.

Access control fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Select what kind of object this ACL rule secures. The type of object determines how the object is named and what operations are available. This field becomes read only after the ACL rule is created. If you want to change the type, you must delete the ACL and create a new one with the correct type.</td>
</tr>
<tr>
<td>Operation</td>
<td>Select the operation this ACL rule secures. Each object type has its own list of operations. An ACL rule can only secure one operation. To secure multiple operations, create a separate ACL rule for each.</td>
</tr>
<tr>
<td>Admin overrides</td>
<td>Select this check box to have users with the admin role automatically pass the permissions check for this ACL rule. Admin users pass regardless of what script or role restrictions apply. However, the nobody role, which only ServiceNow personnel can assign, takes precedence over the admin override option. If an ACL is assigned the nobody role, admin users cannot access the resource even when Admin overrides is selected. See Base system roles. Clear this check box if administrators must meet the permissions defined in this ACL rule to gain access to the secured object. Since administrators always pass role checks (see the description of the Requires role field), use the condition builder or Script field to create a permissions check that administrators must pass.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Active</td>
<td>Select this check box to enforce this ACL rule.</td>
</tr>
<tr>
<td>Advanced</td>
<td>Select this check box to display the <strong>Script</strong> field.</td>
</tr>
<tr>
<td>Name</td>
<td>Enter the name of the object being secured, either the record name or the table and field names. The more specific the name, the more specific the ACL rule. You can use the wildcard character asterisk (<em>) in place of a record, table, or field name to select all objects that match a record type, all tables, or all fields. You cannot combine a wildcard character and a text search. For example, inc</em> is not a valid ACL rule name, but incident.* and *.number are valid ACL rule names. <strong>Note:</strong> Click the blue triangle to manually enter the record name or the table and field names of the object being secured. Use this option to secure an object that does not appear in the dropdown.</td>
</tr>
<tr>
<td>Description</td>
<td>Enter a description of the object or permissions this ACL rule secures.</td>
</tr>
<tr>
<td>Requires role</td>
<td>Use this list to specify the roles a user must have to access the object. If you list multiple roles, a user with any one of the listed roles can access the object. The Requires role list appears as a related list. <strong>Note:</strong> Users with the admin role always pass this permissions check because the admin role automatically grants users all other roles.</td>
</tr>
<tr>
<td>Condition</td>
<td>Use this condition builder to select the fields and values that must be true for users to access the object.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| Script | Enter a custom script describing the permissions required to access the object. The script can use the values of the current and previous global variables as well as system properties. The script must generate a true or false response in one of two ways:  
  - return an answer variable set to a value of true or false  
  - evaluate to true or false  
  In either case, users only gain access to the object when the script evaluates to true and the user meets any conditions the ACL rule has. Both the conditions and the script must evaluate to true for a user to access the object.  
  
  **Note:** If the evaluated item is in a related list, current points to the item the related list is on, not to the current item the ACL is for. However, If the item you are evaluating the ACL for is not in a related list, current points to the actual item. |
5. Right-click the form header and select **Save**.
Secure records in an embedded list

To apply security to the records in embedded lists, limit editing and deleting records in embedded lists to specific roles.

Role required: security_admin

1. Navigate to **System Security > Access Control (ACL).**
2. Open the **Write** or **Delete** record for the appropriate table.
3. In the Requires Role section of the form, add the roles that have write or delete permission for that table.
4. Save the changes.

   When records from the associated table appear in an embedded list, the edit and delete options are available only to users with the specified roles.

**Contextual Security Manager**

Contextual Security Manager protects your data by controlling read, write, create, and delete authorization.

**Key advantages**

The Contextual Security Manager is aware of the system table hierarchy, enabling you to create specific security rules for a field based on where in the hierarchy it is displayed. Benefits of the Contextual Security Manager include:

- **Contextual security**: Secure a record based on the contents of the record.
- **Hierarchical security**: Apply security rules to any level in the object hierarchy.

**Securing fields and tables**

With the legacy Simple Security Manager, you could secure fields and tables by adding roles to the appropriate dictionary entry. With the Contextual Security Manager, these dictionary roles are no longer tested. Instead, the system looks for ACL rules on fields and tables.

**Warning:** After you install the Contextual Security Manager, you must secure fields and tables via ACL rules. Even if you configure the dictionary form and add roles to a dictionary entry, no change in rights occurs.

**Contextual security and roles**

You can grant roles to users or groups. However, after installing the Contextual Security Manager, the roles field on the user record is no longer checked and no longer appears on your user and group forms. Instead, you must add roles to the Roles related list instead of to the user or group record.

Applications and modules contain lists of the roles required to view them. For example, to view the System Definition application, the admin role is required. Security rights for applications and modules are still defined using role arrays.

Both catalog items and catalog variables contain lists of the roles required to view them. Security rights for catalog items and catalog variables are still defined via these role arrays.

Under the Contextual Security Manager, a group still automatically inherits any role granted to the group when the inherits flag for the role is set to true.
Activating the Contextual Security Manager

The Contextual Security Manager is active in the base system. If there are many duplicate entries in the User Roles table, you may need to upgrade to Contextual Security: Role Management V2 to eliminate duplicate roles. Plugins include:

**Contextual Security: Role Management [com.glide.role_management]**

Provides contextual security functionality. This plugin is automatically installed.

**Contextual Security: Role Management V2 [com.glide.role_management.inh_count]**

Prevents duplicate entries caused by inherited roles in the User Roles [sys_user_has_role] table. This plugin is automatically installed on new instances and can be activated for upgrades. The Contextual Security: Role Management Enhancements plugin is a previous version of this plugin. The Role Management Enhancements plugin does not include the RoleManagementVerify() script. This script returns a list of changes that an upgrade will perform, enabling you to monitor changes made by the plugin.

**Note:** After activating Role Management V2, you must set the glide.role_management.v2.audit_roles system property to allow the Audit Roles table to create audit records related to user roles. To learn more about setting this property and about the Audit Roles table, see:

- Enable role auditing with Contextual Security: Role Management V2.
- Contextual Security: Role Management plugin (instance security hardening) in Instance Security Hardening Settings.
- Audit user roles

Prevent duplicate entries with Contextual Security: Role Management V2

Roles inherited from other roles are added as individual entries in the User Roles table [sys_user_has_role], potentially causing one role to have duplicate entries. Contextual Security: Role Management V2 eliminates these duplicate entries and prevents future duplicates.

Eliminate duplicate entries through inheritance count

Contextual Security: Role Management V2 uses the Inheritance Count (inh_count) column to track the number of times a role is inherited from another role or group. In the User Roles [sys_user_has_role] table, a user can inherit a specific role only one time, eliminating duplicate entries. The Inheritance Count (inh_count) column is read-only and calculates the number of times the user inherits a role.

Activation changes

Contextual Security: Role Management V2 is automatically installed on new instances and can be activated for upgrades. When activated, Contextual Security: Role Management V2 replaces both Contextual Security and Contextual Security: Role Management Enhancements.

When Contextual Security: Role Management V2 is activated, the following columns are deprecated, but remain in the User Roles table for backward compatibility:

- granted_by (used only by Role Delegation)
- included_in_role
- included_in_role_instance
CAUTION: If these columns are in use in any custom scripts on your instance, do not upgrade to Role Management V2.

Visualize role inheritance through the Role Inheritance Map

The Role Inheritance Map displays a visual representation of inherited roles. You can use this map to understand the roles represented in the Inheritance Count (inh_count) column. To view the Role Inheritance Map, configure the User Roles [sys_user_has_role] table to display the Role Inheritance Map column.

Role Inheritance Map

Upgrade to Contextual Security: Role Management V2

Contextual Security: Role Management V2 is automatically installed on new instances. You can upgrade from Contextual Security: Role Management to Contextual Security: Role Management V2 to eliminate duplicate roles in the User Roles table and prevent future duplicates.

Role required: admin, security_admin

You must have the admin role and Elevate to a privileged role to obtain the effective security_admin role.

Note: Before upgrading to Contextual Security: Role: Management V2, you must enable the Audit Roles table to create audit records related to user roles. To learn more about setting the required system property, see Enable role auditing with Contextual Security: Role Management V2.

This procedure describes how to upgrade your Contextual Security role and how to activate the related plugins described in the following table.
Plugins for Contextual Security: Role Management V2

<table>
<thead>
<tr>
<th>Plugin</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Contextual Security: Role Management V2 [com.glide.role_management.inh_count]</td>
<td>Prevents duplicate entries in the User Roles [sys_user_has_role] table.</td>
</tr>
</tbody>
</table>

Before upgrading from Contextual Security: Role Management to Contextual Security: Role Management V2, test the results of an upgrade by running the script. The script returns a list of changes that an upgrade will perform. If the changes are acceptable, install the Contextual Security: Role Management V2 plugin. If the changes are not acceptable, do not install the Contextual Security: Role Management V2 plugin. Alternatively, you can perform the upgrade and then manually make any necessary changes.

1. Test the impact of an upgrade prior to upgrading by running the following script.
   a) Navigate to System Definition > Scripts - Background.
   b) Run the following script in global scope:

   ```java
   new RoleManagementVerify().verifyInheritedRoles();
   ```

   For large sys_user_has_role tables, the execution may take up to several hours to complete. Do not edit or add user roles during this time.

   Example result based on test data:

   ```
   *** Script: 2016-12-01 19:58:54 Starting checking of inherited roles for all users...
   *** Script: User: itam, inherited roles to be ADDED: financial_mgmt_user
   *** Script: User: bernard.laboy, inherited roles to be DELETED: api_analytics_read, pa_viewer, rest_api_explorer, a123
   *** Script: User: bernard.laboy, inherited roles to be ADDED: dependency_views
   *** Script: Number of inherited-role records in sys_user_has_role, current: 260, after re-calculation: 258
   *** Script: Number of users with discrepancies for inherited roles: 2
   *** Script: 2016-12-01 19:58:55 Finished checking of inherited roles for all users!
   ```
   c) Evaluate the script results to determine whether the proposed changes are acceptable.

2. Activate the Contextual Security: Role Management V2 plugin.
   a) Navigate to System Definition > Plugins.
   b) Find and click the plugin name.
   c) On the System Plugin form, review the plugin details and then click the Activate/Upgrade related link.
   d) Click Activate.

After activating Role Management V2, the changes outlined in the script result are enacted. The Inheritance Count (inh_count) column in the User Roles table is read-only and automatically reflects the number of times the user inherits a role.
Enable role auditing with Contextual Security: Role Management V2

Set a system property to enable the Audit Roles table to create audit records related to user roles.

Role required: admin

When enabled, the Audit Roles [sys_audit_role] table maintains changes to user records. For more information about role audits, see Audit user roles. If the Contextual Security: Role Management V2 [com.glide.role_management.inh_count] plugin is installed, you must set a system property to `true` to enable role auditing.

2. Add the `glide.role_management.v2.audit_roles` system property and set it to `true`.

   If the Contextual Security: Role Management V2 [com.glide.role_management.inh_count] plugin is installed, setting this property to `true` enables the Audit Roles [sys_audit_role] table to create records when user roles change.

Double-check form submission

When the system determines that a particular field (such as task.number) should not be written to by the current user, the system renders that field in a read-only mode, which is why the number field is not writable on most incidents.

If you set the system to double-check the values of any incoming fields for writability, then the system applies the same set of security rules to the inbound leg of a transaction. When you submit an incident, for example, the system double-checks to determine if the number field can be written to before posting any changes.

If you tell the system not to double-check inbound transactions, then the system allows you to write to a nominally read-only field if that is the transaction the client sends back. In many deployments this is actually a desirable behavior if, for example, you are using client scripts to set nominally read-only fields in response to user selections in other, writable fields.

<table>
<thead>
<tr>
<th>Property</th>
<th>Location</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Double check security on inbound transactions during form submission (rights are always checked on form generation)</td>
<td>System Properties &gt; Security</td>
<td>Disabled (no double-checking)</td>
</tr>
</tbody>
</table>

Default deny property

The default deny property (`glide.sm.default_mode`) controls the security manager default behavior when the only matching ACL rules are the wildcard table ACL rules.

A set of wildcard table ACL rules for the most common record-based operations are available: read, write, create, and delete. A significant number of ACLs to provide role-based access to system tables are also available. For example, there are ACLs that grant `sys_script` access to the `business_rule_admin` role because that role is documented as being able to manage business rules.

Use the `glide.sm.default_mode` property to deny or allow these operations on all tables:

- **Deny Access**: The wildcard table ACL rules restrict the read, write, create, and delete operations on all tables unless the user has the admin role or meets the requirements of another table ACL rule. Other operations, such as `report_on` and `personalize_choices`, are unaffected by this setting.
- **Allow Access**: The wildcard table ACL rules allow the read, write, create, and delete operations on all tables unless there are specific table ACL rules in place to restrict such operations.

You cannot reset `glide.sm.default_mode` to Allow Access once it has been set to Deny Access.
**Note:** By default, the wildcard table ACL rules are the only ACL rules that check for the value of the `glide.sm.default_mode` property. If you want to control other operations with this setting, create your own ACL rules to check for this property value. To learn more about this property, see Default deny (instance security hardening) in Instance Security Hardening Settings.

### Advanced ACL configuration

In addition to creating new ACLs or modifying existing ones, you can configure other aspects of ACL functionality.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Apply ACL script conditions to reference fields</td>
<td>Enable a property to allow script conditions to apply to reference fields if you want to control access to the data that a reference field displays on a form or in a list. There might be an impact to the performance of your instance if you enable this.</td>
</tr>
<tr>
<td>Apply ACLs to AJAXGlideRecord (client-side Glide record)</td>
<td>Apply ACLs to GlideAjax API calls so that the system queries only the data that the currently connected user has rights to access.</td>
</tr>
<tr>
<td>Evaluate the admin override at the access level</td>
<td>Force ACL evaluation for admin overrides at the access level. By default, users with the admin role automatically pass the permissions check for this ACL rule when the Admin Overrides option is selected on the ACL rules form.</td>
</tr>
<tr>
<td>Use ACL debugging and troubleshooting tools</td>
<td>Use tools like the ACL watcher, field level debugging, and access ACL rule output messages to help you troubleshoot and debug ACLs.</td>
</tr>
</tbody>
</table>

### Provide external users access to a table

To enable users with only the `snc_external` role to access the list view of a table, you must create a series of ACLs.

Role required: security_admin

1. **Elevate to the security_admin role.**
2. **Create a new ACL with the following settings:**
   - **Type:** `ui_page`
   - **Operation:** `read`
   - **Name:** `{table_name}_list`
   - **Required role:** `snc_external`

3. On the default `read` ACL for the table, add `snc_external` in the Required role list. Create the ACL if it does not already exist.
4. **Use these settings to create another ACL:**
   - **Type:** `ui_page`
   - **Operation:** `read`
   - **Name:** `{table_name}`
   - **Required role:** `snc_external`
5. Use these settings to create another ACL to give the user write access to a field in the table:

- **Type**: record
- **Operation**: create
- **Name**: `{table_name} {column_name}`
- **Required role**: snc_external

Repeat this step for every field that you want to give the user write access to. Use an asterisk (*) instead of the column name to provide access to all fields at once.

**Apply ACL script conditions to reference fields**

If you want to enable script conditions for reference fields, you can add a system property. The default behavior is intended to improve instance performance. If you want to enable script conditions for reference fields, add the following system property.

**System property**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.sys_reference_row_check</td>
<td>Controls whether the script conditions of Access Control Rules apply to a table's reference fields.</td>
</tr>
<tr>
<td></td>
<td>• Type: true</td>
</tr>
<tr>
<td></td>
<td>• Default value: <strong>false</strong></td>
</tr>
<tr>
<td></td>
<td>• Location: Add to the System Properties [sys_properties] table</td>
</tr>
</tbody>
</table>

**Apply ACLs to AJAXGlideRecord (client-side Glide record)**

From within client scripts, it is possible to query arbitrary data from the server via the AJAXGlideRecord (renamed GlideAjax) API, by using syntax similar to a server-side glide record. This is an extremely powerful and useful tool in many deployments. You can set a system property to perform ACL validation when server-side records (for example, tables) are accessed using GlideAjax APIs within a client script.

If you choose to apply access control lists (ACL) to GlideAjax API calls, then you can only query data to which the currently connected user has rights to access. For example, if the user is logged in as an ESS user who has no rights to read the cmn_location table, then any GlideAjax API call by the user will fail.

If you run the system without an ACL checking on GlideAjax calls, then the API can return information that the currently logged in user could not otherwise access via the UI.

**Note:** Set this property in **System Properties > Security**.

<table>
<thead>
<tr>
<th>Property</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Apply standard security ACLs to AJAXGlideRecord calls</td>
<td>ACL checking enforced</td>
</tr>
</tbody>
</table>

**Note:**

To learn more about this property, see Enabling AJAXGlideRecord ACL checking (instance security hardening) in Instance Security Hardening Settings.
Evaluate the admin override at the access level

If you want to force ACL evaluation for admin overrides at the access level, you can add a system property.

Role required: security_admin

ACLs are evaluated cumulatively. If there are number of ACLs on any given field and the Admin Overrides option is false (not selected) on one of them, then the effective admin overrides for all the ACLs are considered to be false. This causes admins to be unable to pass even the ACL where the override should be in effect.

- Add the following property to the system properties table:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.security.admin.override.accessterm</td>
<td>Evaluates the admin override condition at the access term level.</td>
</tr>
<tr>
<td></td>
<td>- Type: true</td>
</tr>
<tr>
<td></td>
<td>- Default value: true for new instances, false for upgrades</td>
</tr>
<tr>
<td></td>
<td>- Location: Add to the System Properties [sys_properties] table</td>
</tr>
</tbody>
</table>

ACL debugging tools

Field level debugging and access ACL rule output messages are available to help you troubleshoot and debug ACLs. The ACL configuration watcher lets you know what related ACLs exist when you modify one.

Field level debugging

When debugging is enabled, a small bug icon (#) appears beside each field with an ACL rule. Clicking the icon lists the ACL rules that apply for the field and the evaluation results.

Field level security on an incident

After enabling ACL debugging, you can impersonate another user to see what ACL rules the user passes and fails. When you impersonate a user, you can only see what that user is allowed to see. For example, you cannot view a record that an ACL prevents the user from seeing. To make debugging easier, read-only access to certain ACL-related tables is enabled by default, even when impersonating a user that does not have read access to the tables. To change this functionality, set the following property to false.

To enable ACL rule debugging, navigate to System Security > Debug Security Rules.
<table>
<thead>
<tr>
<th>System property</th>
<th>Description</th>
<th>Default setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.security.access_acl_as_impersonator</td>
<td>Allows read access to the following tables while impersonating a user: sys_security_acl, sys_security_operation, sys_security_type, and sys_user_role. As a result, the impersonating user can read data that the impersonated user cannot read.</td>
<td>true</td>
</tr>
</tbody>
</table>

**Note:** When the property is set to false, the impersonated user might be prevented from reading ACL-related data. In this case, a second session logged in as admin or security_admin might be required to debug ACLs.

### ACL rule output messages

ACL debugging displays ACL rule output messages at the bottom of each list and form. The output message displays the following:

<table>
<thead>
<tr>
<th>Message element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIME</td>
<td>The total time used to process this ACL rule.</td>
</tr>
<tr>
<td>PATH</td>
<td>Information that uniquely identifies each ACL rule in the format: &lt;ACL rule type&gt;/&lt;ACL rule name&gt;/Operation.</td>
</tr>
<tr>
<td>CONTEXT</td>
<td>The object being evaluated by the ACL rule.</td>
</tr>
<tr>
<td>RC</td>
<td>The return code of the ACL rule. A true value passes the ACL rule. A false value fails the ACL rule.</td>
</tr>
</tbody>
</table>
| RULE            | A brief summary of processors and scripts, followed by ACL results for each table-level and field-level ACL evaluation. Most ACL evaluations show an overall pass or fail result followed by a breakdown of the results for each type of ACL criteria:  
  - iAccessHandler: An internal system check using hidden source code on the platform. This is a system security check that you cannot modify. IAccessHandler can grant or deny access to a resource without evaluating ACLs. If IAccessHandler is ignored, then the ACLs are evaluated. You cannot modify the IAccessHandler checks in any way. For example, an IAccessHandler implementation is used for access checks on application resources and this cannot be changed. This is available starting with the Istanbul release.  
  - Roles: Verification that the user has the correct role.  
  - Condition: Verification that the user passed the condition specified on the ACL rule (if any).  
  - Script: Verification that the user passed the script specified on the ACL rule (if any). |
The icons that appear show how the ACL was evaluated:

<table>
<thead>
<tr>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A green checkmark (✔️)</td>
<td>Indicates the table or field passed the criteria.</td>
</tr>
<tr>
<td>A red x icon (❌)</td>
<td>Indicates the table or field did not pass.</td>
</tr>
<tr>
<td>An empty gray circle icon (〇)</td>
<td>Indicates the ACL evaluation did not need to be performed.</td>
</tr>
<tr>
<td>A blue checkmark, x, or empty circle</td>
<td>Indicates that the ACL was taken from a cached result of a previous ACL check. The icons mean the same as the above.</td>
</tr>
</tbody>
</table>

You can perform these actions on the ACL debug output:

- Select or clear these check boxes at the top of the debug output:
  - **Security rules**: Show or hide the results of the ACL checks.
  - **Others**: Show or hide other warnings or messages.

- Click the name of the ACL next to any of the output messages to open that ACL record.

- Hover the cursor over any of the icons for the four ACL checks to see more information.

**ACL troubleshooting reference**

A list of common ACL rule errors and their solutions.

Enable debugging to help troubleshoot an issue.

<table>
<thead>
<tr>
<th>Error or symptom</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>You cannot access records from a custom table.</td>
<td>Create a table ACL rule for the custom table granting users access to the table. Without an explicit table ACL rule, users must pass the permissions in the table wildcard (*) ACL rule, which by default restricts access to administrators only. Enable debugging and determine what ACL rules are evaluated for the custom table.</td>
</tr>
</tbody>
</table>
Error or symptom | Solution
---|---
You create a custom ACL rule that does not work properly. | The most likely problems are that another rule takes precedence over your custom rule in the processing order or that the user does not meet all the permission requirements for the object type. Enable debugging and verify that the ACL rule is being evaluated.

Your field ACL rule does not work properly. | There is likely a table ACL rule that the user has not met. Enable debugging and determine what ACL rules are evaluated for the field. Verify that there is not a conflicting table ACL rule or duplicate field ACL rule.

Your table ACL rule does not work properly. | There is either an ACL rule higher in the processing order or a duplicate table ACL rule interfering with the table ACL rule. Enable debugging and determine what ACL rules are evaluated for the table.

You can see a field in a list but not in form. | It is possible that the ACL rule conditions or script are being triggered in the list but not in the form. Enable debugging and determine when the ACL rules evaluate to true. Update the conditions or script to have the same behavior on the list and form.

You receive an error message when trying to execute a processor or client-callable script include. | There is an ACL rule for the processor or client-callable script include that the user has not met. If the user should have access to the object, enable debugging and determine what ACL rules are evaluated for the processor or script include. Update the ACL rule or the user roles as needed to access the object.

---

**ACL configuration watcher**

The ACL configuration watcher lets you know what related ACLs exist on a table when you insert, update, or delete an ACL on the same table.

The ACL configuration watcher is an interceptor window that displays every time you make important changes on the Access Control [sys_security_acl] table. It displays a security rules summary window where you can view ACLs related to the one you are modifying. You cannot modify any ACLs from the security rules window. To make any modifications, close the watcher window and go to those ACLs.

The ACL configuration watcher does not appear in the following situations:

- If you save or update an ACL record without actually making any changes.
- If you make minor updates (not an insert or delete), such as updating scripts, conditions, and the admin-overrides option.
- If the ACL record is not active.

**ACL Security Rules window**

The configuration watcher shows the ACL execution plan. The execution plan is displayed in the security rules pop-up window. You can view this kind of information:

**ACL configuration window elements**

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>red highlight</td>
<td>An ACL that is deleted or deactivated.</td>
</tr>
<tr>
<td>Item</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>blue highlight</td>
<td>An ACL that is modified.</td>
</tr>
<tr>
<td>green highlight</td>
<td>An ACL that is added or becomes active.</td>
</tr>
<tr>
<td>Masked</td>
<td>An ACL that was effective until you made a change.</td>
</tr>
<tr>
<td>Unmasked</td>
<td>An ACL that was just made effective when you made a change.</td>
</tr>
</tbody>
</table>

**Verify Security Rules for "vtb_task.short_description"**

**Configuration watcher example**

Show ACL execution plan
Administrators can view how ACLs relate to each other by viewing an execution plan for any ACL in the instance.
Role required: security_admin

1. Elevate to a privileged role.
2. Open an ACL that is a record-type ACL.
3. Click **Show ACL Execution Plan**.

The security rules window appears for the ACL.

<table>
<thead>
<tr>
<th>Security Rules for &quot;vtb_task.description&quot;</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Write</strong></td>
</tr>
<tr>
<td>Row level</td>
</tr>
<tr>
<td>Field level</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

4. Click **Show all** to show all related ACLs, including those ACLs that are overridden and generic ACLs that apply to all records. Overridden ACLs have a line through the name, and generic ACLs have the wildcard character asterisk (*) for the name.

5. Click **Show Effective** to show only the immediate ACLs related to the one you are viewing. This action hides the ACLs on tables from which the ACL table is extended and the generic wildcard (*) ACLs.

Use the ACL configuration watcher

Use the ACL configuration watcher after you elevate to security_admin role.

Role required: security_admin

Elevate to a privileged role

1. Open an ACL that is a record-type ACL.
2. Perform an action on the ACL, such as modifying it, or selecting an option from the context menu like **Insert**.
3. If you modified any values on the Access Control form, right-click the header and select **Save** or click **Update** or **Delete**.

The Security Rules window appears. The system did not yet perform the database action on the ACL, so the changes are not yet saved.

These are examples of security rules on the Visual Task Board application's Private Task [vtb_task] table. See **ACL configuration watcher** for a description of the items on this window.
4. Just as with the execution plan, you can click **Show all** to show all related ACLs, including those that are overridden and generic ACLs that apply to all records, or click **Show Effective** to show only the immediate ACLs related to the one you are viewing.

5. Hover your mouse over any of the ACLs to see a description.

### Explicit Roles

You can give both internal users and external users access to your instance. However, you might not want both types of users to have the same level of access. To provide added security, every user must have at least one role so that the instance can distinguish between internal and external users.

As of the release, no user can have both of the explicit roles (snc_internal and snc_external). Groups and role containment cannot include both roles, either, since that would cause any group member or user who is assigned to such a group or such a role to automatically have both roles. The aborts any operation that would create such a scenario.

External users must obtain, at minimum, the snc_external role. The snc_external role indicates that the user is external to your organization. They should not have any access to resources unless explicitly allowed through ACLs for the snc_external role or additional roles that inherit the snc_external role. By default, users with the snc_external role cannot access:

- Scripted REST API resources that are not marked external.
- Tables without the role that inherits the snc_external role or the public role.
- Non-record type resources, such as processors and UI pages without the snc_external role or a role that inherits the snc_external role.
- dashboards.

Do not mark the snc_internal role as elevated. Otherwise, internal users cannot access the instance.

**Note:** You can set up encryption contexts with the snc_internal and snc_external roles. However, adding encryption contexts to more detailed roles is recommended. For more information, see .

### Explicit Roles plugin

When the Explicit Roles plugin is activated:

- All users must have the snc_internal role to access internal resources or the snc_external role to access external resources. Users without either explicit role can access only public resources.
- All existing users are automatically assigned the snc_internal role. This role does not change existing access levels or system behavior. Instead, it provides a category to differentiate internal users from external users. All internal users maintain the same level of access as before the plugin was activated.

**Tip:** To prevent changing existing functionality for users, activating the Explicit Roles plugin assigns the snc_internal user role to all existing users in the instance. This includes any external users added before
the Explicit Roles plugin was activated. After the Explicit Roles plugin is activated, do the following for all external users added before the Explicit Roles plugin was activated:

• Remove the snc_internal role.
• Add the snc_external role.

Doing the preceding ensures that external users added before activating the Explicit Roles plugin do not have access to internal resources that should be available only to internal users.

• Newly created users are automatically assigned the snc_internal role when they first attempt to log in to the instance, unless they have been explicitly assigned the snc_external role. You can add the snc_external role to a new user before they first log in to the instance to provide external user rights.

**Important:** Activate this plugin during a maintenance window or when few users are logged in. Users currently logged in when the plugin is activated will not be dynamically assigned the snc_internal role. Rather, users must log out and log back in to be assigned the snc_internal role. Once the plugin is activated, you can add or remove the snc_internal and snc_external roles at any time to change user rights.

• All existing ACLs that do not have a role requirement are automatically assigned the snc_internal role. Because both existing ACLs and users are assigned the snc_internal role, existing access levels do not change.
• Newly created ACLs that do not have a role requirement are automatically assigned the snc_internal role. This role assignment does not apply to a newly created ACL with a role assigned.
• For all existing Processor [sys_processor] records or newly created Processor [sys_processor] records with **Type=script**, the snc_internal role is automatically added to the Roles field if the field is empty.
• To restrict access to UI pages to internal users, the plugin automatically assigns the snc_internal role to the * ACL with a **Type of ui_page**.
• To restrict access to processors to internal users, the plugin automatically assigns the snc_internal role to the * ACL with a **Type of processor**.
• External users must obtain, at minimum, the snc_external role to access the instance. This role must be manually granted to external users. Access to records is granted through ACLs.

Do not move system update sets among instances with and without the Explicit Roles plugin enabled. For more information, see System update sets.

**Note:** This plugin also requires the Contextual Security Manager plugin.

**Providing table access to external users**

You can provide external users access to a table by adding a role to the table that inherits the snc_external role. For more information, see Provide external users access to a table.

**The hasRoles() method**

The hasRoles() method is still available, but is deprecated in the Geneva release. Use the hasRole(role name) method instead.

If you do use the hasRoles() method, note these changes:

• This method automatically excludes the default snc_internal role when it checks for roles. This means that if a user has only the snc_internal role, the hasRoles() method still returns false.
• If the user has the snc_external role, the method returns false because the instance considers external users to be without a role.

**Mutual exclusion: snc_external versus snc_internal**

The prevents users from having both the snc_external role and the snc_internal role. The applies this mutual exclusion everywhere in the system and writes error messages to the logs for each conflict.

**Note:** ACLs can have both roles if the ACL resources should be accessible to all users.

Example: Adding both explicit roles to a user (direct collision):

1. Assign user Abel Tuter the snc_internal role.
2. Assign user Abel Tuter the snc_external role.

Result: Adding the snc_external role fails because Abel Tuter has the snc_internal role.

Example: Adding both explicit roles to a group (direct collision):

1. Consider a group called Test Group that currently has no explicit roles assigned to the group.
2. Add Abel Tuter to the Test Group.
3. Add the snc_external role to Test Group.

Result: Adding the snc_external role fails because Abel Tuter already has the snc_internal role and can't have both roles.

Example: Adding an explicit role to a group where a group member has the conflicting explicit role (indirect collision):

1. Assign user Abel Tuter the snc_internal role.
2. Consider a group called Test Group that currently has no explicit roles assigned to the group.
3. Add Abel Tuter to the Test Group.
4. Add the snc_external role to the Test Group.

Result: Adding the snc_external role to the group fails because Abel Tuter would inherit the snc_external role through group membership. Both explicit roles would be assigned to the same user, which isn't allowed.

For other examples, see the following table:

<table>
<thead>
<tr>
<th>Role</th>
<th>Attempted action</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Direct collision</td>
<td></td>
<td></td>
</tr>
<tr>
<td>The user has the snc_internal role.</td>
<td>Add the snc_external role.</td>
<td>The action is aborted.</td>
</tr>
<tr>
<td>The user has the snc_external role.</td>
<td>Add the snc_internal role.</td>
<td>The action is aborted.</td>
</tr>
<tr>
<td>The user has no explicit role.</td>
<td>Add the snc_internal or snc_external role.</td>
<td>The role is added.</td>
</tr>
<tr>
<td>The user has both explicit roles (existing collision).</td>
<td>Add the user to a group with no roles.</td>
<td>The action is aborted.</td>
</tr>
<tr>
<td>A role not associated with any users contains the snc_internal role.</td>
<td>Add the snc_external role.</td>
<td>The action is aborted.</td>
</tr>
<tr>
<td>A role not associated with any users contains the snc_external role.</td>
<td>Add the snc_internal role.</td>
<td>The action is aborted.</td>
</tr>

<tr>
<td>A group with no members has no roles.</td>
<td>Add the snc_internal or snc_external role.</td>
<td>The role is added.</td>
</tr>
</tbody>
</table>

**Indirect collision**

<table>
<thead>
<tr>
<th>Role containment with collision</th>
<th>1. Grant a role called Test Role to a user with the snc_internal role.</th>
<th>The action is aborted.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Role containment without collision</td>
<td>1. Grant a role called Test Role to a user with no roles.</td>
<td>The role is added to both the user and Test Role.</td>
</tr>
<tr>
<td></td>
<td>2. Add the snc_external role to Test Role.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Group containment with collision</th>
<th>1. Add a user who has the snc_internal role to a group called Test Group 2 (child of Test Group 1).</th>
<th>The action is aborted.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>2. Add the snc_external role to Test Group 2.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>3. Add the snc_external role to a parent group called Test Group 1 (parent of Test Group 2).</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Group containment without collision</th>
<th>1. Add a user with no roles to a group called Test Group 2 (child of Test Group 1).</th>
<th>The role is added to the parent group, the child group, and the user.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>2. Add the snc_external or snc_internal role to Test Group 1 (parent of Test Group 2).</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Group containment plus role containment with collision</th>
<th>Add contains_external to Test Group 1, the parent of Test Group 2.</th>
<th>Test Group 1 and Test Group 2 both get contains_external, but don’t explicitly get the snc_external role.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Add the snc_internal role to Test Group 2, the child of Test Group 1.</td>
<td>The action is aborted.</td>
</tr>
</tbody>
</table>
### Role

<table>
<thead>
<tr>
<th>Attempted action</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Remove Test Group 1 as the parent of Test Group 2.</td>
<td>The action is aborted.</td>
</tr>
<tr>
<td>2. Add the snc_internal role to Test Group 1.</td>
<td>Repeat for already nested groups, with the same expectation.</td>
</tr>
<tr>
<td>3. Add the snc_external role to Test Group 2.</td>
<td></td>
</tr>
<tr>
<td>4. In Test Group 2, set Test Group 1 as the parent group and save.</td>
<td></td>
</tr>
</tbody>
</table>

The cause of an aborted action appears in the error message and must be addressed before another attempt succeeds. For direct cases, such as adding an explicit role to an individual user, verify which explicit role the user should have. If the user has the wrong explicit role, it must first be removed, and then the correct explicit role must be added.

For indirect cases, such as adding an explicit role to a group (so that a group member would be assigned both explicit roles), evaluate whether that user should be in the group. Also determine whether the group should be given the explicit role, including any inheritance through group hierarchy and role containment.

Note that reports only the first potential collision encountered. If repeated attempts continue to fail after remediation, with a new root cause each time, re-evaluate the relevant user/group/role interdependence more broadly. You may want to rethink how groups and role containments are structured.

## Request Explicit Roles

Activate Explicit Roles by requesting the Explicit Roles plugin (com.glide.explicit_roles) through the Now Support Service Catalog.

Role required: admin

**Important:** Activate this plugin during a maintenance window or when few users are logged in. Users currently logged in when the plugin is activated will not be dynamically assigned the snc_internal role. Rather, users must log out and log back in to be assigned the snc_internal role. Once the plugin is activated, you can add or remove the snc_internal and snc_external roles at any time to change user rights.

1. Navigate to System Applications > All Available Applications > All.
2. On the All Applications page, click **Request Plugin** to open the Request form on HI.
3. On Now Support, select the redirect link to access the Now Support Service Portal Service Catalog.

<table>
<thead>
<tr>
<th>Activate Plugin request form</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Field</strong></td>
</tr>
<tr>
<td>Target Instance</td>
</tr>
<tr>
<td>Plugin Name</td>
</tr>
<tr>
<td>Specify the date and time you would like this plugin to be enabled</td>
</tr>
<tr>
<td>Reason/Comments</td>
</tr>
</tbody>
</table>

4. On the form, fill in the fields.

5. Click Submit.

**Elevated privilege roles**

Elevated privilege roles require you to manually accept the responsibility of using the role before you can access the features of the role.

By default, you do not have elevated privilege roles upon login. You must manually elevate to the privilege of the role. An elevated privilege role lasts only for the duration of your user session. Session timeout or logout removes the role.

You can designate any role as an elevated privilege role, and then assign that role to one or more users. Do this when you want to restrict users from having access to the rights that the role provides immediately after login. You can designate the privilege role on the Role form. See Create a role for instructions.

To use an elevated role, you must meet these conditions:
• The elevated role must be assigned to you.
• You must manually elevate to a specific elevated role to get its privileges, even if you are already elevated to a second elevated role that contains the first elevated role.

For example, if elevated role A contains elevated role B, even if you elevate to role A, you must still elevate to role B to get its privileges.

The admin role

To grant the admin role to a user, the granting user must also have the admin role. For example, a user with only the user_admin role cannot grant the admin role to other users.
• Non-admin users cannot add a user to a group that contains the admin role.
• To grant the security_admin role to a user, the granting user must also have the admin role and must elevate to the security_admin role before granting the security_admin role to other users. A user with only the admin role cannot grant the security_admin role to other users.
• A user without the security_admin role cannot add a user to a group that contains the security_admin role.

Warning: The use of elevated privilege on the admin role is not supported and may cause unexpected behavior. To require administrators to manually elevate, see Force administrators to manually elevate.

The security_admin role

In the base system, the security_admin role is the only role that has elevated privileges. This role is automatically assigned to the user who is the default System Administrator (admin) user. It provides access to ACLs and High Security Settings.
Roles assigned to the System Administrator (admin) user

Note: To see this role, you must actually elevate to the security_admin role first. If you are logged in as the System Administrator (admin) user only, you cannot see the security_admin record in the list of roles.
The security_admin role record

security_admin role

The security_admin role is an elevated privilege role provided with High Security Settings that lets users create and change access controls and change High Security Settings.

In the base system, only the default System Administrator (admin) user has the security_admin role. Since it requires elevating privileges, the admin user does not have this role at login. After elevating privileges, the admin user has the security_admin role for the duration of the user session.
**Note:** The record for the System Administrator (admin) role is only visible to users who elevate privileges to the security_admin role.

To maintain high security, the security_admin role requires elevating privileges. Limit the users and groups to which you assign this role.

**Elevate to a privileged role**

The base system admin can elevate to a privileged role to have access to the features of High Security Settings.

Role required: admin

**Note:** If you grant additional users the admin role, they cannot elevate to a privileged role. Only the out-of-box admin can elevate.

1. Do the appropriate action for your version of the UI:

| UI16 |  
|------|---
| a.   | In the banner frame, click your user name.  
| b.   | Select **Elevate Roles**. |
In the banner frame, click the lock icon (🔒) by your user name.

A dialog box appears.

2. Select an elevated role and click OK. This role grants the user elevated privileges to all resources controlled by the role for the remainder of the session. When the user logs out, the elevated privileges are terminated and must be reestablished at the next login. When elevated privileges are activated, the icon has an unlocked appearance.

Note: Any edits being made when the page reloads are lost.

**Force administrators to manually elevate**

A property is available to force all users with the administrator role to manually select the role they want to elevate to.

Role required: security_admin

1. Log in as admin.
2. Elevate your role to security_admin.
3. Navigate to sys_properties.list.
4. Search for and select the glide.security.strict_elevate_privilege property.
5. Set the Value field to true and click Submit.

When the user logs in, they are presented with a dialog window to select the role to which they can elevate.
Login and authentication security

Configure login security options to control access to your instance.

Security options

You can control several aspects of user login and authentication security:

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
<th>Related topics</th>
</tr>
</thead>
</table>
| Log in and log out controls | Control several dimensions of the log in and log out process for users, such as specifying a landing page that the user sees upon login and control how users log out. | • Define login scenarios  
• Enable the logout confirmation prompt  
• Remove the Logout button  
• Installation exits  
• Specify lockout for failed login attempts |
| Authentication security | Control the password reset process and features like the Remember Me option. You can also use IP address-based controls for access to the instance and implement a nonce to be used with single sign-on digest authentication. | • Strengthen password validation rules  
• Example: The default self-service Password Reset process  
• Change settings for the Remember me check box and cookie  
• IP range based authentication  
• Implementing a nonce |
Define login scenarios

You can direct all users to the same page after login.

Role required: admin

When users log on to an instance directly, such as going to http://[instance_name].service-now.com/, the system does the following:

1. Accesses the value in the property `glide.entry.page.script`. The default value of the property is derived from a script include named `CMSEntryPage`.
2. Directs the user to the instance login page if the entry page requires a login.
3. Applies login rules, if any, to the user.

To force the system to direct all users to the same page after login:

1. Navigate to `Content Management > Configuration > Configuration Page`.
2. Select a value for the `Login page` field, or create a new page as desired. If this page is not the site default page, it always redirects here. If it is a site default page, it applies login rules. If this value is null, the system uses `navpage.do` as the entry page. Do not enter a login page here; otherwise, users need to log in twice.

Logging Into an Instance to access a record:

When users log into an instance to access a record by its globally unique identifier (sys_id), such as http://[instance].service-now.com/incident.do?sys_id={sys_id}, then the system does the following:

a. Directs the user to a login page if not already logged in.

b. Directs the user to the appropriate record if they are allowed to access it. If the user does not have access rights to the record, a denial of access message appears.

Logging Into the Service Portal or a CMS site:

When users log on the Service Portal or a CMS site, such as http://<instance>.service-now.com/site-name/page.do, the system does the following:

- If there is a value in the `Login page` field on the Service Portal or the CMS site form, it directs the user to that login page and applies login rules, if any, to the user.
- If there is no login page specified, it directs the user to the value in the `Home page` field on the Service Portal or the CMS site form.

Logging Into the Service Portal or a CMS Site to access a record:

When users log on to the Service Portal or a CMS site to access a record, such as http://{instance}.service-now.com/ess/incident_detail.do?sysparm_document_key=incident,{sys_id}, the system follows the same procedure and finally takes the user to the record. If the user does not have access rights to the record, a denial of access message appears.

Logins and the employee self-service portal

The system keeps track of the first starting page that a user is trying to access even if the user wants to log in to the Employee Self-Service Portal.

Consider the following scenarios.

Example 1:

1. A user is not logged in, and then tries to access a record using a specific SYS ID in the URL.
2. The system redirects the user to the login page.
3. Rather than logging in, the user tries to access another site, such as the Employee Self-Service (/ess) Portal.
4. The system redirects the user to the login page again.
5. The user logs in and is redirected to the record that the user was first trying to access rather than the Employee Self-Service Portal.

Example 2:
1. A user is not logged in, and then tries to access a record using a specific SYS ID in the URL through the Employee Self-Service (/ess) Portal.
2. The system redirects the user to the login page.
3. Rather than logging in, the user tries to access another record through the Employee Self-Service Portal.
4. The system redirects the user to the login page again.
5. The user logs in and is redirected to the first record rather than the second.

Specify a login landing page

By default, users see their homepage upon login. You can specify a different login landing page by using a system property or the content management system.

Role required: admin

To specify a login landing page for all users, change the property value on the sys_properties table.

1. Type sys_properties.list in the navigation filter.
2. Locate the glide.login.home system property.
3. In the Value field, enter the name of the page that all users see upon login.

Use <page name>.do; you may omit the http://''instance''.service-now.com/ portion of the URL. To determine the page name or the URL of a page in the system, you can point to a link. Some possible pages are welcome.do and incident.do.

To specify a dashboard landing page, set the property to $dashboards.do?dashboard=<SYS_ID>. Replace <SYS_ID> with the sys_id of the dashboard.

Note: This property is system-wide, so setting it affects all users.

You can also specify a login landing page with the content management system.

Specify lockout for failed login attempts

The system provides inactive script actions that enable you to specify the number of failed login attempts before a user account is locked and to reset the count after a successful login.

Role required: admin

Navigate to System Policy > Script Actions to view or activate the scripts.

Note: Starting with the Kingston release, following a zBoot, the script actions SNC User Lockout Check with Auto Unlock and SNC User Clear are activated.
To learn more about properties that affect failed login attempts, see Managing failed login attempts (instance security hardening) in the Instance Security Hardening Settings.

<table>
<thead>
<tr>
<th>Script action</th>
<th>Description</th>
</tr>
</thead>
</table>
| SNC User Lockout Check with Auto Unlock | • Uses the value of the glide.user.max_unlock_attempts property to set the limit for failed login attempts.  
• Unlocks the user account after the time period that is specified for the glide.user.unlock_timeout_in_mins property. If no value is specified, then the system unlocks the user account after the default period of 15 minutes. |
| SNC User Lockout Check | Tracks the number of failed login attempts and locks the user account after a specified number of failed login attempts (default: 5). |
| SNC User Clear | Updates the user record after a successful login: Resets the number of failed login attempts and updates the date of the last login. |

Each time a user attempts to log in, the action is recorded in an event log. You can view a log of failed login attempts.

1. Navigate to System Policy > Event Logs.
2. Filter for login.failed in the Name field. You can view the attempted login name, date, and IP address logged for the attempt.

Make UI pages public or private

You can make pages public if you want your users to see the pages without logging in.

Role required: admin

Most pages are only viewable by logged in users. A limited number of pages are public so that users do not have to log in to view them, such as the welcome page, the front page, and the login and logout pages.

⚠️ Warning: Several base system public pages are required for the functionality of many features. Do not disable base system public pages.

1. In the application navigator filter, type sys_public.list.
2. Click New.
3. In the sys_public table, create a record with the following values.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Page</td>
<td>The name of the page. For example: $sp</td>
</tr>
<tr>
<td>Active</td>
<td>When selected, the page is publicly accessible. Deselect the Active option when you want the page to be private.</td>
</tr>
</tbody>
</table>

4. Click Save.

By setting active to true, the page is public, so anyone visiting <instance_name>/sp or <instance_name>/sp.do can access the page.

Enable the logout confirmation prompt

You can enable a logout confirmation prompt to prevent users from inadvertently logging themselves out.
Role required: admin

Note: The following procedure only works in UI versions earlier than UI16, which is the most recent and most commonly used one.

1. Navigate to System Properties > System.
2. Locate the Prompt user to confirm a logout request property and select the check box.
3. When the user clicks the Logout button, a confirmation dialog box displays.

![Confirmation dialog box](example.png)

Remove the Logout button

You can remove the Logout button to prevent inadvertent logouts.

Role required: admin

Note: The following procedure does not work in UI16.

1. Navigate to User Administration > User Preferences.
2. Delete the system preference user.can.logout.

Installation exits

Installation exits are customizations that exit from Java to call a script before returning back to Java.

Note: Functionality described here requires the Admin role.

Available installation exits

Navigate to System Definition > Installation Exits. Some installation exit names (Login, Logout, ValidatePassword, ExternalAuthentication) are reserved and cannot be changed. Other installation exits can override these with custom script that replaces the script in the default installation exit.

The following installation exits are available in the base system:

<table>
<thead>
<tr>
<th>Installation Exit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Login</td>
<td>Takes a username and password pair and authenticates with the user object</td>
</tr>
<tr>
<td>Logout</td>
<td>Takes the user to the welcome page upon signing out; can be overridden by LogoutRedirect</td>
</tr>
</tbody>
</table>
### Installation Exit

<table>
<thead>
<tr>
<th>Installation Exit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LogoutRedirect</td>
<td>Takes the user to a specified URL upon signing out</td>
</tr>
<tr>
<td>ExternalAuthentication</td>
<td>Authenticates using header, parameter, or cookie; can be overridden by DigestSingleSignOn and PGPSingleSignOn</td>
</tr>
<tr>
<td>DigestSingleSignOn</td>
<td>Authenticates using header, parameter, or cookie and decrypts Digest encryption</td>
</tr>
<tr>
<td>PGPSingleSignOn</td>
<td>Authenticates using header, parameter, or cookie and decrypts PGP encryption</td>
</tr>
<tr>
<td>ValidatePassword</td>
<td>Active by default, starting with the Helsinki release; allows customers to define their own password validation; can be overridden by ValidatePasswordStronger</td>
</tr>
<tr>
<td>ValidatePasswordStronger</td>
<td>Requires passwords be at least 8 characters long and contain a digit, an uppercase letter, and a lowercase letter</td>
</tr>
<tr>
<td>GetIntegrationSessionTimeout</td>
<td>Implements the default integration session timeout behavior.</td>
</tr>
</tbody>
</table>

### Login modifications

The following modification to the `Login` installation exit sets each user's session timeout value as the user is logging in. In this particular example, if the user name is `admin`, the session is set to timeout in 30 seconds.

```javascript
gs.include("PrototypeServer");

var Login = Class.create();
Login.prototype = {
  initialize : function() {
  },

  process : function() {
    // the request is passed in as a global
    var userName = request.getParameter("user_name");
    var userPassword = request.getParameter("user_password");

    var authed = GlideUser.authenticate(userName, userPassword);
    if (authed) {
      // ***********************************************************
      // customization - if the userName == admin, set the session
      // timeout to be 30 seconds. You can implement your own
      // session timeout algorithm here by checking to see if a user
      // belongs to a certain group or has a certain role.
      // Values of setTimeout exceeding 1440 minutes are
      // treated as one day (1440 minutes).

      if (userName == "admin") {
        request.getSession().setMaxInactiveInterval(30);
      }
      // ***********************************************************
      return GlideUser.getUser(userName);
    }

    this.loginFailed();
  }
};
```
return "login.failed";
},

loginFailed : function() {
    var message = GlideSysMessage.format("login_invalid");
    var gSession = GlideSession.get();
    gSession.addErrorMessage(message);

    var userName = request.getParameter("user_name");
    EventManager.queue("login.failed", ",", userName, ",");
}
}

Session timeout can also be set according to IP address.

gs.include("PrototypeServer");

var Login = Class.create();
Login.prototype = {
    initialize : function() {
    },

    process : function() {
        // the request is passed in as a global
        var userName = request.getParameter("user_name");
        var userPassword = request.getParameter("user_password");

        var authed = GlideUser.authenticate(userName, userPassword);
        if (authed) {
            // **************************************************************
            // customization - if the user is logging in from a particular IP
            // range starting with XXX.XXX you can implement your own
            // session timeout algorithm here by checking the login IP
            // / *
            // Values of setMaxInactiveInterval exceeding 1440 minutes are
            // treated as one day (1440 minutes).
            var clientIP = gs.getSession().getClientIP().toString();
            if (clientIP.indexOf('XXX.XXX') == 0) {
                // set to 10 hours
                request.getSession().setMaxInactiveInterval(60 * 60 * 10);
            }
            // **************************************************************
            return GlideUser.getUser(userName);
        }

        this.loginFailed();
        return "login.failed";
    },

    loginFailed : function() {
        var message = GlideSysMessage.format("login_invalid");
        var gSession = GlideSession.get();
        gSession.addErrorMessage(message);

        var userName = request.getParameter("user_name");
        EventManager.queue("login.failed", ",", userName, ",");
    }
}
Strengthen password validation rules

You can customize password strength validation rules for the change password screen by overriding the installation exit associated with password validation.

1. Navigate to System Definition > Installation Exits.
2. Locate ValidatePassword (inactive by default) and ValidatePasswordStronger (active by default, starting with the Helsinki release).
3. The ValidatePasswordStronger script (below) is a sample script that overrides the ValidatePassword script by using regular expressions to require that passwords be a minimum of 8 characters long, contain a numeric digit, and contain mixed-case letters.

```javascript
gs.include("PrototypeServer");
var ValidatePasswordStronger = Class.create();
ValidatePasswordStronger.prototype = {
  process : function() {
    var user_password = request.getParameter("user_password");
    var min_len = 8;
    var rules = "Password must be at least " + min_len + " characters long and contain a digit, an uppercase letter, and a lowercase letter."
    if (user_password.length() < min_len) {
      gs.addErrorMessage("TOO SHORT: " + rules);
      return false;
    }
    var digit_pattern = new RegExp("[0-9]", "g");
    if (!digit_pattern.test(user_password)) {
      gs.addErrorMessage("DIGIT MISSING: " + rules);
      return false;
    }
    var upper_pattern = new RegExp("[A-Z]", "g");
    if (!upper_pattern.test(user_password)) {
      gs.addErrorMessage("UPPERCASE MISSING: " + rules);
      return false;
    }
    var lower_pattern = new RegExp("[a-z]", "g");
    if (!lower_pattern.test(user_password)) {
      gs.addErrorMessage("LOWERCASE MISSING: " + rules);
      return false;
    }
    return true; // password is OK
  }
}
```

The script variable created by Class.create() must have the same name as the installation exit itself—"ValidatePasswordStronger" in this example. The script implements the process() function which returns true if the password is acceptable and false if the password must be revised. The gs.addErrorMessage function can be used to return error messages on the change password screen. You can try this Installation Exit in your instance by checking the active flag and updating the record. Be sure and clear the cache after doing this so the change is recognized.

Also, keep in mind that modifying these scripts will not change the default ServiceNow behavior: Blank passwords are still prohibited by default and the password and verify password fields must match.
To test, check the **Password needs reset** box on a user record then login with that user. Validation will occur at the point that the user attempts to set the password. Validation does not apply when an admin user updates the password in the user record directly (the admin can put anything in the password field).

**Note:** The change password screen only applies to customers who do not use single sign on and are not integrated with their local LDAP.

**Example: The default self-service Password Reset process**

The default self-service Password Reset process enables a user to reset the password without assistance from service desk agents.

**The default self-service password reset flow**

1. If a user does not remember the password, the user can click the **Forgot Password?** link on the login screen.

2. The Password Reset application starts. On the **Identity** page, the user identifies himself or herself by entering a **Username**.

3. On the **Verify** page, the user proves that they are the person who is associated with the username. In this example, the user enters the email address that is associated with the user profile. The admin can configure a different verification method or can require additional verifications, for example, a personal question that only the user can answer.
4. The Reset page tells the user to check email for instructions.

5. The user opens the email and clicks the here link to reset the password. The link is valid for a period that you specify (use the `password_reset.request.expiry` property).

6. The Reset Password page guides the user to reset the password.

The default self-service Password Reset process (`com.glideapp.password_reset`) defines:

- The URI that specifies where users are redirected when they click Forgot Password?. By default this value is `/Spwd_reset.do?sysparm_url=ss_default`, which is the same value used in the `glide.security.password_reset.uri` property. In previous releases, this value was set to `/reset_password.do`.
- The Enable Password Reset URL option, which specifies that the user should receive an email with a link to reset their password after they click Forgot Password?.
- The Personal Data - Enter Email Address verification flow that specifies the three-step password reset flow.

See for instructions on accessing this form and configuring the fields.
Modify the Password Reset notification email text

Users of the self-service Password Reset process receive an email notification when they request password reset. You can modify the text of the email and other aspects of the notification.

Role required: admin

This process is relevant only if users are subscribed to the notification.

1. Navigate to System Notification > Notifications.
2. Select the Password Reset URL notification.
3. Modify the text of the email in the What it will contain section.

For information on configuring other aspects of the notification, see Create an email notification.

Configure Password Reset properties

You can specify properties that configure the Password Reset experience for end users.

Role required: password_reset_admin

While there are no range limits for the values you can enter for properties, consider using only positive integer values starting at 1. When you determine the limit for the upper range of a property, consider the task that the user is performing.

For example, you would not want to allow 100 attempts for users to verify their identity. A more common value is 3 attempts. Similarly, you may not want to force users who are completing the enrollment process to spend time selecting and answering 30 security questions. The more commonly used number of security questions is between 5 and 7.

1. Navigate to Password Reset > Properties.
2. Update settings as needed and then click Save.

</tr>
</tbody>
</table>

**Note:** Several components in the Self Service Password Reset (com.snc.password_reset) plugin and the Password Reset (com.glideapp.password_reset) plugin control the password reset flow. The following properties affect Password Reset, but do not appear on the Password Reset Properties page:

- You can add the glide.pwd_reset.onetime.token.validity property to the System Properties [sys_properties] table to specify the number of hours that the Password Reset token should be valid. Default: 12.

**Note:** The setting for the password_reset.request.expiry property (time period during which a user must perform the Password Reset process) takes precedence over the setting for glide.pwd_reset.onetime.token.validity.

Properties accessible from the System Properties [sys_properties] table:

- For Password Reset on mobile devices, you can specify the URL that the user is taken to when user taps the Forgot password? button. See the glide.security.password_reset.uri property in High Security Settings. Default: /pwd_reset.do?sysparm_url=ss_default
- If glide.security.forgot_password.display.link is set to true, displays the Forgot Password? link on the login page.
Change settings for the Remember me check box and cookie

When the Remember me check box is selected at login, a cookie is stored on the user's computer. This cookie automatically authenticates the user upon subsequent visits.

If the user logs out, the cookie is destroyed. The default value of the Remember me check box is controlled by one property, and whether or not the check box appears on the login page is controlled by a different property.

Two properties, glide.ui.user_cookie.life_span_in_days and glide.ui.user_cookie.max_life_span_in_days control the glide_user system generated cookie expiration value. When a user accesses an instance with 'remember me' enabled, the access resets the cookie expiration period until the maximum (glide.ui.user_cookie.max_life_span_in_days) life span limit is reached.

Note: To learn more about these properties, see the following topics in Instance Security Hardening Settings:
• Absolute session timeout (instance security hardening)
• Session window timeout (instance security hardening)

Change the default value of the Remember me check box

You can change the default value of the Remember me check box.

Role required: admin

1. Navigate to System Properties > UI Properties.
2. Locate the Default value of "Remember me" checkbox on login page property (glide.ui.remember.me.default).
3. To set the default value of the Remember me check box to No, clear the property check box.
4. To restore the default value of the Remember me check box to Yes, select the property check box.

Remove the Remember me check box

You can remove the Remember me check box so users do not have access to this feature.

Role required: security_admin

Note: To learn more about this property, see Remove remember me (instance security hardening) in Instance Security Hardening Settings.

1. Elevate your role to security_admin.
3. Locate the Remove "Remember me" checkbox from login page property (glide.ui.forgetme).
4. Select the property check box.
   This setting removes the Remember me check box, invalidates existing cookies, and disables Remember me functionality entirely.
5. To restore the Remember me check box to the login page, clear the property check box.

IP range based authentication

One way to secure a web-based application is to restrict access based on the IP address.

You can block access to a specific address or range of addresses that you suspect belong to malicious individuals. The instance allows you to control access by IP address.
Notes and Limitations:

- The system won't let you lock yourself out, so if you try to add a rule such that your current address would be locked out, the system warns you and refuses your insert.
- If you're inside of a corporate intranet, be very careful about setting up your IP rules. The IP address you see on your own computer (like 10.10.10.25) generally bears no relationship to the IP address you'll actually appear as out on the internet. Your company likely proxies and/or NATs your address into a predictable set of outbound addresses which you'll likely need to ask your network team about.
- A user whose access is restricted based on an access rule gets a 403 error on their browser.
- Restricted users do not use transactions, semaphores, or count towards any server resource counts.
- This feature does not supersede or override your existing access control rules if, for example, you're running a VPN to our data center. It's an additional check that must be met in addition to any access controls we may have set up on your PIX.
- Allow rules always supersede deny rules. So if an address is both allowed (by one rule) and denied (by a second rule) it is, in fact, allowed.
- Asterisks and CIDR blocks are not currently supported.
- Regarding forwarded proxy addresses, the allow rules are applied to each address in the chain and then the deny rules are applied to each address in the chain if none of the allow rules matched.

**Note:** To learn more about the com.snc.ipauthenticator and glide.ip.authenticate.strict properties, which restrict instance access to specific IP ranges, see the following topics in Instance Security Hardening Settings:
- Restrict access to specific IP ranges (instance security hardening)
- Strict IP restriction (instance security hardening)

### IP Address Access Control

Apply an IP access control to outbound traffic, inbound traffic, or bidirectional traffic. The system only blocks an IP address if a matching Deny rule exists and no matching Allow rule exists. By default, there are no restrictions on access to your instance.

**Role required: admin**

1. Navigate to **System Security > IP Address Access Control** to see a list of your IP access controls. You might have to activate the IP Range Based Authentication [com.snc.ipauthenticator] plugin.
2. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>The type of access control rule to include.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Allow</strong>: Any IP address in this range can interact with this instance.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Deny</strong>: Any IP address in this range cannot interact with this instance unless it is listed in an Allow rule. Also, when adding deny rules, you cannot deny your own public IP address or your instance does not update a deny rule.</td>
</tr>
</tbody>
</table>

**Note:** To support maintenance, upgrades, and Customer Service and Support, some ServiceNow internal IPs cannot be blocked by Deny rules.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Direction</td>
<td>The direction of the IP access control rule.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Inbound</strong>: Allows or denies inbound transactions.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Outbound</strong>: Allows or denies outbound transactions.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Bidirectional</strong>: Allows or denies both inbound and outbound transactions.</td>
</tr>
</tbody>
</table>
## Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active</td>
<td>When selected, the form is active.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the access control.</td>
</tr>
<tr>
<td>Range Start</td>
<td>The starting range of IP addresses to allow or deny.</td>
</tr>
<tr>
<td>Range End</td>
<td>The ending range of IP addresses to allow or deny.</td>
</tr>
</tbody>
</table>

**Note:** These rules also affect transferring update sets. To ensure that IP address access control does not cause update sets to fail, add the target instance as an exception.

**Note:** To limit access to specific VPN addresses only, enter a Deny range of 0.0.0.0 through 255.255.255.255 into the Deny field, and only enter the specific allowed VPN ranges.

3. Click **Submit**.

### Find denied IP addresses

Denied IP addresses are by default not viewable from the system logs. However, you can still find them in the instance's node log files.

**Role required:** admin

Log entries for blocked IP address appear as follows:

```
```

1. Navigate to **System Logs > Utilities > Node Log File Browser**.
2. Browse the logs by criteria, such as time period and message.
3. You can also download log files when you know which log you are looking for, by navigating to **System Logs > Utilities > Node Log File Download**.

### Implementing a nonce

You can implement a nonce to be used with single sign-on digest authentication.

To use a nonce with the unencrypted token or encrypted token methods of single sign on, these steps apply with only a few minor changes.

**Note:** The nonce is used only for login requests, not for any other type of request. If the system receives a nonce value after login, the nonce is not consumed.

### Benefits

The usage of a nonce prohibits a malicious user from performing a replay attack in order to log into your system.

### Nonce process flow

When a customer has implemented the digested token Single Sign-on and wishes to add the security of a nonce, they follow a certain process flow.
1. A user logs into the customer's portal.

2. The customer generates the required SSO parameters and appends a random nonce to the end. For example, if the customer were forwarding the authentication response via the query string, it may look something like this:

   SM_USER=itil&DE_USER=V1QuWMnxSfBgfRS099XOcAjKo5Q=&NONCE=1407743018

The instance receives this request and retrieves the authentication variables. Before attempting to verify the integrity of the authentication response, the instance checks the nonce against an internal table (u_authentication_nonce) to verify that it does not yet exist. If the nonce does not exist within that table, the nonce is then added to the table and the authentication process is allowed to continue. However, if that nonce value already exists within the table, the authentication attempt is cancelled and an error code of failed_missing_requirement is returned, which typically takes the user back to the login page.

**Implement a nonce**

Add a cryptographic nonce to the authentication header to ensure that it can only be used once.

- Create a system property called glide.authenticate.header.nonce_key and set its value to whatever variable name you're using for the nonce, such as NONCE or NCE.
- Create a new table called u_authentication_nonce. Add a field to the table called u_nonce.
- Go to System Properties > Installation Exits and create an item called DigestSingleSignOnNonce which overrides ExternalAuthentication (see image below).

![Installation Exit](image)

- Add the following code to the script portion of the newly created DigestSingleSignOnNonce.

```javascript
gs.include("PrototypeServer");
var DigestSingleSignOnNonce = Class.create();
DigestSingleSignOnNonce.prototype = {
    process : function() {
        var headerKey = GlideProperties.get("glide.authenticate.header.key", "SM_USER");
        var headerDigestKey = GlideProperties.get("glide.authenticate.header.encrypted_key", "DIGEST");
        var headerNonceKey = GlideProperties.get("glide.authenticate.header.nonce_key", "NCE");
```
var fieldName = GlideProperties.get("glide.authenticate.header.value", "user_name");
var fkey = GlideProperties.get("glide.authenticate.secret_key");

// Look in the Headers
var data = request.getHeader(headerKey);
var encdata = request.getHeader(headerDigestKey);
var nonce = request.getHeader(headerNonceKey);

// If not, then check the URL Parameters
if (data == null || encdata == null || nonce == null) {
  data = request.getParameter(headerKey);
  encdata = request.getParameter(headerDigestKey);
  nonce = request.getParameter(headerNonceKey);
}

// then maybe its a cookie
if (data == null || encdata == null || nonce == null) {
  var cookies = request.getCookies();
  data = GlideCookieMan.getCookieValue(cookies, headerKey);
  encdata = GlideCookieMan.getCookieValue(cookies, headerDigestKey);
  nonce = GlideCookieMan.getCookieValue(cookies, headerNonceKey);
}

// if found run encryption
if (data != null && encdata != null && nonce != null) {
  try {
    // Replace all spaces with plus(+)’s, converted in url
    encdata = encdata.replaceAll(' ', '+');

    // ----- Encrypt the username|nonce
    var key = this.getDigest(data + "|" + nonce, fkey);

    // Check for match of received encoded data
    // and your encoding of user name
    if (encdata == key) {
      var ugr = new GlideRecord("sys_user");
      ugr.initialize();
      if (!ugr.isValidField(fieldName)) {
        GlideLog.warn("External authorization is set to use field: "+
        fieldName + " which doesn't exist");
        return "failed_missing_requirement";
      }
      ugr.addQuery(fieldName, data);
      ugr.query();
      if (!ugr.next()) { return "failed_authentication";
        ugr.initialize();
        ugr.addQuery(fieldName, data);
        ugr.query();
        if (!ugr.next())
          return "failed_authentication";
      }
      if (this.processNonce(nonce)) {
        var userName = ugr.getValue("user_name");
        return userName;
      } else return "failed_missing_requirement";
  
  } else return "failed_missing_requirement";
}
} else {
    return "failed_authentication";
}
} catch(e) {
    gs.log(e);
    return "failed_authentication";
} // Encoded data didn't match received encoded data
} else {
    return "failed_missing_requirement";
}
,

getDigest : function( data, fkey ) {
    try {
        // default to something JDK 1.4 has
        var MAC_ALG = "HmacSHA1";
        return SncAuthentication.encode(data, fkey, MAC_ALG);
    } catch (e) {
        gs.log(e.toString());
        throw 'failed_missing_requirement';
    }
},

processNonce : function( sentNonce ) {
    var ngr = new GlideRecord("u_authentication_nonce");
    ngr.addQuery("u_nonce", sentNonce);
    ngr.query();
    if (ngr.next()) {
        gs.log("This SSO entry has already been processed! (Nonce: " + sentNonce + ")");
        return false;
    }
    var ngrNew = new GlideRecord("u_authentication_nonce");
    ngrNew.initialize();
    ngrNew.u_nonce = sentNonce;
    ngrNew.insert();
    gs.log("Inserted new nonce: " + sentNonce);
    return true;
}

- Once you've saved your new installation exit, go to the DigestSingleSignOn installation exit and make sure that it is set Active=false.

Your instance should now be configured to implement a nonce.

Certificates

Your instance requires certificates to establish secure connections and validate signatures.

Certificates are used for features such as:

- LDAPS
- Outbound web services mutual authentication
- Web services security
• MID Server

In order to use a certificate, you need to generate or purchase a certificate for the secured server or client and upload it to an instance.

LDAP certificates

An SSL certificate is required for the instance to establish an LDAP over SSL (LDAPS protocol) connection with an LDAP server.

The instance accepts two types of LDAP certificates:

<table>
<thead>
<tr>
<th>Certificate</th>
<th>Type</th>
<th>Required for</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDAP server certificate</td>
<td>Any supported type</td>
<td>All LDAP configurations</td>
</tr>
<tr>
<td>LDAP client certificate</td>
<td>Java keystore type</td>
<td>Mutual authentication</td>
</tr>
</tbody>
</table>

If there are multiple server certificates, the instance tries each server certificate in turn until the LDAP server allows the connection. If you use multiple LDAP servers, be sure to include the SSL certificate for each LDAP server.

If your LDAP server requires mutual authentication, which requires the client to present a certificate in addition to the server, you must also provide your LDAP server’s client certificate in a Java keystore type certificate.

Certificate criteria

A valid certificate must meet these criteria:

• The certificate can have a key size up to 2048 bits.
• The certificate must have one of these file extensions:

<table>
<thead>
<tr>
<th>Extension</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DER</td>
<td>The Distinguished Encoding Rules format is a binary message transfer syntax. This format also supports the .CER and .CRT file extensions.</td>
</tr>
<tr>
<td>CER</td>
<td>Certificate file extensions for certificates using the Distinguished Encoding Rules format.</td>
</tr>
<tr>
<td>CRT</td>
<td>Certificate file extensions for certificates using the Distinguished Encoding Rules format.</td>
</tr>
<tr>
<td>PEM</td>
<td>The Privacy Enhanced Mail format is a base-64 encoded DER certificate enclosed between &quot;-----BEGIN CERTIFICATE-----&quot; and &quot;-----END CERTIFICATE-----&quot; text strings.</td>
</tr>
</tbody>
</table>

Certificate trust

By default, your instance trusts only certificates from a Certificate Authority (CA) recognized in the Java Virtual Machine (JVM). In this case, your instance does not trust self-signed certificates.
Generate an LDAP client certificate

Generate an LDAP client certificate for mutual authentication using OpenSSL. The final output is a PKCS#12 certificate stored within a Java keystore.

Role required: admin

See the OpenSSL documentation for more information about generating certificates. These steps assume you have access to OpenSSL.

Enter these commands in a command line interface.

1. Generate a self-signed client certificate.
   For example, this command creates a client certificate test1-cert.crt based on the test1-key.key private key.
   
   ```
   openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout test1-key.key -out test1-cert.crt
   ```

2. Convert both the certificate file and private key to PKCS#12 (a file with a .pfx or .p12 extension).
   For example, this command converts the client certificate and private key to a PKCS#12 certificate called test1-certificate.pfx.
   
   ```
   openssl pkcs12 -export -out test1-certificate.pfx -inkey test1-key.key -in test1-cert.crt
   ```

3. Generate the Java Key Store and import the pkcs12 file into it.
   For example, this command imports the certificate to the test1.jks Java keystore.
   
   ```
   keytool -importkeystore -srckeystore test1-certificate.pfx -srcstoretype PKCS12 -destkeystore test1.jks
   ```

4. Upload the certificate in the keystore file (test1.jks) to the instance.

Upload a certificate to an instance

Generate a server certificate

You can use keytool to generate a new Java keystore file, create a certificate signing request (CSR), and import the private key, public certificate pair, and signed certificates into the keystore.

Role required: admin

See the Java keytool documentation for more information on generating keys and CSRs.

Enter these commands in a command line interface:

1. Generate a Java keystore and key pair.
   For example, this command creates a keystore called my.keystore and generates a private key called mydomain within the keystore.
   
   ```
   keytool -genkey -alias mydomain -keyalg RSA -keystore my.keystore
   ```

2. Generate a CSR for an existing Java keystore.
   For example, this command generates a CSR called mydomain.csr or the mydomain key.
   
   ```
   keytool -certreq -alias mydomain -keystore my.keystore -file mydomain.csr
   ```
3. Import a root or intermediate certificate authority, or CA, certificate to the Java keystore. For example, this command imports the CA certificate for Thawte. This command assumes that Thawte was the CA that signed the CSR.

```
keytool -import -trustcacerts -alias root -file Thawte.crt -keystore my.keystore
```

4. Import a signed primary certificate to the Java keystore. For example, this command imports the signed certificate mydomain.crt into the keystore.

```
keytool -import -trustcacerts -alias mydomain -file mydomain.crt -keystore my.keystore
```

5. Upload the certificate in the keystore file (my.keystore) to the instance.

**Upload a certificate to an instance**

### Upload a certificate to an instance

You can add a certificate to the instance from the Certificates module.

Role required: admin

When a certificate is updated on the ADFS server, you also need to upload an updated certificate to the instance.

1. Navigate to **System Definition > Certificates**.
2. Click **New**.
3. Fill in the following fields (see table).

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Specify a unique name for the certificate.</td>
</tr>
<tr>
<td>Expiration notification</td>
<td>[Optional] Select whether you want to send a notification when the certificate is about to expire.</td>
</tr>
<tr>
<td>Active</td>
<td>Select whether the instance should use this certificate for secure communications and signing requests.</td>
</tr>
<tr>
<td>Short Description</td>
<td>[Optional] Enter a text description of the certificate such as the requester or server name.</td>
</tr>
<tr>
<td>Format</td>
<td>Select the certificate format. The instance supports the PEM and DER formats.</td>
</tr>
<tr>
<td>Type</td>
<td>Select the certificate container. The instance recognizes certificates from trust stores, Java keystore, and PKCS#12 keystores.</td>
</tr>
<tr>
<td>PEM Certificate</td>
<td>Enter the base-64 encoded PEM-formatted text containing the DER certificate. The instance decodes the certificate to populate the <strong>Valid from</strong>, <strong>Expires</strong>, <strong>Expires in days</strong>, <strong>Issuer</strong>, and <strong>Subject</strong> fields.</td>
</tr>
</tbody>
</table>

4. Click **Submit**.

During the upload, the module extracts and displays the certificate's read-only properties in these fields:

- Valid from date
- Expiration date
- Issuer
- Subject of the certificate
5. Click **Validate Stores/Certificates** to check if the certificate is correct. If the instance encounters any errors with the certificate or keystore, it displays an error message.

**Upload a trusted server certificate**

By uploading the service provider's trusted server certificate, the instance ensures it is connecting to a valid and secure service.

Role required: admin

The instance validates outbound Web Service calls by using the certificate provided by the service provider.

1. Create a new Certificate record with the type "Trust Store Cert".
2. Do one of the following actions:

- Attach the service provider’s DER formatted certificate.

- Copy and paste the service provider’s PEM format certificate into the **PEM Certificate** field.
**Web service security**

Enforce security using basic authentication, mutual authentication, or WS-Security.

**Basic Authentication**

To enforce basic authentication on each request for a WSDL document or posting of SOAP messages, you may set the property `glide.basicauth.required` to `true`. If you do so, each WSDL or SOAP request would have to contain the "Authorization" header as specified in the Basic Authentication protocol. Because the request is non-interactive, the **Authorization** header is always required during a request.

Supplying basic authentication information whether or not it is required has the added advantage that the data created or updated as a result of the Web Service invocation is done on behalf of the user supplied in the basic authentication credentials. As an example, when creating an Incident record, the journal fields have the user id of the basic authenticated user, instead of the default **Guest** user.

To make the authorization header ignore the capitalization rules, use the `glide.security.script.include.name.case.insensitive.list` property. You can modify this property in the System Properties [sys_properties] table and add the script includes that are necessary to process the authentication. By default, this property has these values:

- BasicAuth
- CustomAuth

Add other script includes as needed.

To supply basic authentication when using Perl and the SOAP::Lite libraries, you can implement the following function:

```perl
sub SOAP :: Transport :: HTTP :: Client :: get_basic_credentials { return 'user_name' => 'password' ; }
```

- When using C# .NET VS 2005 or older, you can take advantage of the Credentials object, for example:

  ```csharp
  
  service . ServiceNow proxy = new service . ServiceNow ( ) ;
  service . get getService = newservice . get ( ) ;
  service . getResponse getServiceResponse = new service . getResponse ( ) ;
  
  try {
  proxy . Credentials = cred ;
  getService . sys_id = "bf522c350a0a140701972dbf876f1610" ;
  getServiceResponse = proxy . get (getService ) ; catch (Exception ex )
  }
  ```

- When using C# .NET VS 2008, you can take advantage of the ClientCredentials object, for example:

  ```csharp
  Demo_Incident. ServiceNowSoapClient client = new Test08WebService .
  Demo_Incident. ServiceNowSoapClient ( ) ;
  client . ClientCredentials . UserName . Username = "admin" ;
  ```
Then in your app.config file look for the following and change "None" to "Basic":

```
<transport clientCredentialType= "None" proxyCredentialType= "None" realm= "" />
```

- When using VB .NET taking advantage of the Credentials object would look like the following:

```vbnet
Sub Main()
    Dim cred As New System.Net.NetworkCredential( "user_name", "password")
    Dim proxy As New VB_Democm.incident.ServiceNow
    Dim getIncident As New VB_Democm.incident.get
    Dim getResponse As New VB_Democm.incident.getResponse
    proxy.Credentials = cred
    getIncident.sys_id = "[your sysID here]"
    getResponse = proxy.get(getIncident)
End Sub
```

The resulting response when Basic Authentication is turned on and no credentials are supplied looks like this:

```html
<html> <head > <title >Apache Tomcat/5.0.28 - Error report </title > <style > <!--H1 {font-family:Tahoma,Arial,sans-serif;color:white;background-color:#525D76;font-size:22px;} H2 {font-family:Tahoma,Arial,sans-serif;color:white;background-color:#525D76;font-size:16px;} H3 {font-family:Tahoma,Arial,sans-serif;color:white;background-color:#525D76;font-size:14px;} BODY {font-family:Tahoma,Arial,sans-serif;color:black;background-color:white;} B {font-family:Tahoma,Arial,sans-serif;background:white;color:black;font-size:12px;} A {color&nbsp;:
black;} A.name {color&nbsp;: black;} HR {color&nbsp;: #525D76;}-->
</style > </head > <body > <p >HTTP Status 401 -
</p>
<p ><b >type </b> Status report </p>
<p ><b >message </b> <u >This request requires HTTP authentication ().</u>
</p>
<p ><b >description </b> "1" noshade = "noshade" > <p >"1" noshade = "noshade" > <p >"1" noshade = "noshade" > <p >Apache Tomcat/5.0.28 <= h3 > </body ></html>
```

### Setting up mutual authentication

Mutual authentication establishes trust by exchanging secure sockets layer (SSL) certificates.

Before connecting to a server, the client requests an SSL certificate. The server responds by requesting that the client send its own certificate. Both respond by validating the certificates and sending acknowledgments before initiating an HTTPS connection.

Administrators do the preliminary work of setting up a keystore and generating certificates before certification requests are fulfilled.

**Warning:** This feature enables mutual authentication on outbound https connections and inbound https connections.
Creating the Key Store

The instance currently supports uploading a Java keystore file to contain the private key, public certificate pair, and its signed certificates.

The following steps use commands that allow you to generate a new Java Keytool keystore file, create a certificate signing request (CSR), and import certificates. Any root or intermediate certificates need to be imported before importing the primary certificate for your domain. Type these commands in a command line interface.

1. Generate a Java keystore and key pair.
   ```
   keytool -genkey -alias mydomain -keyalg RSA -keystore my.keystore
   ```

2. Generate a CSR for an existing Java keystore.
   ```
   keytool -certreq -alias mydomain -keystore my.keystore -file mydomain.csr
   ```

3. Import a root or intermediate certificate authority CA certificate to an existing Java keystore.
   ```
   keytool -import -trustcacerts -alias root -file Thawte.crt -keystore my.keystore
   ```

4. Import a signed primary certificate to an existing Java keystore.
   ```
   keytool -import -trustcacerts -alias mydomain -file mydomain.crt -keystore my.keystore
   ```

Setting up the Key Store

Now that the key store has been created, it can be uploaded to the Certificates table. On the System Definition > Certificates page, click New and set the following fields:

- Enter a certificate Name.
- Store the key store as Active.
- Set Type = Java Key Store.
- Provide a Key store password. This is the password that was used to create the keystore.

Click Submit to create the Java Key Store entry.
Specifying a Trusted Server Certificate

During an outbound SSL connection, which is an HTTPS Web Service call, it is possible to specify a certificate provided by the service provider that ensures the validity of the service provider during the SSL connection. For example, a browser attempting to connect to a secure service which identifies itself by a certificate.

By uploading the trusted server certificate, ServiceNow ensures that the service it is connecting to is valid and secure.

Create a new Certificate entry with the type of "Trust Store Cert" and attach a DER formatted certificate, or copy and paste its PEM format into the **PEM Certificate** field.

Processing Mutual Authentication Requests

**Certificate Exchange**

- When a client requests the server certificate for authentication, a certificate signing request (CSR) is generated.
- To respond to a CSR, the server generates two unique cryptographic keys: A public key, which is used to encrypt messages to the server and a private key, which is used to decrypt messages. Both keys are kept in the Key Store.
- Keys are used to decrypt the client secure messages so they can be read by the server. Any outgoing connection that is going to be HTTPS verifies the certification by checking the Key Store, offering its public certification, and uses the trust store certificates to verify mutual trust back.
- To complete the secure link between the client and the server, the server matches the certificate to the corresponding private key. Because only the server has access to the private key, the server can decrypt the data from the client.

Here is an example of a command that registers MYHTTPS with the `com.glide.certificates.DBKeyStoreSocketFactory` socket factory on port 443. The database key store factory is used during the SSL exchange process to offer a client certificate for mutual authentication.

```bash
glide.httpclient.protocol.myhttps.class = "com.glide.certificates.DBKeyStoreSocketFactory"
glide.httpclient.protocol.myhttps.port = "443"
```
Having the above configuration affects any outbound myhttps://host.domain.com/target URL to use the custom socket factory and exchange certificates during SSL.

**Note:** Overriding the default HTTPS protocol socket factory affects every outbound HTTPS connection. This is usually undesirable.

The server responds by sending a certificate. Is this a certificate that the client accepts? If yes, a message is sent to the server accepting the certificate and a secure channel is initiated. If the certificate is not accepted, it may mean that the root authority is needed for certification.

**WS-Security**

Support for WS-Security 1.1 in the form of WSS X.509 Token Profile and WSS Username Token Profile is available for incoming SOAP requests.

The configuration to use WS-Security is separate from the requirement to enforce Basic Authentication, and is enforced when the SOAP envelope contains the WS-Security headers.

**WS Security Profiles**

The WS Security Profile module lists the WS-Security profiles that are currently in effect. The Order of the profiles indicates the order of authentication that is checked, all profiles are checked during the incoming SOAP request, when a profile fails authentication, it does not execute the next one in order. The Bind session check box indicates which profile to use to assume the session’s identity, there can only be one “bound” session.

**WS Security List**

**WSS X.509 Token Profile**

Use the X.509 authentication framework as defined by the Web Services Security: SOAP Message Security specification. An X.509 certificate specifies a binding between a public key and a set of attributes that includes (at least) a subject name, issuer name, serial number, and validity interval. An X.509 certificate is used to validate a public key that is used to sign the incoming SOAP message. Upload the certificate in the Certificate module and reference it in the X509 Certificate field. If this is a bound session, select the user to impersonate when the WS-Security authentication succeeds.

See the following document: [http://www.oasis-open.org/committees/download.php/16785/wss-v1.1-spec-os-x509TokenProfile.pdf](http://www.oasis-open.org/committees/download.php/16785/wss-v1.1-spec-os-x509TokenProfile.pdf)
WS x509

WSS Username Token Profile

In addition to specifying the X.509 Token Profile, a UsernameToken can also be supplied in the SOAP request. A UsernameToken is used as a means of identifying the requester by "username", and optionally using a password (or shared secret, or password equivalent) to authenticate that identity to the instance. The UsernameToken profile cannot be used independent of the X.509 Token Profile currently.

1. Authenticate using the Username of the incoming SOAP request to lookup a User by the specified User field to match UserName value. The password value in the incoming Username Token is used to authenticate the request. When the Bind session option is selected, the user that authenticates successfully is used for the session.

2. Authenticate using a separate pair of user name / password that is unrelated to users in the User table. When the Bind session option is selected, the user that is specified in the Run as user field is used for the session.

Example WS-Security SOAP Envelope Headers

Note:

This sample has been formatted with line returns to fit the content into the frame.

```xml
HTML sanitizer

Remove unwanted code and protect against security concerns such as cross-site scripting attacks by sanitizing HTML markup in HTML fields and translated HTML fields.

The HTML sanitizer works by checking the built-in inclusion list for markup that you always want to preserve. The sanitizer provides the HTMLSanitizerConfig script include that administrators can use to modify the built-in inclusion list. Items can also be added to the exclusion list, which overrides the inclusion list, to remove HTML markup.

The following types of items can be added to inclusion and exclusion lists:

- Global attributes
- Any HTML elements

Note: By default, URL attributes like href and src support only these protocols:
- http
- https
- mailto
- data

For example:

```
<a href="https://community.servicenow.com/community">Now Community</a>
```
Note: To learn more about the glide.html.sanitize_all_fields property that controls use of the HTML sanitizer, see HTML sanitizer (instance security hardening) in Instance Security Hardening Settings.

Configure urlAttributes and the protocols

You can configure urlAttributes and their protocols in the HTMLSanitizer script include. For example:

```javascript
HTML_WHITELIST : {
    urlAttributes: { "protocols" : [ "file", "notes" ] },
    - -
    - -
}
```

Because notes is in the inclusion list in the example above, this URL is not sanitized:

```html
<a title="Lotus" href="Notes://ABC/X575C90019DE33/
ABC594DCB76D86EB4925653E0011C4C1/Z290B7E2D33964749257EEA003456FD">Lotus</a>
```

The Default Inclusion List

```javascript
BUILTIN_HTML_WHITELIST :{
    globalAttributes:{ attribute:["id","class","lang","title","style"],
                        attributeValuePattern:{}},

    label:{ attribute:["for"],

    font:{ attribute:["color","face","size"],

    a:{ attribute:["href","nohref","name","shape"],

    img:{ attribute:
        ["src","name","alt","border","hspace","vspace","align","height","width"],

    table:{ attribute:
        ["border","cellpadding","cellspacing","bgcolor","background","align","no resize","height","width","summary","frame","rules"],

    th:{ attribute:
        ["background","bicolor","abbr","axis","headers","scope","nowrap","height","width","align","off","char","colspan","rowspan"],

    td:{ attribute:
        ["background","bicolor","abbr","axis","headers","scope","nowrap","height","width","align","off","char","colspan","rowspan"],

    tr:{ attribute:["background","height","width","align","valign","char off","char"],

    thead:{attribute:["align","valign","char off","char"]},

    tbody:{attribute:["align","valign","char off","char"]},

    tfoot:{attribute:["align","valign","char off","char"]},
```

Enable HTML sanitizer

The HTML sanitizer provides a property to enable or disable the sanitizer for all HTML fields in the system.

Role required: admin

By default, the property is set to true for new instances.

1. In the navigation filter, enter `sys_properties.list`.
2. Set the properties `glide.html.sanitize_all_fields` and `glide.translated_html.sanitize_all_fields` to true.

   **Note:** To learn more about this property, see HTML sanitizer (instance security hardening) in Instance Security Hardening Settings.

   If the properties do not exist in the System Properties table, you can add them.

Configure HTML sanitizer

You must modify a script include to make configuration changes to the HTML sanitizer.

Role required: admin

1. Navigate to System Definition > Script Includes.
2. Open HTMLSanitizerConfig.
3. To add items to the exclusion list, use the HTML BLACKLIST class. To add items to the inclusion list, use the HTML WHITELIST class.

   Use this format:

   ```
   HTML_XXXXLIST :{
       globalAttributes :{
           attribute:[attribute-name1,...],
           attributeValuePattern:{ attribute-name2:attribute-value-regex-pattern,...}
       },<html-element-name>:{// Same as Above},----}
   ```

   • **globalAttributes** contains attribute or attributeValuePattern items that are applicable globally for all the HTML elements.
   • **attribute** is a comma-separated list of attributes.
   • **attributeValuePattern** is a dictionary of attribute to attribute-value-regex-pattern pairs. The attribute-value-regex-pattern is a regular expression which has to match the attribute value.

   Consider the following example:

   ```
   HTML_WHITELIST:{
       globalAttributes:{
           attribute:["id","name"],},
       img:{
           attribute:["style","align"],
   ```
It adds the following items to the inclusion list:

- The global attributes id and name. This is a list of strings that can be applied globally to all the elements.
- The img element where the attributes are style and align.
- The img element where the source attribute of the image is a file with the .jpeg extension. This is an example of a regular expression pattern that matches an attribute value.
- The iframe element.

**Enable sanitization on individual fields**

You can use field attributes to enable or disable the sanitizer on individual fields.

Role required: admin

You need to first set the sanitizer property to false, and then enable the sanitizer on a per-field basis for any form.

1. Navigate to the sys_properties table and set the `glide.html.sanitize_all_fields` to **false**. This disables the sanitizer for all HTML fields in the system.
2. Navigate to the form that contains the HTML field.
3. Right-click the HTML field label, and select **Configure Dictionary**. The Dictionary Entry form opens for the HTML field.
4. Enter one of the following in the Attributes field:
   - To disable sanitization enter `html_sanitize=false`
   - To enable sanitization enter `html_sanitize=true`
5. Click **Update**.
6. To enable the HTML sanitizer for translated HTML fields, set the `glide.translated_html.sanitize_all_fields` property is **true**.

**Enable HTML Sanitizer logging**

When the HTML sanitizer removes elements or attributes, they are added to the system log.

You can review these sanitized elements by adding `/syslog_list.do?sysparm_query=source%3DHTMLSanitizer` to your instance URL.

1. To review these sanitized elements add `/syslog_list.do?sysparm_query=source%3DHTMLSanitizer` to your instance URL.
2. To enable or disable logging, add the `glide.html_sanitize.discarded_log.enable` property to the system properties and set the value to **true** (enabled) or **false** (disabled). This property is **true** by default.

**Encryption on the Now Platform**

Encryption is the process of scrambling data so that only authorized parties can understand information. Use encryption to protect sensitive information.

Encryption keys, formed from strings of bits used with an encryption algorithm, convert plaintext data into ciphertext that remains indecipherable to anyone who does not have access to the correct key.
Encryption gains its security benefits from the combination of the strength of the algorithms used and key management. ServiceNow key management makes encryption an effective control that is based on NIST 800-57 guidelines.

**Encryption on the Now Platform**

Information for all data may not require encryption. Consider the additional time required to process large amounts of data supported across every application. Therefore, determine the supported fields to be encrypted and use any of these Now Platform options:

**Platform Encryption**

Platform Encryption utilizes the Key Management Framework (KMF), which provides key-protection and key lifecycle management for application-level field encryption. All keys are protected with a key-wrapping hierarchy ultimately rooted in FIPS 140-2-L3 Hardware Security Modules (HSM). In addition to allowing for segregation of duties, KMF allows lifecycle management of the keys that encrypt and decrypt data on your instance to NIST 800-57 best practice. A subscription is required to enable Platform Encryption. For more information, see Platform Encryption and Key Management Framework (KMF).

**Encryption Support**

Encryption Support, also known as Column Level Encryption (CLE), is a built-in feature which permits encryption of string, date, date/time, or attachment fields using AES-128 or AES-256 in encryption contexts. You can encrypt existing non-system string fields or newly created fields. Column Level Encryption (CLE) contexts permit and deny access to encrypted data based on user role. See Encryption Support for more information.

**Edge Encryption**

Edge Encryption encrypts sensitive data on your company premises before sending it over the internet to your instance (encrypted in transit), where it remains encrypted at rest. Also referred to as ‘client-side’ encryption, Edge requires all bi-directional user traffic to pass through proxies that are maintained on your infrastructure. You have the full control over your key management, as the keys are stored within your proxy on your infrastructure and ServiceNow cannot decrypt your ciphertext to access your keys.

For more information, see Edge Encryption.

**Database Encryption**

Database Encryption enables all data to be protected with symmetric AES-256 encryption, whether the database is online or offline. From the Now Platform perspective, all data flows in decrypted. This capability is available for all supported releases. For more information, see Database encryption and full-disk encryption.

**Key Management Framework (KMF)**

The ServiceNow Key Management Framework (KMF) provides a secure and comprehensive interface for instance-side cryptographic key management services.

**Explore**

Understanding the Key Management Framework

The Key Management Framework (KMF) API/UX lets you fully customize and manage how cryptographic operations are performed on your ServiceNow instance.

In accordance with NIST 800-57 guidelines, KMF provides the following capabilities:

- Segregation of duties with dedicated roles for cryptographic management and operations, auditing, and integration
- Cryptographic modules enable configuration of cryptographic specifications for unique cryptographic purposes and key types
  - Symmetric key: Encryption and decryption, key wrapping and unwrapping, and authentication
  - Asymmetric key: Digital signature generation and verification, encryption and decryption, key wrapping and unwrapping
- Key lifecycle management to generate, rotate, revoke, and suspend keys, including support of several key lifecycle states
- Enforcement of access controls (module access policies), ensuring that only specified users are granted access to the cryptographic modules
- Key protection: FIPS 140-2-L3 hardware root of trust (RoT), Public Key Infrastructure (PKI), key hierarchy, and envelope encryption
- Auditing that includes key usage statistics

KMF activation

KMF is active by default.

Note: KMF does not support domain separation, but can be used with on-premise instances.

In order to use Platform Encryption or Column Level Encryption contexts, one of these plugins must be active:

Platform Encryption (com.glide.now.platform.encryption)

Platform Encryption uses the Platform Encryption with Key Management Framework through cryptographic modules and module access policies. For more information on obtaining Platform Encryption see Platform Encryption and Activate Platform Encryption.

Encryption Support (com.glide.encryption)

Encryption Support, also known as Column Level Encryption, uses encryption contexts based on role. For more information on Encryption Support see Encryption Support.

It is recommended that you use Platform Encryption, which is the successor to Encryption Support.

How KMF works

This graphic shows you the components that comprise KMF:

- The cryptographic module is the basis for defining the encryption method.
- The cryptographic specification is a configuration that defines an algorithm for encryption.
• The specification also lets you define the key for the module. Use a ServiceNow key or bring your own customer-supplied key using Platform Encryption.
• A module access policy is an instance-level policy that places limits on cryptographic modules. An example is setting the duration for the key validity.

For more information on KMF, start with Cryptographic module overview.

The Key Management Framework (KMF) introduces specific roles for cryptographic module and key management related configurations. Only KMF Admins can assign users to other KMF roles. See KMF roles for more information.

For more information on the encryption framework that replaces CLE, see Platform Encryption.
Cryptographic module overview
Cryptographic modules are the centerpiece of KMF. They define the specific cryptographic mechanisms used for cryptographic operations for a given use case.

An example is using AES-CBC with a 256-bit symmetric key to encrypt and decrypt data within an HR application, using Platform Encryption. Cryptographic modules also support best-practice key lifecycle management (generate, rotate, renew, revoke, suspend) and are the basis for defining the encryption method. See Key lifecycle states for details.

Logically, cryptographic modules are composed of the following components:

- Cryptographic specification: Defines cryptographic purpose and algorithms.
- Cryptographic keys: Define as either a ServiceNow key or with Platform Encryption, use your own customer-supplied key.
- Module access policies and module policy exceptions: Instance-level definition of cryptographic modules, such as how long the key is valid.

The following screen shows these high-level components in a cryptographic module:
Cryptographic module components

How KMF works

Cryptographic purpose and algorithms encompass algorithm definition, which includes algorithm (for example, AES), operation mode (for example, GCM), key size (for example, 128-bit), and cryptographic purpose. A default cryptographic specification template is provided out-of-the-box with recommended NIST algorithms and key sizes for configuration. See Cryptographic purpose, algorithms, and key information for details.
The cryptographic keys component involves the creation of the cryptographic module’s key. Generate cryptographic keys on the instance by ServiceNow or import customer supplied keys. This component also includes lifecycle definition and key management actions (for example, rotate).

Module access policies are the access controls mechanisms that can be applied to the cryptographic modules.

- Encryption Support: Module access policies can be based on scope (basic), role, or script.
- Platform Encryption: Policies can be based on scope (basic) or KMF Resource Exchange.

Refer to Create module access policy for details.

Module access policies can be used across multiple modules. Refer to Multiple modules access policy for details.

**Instance level keys in KMF**

The KMF architecture introduces a specific key structure built with security in mind. Using a Hardware Security Module (HSM), KMF uses envelope encryption to ensure that all platform keys under KMF management are protected through a chain of keys. Customer Data Encryption Keys (CDEKs) created by KMF are also included.

At the instance level, KMF defines several internal keys that are used internally for varying cryptographic purposes throughout the platform.

<table>
<thead>
<tr>
<th>Key</th>
<th>Location</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Root Key (RK)</td>
<td>HSM</td>
<td>Root key used to decrypt the IRK.</td>
</tr>
<tr>
<td>Instance Root Key (IRK)</td>
<td>HSM</td>
<td>Unique per instance, the IRK is used to envelope encrypt several instance internal keys.</td>
</tr>
<tr>
<td>Instance Keyed-hash Message Authentication Code Key (HMAC IHK)</td>
<td>Instance</td>
<td>Unique per instance, the IHK is used internally for HMAC purposes.</td>
</tr>
<tr>
<td>Instance Key Encryption Key (IKEK)</td>
<td>Instance</td>
<td>Unique per instance, the IKEK is used internally to envelope encrypt key material.</td>
</tr>
<tr>
<td>Instance Asymmetric Encryption Key (IAEK)</td>
<td>Instance</td>
<td>Unique per instance, the IAEK is used internally for asymmetric encryption purposes.</td>
</tr>
<tr>
<td>Instance Signature Key (ISK)</td>
<td>Instance</td>
<td>Unique per instance, the ISK is used internally for signing purposes.</td>
</tr>
<tr>
<td>Customer Data Encryption Key (CDEK)</td>
<td>Instance</td>
<td>Generated by customers, encryption keys created through KMF are envelope encrypted by the IKEK.</td>
</tr>
<tr>
<td>Instance Data Replication Data Encryption Keys (IDR DEKs)</td>
<td>Instance</td>
<td>Specific encryption keys use for the Instance Data Replication (IDR) process.</td>
</tr>
</tbody>
</table>

The instance root key (IRK) and instance internal key (IKEK) are unique per instance. The figure below provides an overview of the key relationships.

**Note:** The preceding table and the following figure show only a few examples of customer/app keys that are managed and protected by KMF.
Store on HSM

Root Key

Instance Root Key

Instance Internal Keys

IAEK

ISK

Customer/App Keys

Module keys

IDR DEKs

Unique per Instance
Envelope encryption is the practice of encrypting a key with another key. The following figure provides an example of the envelope encryption. Here, CDEKs are envelope encrypted by the IKEK, which in turn is envelope encrypted by the IRK, which is finally envelope encrypted by the RK. Since the IRK is only be accessed by the HSM, the IKEK must be uploaded for decryption.

Cryptography purpose, algorithms, and key information
Cryptographic specifications can be tailored to a specified cryptographic purpose, covering both asymmetric and symmetric key-based cryptographic operations. Selection of a cryptographic purpose offers further choices, namely to a set of supported algorithms and key length configurations.

<table>
<thead>

</table>

* AES-CBC (symmetric data encryption/decryption, symmetric key wrapping/unwrapping) supports equality persevering options. # utilizes AES-CBC. ** AES-GCM has data integrity built in.

The configuration of these parameters is covered in Create a cryptographic module.

**Key lifecycle states**

KMF supports several cryptographic key lifecycle states through the enforcement of specific allowable actions. For example, only keys that are in the active state can be used for their intended cryptographic purpose. The following table provides further detail on the varying key lifecycle states.

### Key lifecycle definitions

<table>
<thead>
<tr>
<th>Key lifecycle state</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>generated</td>
<td>Multiple keys can exist in the generated state for a given cryptographic specification in a cryptographic module. A generated key can be moved to an active state when no active key exists for the given cryptographic specification. The first key generated is automatically set to active.</td>
</tr>
<tr>
<td>active</td>
<td>There can be only one active key for a given cryptographic specification in a cryptographic module.</td>
</tr>
<tr>
<td>resume</td>
<td>Not a literal key state. A Resume Key UI action is available on suspended keys to move them back to an active state when no other active key exists for the given cryptographic specification in a module.</td>
</tr>
<tr>
<td>renewed</td>
<td>Considered an active key that can be renewed any number of times. A key can be renewed only when an expiration date is available, as it is a process of extending the lifecycle period of the key.</td>
</tr>
</tbody>
</table>

**Note:** The difference between the activation date and expiration date is calculated and the expiration date adjusted to the duration from the current day.

| rotated             | Key rotation results in deactivating the current active key and making another key active. The new active key based on either: (1) generation of a new key or (2) pointing to an existing (imported) key. Any active key can be rotated. |

**Note:** When generating a new key, the new key is set to active even though there are key(s) in a generated state for the given cryptographic specification.
### Key lifecycle state

<table>
<thead>
<tr>
<th>Key lifecycle state</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deactivated</td>
<td>Any active key can be deactivated. Multiple deactivated keys may exist in a cryptographic specification. For example, when a key is rotated the active key is deactivated. Deactivated keys cannot be used to generate new content, such as encrypting and signing, but may still be used to identify purposes of existing content: decryption, verification, etc. (until destroyed).</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Compromised and revoked keys are treated as deactivated keys.</td>
</tr>
<tr>
<td>suspended</td>
<td>There could be several keys in the suspended state for a given cryptographic specification in a cryptographic module. When the key is suspended, the key can be resumed and moved back to an active state if no other active key exists for that cryptographic specification for the given cryptographic module.</td>
</tr>
<tr>
<td>compromised</td>
<td>Several keys can exist in the compromised state for revocation in a given cryptographic specification. Any active or suspended key can be moved to a compromised state. Compromised keys cannot be used to generate new content, such as encrypting or signing, but may still be used to identify the purpose of existing content: decryption, verification, etc., until destroyed.</td>
</tr>
<tr>
<td>revoked</td>
<td>There could be several keys in revoked state for a given cryptographic specification. Any active or suspended key can be moved to the revoked state. Revoked keys cannot be used to generate new content, such as encrypting or signing, but may still be used to identify the purpose of existing content: decryption, verification, etc., until destroyed.</td>
</tr>
<tr>
<td>destroyed</td>
<td>There could be several keys in a destroyed state for a given cryptographic specification in a cryptographic module. When a key is destroyed, the key can no longer be used for any cryptographic purposes as the key material is permanently deleted/destroyed. Any deactivated key can be destroyed using lifecycle automation when it has not been used in the designated timeframe. The default timeframe is three months, however this value is configurable.</td>
</tr>
</tbody>
</table>

### KMF roles

The Key Management Framework (KMF) introduces specific roles for cryptographic module and key management-related configurations.

**Important:**

To assign the KMF admin role, you must have both the admin and security_admin roles.

Use the KMF admin role to assign other KMF roles.
<table>
<thead>
<tr>
<th>Role</th>
<th>Role Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>KMF admin</td>
<td>sn_kmf.admin</td>
<td>The administrator within the KMF application for all KMF related functions. Only users with the KMF admin role can assign KMF roles. KMF cryptographic manager permissions are also inclusive in the KMF admin role.</td>
</tr>
<tr>
<td>KMF cryptographic manager</td>
<td>sn_kmf.cryptographic_manager</td>
<td>Assigned to a user by a KMF admin. KMF cryptographic managers can perform create, read, and update operations on cryptographic modules (association of keys to cryptographic usage and algorithm configurations) and module access policies. Also, KMF cryptographic managers can perform key management (generate, rotate, revoke) and life cycle operations.</td>
</tr>
<tr>
<td>KMF auditor</td>
<td>sn_kmf.cryptographic_auditor</td>
<td>Assigned to a user by a KMF admin. KMF cryptographic auditors can view cryptographic module information, key metadata, and life cycle-related details, as well as module access policy information.</td>
</tr>
<tr>
<td>KMF integrator</td>
<td>sn_kmf.cryptographic_integrator</td>
<td>Assigned to a user by a KMF admin. KMF integrators can access and utilize (integrate) cryptographic modules in third party applications.</td>
</tr>
</tbody>
</table>

Assign KMF roles

Administrators with the security_admin role can assign KMF admins, who in turn can assign other KMF roles.

Role required: admin and security_admin

You must elevate to the security_admin role before assigning the KMF admin role. For instructions, see .

1. Elevate to the security admin role.
2. Navigate to **User Administration > Users** and select the user you want to be the KMF admin.
3. Verify that the user already has the admin and security_admin roles. If not, click **Edit** under the Roles related list and add **admin** and **security_admin**.
4. Navigate to **System Security > Key Management Administration**.
5. Select the user you want to be KMF admin in the **Available Users** column and move them to the **Selected User(s)** column.

6. Click **Save**.
7. Navigate to **User Administration** > **Users** and select the user you just gave the KMF admin role to. That user now has the sn_kmf.admin role in the Roles related list. That user can now assign other KMF roles.

If you have the KMF admin role, follow these steps for assigning other KMF roles:

1. Navigate to **User Administration** > **Users** and select the user you want to have another KMF role, such as KMF Cryptographic Manager.
2. In the Roles related list, click **Edit** and select the KMF roles you want to assign the users. All KMF roles start with `sn_kmf`.

Configure field encryption settings to select key type

Cryptographic managers have the choice to use ServiceNow supplied keys for encryption or your own customer-supplied keys (CSK) with Platform Encryption on the Now Platform.

This topic applies to both Platform Encryption and Column Level Encryption. Customer-supplied keys are only available with Platform Encryption.

1. Navigate to **System Security > Field Encryption Settings**.
2. From the Field Encryption Settings, select either **ServiceNow Generated Keys** or **Customer Supplied Keys** from the **Key Source** list.

   ![Field Encryption Settings](image)

   **Field Encryption Settings**

   **Key Source**

   ![ServiceNow Generated Keys](image)

   ![Customer Supplied Keys](image)

   **Key source selection**

   This option changes the `com.glide.encryption.cle_kmf.key_source` property to either **ServiceNow Generated Keys** or **Customer Supplied Keys**.

3. Click **Save**.

   - If you are using your own customer supplied keys, see [Properties for customer supplied keys](#).
   - If you are using ServiceNow supplied keys, start creating your cryptographic module. See [Create a cryptographic module](#).

**Create a cryptographic module**

Create a cryptographic module to define the mechanisms used for cryptographic operations. After you create the module, create a cryptographic specification, define an algorithm for encryption, and generate the key.

Role required: `sn_kmf.cryptographic_manager`

This procedure describes options that are available with KMF out of box and options that should be used with Platform Encryption functionality. Platform Encryption functionality is available only when the `column_level_encryption`(com.glide.now.platform.encryption) plugin is active and `column_level_encryption` is the parent crypto module. See [Activate Platform Encryption](#) for more information on obtaining Platform Encryption.

1. Navigate to **Key Management > Cryptographic Modules > Create New**.
2. Complete the form:

   **Cryptographic Modules fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Module name</td>
<td>Alphanumeric string referenced when running scripts</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Crypto spec template</td>
<td>Select the <strong>Default</strong> template to use to create the cryptographic module, as it contains mappings of many crypto purposes to crypto specifications and recommended algorithms.</td>
</tr>
<tr>
<td>Application</td>
<td>Read only. Click the information icon to open the Store Application information for the ServiceNow Key Management Framework.</td>
</tr>
<tr>
<td>Name</td>
<td>Read only. Crypto module name prepended with application scope name, &quot;sn_kmf.&quot;</td>
</tr>
<tr>
<td>Crypto module lifecycle state</td>
<td>The term lifecycle refers to the creation, use, and deactivation of a cryptographic module. Set to <strong>Draft</strong> initially during configuration. When using the module, set this field to <strong>Published</strong>. When selecting the Default template, the module is automatically set to Published.</td>
</tr>
<tr>
<td>Parent crypto module</td>
<td>There are internal modules that are provided base system:</td>
</tr>
<tr>
<td></td>
<td>• <strong>cm_glide_encrypter</strong>: Do not select this option.</td>
</tr>
<tr>
<td></td>
<td>• <strong>key_import</strong>: Use to import a key from web services</td>
</tr>
<tr>
<td></td>
<td>Choose a parent of the cryptographic module to define crypto module constraints.</td>
</tr>
<tr>
<td></td>
<td>• If only KMF is active and Platform Encryption is not active, do not select a parent.</td>
</tr>
<tr>
<td></td>
<td>• For Platform Encryption functionality, select <strong>column_level_encryption</strong> for Symmetric Data Encryption/Decryption with AES- CBC 256 for column and attachment encryption. See Cryptographic purpose, algorithms, and key information for details.</td>
</tr>
</tbody>
</table>

3. Click **Submit**.

After submitting successfully, you should see your cryptographic module in the Cryptographic Modules table. The system prepends the name with the scope to avoid conflict with other scoped applications. For example, if you created a module with the name `my_crypto_module` in the global application scope, the name is saved as `global.my_crypto_module`. 
4. Click the newly created cryptographic module to open the configuration options. On the **Crypto Specifications** tab, click **New**.

![Crypto Specifications](image)

**Crypto Specifications**

<table>
<thead>
<tr>
<th>Crypto Specifications</th>
<th>Module Keys</th>
<th>Module Policy Exceptions</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Crypto module = test</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Key alias</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Crypto purpose</strong></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
5. Complete the Algorithm Definition Form:

This example shows AES CBC-256 encryption. If Platform Encryption is active and the parent module is `column_level_encryption`, only Symmetric Data Encryption/Decryption AES CBC-256 applies as the crypto purpose.

**Algorithm Definition fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Crypto module</td>
<td>Read only. Name of the selected cryptographic module displays.</td>
</tr>
<tr>
<td>Crypto purpose</td>
<td>Select the purpose of this module. For example, you might use it for data encryption, signature generation, or key wrapping.</td>
</tr>
<tr>
<td>Algorithm</td>
<td>Type of algorithm used to accomplish the crypto purpose. Adjusts automatically based on the selected Crypto purpose.</td>
</tr>
<tr>
<td>Operation mode</td>
<td>This field may display based on the selected Crypto purpose.</td>
</tr>
<tr>
<td>Size</td>
<td>Select the bit size for encryption. 256-bit is the most secure size. This refers to Symmetric Data Encryption/Decryption and should be set when you enable the Platform Encryption and select <code>column_level_encryption</code> as the parent.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Hash</td>
<td>Select a hash. (Not supported with Platform Encryption functionality.</td>
</tr>
<tr>
<td>Equality preserving</td>
<td>Enables non-deterministic encryption. Selecting this option means that if the same data is encrypted more than once, the encryption is different each time. When non-deterministic encryption is enabled, you are unable to filter a list of encrypted data using equality comparison operators because the encoded data is always different.</td>
</tr>
<tr>
<td>Integrity</td>
<td>Integrity is provided when GCM operation mode is selected. This does not apply for Platform Encryption functionality.</td>
</tr>
</tbody>
</table>

6. Click **Next**.
7. The Lifecycle Definition list loads. View existing lifecycle definition data in the table.

**Lifecycle Definition fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Crypto purpose</td>
<td>Read only. Purpose of this module.</td>
</tr>
<tr>
<td>Algorithm</td>
<td>Read only. Algorithm used to accomplish the crypto purpose. Refer to for algorithm details.</td>
</tr>
<tr>
<td>Crypto module</td>
<td>Read only. Name of the crypto module.</td>
</tr>
</tbody>
</table>

8. Optional: Define the lifecycle of the key in the list at the bottom of the same Lifecycle Definition form:

**Key Lifecycle fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applies to</td>
<td>Key that the lifecycle applies to.</td>
</tr>
<tr>
<td>For field</td>
<td>Field that the life cycle applies to.</td>
</tr>
<tr>
<td>Key type</td>
<td><strong>Relative</strong> lets you define a lifecycle policy relative to other lifecycle events such as generation, activation, and deactivation. <strong>Absolute</strong> lets you define an actual date for this lifecycle event.</td>
</tr>
<tr>
<td>Lifecycle default</td>
<td>Read only. Will display a value if set.</td>
</tr>
<tr>
<td>Order</td>
<td>Enter the order in which to process the crypto specification.</td>
</tr>
<tr>
<td>Relative duration</td>
<td>Number of years, months, or days the key is valid.</td>
</tr>
<tr>
<td>Relative duration type</td>
<td>Duration of the life cycle: <strong>Years</strong>, <strong>Months</strong>, or <strong>Days</strong>.</td>
</tr>
<tr>
<td>Relative operation</td>
<td><strong>Before</strong> or <strong>After</strong>.</td>
</tr>
<tr>
<td>Relative to</td>
<td>Field the duration is relative to.</td>
</tr>
</tbody>
</table>

9. Optional: Click **Update**.
10. Click **Next**.
11. Complete the Key Origin form.
   See Generate a cryptographic key for details on using ServiceNow keys.
   If you are supplying your own keys for Platform Encryption, first Configure and upload your customer supplied key.

12. Click Next.
   It takes several seconds before the Key Creation form appears.

13. Click the Module Keys tab to view the key.

14. Set the Crypto module lifecycle state to Published.

Create module access policy

**Configure key lifecycle states**

After you have created a cryptographic specification, you can configure the lifecycle actions for the keys in your instance.

Role required: kmf_crypto_admin

1. Navigate to Key Management > Cryptographic Modules > All.
2. Select the cryptographic module that controls the lifecycle of a key.
3. Click the key alias link for a crypto module in the Crypto Specifications related list.

4. Click the key from the Crypto Specifications tab.
   The Algorithm Definition page opens for the selected key.
5. Click Next.
   Default Key Lifecycle values are created based on the selected algorithms for the crypto specification.
6. Select a Key Lifecycle from the **Applies to** column on the Lifecycle Definition step for the crypto specification.

### Key Lifecycle configuration

**Key Lifecycle fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applies to</td>
<td>Read only. Key that the lifecycle applies to.</td>
</tr>
</tbody>
</table>
### Key lifecycle management "For field" values

**Field** | **Description**
--- | ---
For field | Select the type of control for the key that the lifecycle applies to.

**Type**
- Select if the valuation for the key lifecycle is a relative value or an absolute value:
  - **Relative**: Enter a value that depends on other data entries in the system, such as key generation, activation, and deactivation.
  - **Absolute**: Enter an exact value, such as a date.

**Lifecycle default** | Read only. Displays a value if set.

**Order** | Enter the sequence in which to process the key lifecycle state for the crypto specification.

**Relative duration type** | Duration of the lifecycle: **Years**, **Months**, or **Days**.

**Relative duration** | Number of years, months, or days the key is valid.

**Relative operation** | **Before** or **After**.

**Relative to** | Field the duration is relative to.

### Create module access policy

Module access policies are the access control mechanisms on cryptographic modules.

Role required: sn_kmf.cryptographic_manager
Note: Module access policies replace the role and user that were specified in encryption contexts.

This procedure describes options that are available with KMF out of box, and options that should be used with Platform Encryption functionality. Platform Encryption functionality is available only when the Platform Encryption (com.glide.now.platform.encryption) plugin is active and `column_level_encryption` is the parent crypto module. See [Activate Platform Encryption](#) for more information on obtaining Platform Encryption. The parent crypto module options are described in [Create a cryptographic module](#).

Policies can be based on scope (basic), role, script or resource exchange. For Platform Encryption functionality, only role and resource exchange are supported.

To use a cryptographic module, you must configure correct module access policies to grant the right access. Without an access policy associated with the cryptographic module, encrypted data is not visible to users (fields and columns in lists are blank).

In this image, you can see how a lack of an access policy on an encrypted field, which in this case is the Short Description field on the Incident table, hides the content from all users. With an access policy in place, users with the allowed role are able to see the encrypted data.
### Without correct access policy

<table>
<thead>
<tr>
<th>Incident</th>
<th>Date</th>
<th>Time</th>
<th>Description</th>
<th>Caller</th>
</tr>
</thead>
<tbody>
<tr>
<td>INC000002</td>
<td>07/22/2019</td>

(Excerpt from ServiceNow documentation on encrypted incident short descriptions with and without access policies)
1. Navigate to **Key Management > Module Access Policies > All**.

When you create a cryptographic module, an auto-generated Module Access Policy is created and will be listed in the table.

2. Click **New**.

3. Complete the form.

Module Access Policies fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policy name</td>
<td>Enter a name for the policy.</td>
</tr>
<tr>
<td>Crypto module</td>
<td>Click the search icon to select a module.</td>
</tr>
</tbody>
</table>
| Type                   | • **Basic**: Controls access by Scope.  
                          • **Script**: Control access by script.  
                          • **Role**: Controls access by user role.  
                          • **Resource Exchange**: Control access using the Resource Exchange.  
                          
                          For Platform Encryption functionality, you can select only the Role or Resource Exchange types.  
                          
                          If the parent module is not **column_level_encryption**, you can select any of type.                                                                                                                                                                                        |
| Target Scope           | Field is visible as an identifier for the **Basic** Type. Refers to the functionality/scope for the policy. Select the applications from the search menu.  
                          Target scope is not supported if the parent module is **column_level_encryption**.                                                                                                                                                                                                 |
| Target Role            | Field is visible as an identifier for the **Role** Type. Role to which this policy applies.  
                          Target roles are supported by both KMF and by Platform Encryption when the parent module is **column_level_encryption**.                                                                                                                                                              |
| Script Table           | These fields appear when you select Script as the type.  
                          Field is visible as an identifier for the **Script** Type. Select a table to which this policy applies. Document to which this policy applies. Select the **Table name** and then the related document for the policy.  
                          The first time a script calls a cryptographic module, access to the module is denied, and the developer receives an error. This gives you, the module owner, the ability to grant or refuse access to your module.  
                          Target scripts are not supported if the parent module is **column_level_encryption**. See Configure script access to encrypted data for details.                                                                 |
<p>| Resource Exchange      | These options appear when you select Resource Exchange the type.                                                                                                                                                                                                                   |
| Crypto Spec            |                                                                                                                                                                                                                                                                                                                                             |</p>
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Approval Type</td>
<td>Resource exchange is supported by both KMF and by Platform Encryption when the parent module is <code>column_level_encryption</code>. Select the crypto specification, One-time or Recurring, and the URL of the target instance. See KMF Resource Exchange for more information.</td>
</tr>
<tr>
<td>Target Instance Host</td>
<td></td>
</tr>
<tr>
<td>Active</td>
<td>Select to activate the policy.</td>
</tr>
<tr>
<td>Result</td>
<td>Select one of the following:</td>
</tr>
<tr>
<td></td>
<td>• <strong>StrictReject</strong> to reject access under all circumstances</td>
</tr>
<tr>
<td></td>
<td>• <strong>Reject</strong> to prevent users with the <strong>Target Role</strong> or <strong>Target Scope</strong> from accessing this crypto module unless another policy allows them access</td>
</tr>
<tr>
<td></td>
<td>• <strong>Track</strong> to permit access and monitor use of the module</td>
</tr>
</tbody>
</table>

4. Click **Submit**.

5. Select the policy name (not the module name) associated with the cryptographic module you want to examine.

**Multiple modules access policy**
You can encrypt data using multiple cryptographic modules. If each module has its own access policy based on a role, for example, users with different roles can encrypt data on the same table but they can still be prevented from viewing each others encrypted data.

- **Note:** Only Platform Encryption on columns supports multiple modules. Attachment encryption does not.

1. Create multiple cryptographic modules and an access policy for each one.
   Make sure that you grant different roles to the different cryptographic modules through the access policies.

2. Navigate to **System Security > Field Encryption > Encrypted Field Configurations**.
   If you need more information on Encrypted Field Configurations, see Set encrypted field configurations.

3. In the **Type** field, you must select **Column**. Attachment encryption does not support multiple modules.
4. Select **Multiple Modules** in the **Method** field.

Set method to multiple modules

5. Select the **Table** and the **Column** in the table that you want to encrypt.
6. Click **Submit**.

Newly created data for the specified field is encrypted with the key of the relevant module. When a user with the role specified in module A's access policy writes to the specified table, the data is encrypted with module A's key. Only users with the same role can read the data.

Let's say that you want to encrypt the Short Description column on the Incident table. You would do the following:

1. Create two cryptographic modules A and B.
2. For each module, create a module access policy.
   
   For module A, give users with an HR role access. For module B, give users with a Sales role access.
3. Create an Encrypted Field Configuration record specifying the Short Description column on the Incident table, and make sure that you select **Multiple Modules** in the **Method** field.
4. Have two users, one with the HR role (user A) and one with the Sales role (user B), create an incident with a short description, and then have both users look at the list of incidents.

   The short description for the incident created by the user with the HR role is encrypted by the key for module A. Likewise, the short description for the incident created by the user with the Sales role is encrypted by the key for module B.

   Although all users with the HR and Sales roles have access to incidents, only a user with the HR role can decrypt and view the short description for those incidents created by user A, who had the HR role. Likewise, only users with the Sales role can decrypt and view the short descriptions for those incidents created by the user B, who had the Sales role.
Create a cryptographic module lifecycle policy

A cryptographic module policy is an instance-level policy that places limits on cryptographic modules, such as how long the key is good for. Create policies to safeguard cryptographic modules by limiting their exposure.

Role required: sn_kmf.cryptographic_manager

The more exposure a cryptographic key has, the more likely it can be compromised. Safeguard keys by limiting how long the keys can be used and who can use them.

The following features govern cryptographic modules:

- Instance policies set boundaries for the instance. For example, if you specify in the instance policies that the expiration date should never be more than two years after the activation date, you cannot use the lifecycle rules to set an expiration date five years after the activation date.
- Instance lifecycle templates allow you to set different policies for different keys. Templates offer default lifecycle rules for cryptographic modules so that they don't have to be re-created for every module. For example, you can set different expiration dates for symmetric data encryption keys than for public key wrapping keys.
• Lifecycle rules affect the keys directly. For example, if you specify in the lifecycle rules that the expiration date should be two years after the activation date, keys will expire two years after the activation date.

1. Navigate to **Key Management > Lifecycle Policies > Instance Policies**.
2. Click **New**.
3. Complete the form.

**Cryptographic Lifecycle Policies fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applies to</td>
<td>Read only. The key the lifecycle applies to.</td>
</tr>
<tr>
<td>Active</td>
<td>Select to activate the policy.</td>
</tr>
<tr>
<td>Policy condition</td>
<td>Conditional statements that specify when to activate, renew, deactivate, and destroy the cryptographic module.</td>
</tr>
<tr>
<td>Result</td>
<td><strong>Reject</strong> to revoke access to the cryptographic module, or <strong>Track</strong> to permit access and monitor use of the cryptographic module.</td>
</tr>
</tbody>
</table>

If you want to add exceptions to this lifecycle policy at the module level, see **Create module policy exceptions**.

**Create module policy exceptions**

Create a module policy exception to change the lifecycle policy of a key at the module level for an instance. The exception(s) applies only to that module and not to the entire instance.

Role required: **sn_kmf.cryptographic_manager**

For example, if the administrator configured symmetric keys to be limited to one year at the instance level, an exception can be made at the module level to be two years.

1. Navigate to **Key Management > Cryptographic Modules > All**.
2. Select the cryptographic module that will use the policy exceptions.
3. In the Cryptographic Module table, select the **Module Policy Exceptions** tab.
4. Click **New**.
5. Complete the form.

**Module Policy Exceptions fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Crypto Module</td>
<td>Read only, name of the module selected.</td>
</tr>
<tr>
<td>Applies to</td>
<td>The specified key is auto-populated.</td>
</tr>
<tr>
<td>Key Type</td>
<td>Select the key type, as the exception policies are related to a specific key. Multiple exception policies can be created per crypto module.</td>
</tr>
<tr>
<td>Policy condition</td>
<td>Choose the qualifying conditions from the drop-down and complete the additional constraint criteria.</td>
</tr>
<tr>
<td>New criteria</td>
<td>Select additional policy conditions, as required.</td>
</tr>
<tr>
<td>Result</td>
<td>Select to <strong>Reject</strong> to reject usage of the key or <strong>Track</strong> to allow usage of it when the criteria is met.</td>
</tr>
</tbody>
</table>

6. Click **Submit** to be returned to the Cryptographic Module table.
Generate a cryptographic key

Generate an encryption key that converts data into ciphertext, which remains indecipherable to anyone who does not have access to the correct key. Cryptographic managers have the choice to use ServiceNow supplied keys or your own customer supplied keys (CSK) for encryption on the Now Platform.

Role required: sn_kmf.cryptographic_manager

See Configure field encryption settings to select key type to configure your instance to use either ServiceNow generated keys. For Platform Encryption see Properties for customer supplied keys to use your own customer-supplied key.

1. Navigate to Key Management > Cryptographic Modules > All.
2. Select the crypto module for the key generation and select the crypto specification.
3. Navigate to the Key Origin tab by clicking Next.
4. On the Key Creation form, click Generate Key.
   The crypto specification data is pre-populated based on previous information added and key origin configuration.
5. Review these read-only fields based on your configuration:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Crypto Module</td>
<td>Name of the module.</td>
</tr>
<tr>
<td>Key alias</td>
<td>Name of the key.</td>
</tr>
<tr>
<td>Crypto purpose</td>
<td>Purpose of the module.</td>
</tr>
<tr>
<td>Origin</td>
<td>Populated based on field configuration settings. For customer supplied keys, refer to Wrap your customer supplied key</td>
</tr>
<tr>
<td>Algorithm</td>
<td>Algorithm used to accomplish the crypto purpose.</td>
</tr>
</tbody>
</table>

Generate key
6. Click **Generate Key** to initiate the creation of a key for this cryptographic module.
   
   Multiple keys can exist for a given cryptographic module, but, only one key can be active at a time. Refer to Key management actions for additional information.
   
   The algorithm definition screen will open. Select options for the key generation. Repeat this step to generate multiple keys for the selected crypto module.
   
   Secure information for the key is stored on the Module Keys tab.
   
   Access the existing keys by selecting a filter in the Module keys table. Select a key to perform key management actions.
   
   After you generate the key, the Cryptographic Module form reloads showing you the specification.

7. Click the **Module Keys** tab to view the key.

8. Set the **Crypto module lifecycle state** to **Published**.

Configure script access to encrypted data

Execute a script to run the cryptographic module policy for a cryptographic purpose.

Role required: sn_kmf.cryptographic_manager

For KMF, policies can also be based on scripts. When an access policy is triggered for script access, the back-end script can execute the module policy actions from the script.

**Note:** Platform Encryption supports module access policies based on role or resource exchange. Script access is not supported.

Scripts are used to analyze data. If an analyzed field is encrypted, a module access policy can be entered for that script so the encrypted field can be accessed from the script.

Cryptographic modules can support one or more encryption purposes, such as Asymmetric Data Decryption and Symmetric Data Decryption. Each cryptographic purpose requires the generation of an encryption key and defined cryptographic purpose.

The following are required to successfully execute an encryption script request:

- The referenced cryptographic purpose must be defined in the cryptographic module.
- There must be an active generated key for the cryptographic module.
- Set the Module Access Policy type to **script**.

Examples of uses are for business rules and Script Includes. This procedure uses a script for Business Rules.

1. Create a cryptographic module with the symmetric data encryption/decryption algorithm. Refer to Create a cryptographic module for details.

2. Navigate to **System Definition > Business Rules**.
3. Click **New**.
A business rule is a server side script that runs when a record is displayed, inserted, deleted, or when record is opened. Use business rules to automatically change values in form fields when the specified conditions are met. Click Add to add a new business rule.

Specify whether the business rule should run on insert or update. Use filter conditions to specify under which conditions the business rule should run.

- **When**:
  - Before INSERT
  - After INSERT
  - Before UPDATE
  - After UPDATE
  - Before DELETE
  - After DELETE

- **Filter Conditions**:
  - Add Filter Condition
  - Add "OR" Clause
  - Add "AND" Clause
  - Add "NOT" Clause
  - Add "LIKE" Clause
  - Add "IN" Clause

- **Rate Conditions**:

Submit
4. Complete the form:

**Business Rule fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a name for the business rule.</td>
</tr>
<tr>
<td>Table</td>
<td>Select <em>Incident [incident]</em> from the drop-down list.</td>
</tr>
<tr>
<td>Application</td>
<td><em>Global</em> is selected by default</td>
</tr>
<tr>
<td>Active</td>
<td>Mark the rule as <em>Active</em>.</td>
</tr>
<tr>
<td>Advanced</td>
<td>Select the check box to display advanced options.</td>
</tr>
<tr>
<td>“When to run” tab</td>
<td>Enable <em>Insert</em> and <em>Update</em> fields.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>&quot;Advanced&quot; tab</td>
<td>Paste the following script text in line 3,</td>
</tr>
<tr>
<td></td>
<td>// Add your code here line:</td>
</tr>
<tr>
<td></td>
<td>var gc = global.GlideCryptoModule.getModule('global.acme_mod');</td>
</tr>
<tr>
<td></td>
<td>var value = 'test';</td>
</tr>
<tr>
<td></td>
<td>var encrypted = gc.encryptData(value);</td>
</tr>
<tr>
<td></td>
<td>gs.info('value: ' + value);</td>
</tr>
<tr>
<td></td>
<td>gs.info('Encrypted: ' + encrypted);</td>
</tr>
<tr>
<td></td>
<td>var decrypted = gc.decryptData(encrypted);</td>
</tr>
<tr>
<td></td>
<td>gs.info('Decrypted: ' + decrypted);</td>
</tr>
<tr>
<td></td>
<td>gs.info(decrypted == value);</td>
</tr>
</tbody>
</table>

Note: Refer to the "Business Rules Advanced Tab" image below for details.

```
function executeRule(current, previous) {
    var gc = global.GlideCryptoModule.getModule('global.acme_mod');
    var value = 'test';
    var encrypted = gc.encryptData(value);
    gs.info('value: ' + value);
    gs.info('Encrypted: ' + encrypted);
    var decrypted = gc.decryptData(encrypted);
    gs.info('Decrypted: ' + decrypted);
    gs.info(decrypted == value);
}
```

5. Click Submit.
6. **Navigate to Key Management > Module Access Policies > All.**

   **Note:** For additional information, refer to Create module access policy.

7. Click **New**.

8. Complete the form.

   **Module Access Policies fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policy name</td>
<td>Enter a name for the policy.</td>
</tr>
<tr>
<td>Crypto module</td>
<td>Click the search icon to select a module with the symmetric data encryption/decryption algorithm.</td>
</tr>
<tr>
<td>Type</td>
<td>Select Script to control access by script.</td>
</tr>
<tr>
<td>Script Table</td>
<td>Select a value from the script table drop-down list. For this example, select Business Rule [sys_script].</td>
</tr>
<tr>
<td>Target Script</td>
<td>Select the script document for the policy. Select the Table name and then the related document for the policy. For this example, select the Business Rule that you created in previous steps. The first time a script calls a cryptographic module, access to the module is denied and the requester receives an error. The module owner can grant or refuse access to the module.</td>
</tr>
<tr>
<td>Active</td>
<td>Select to activate the policy.</td>
</tr>
<tr>
<td>Result</td>
<td>To give the script access to the module, select Track in the Result field.</td>
</tr>
</tbody>
</table>

9. Click **Submit**.

   The Module Access Policy for the script is available in the system.

A module access policy is automatically created when a script attempts to use a module. The module name is preceded with "AutoGen-". For example, the "Module-TestPolicy" module is listed as "AutoGen-Module-TestPolicy" in the Policy name column.

The Crypto Caller Policy form lists the caller policy you selected. The Target Scope field specifies the scope of the script attempting to use the module.

**View declined cryptographic module usage requests**
View cryptographic modules that rejected encryption requests made by scripts because of unsupported encryption mechanisms.

**Role required: sn_kmf.cryptographic_manager**

Cryptographic modules can support one or more encryption purposes, such as Asymmetric Data Decryption and Symmetric Data Decryption. Each cryptographic purpose requires the generation of an encryption key. Encrypted data can only be accessed based on the module access policy. If a script tries to use a cryptographic module for a purpose not defined in the module or without an encryption key, the script cannot access to the encrypted data. To successfully run a script to access encrypted data, create an encryption key for which the encryption method script is designed.
In the following example, a cryptographic purpose was assigned to a cryptographic module, but a key was never generated for it.

Navigate to **Key Management > Module Key Policies > Module Key Rejections**.

A list of crypto modules that rejected requests displays along with the encryption key that used in the corresponding script.

![Module Key Rejections Table](image)

**Module Key Rejections**

![Note:](image)

Note: If a different script attempts to use the same cryptographic module using the same key type, the value for **Last enforced** updates. Another row does not generate.

In this example, at 2020-02-10_15:55:17, the first module rejected a request because module1’s key is compromised. At 2020-02-10_07:24:05, the second module rejected a request because the second module’s key is suspended.

To give scripts permission to use the encryption module the next time they run, create a module access policy for script encryption. For more information, refer to **Configure script access to encrypted data**.

**Schedule mass encryption, decryption, and rekeying jobs**

Schedule encryption, decryption, and rekeying jobs to run at a time that is best for your instance.

Encryption, decryption, and rekeying jobs can be time and resource intensive, so consider scheduling at non-peak hours. Also ensure that the user scheduling the job has the appropriate access for each job.

Role required: **sn_kmf.cryptographic_manager**
Mass encryption and decryption is also available from the Encrypted Field Configurations form. See Run mass encryption or decryption for instructions.

1. Navigate to **System Security > High Security Settings > Security Jobs**.
2. Click **New**.
3. Complete the scheduling form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the encryption, decryption, or re-keying job.</td>
</tr>
<tr>
<td>Type</td>
<td>Job type:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Key Migration Context to Module</strong>: Mass migration of Encryption Context keys to Encryption Modules, including creation of Module Access Policies records for access controls on the Encryption Modules</td>
</tr>
<tr>
<td></td>
<td>• <strong>Data Migration Context to Module</strong>: Migrates data encrypted by Encryption Contexts to Encryption Modules</td>
</tr>
<tr>
<td></td>
<td>• <strong>Mass Encryption Module</strong>: Encrypts any pre-existing value in the defined column/field used in the Field Encryption Configuration</td>
</tr>
<tr>
<td></td>
<td>• <strong>Mass Decryption Module</strong>: Decrypts any pre-existing value in the defined column/field used in the Field Encryption Configuration with Single Module.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Mass Decryption Multi Module</strong>: Decrypts any pre-existing value in the defined column/field used in the Field Encryption Configuration with Multiple Module.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Module Rekeying</strong>: Re-encrypts any pre-existing value in the defined column/field used in the Field Encryption Configuration using the current active key for the module.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Migrate Attachment Context to Module</strong>: Encrypts any pre-existing attachment on the table defined in the Field Encryption Configuration. Any attachment previously encrypted with a context is re-encrypted with the module.</td>
</tr>
<tr>
<td>State</td>
<td>The initial job state is New. After the job has been executed as scheduled, the state will update accordingly</td>
</tr>
<tr>
<td>Time window start</td>
<td>Start time for the job in 24-hour format.</td>
</tr>
<tr>
<td>Time window end</td>
<td>End time for the job in 24-hour format.</td>
</tr>
<tr>
<td>Table</td>
<td>Table to be encrypted or decrypted.</td>
</tr>
<tr>
<td>Field</td>
<td>Field to be encrypted or decrypted.</td>
</tr>
<tr>
<td>Summary</td>
<td>Job status information when the job is running, has completed, or has errors.</td>
</tr>
</tbody>
</table>

**Note:** Because of system overhead, you should schedule mass encryption, decryption, and rekeying jobs to run at non-peak hours. The Now Platform runs the job between the **Time window start** and
Time window end. If the job is not complete in one processing window, it continues during the next specified processing window until all processing is complete.

4. Click **Submit**.

5. After you schedule a job, you can do the following.
   - Click **Cancel Job** to cancel a running job.
   - Click **Start** to start a job immediately.
   - Click **Update** to save any changes you make to the job schedule.
   - Click **Delete** to delete the scheduled job.

Run mass encryption or decryption
You can run mass encryption on encryption configurations. Before deleting an encrypted field configuration, run a mass decryption to decrypt previously encrypted values.

Role required: security_admin
You can also create scheduled jobs for mass encryption and decryption. See Schedule mass encryption, decryption, and rekeying jobs for instructions.

Mass encryption and decryption are available only when an encrypted field configuration uses the single cryptographic module. Mass decryption is available for both the single and multiple encryption context methods.

Note: You should run mass encryption and decryption only during non-peak hours because the operations are resource and time intensive.

1. Navigate to **System Security > Field Encryption > Encrypted Field Configurations**.
2. Open the encrypted field configuration for the field you would like to mass encrypt or decrypt.
3. Under Related Links, select an available option.
   - **Schedule Mass Decryption job**
   - **Schedule Mass Encryption job**
4. Confirm your selection in the dialog.

If running a mass encryption, all values are encrypted with the encryption context defined in the encrypted field configuration record. If running a mass decryption, only fields encrypted with an encryption context you have access to are decrypted.

Note: If you attempt to **Delete** a configuration with encrypted fields, you receive the message **Please run a Mass Decryption in every encryption context where applicable before deleting to ensure the data is not encrypted.** Press **Cancel** and run a mass decryption before deleting the configuration.

Key management actions
One of the core features of KMF is to provide the capability to manage keys, such as revoking or rotating keys. KMF properly secures sensitive data with the most up-to-date encryption materials and lifecycle operations.

The following table provides a summary of the key lifecycle operations and management actions. The cryptographic module purpose is applied to the data with the cryptographic module configuration and have no impact on data.

<table>
<thead>
<tr>
<th>Key management action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Generate key</td>
<td>Generates a new key for the given cryptographic module. A first generated key is set to active.</td>
</tr>
<tr>
<td>Key management action</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>Rotate key</td>
<td>Deactivates the current key and generates a new one. The new module key is set to current (active).</td>
</tr>
<tr>
<td>Revoke key</td>
<td>Marks the current key and lifecycle state as revoked. The cryptographic module auto-generates a new key on new data and sets the key status to active. Revoke means that the key is no longer used for encryption. However, it can still be used for decryption. You cannot destroy a key.</td>
</tr>
<tr>
<td>Suspend key</td>
<td>Marks the current key as suspended. Manually reactivate the suspended key or revoke the suspended key to generate a new module key before using this cryptographic module again</td>
</tr>
<tr>
<td>Renew key</td>
<td>Extends the life of the current key. The Renew button becomes available under the following circumstances: • You are assigned the cryptographic manager role. • The lifecycle state is marked to either Active or Renewed. • An expiration date is set in the module lifecycle definition.</td>
</tr>
</tbody>
</table>

**View and manage keys**

Review the status of any key to determine further key action, such as when to renew, rotate, suspend, deactivate, or destroy a current key.

Role required: sn_kmf.cryptographic_manager

1. Navigate to **Key Management > Cryptographic Modules > All**.
2. Select a cryptographic module.

   The Cryptographic Module <module-name> form appears.
3. On the Module Keys tab, click the key alias to review the key status on the Lifecycle <key name> form.
4. Review the form, as all fields are read-only.

**Cryptographic Lifecycle Key fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Generation date</td>
<td>Displays the date the key was generated</td>
</tr>
<tr>
<td>Activation date</td>
<td>Displays the date the key was activated</td>
</tr>
<tr>
<td>Last renewal date</td>
<td>Displays the date the key was last renewed</td>
</tr>
<tr>
<td>Last rotated date</td>
<td>Displays the date the key was last rotated</td>
</tr>
<tr>
<td>Deactivation date</td>
<td>Displays the date the key was deactivated</td>
</tr>
<tr>
<td>Destruction date</td>
<td>Displays the date the key was destroyed</td>
</tr>
<tr>
<td>Key lifecycle state</td>
<td>Displays which state the key lifecycle is in</td>
</tr>
<tr>
<td>Future activation date</td>
<td>Displays the future date of which the key activates</td>
</tr>
<tr>
<td>Future renewal date</td>
<td>Displays the future date of which the key renews</td>
</tr>
<tr>
<td>Future rotation date</td>
<td>Displays the future date of which the key rotates</td>
</tr>
</tbody>
</table>
5. To perform an action on the key, click one of the following to take effect immediately:

- **Revoke Key**: Select to deactivate the key and generate a new key. Enter the reason why you are revoking the key.
- **Rotate Key**: Select to deactivate the current key and to generate a new key in its place. The new key is listed in the Module Key table and the Key Version number increments by 1.
- **Suspend Key**: Select to deactivate the current key for an allotted time period.

**Rotate keys**

For increased security, you should rotate your keys on a pre-determined schedule. Unlike encryption contexts, KMF encryption modules support a rekey of records for re-encryption with a new key.

Role required: sn_kmf.cryptographic_manager

Encryption modules support a rekey of records for re-encryption with a new key. The following demonstrates how to manually perform a key rotation operation on a KMF cryptographic module.

1. Navigate to **Key Management > Cryptographic Modules > All**.
2. Select the cryptographic module for key rotation.
3. On the **Module Keys** tab, select the Active key.

![Module Keys Tab](image)

Select the active key
Rotate key

4. Click Rotate Key.
   The key lifecycle state changes to "Deactivated." The Last rotated date, the Deactivation date, and the Key version updates.
5. Return to Cryptographic Module > Module Keys.

Module key rotation

There is an extra module key listed in the table. The newly rotated key becomes "Active" and the previous key is "Deactivated."

Import key from web service

To upload a customer supplied key, you can import a private key using a secure web service with KMF-CLE.

Role required: sn_kmf.cryptographic_manager

1. Navigate to Key Management > Cryptographic Modules > Create New.
2. Complete the form. Be sure to select `key_import` as the **Parent crypto module**.

![Cryptographic Module Form]

**Parent crypto module:** `key_import`

See [Create a cryptographic module](#) for details.

3. Select the cryptographic module from the list.
4. Click the module from the **Crypto Specifications** related list.
5. For the Origin select **Import from web service** from the Algorithm Definition step.

**Algorithm Definition Origin**

KMF Import key endpoint access is required to complete the key import process.
6. Right-click in the header bar and select **Copy sys_id**.

7. Using an API client, such as Postman, in the request **GET** field, enter: `:16001/api/sn_kmf/key/import`
   **Params**: `cryptoSpecSysID`
8. Paste the sys_id to replace the existing **Query Params Value** for the `cryptoSpecSysID`.

![Image of API request](image_url)

- **cryptoSpecSysID value**

9. In the body, select **Binary** and attach your key file to upload.
   If prompted, select **Authentication Basic** and enter the ServiceNow crypto admin credentials.

10. Click **Send**.
    The key is uploaded to the **Module Keys** related list.
11. Return to the cryptographic module and click the Module Keys related list to view the uploaded key.

Key imported from web services
KMF Resource Exchange

Resource Exchange is a KMF feature that gives you the capability to exchange resources between instances in a secure manner.

Terminology

When using the Resource Exchange, reference the following terminology:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resource Exchange</td>
<td>The process to exchange resources across instances</td>
</tr>
<tr>
<td>Key Exchange (KE)</td>
<td>The process to exchange keys over instances</td>
</tr>
<tr>
<td>Key Source Instance (Key Source)</td>
<td>The instance that owns the keys</td>
</tr>
<tr>
<td>Target Instance</td>
<td>The instance that requests the keys.</td>
</tr>
</tbody>
</table>

Overview

Resource Exchange leverages KMF’s cryptographic APIs to provide confidentiality, integrity, authentication, and non-repudiation. Currently, Resource Exchange supports the Key Exchange functionality. KMF Key Exchange generates automatic key exchange requests for cryptographic modules with a column_level_encryption parent module for new instances and during upgrades when using Platform Encryption modules.

KMF Key Exchange

KMF Key Exchange is a subset function of KMF Resource Exchange. Key Exchange securely transfers encryption module keys across multiple instances.

Overview of Key Exchange

KMF Key Exchange securely transfers keys across instances, from source instance to target instance. Key Exchange supports multiple modes of operations, and is out-of-the-box automated for the System Clone case. For system cloning, the cryptographic module keys (Platform Encryption) are transferred over as part of the system clone process. Another application use case for Key Exchange is Instance Data Replication (IDR).

Supported modes

Key Exchange supports three modes on the module crypto spec level:

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Automatic (no configuration, default behavior)</td>
<td>For System Clones, all Platform Encryption module keys are sent over automatically during the cloning process without configuration.</td>
</tr>
</tbody>
</table>
### Government Community Cloud (GCC)

ServiceNow instances in the GCC environment require a workaround to Resource Exchange that requires customer-supplied key usage. For details, contact You must upload a customer-supplied key to the target instance after cloning the source instance.

**Configure Key Exchange**

KMF Key Exchange generates automatic key exchange requests for supported cryptographic modules during the instance’s fresh installation and the upgrade. KMF manages the data encryption key locally for the instance.

Role required: sn_kmf.cryptographic_manager

KMF crypto specifications/module configuration

KMF Key Exchange uses the `com.glide.kmf.global` plugin and the `glide_encryption.auto_key_exchange.enabled` system property to manage how keys are handled during an instance clone:

- **Automatic Key Exchange**: Out-of-box property `glide_encryption.auto_key_exchange.enabled` is true by default, meaning that automatic key exchange is activated when cloning an instance. The property is cloned over to the target instance.
- Users can turn off automatic key exchange by setting the property to false.

A post-cloning script running on the target instance sends requests to the key source instance during data cloning:

- Set `glide_encryption.auto_key_exchange.enabled` to true: Sends the auto key exchange requests to the key source.
- Set `glide_encryption.auto_key_exchange.enabled` to false: The post-cloning script deletes the auto key exchange requests.

1. Navigate to **Key Management > Resource Exchange Requests > New.**

<table>
<thead>
<tr>
<th>Exchange Frequency</th>
<th>Adhoc</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source Instance Sys Id</td>
<td>71235f432890cfe98742</td>
</tr>
<tr>
<td>Source Instance Host</td>
<td><a href="mailto:testnode1@testservicenow.com">testnode1@testservicenow.com</a></td>
</tr>
<tr>
<td>Crypto Specifications</td>
<td>test12345</td>
</tr>
</tbody>
</table>

**Resource Exchange Request**
2. Complete the form:

**Resource Exchange Request fields**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exchange Frequency</td>
<td>• <strong>Adhoc</strong>: Sends ad hoc requests from the key source instance to the target instance</td>
</tr>
<tr>
<td></td>
<td>• <strong>One Time Clone</strong>: One time clone of the keys from the source crypto specifications to the target instance</td>
</tr>
<tr>
<td></td>
<td>• <strong>Recurring Clone</strong>: Clones keys from the selected source crypto specifications to the target instance on a defined recurring basis</td>
</tr>
<tr>
<td>Source Instance Sys_id</td>
<td>Enter the system id for the source instance that hosts the keys</td>
</tr>
<tr>
<td>Source Instance Host</td>
<td>Enter the name of the host instance</td>
</tr>
<tr>
<td>Crypto Specifications</td>
<td>The keys from the crypto specification from a crypto module define the keys to clone.</td>
</tr>
</tbody>
</table>

**Note:** Click the lookup icon to browse available cryptographic specifications.
3. Click **Submit**.
   The Resource Exchange Request displays in the table. There is an entry for both the request record on the Target Instance side and also an entry in the Host Instance.

   The entry shows the status of the Request, as well as the number of keys imported to the target or exported from the host.
# Request Record (on Target Instance side)

<table>
<thead>

Recurring Key Exchange walkthrough
This walk through shows you how to set up a recurring key exchange in your instance using KMF and Resource Exchange.

This walk through shows you how a target instance requests keys from a host instance.

Before you can perform this key exchange procedure, you must clone an instance.

1. Create a crypto module or access an existing crypto module for key exchange. Ensure that keys are generated in the crypto module. Refer to Create a cryptographic module for details.
2. Define a module access policy of type Resource Exchange for the crypto module or select an existing record from the instance. Refer to Create module access policy for details.
3. From the host instance that you cloned, navigate to Key Management > Resource Exchange Requests > New.
4. Complete the form and select Recurring Clone as the Exchange Frequency.
5. From the target instance of the clone, navigate to Key Management > Resource Exchange Requests.
6. The request from the host instance is displayed in the table.

View key exchange
The administrator approves the request and the status updates to **Request Approved** and the **Imported Key Count** is listed.

For both one-time and recurring clone requests, a module access policy of type KE automatically generates. You do not have to manually configure a policy. At clone time, this policy on source invokes to auto-approve the request (and send keys to the newly cloned target).

8. Return to the host instance.
9. View the Resource Exchange Request to show the number of exported keys.
10. View the Module Access Policy that displays the Type as **Resource Exchange**.

---

**Resource Exchange in Module Access Policy**

**Platform Encryption**

Platform Encryption utilizes the Key Management Framework (KMF) to enable you to fully customize and manage how fields and attachments are encrypted and decrypted on your instance.

Platform Encryption is the successor to Column Level Encryption (CLE) using Key Management Framework (KMF) and its full support of key management functions. Platform Encryption provides key-protection and key lifecycle management for application-level field encryption. All keys are protected with a key-wrapping hierarchy that’s ultimately rooted in FIPS 140-2-L3 Hardware Security Modules (HSM).

Platform Encryption gives you the ability to manage how supported fields are encrypted and decrypted in accordance with NIST 800-57 best practice. It also enables you to use the most updated version of field-level encryption, including integration with for proper key protection and management. A subscription is required to utilize Platform Encryption.

**Note:** Platform Encryption supports on-premise customers. It does not support Domain Separation.
Encryption overview

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Support for key management** | Fundamental to Platform Encryption is the Key Management Framework (KMF). Gain the following capabilities:  
  - Key lifecycle management  
  - Key rotation. See Rotate keys for details.  
  - Key protection and key generation with FIPS 140-2-L3 High Security Modules (HSMs)  
  - Segregation of roles and duties  
  - The secure transfer of data encryption keys between instances, such as production and non-production instances  
  - Customer Supplied Keys (CSK) with key-wrapping  
  - Non-deterministic encryption  
  - Mass encryption/decryption  
  - Auditing of key access/use  
  
  See Key Management Framework (KMF) for details. |
| **Customer-supplied key** | Support for customer supplied keys  
  One of the biggest benefits of Platform Encryption is that you can use your own keys for encryption. Administrators have the choice to use ServiceNow supplied keys or your own customer supplied keys (CSK) for encryption on the Now Platform.  
  You can also manage the key life cycle and decide when to revoke, rotate, and inactivate the keys. After you enable customer supplied keys and create a cryptographic module, you must download a token and public key (ephemeral). You use the token and public key to wrap your key and upload it to the instance. If you want to start using customer supplied keys, see Configure field encryption settings to select key type and Properties for customer supplied keys. |
| **Support for both field encryption and attachment encryption** | Both field encryption and attachment encryption utilize cryptographic modules and access policies through Encrypted Field Configurations. Attachment encryption is configured to a single cryptographic module and role. See Set encrypted field configurations for more information. |
Column Level Encryption and Platform Encryption

Platform Encryption with the Key Management Framework offers an alternative encryption solution to you compared to Column Level Encryption (CLE). See Understanding the Key Management Framework for details on how Platform Encryption with KMF compares to CLE.

See Cryptographic purpose, algorithms, and key information for encryption/decryption algorithms supported.

KMF in Platform Encryption vs. CLE (with encryption contexts)

Column Level Encryption (CLE) specifies encryption contexts for the creation of encryption keys. Contexts assign based on role to uses. These encryption contexts provide only rudimentary key management capabilities.

Platform Encryption is the successor to column level encryption using KMF and its full support of key management functions. Specifically, Platform Encryption utilizes KMF’s cryptographic modules, granting you more control of server-side encryption. KMF ensures proper data encryption key protection using key hierarchy and envelope encryption. Cryptographic modules use specifications and access policies with lifecycle management control over the key for the module, whether it’s a ServiceNow key or your own customer supplied key.

The Encrypted Field Configuration form is used in both. With Platform Encryption, you choose the type of encryption: column encryption or attachment encryption.

- In the CLE model, encryption is performed via encryption contexts. Each context is mapped to a role, which is mapped to a user.
- With Platform Encryption, your instance encrypts data through cryptographic modules that you configure. You can create an access policy for each module based on role or resource exchange. See Understanding the Key Management Framework and Cryptographic module overview for an explanation of what modules are and how they work. See Create a cryptographic module and Create module access policy for instructions.

Tip:

Once you enable Platform Encryption, you can still use Column Level Encryption (CLE) framework.

If you choose not to activate Platform Encryption, you can still use CLE. Column Level Encryption contexts permit and deny access to encrypted data based on user role. See Encryption Support for information.

API support

Platform Encryption updates the setDisplayValue() and setValue() APIs so they can insert encrypted data for encrypted fields. It also enables getDisplayValue() and getValue() to return cleartext values.

The following script illustrates these API changes when the Incident short description is encrypted:

```javascript
var gr = new GlideRecord('incident'); //creates a new incident
gr.setValue('short_description','test123'); //sets the value to test123
var sys_ID = gr.insert(); //inserts the record in the Incident table.
gs.info(gr.getValue('short_description')); //displays the unencrypted value
```

If you use getValue() to get encrypted text, your script no longer returns the ciphertext. Your scripts return the plaintext, assuming that the user has access to the cryptographic module. If the user does not have access to the cryptographic module, getValue() returns the ciphertext.
Activate Platform Encryption

You can activate the Platform Encryption plugin (com.glide.now.platform.encryption) after you purchase a subscription.

Role required: admin

The following items are installed or modified with the Platform Encryption plugin (com.glide.now.platform.encryption):

- The Encryption Support (com.glide.encryption) plugin is also activated.

**Note:** The Key Management Framework (com.glide.kmf.global) plugin is already active by default.

- The glide_encryption.cle_replatforming_with_kmf property is set to opt_in.
- The glide_encryption.set_value_support_cle.disabled property is set to false, which turns on the SetValue feature. The SetValue support enables both setDisplayValue() and setValue() APIs to support encrypted data. It also enables both getDisplayValue() and getValue() to return clear text values.
- Two scheduled jobs are enabled:
  - **autoKeyMigration**: Migrates encryption context keys to Key Management Framework (KMF) Cryptographic Module Keys.
  - **autoDataMigration**: Migrates data that you already encrypted to use the KMF Cryptographic Module key.

Administrators can modify when these scheduled jobs run, and can pause or restart them at any time.

**CAUTION:**

Once you enable Platform Encryption, you cannot roll back to the Column Level Encryption framework.

1. Navigate to **System Applications > All Available Applications > All**.
2. Find the plugin, **Platform Encryption - com.glide.now.platform.encryption** using the filter criteria and search bar.
   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel. For more information, see **Request a plugin**.
3. Click **Install**, and then in the Activate Plugin dialog box, click **Activate**.

**Note:** When domain separation and delegated admin are enabled in an instance, the administrative user must be in the global domain. Otherwise, the following error appears: Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.

Migrating to Platform Encryption

Scheduled jobs migrate your keys and encrypted data from Encryption Support to Platform Encryption.

You can review the scheduled jobs by navigating to **System Security > High Security Settings > Security Jobs**:

- **autoKeyMigration**: Migrates encryption context keys to Key Management Framework (KMF) Cryptographic Module Keys.
- **autoDataMigration**: Migrates data that you already encrypted to use the KMF Cryptographic Module key.

You can modify when these scheduled jobs run, and can pause or restart them at any time.
Verify that the encrypted field configurations are using your newly migrated module keys by navigating to System Security > Field Encryption > Encrypted Field Configurations. Look for the following items:

- The Method field is Single Module.
- The Crypto module field is populated with the name of the cryptographic module that the system automatically creates. The system adds cm in front of the name of the encryption context. You can review that module and the module access policy, both of which are active and published.

Properties for customer supplied keys

If the Platform Encryption plugin is enabled, you can use system properties to key padding, the size of the ephemeral key pair, and the key validity period of your customer supplied keys.

Platform Encryption with Key Management lets you manage the full key life cycle (rotate, revoke, and destroy) of your data encryption keys. Optionally, you can securely exchange data encryption keys generated within your environment.

Note: The properties in this topic only apply to Platform Encryption functionality. Platform Encryption is available only when the Platform Encryption (com.glide.now.platform.encryption) plugin is active and column_level_encryption is the parent crypto module. See Activate Platform Encryption for more information on obtaining Platform Encryption.

Government Community Cloud (GCC)

ServiceNow instances in the GCC environment require a workaround to Resource Exchange that requires customer-supplied key usage. For details, contact You must upload a customer-supplied key to the target instance after cloning the source instance.

Key properties

After the data encryption key is imported to the instance, a secure wrapping key protects new module keys on the instance. The wrapping key is an instance key encryption key (IKEK) generated by a hardware security module (HSM) on SafeNet KeySecure.

When you provide your own key, you must wrap it with the RSA public key. Three properties define the size, padding algorithm, and validity period of the wrapping RSA key pair:

- **glide.kmf.ephemeral_key.key_padding** controls the key padding scheme for the ephemeral key. The default is OAEP SHA256, but you can also specify SHA1.
- **glide.kmf.ephemeral_key.key_size** controls the key size of the ephemeral key pair. The default key size is 4096, but you can change it to 2048 to support a smaller key size.
- **glide.kmf.ephemeral_key.key_validity_period** defines the period for which the ephemeral key pair is valid. The default is two hours.

Continue to Wrap your customer supplied key.

Wrap your customer supplied key

If you are using customer supplied keys, wrap the private key you want to use for encryption with the downloaded public key.

Note: This procedure only applies to Platform Encryption functionality. Platform Encryption functionality is available only when the Platform Encryption (com.glide.now.platform.encryption) plugin is active and column_level_encryption is the parent crypto module. See Activate Platform Encryption for more...
information on obtaining Platform Encryption and see Create a cryptographic module for more information on selecting the parent crypto module.

- Modify optional properties that control the size, padding algorithm, and validity period of the key.
- You must have your private key (.BIN) for encryption.
- You must have a cryptographic tool to wrap your key. This example uses OpenSSL 1.1.

1. Navigate to **Key Management Framework > Cryptographic Modules > All**.
2. Select the cryptographic module that you created for the customer supplied key from the Crypto Specifications related list.
3. You will be directed to the **Key Creation** step.
4. If you have not previously downloaded the wrapping key, click the link to download the `token_publickey<id>.zip` file. Save the zip file to the same location as your key.

   **Note:** Do not rename the downloaded `token_publickey<id>` file.

5. Unzip the file to your local network.
   The zip file contains two files, an import token and a public key .PEM certificate. Wrap your private key with the public key to encrypt it.
6. Copy the name of the `token_publickey` file to your clipboard.
7. From a command line, use the copied `token_publickey` file name to open the folder of the unzipped files as a placeholder for the wrapped key.
8. Edit this script by replacing the examples with the names of your crypto files. Refer to the **Key wrapping commands** table for details:

```
"downloads user.name$ cd token_publickey_<token>
openssl pkeyutl -encrypt -pubin -inkey publickey_<keyname>.PEM
    -in <keyname.bin>
    -out wrapped_key_material -pkeyopt rsa_padding_mode:oaep -pkeyopt rsa_oaep_md:sha<128 or 256> "
```

**Key wrapping commands**

<table>
<thead>
<tr>
<th>Directions</th>
<th>Command</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open the file directory where you</td>
<td>cd</td>
<td>cd token_publickey123456789</td>
</tr>
<tr>
<td>downloaded the wrapping token</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Paste the name of the</td>
<td>openssl pkeyutl -encrypt -pubin -inkey</td>
<td>publickey_586798643ffff.PEM</td>
</tr>
<tr>
<td>publickey.PEM certificate</td>
<td>publickey_&lt;keyname&gt;.PEM</td>
<td></td>
</tr>
<tr>
<td>Paste the name of your key here</td>
<td>-in</td>
<td>mykey.bin</td>
</tr>
<tr>
<td>Enter the -out command and</td>
<td>-out wrapped_key_material -pkeyopt rsa</td>
<td>N/A</td>
</tr>
<tr>
<td>specify if the key is 128 bit or 256 bit</td>
<td>padding_mode:oaep -pkeyopt rsa_oaep_md:sha256</td>
<td></td>
</tr>
</tbody>
</table>

9. Run the command. A return displays the `token_publickey_<keynumber>`. 
10. The key will be generated and a "wrapped_key_material" file added to the directory.
11. You are ready to upload the wrapped key.

Return to Configure and upload your customer supplied key to upload your wrapped key.

Configure and upload your customer supplied key
You can use your own customer supplied key instead of using the ServiceNow system-generated keys.

**Note:** This procedure only applies to Platform Encryption functionality. Platform Encryption functionality is available only when the Platform Encryption (com.glide.now.platform.encryption) plugin is active and column_level_encryption is the parent crypto module. See Activate Platform Encryption for more information on obtaining Platform Encryption and see Create a cryptographic module for more information on selecting the parent crypto module.

Roles required: security.admin, sn_kmf.cryptographic_manager

If you are NOT supplying your own keys, you do not need to perform this procedure. To create a cryptographic module with ServiceNow keys, go to Create a cryptographic module.

**Important:** You cannot revoke a customer supplied key.

1. Navigate to System Security > Field Encryption Settings and verify that Customer Supplied Keys is selected.

   ![Field Encryption Settings](image)

   **Key source selection**

   2. Click Submit.
   3. Return to Key Management > Cryptographic Module.
4. Click **Create New**.

![Cryptographic Module form]

Create new cryptographic module

5. Complete the Cryptographic Module form as follows:

**Cryptographic Module fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Module name</td>
<td>Enter a name for the module.</td>
</tr>
<tr>
<td>Crypto spec template</td>
<td>Select a cryptographic template.</td>
</tr>
<tr>
<td>Name</td>
<td>Auto-populates based on the module name.</td>
</tr>
<tr>
<td>Crypto module lifecycle state</td>
<td>Select <strong>Published</strong> to activate the crypto module.</td>
</tr>
<tr>
<td>Parent crypto module</td>
<td>Select <strong>column_level_encryption</strong>. You must select <strong>column_level_encryption</strong>; to use customer-supplied keys.</td>
</tr>
</tbody>
</table>

6. Click **Submit**.

7. Select the newly created cryptographic module from the table.

In the **Crypto Specifications** related list, click the auto-generated key alias with the AES 256 CDB algorithm. The system populates the Crypto purpose and the Algorithm for CLE automatically and jumps to the **Key Origin** stage.
8. Notice that **Upload customer supplied key** is the **Origin** and the **Key alias** is already populated.

9. Click **Next** to move to the **Key Creation** stage.

   There are two links:

   - **Download wrapping key** downloads the key in a zip file containing an import token and a public key certificate, `.PEM` file. Use the import token to verify successful key wrapping per security specification for
the instance. Use the public key certificate .PEM file to wrap your customer supplied key securely before uploading it along with the token.

- **Upload customer supplied key** opens the file browser to select the token and the encrypted key that you wrapped.

<table>
<thead>
<tr>
<th>Crypto module</th>
<th>byoktest3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key alias</td>
<td>global.byoktest3</td>
</tr>
<tr>
<td>Download wrapping key</td>
<td>token_publickey_caa896bd7ca0e010f877c0a071289326.zip</td>
</tr>
<tr>
<td>Upload customer supplied key</td>
<td>Upload customer supplied key</td>
</tr>
</tbody>
</table>

**Key creation upload links**

10. Click **Download wrapping key** to save the token. Save the token to the same destination location as the key is saved on your system. Do not rename the downloaded token.

11. Run the BYOK command on a terminal to wrap the key. For more information, refer to **Wrap your customer supplied key**.

12. Click **Upload customer supplied key**.

13. Click **Browse** to select the two files, the wrapped key and the token file.

The attachments window opens and the two files are displayed in the list.

**Wrapped key attachments upload**

Select a file to remove and re-upload, if necessary.
14. Click **OK**.

    You will be returned to the Cryptographic Module screen. A confirmation message displays for a successful upload of the customer key. The key will also be listed in the Module Keys related list.
Confirmation of key upload
Now that you have finished configuring your cryptographic module with your customer-supplied key, move on to Create module access policy.

**Encrypting fields and attachments**

After you create your cryptographic modules, create encrypted field configurations and specify whether to encrypt a field on a table or encrypt attachments. You can use ServiceNow supplied keys or your own customer supplied keys.

**Note:** This topic only applies to Platform Encryption functionality. Platform Encryption functionality is available only when the Platform Encryption (com.glide.now.platform.encryption) plugin is active and column_level_encryption is the parent crypto module. See Activate Platform Encryption for more information on obtaining Platform Encryption and see Create a cryptographic module for more information on selecting the parent crypto module.

**Encryption contexts compared to encryption modules**

In this release, Platform Encryption with encryption modules replaces Column Level Encryption (CLE) and encryption contexts.

<table>
<thead>
<tr>
<th>CLE (encryption contexts)</th>
<th>Platform Encryption (encryption modules)</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can encrypt only individual attachments at the table level.</td>
<td>You can encrypt all of a table's attachments.</td>
</tr>
<tr>
<td>You assign roles to encryption contexts.</td>
<td>You establish module access policies by role or resource exchange, when Platform Encryption is active. Policies accommodate scope, domain, or script access with KMF.</td>
</tr>
<tr>
<td>You can use ServiceNow generated keys or enter a key that you generate through a certificate authority and enter into an encryption context.</td>
<td>You can either use ServiceNow generated keys or provide and manage your own customer supplied keys.</td>
</tr>
</tbody>
</table>

**How to encrypt fields**

1. Specify the key source: system-generated keys or your customer supplied keys (bring your own key) in System Security > Field Encryption Settings.

2. After you specify the key source, create a new cryptographic module or use an existing cryptographic module, access policy, and instance-level lifecycle policy. Start with Create a cryptographic module for instructions. If you use customer-supplied keys, you must follow the directions in Wrap your customer supplied key and Configure and upload your customer supplied key. You can also configure properties for these keys. See Properties for customer supplied keys.

3. Create an encrypted field configuration, which is where you specify the table on which the encryption is performed and either the column in the table or the attachments in the table to encrypt. See Set encrypted field configurations to get started.

**Set encrypted field configurations**

Configure which table columns or attachments that the system should encrypt using a pre-configured cryptographic module. These encrypted field configurations replace encryption contexts.

**Note:** This procedure only applies to Platform Encryption functionality. Platform Encryption functionality is available only when the Platform Encryption (com.glide.now.platform.encryption) plugin is active.
Role required: security_admin

Make sure you are in the correct application scope so you can see the tables in that scope.

You must have a cryptographic module and access policy already created. See Create a cryptographic module to begin.

You should have already decided whether to use ServiceNow supplied keys or your own customer supplied keys on the System Security > Field Encryption Settings form. If you are using your customer supplied key and you have not already configured settings, wrapped the key, and uploaded it to the instance, start with Wrap your customer supplied key.

1. Navigate to System Security > Field Encryption > Encrypted Field Configurations.
2. Click New.
3. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>Type</td>
<td><strong>Column</strong> to encrypt a table column or <strong>Attachment</strong> to encrypt all of a table's attachments. <td>Algorithm Encrypted Preserving [read-only]</td>
<td>Indicates if the crypto module that you selected is already configured to support non-deterministic encryption. This means that if the same data is encrypted more than once, the encryption is different each time.</td>
</tr>
</tbody>
</table>
4. Click Submit.

Platform Encryption examples

These examples walk you through the encryption of fields and attachments using customer-supplied keys.

Column encryption walkthrough

This walkthrough shows you how to encrypt a field in your instance using Platform Encryption with the Key Management Framework. It also shows you how to use your own key.

Note: This procedure only applies to Platform Encryption functionality. Platform Encryption functionality is available only when the Platform Encryption (com.glide.now.platform.encryption) plugin is active and column_level_encryption is the parent crypto module. See Activate Platform Encryption for more information on obtaining Platform Encryption and see Create a cryptographic module for more information on selecting the parent crypto module.

Role required: sn_kmf.admin

This walkthrough starts with an instance where you have already created and uploaded your personal cryptographic key. You could use the ServiceNow key, but this example uses a customer-supplied key.

After the key has been stored in a cryptographic module, you can start configuring fields in your instance, such as salary or social security numbers that have limited access from certain users. Encrypted Field Configuration allows you to specify which authorized personnel can access sensitive data.

We show you two scenarios. One example, in this task, encrypts the Short Description field in an Incident for users who are not authorized to view the sensitive data.

Attachments can also be encrypted and only visible to users who are granted access, or visible to all users that are not restricted from viewing the data. Refer to Attachment encryption walkthrough to encrypt an attachment.

1. Make sure that Platform Encryption is enabled.
2. Create a cryptographic module with column_level_encryption as the parent module.
4. Click New.
5. Complete the form:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Select <strong>Column</strong> to use your personal key.</td>
</tr>
<tr>
<td>Table</td>
<td>Select the table from where the sensitive information is stored. For this example, select Incident (incident).</td>
</tr>
<tr>
<td>Column</td>
<td>Select the column, or specific information, that represents the sensitive date to be encrypted. For this example, select Short description (short_description).</td>
</tr>
<tr>
<td>Active</td>
<td>Mark <strong>Active</strong> to be able to use the field configuration.</td>
</tr>
<tr>
<td>Algorithm Equality Preserving</td>
<td>When selecting column level encryption, this field will be automatically selected, therefore, no action is required.</td>
</tr>
<tr>
<td>Crypto module</td>
<td>Select the module that you created to use with the personal key.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
</tr>
<tr>
<td>Method</td>
<td>Select <strong>Single Module</strong> to use the crypto module for one module. Select <strong>Multiple Modules</strong> to apply the policies across multiple modules.</td>
</tr>
</tbody>
</table>

### Encryption field configuration example

![Encryption field configuration example](image)
6. Click **Submit**.

   Establish a Module Access Policy to assign access to the cryptographic module. Refer to Create module access policy for additional information.

7. From **Key Management** select **Module Access Policies > All**.

8. Click **New**.

9. Complete the form:

   **Module access policy fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policy name</td>
<td>Enter a name for the policy, such as &quot;short description.&quot;</td>
</tr>
<tr>
<td>Crypto module</td>
<td>Select the crypto module that you created to encrypt your key.</td>
</tr>
<tr>
<td>Type</td>
<td>Select <strong>Role</strong> to grant access to the encrypted field for only those that have the assigned role.</td>
</tr>
<tr>
<td><strong>Note:</strong> You can select only <strong>Role</strong> or <strong>Resource Exchange</strong> when Platform Encryption is enabled and column_level_encryption is selected as the parent module.</td>
<td></td>
</tr>
<tr>
<td>Target Role</td>
<td>Select the role that has access to the encrypted field. For this example, select <strong>Admin</strong>.</td>
</tr>
<tr>
<td>Active</td>
<td>Select this check box to be able to use the Module Access Policy.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>-------------</td>
</tr>
<tr>
<td>Result</td>
<td>Select <strong>Track</strong> to enable the access to the field for the selected role. (To restrict access to that field for the selected role, select <strong>Reject</strong> or <strong>Strict Reject</strong>.)</td>
</tr>
</tbody>
</table>

**Module access policy example**

10. Click **Submit**
11. As a KMF Admin, go to **Incident > New.**
The Short description field is visible because we just specified that the Admin role user has access, Track, to that encrypted field. Notice the lock icon under the field name indicating that the field is an encrypted field.

We will now access the Incidents module as an end user to test the encrypted field configuration.

12. Log in as a user that will be restricted from viewing the encrypted data in the configured field.

13. Access the incident number, and the data in the Short description will not be visible.

![Incident Module Screenshot](image)

**Encrypted field level data**

You have now successfully used your private key to control access to a specific field using platform encryption.

**Attachment encryption walkthrough**

This walkthrough shows you how to encrypt an attachment in your instance using column level encryption with the Key Management Framework. It also shows you how to use your own key.

**Note:** This procedure only applies to Platform Encryption functionality. Platform Encryption functionality is available only when the Platform Encryption (com.glide.now.platform.encryption) plugin is active and column_level_encryption is the parent crypto module. See Activate Platform Encryption for more information on obtaining Platform Encryption and see Create a cryptographic module for more information on selecting the parent crypto module.

Role required: kmf cryptographic manager

This walkthrough starts with an instance where you have already created and uploaded your personal cryptographic key. You could use the ServiceNow® key, but this example uses a customer-supplied key.

Upload confidential attachments in your instance and limit access from certain users. Use Encrypted Field Configurations to specify which authorized personnel can access sensitive data.
We show you how to encrypt attachments to only be visible to users who are granted access, or be visible to all users that are not restricted from viewing the data. In this example, we restrict a certain role from being able to access an attachment in the **Incidents** module.

**Note:** Although you can use multiple modules with column encryption, attachment encryption must use single modules.

1. Make sure that Platform Encryption is enabled.
2. Create a cryptographic module with column_level_encryption as the parent module.
3. Navigate to **System Security > Encrypted Field Configurations**.
4. Click **New**.
5. Complete the form:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Select <strong>Attachment</strong> to use your personal key for encrypting an attachment from the selected <strong>Table</strong>. For this example, select <strong>Incident</strong>.</td>
</tr>
<tr>
<td>Table</td>
<td>Select the table to access the sensitive information. For this example, select <strong>Incident [incident]</strong>.</td>
</tr>
<tr>
<td>Active</td>
<td>Mark <strong>Active</strong> to be able to use the field configuration.</td>
</tr>
<tr>
<td>Algorithm Equality Preserving</td>
<td>When selecting column level encryption, this field is visible based on the table selected.</td>
</tr>
<tr>
<td>Crypto module</td>
<td>Select the module that you created to use with the personal key.</td>
</tr>
</tbody>
</table>
Single Module is selected, as the crypto module being used is a single module. Multiple modules are not supported for attachment encryption.

**Encrypted Field Configuration table**

6. Click **Submit**.

   Establish a Module Access Policy to assign access to the cryptographic module. Refer to Create module access policy for additional information.

7. Navigate to **Key Management > Module Access Policies > All**.

8. Click **New**.

9. Complete the form:

   **Module access policy fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Policy name</td>
<td>Enter a name for the policy, such as &quot;Attachment policy.&quot;</td>
</tr>
<tr>
<td>Crypto module</td>
<td>Select the crypto module that you created to encrypt your key.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Type</td>
<td>Select <strong>Role</strong> to restrict access to the encrypted field from users with the assigned role.</td>
</tr>
<tr>
<td>Target Role</td>
<td>Select the role that will not have access to the encrypted field. For this example, select <strong>itil</strong>.</td>
</tr>
<tr>
<td>Active</td>
<td>Select this check box to be able to use the Module Access Policy.</td>
</tr>
<tr>
<td>Result</td>
<td>Select <strong>Strict Reject</strong> to control the access to the attachment from the selected role. (To grant access for the selected role, select <strong>Track</strong>.)</td>
</tr>
</tbody>
</table>

**Module Access Policy form**

10. **Click Submit.**
11. As admin or as a person that created the incident, navigate to **Incidents** and add an attachment to **Activities** on the **Notes** related list.

![Attachment](image)

**Attachment available per role**

12. Log in as a user that restricted from accessing the encrypted attachment.

13. Open the incident and scroll to the **Activities**: section. The link to open the attachment is not accessible for users with the restricted role.

14. You have now successfully used your private key to control access to a specific attachment using column level encryption.
**Encryption Support**

Column Level Encryption (CLE) contexts permit and deny access to encrypted data based on user role.

Column Level Encryption (CLE) is replaced by Platform Encryption

**About Column Level Encryption support**

Implementation of column-level encryption begins with defining one or more encryption “contexts” in your instances of the Now Platform. This process includes selecting the desired encryption algorithm and providing an appropriate secret key. Access to data later encrypted using the feature is role-based, with contexts being associated with roles. Users without the correct role don’t see the field at all, or if they are assigned a role with a different context, a blank field appears. Figure 1 illustrates how role-based encryption is enabled.

![Figure 1 – Role-based encryption example](image)

Here are the results of the relationships in Figure 1:

- User 1 is a member of Role 1, which provides access to Encryption Context 1. User 1 can see the contents of Field A and Field B.
- User 2 and User 3 are members of Group 1. Group 1 is a member of Role 1, which allows everyone in Group 1 access to Encryption Context 1 and allows User 2 and User 3 to see the contents of Field A and Field B.
- User 4 is not a member of any group or role and has no access to Encryption Context 1. Not only does User 4 not have access to Field A or Field B, but User 4 doesn't even see these fields on a form. On a list view, the values would be empty.

You can implement considerably more complex role-based encryption as well.
Having access to an encrypted data field by being assigned an encryption context does not necessarily mean that a user can modify the field. Role-based access also must be implemented appropriately for that field to be accessible to users who are assigned the context via a role.

Customer encryption keys for use with column-level encryption, whether provided by a customer or randomly generated by the instance, are stored in the same unique instance database where the data encrypted by them is stored. As a further security measure, they are re-encrypted with a secondary key unique for that instance, which mitigates direct access to the encryption key for any context, either by an instance administrator or ServiceNow. Column-level encryption optionally lets you store encryption keys in your own hardware security module (HSM) or other key storage appliances or services.

The system does not have access to the user contexts necessary to decrypt data, so some actions are not possible on encrypted data. Column-level encrypted data cannot be filtered or sorted. In releases prior to Kingston, the encrypted data can't be searched, and workflows can't make use of column-level encrypted data. These capabilities, along with scheduled reporting, are executed using a system service that has no access to encrypted data and cannot be assigned the context, groups, or roles to gain access.

Pros:

- Access to encrypted data is determined by user role.
- You can choose the strength of the encryption algorithm: AES-128 or AES-256.
- You can encrypt String text, Date and Date/Time fields, attachments, and URLs.
- Encryption Support provides Equality Preserving encryption.

Cons:

- Encryption Support pre-Orlando doesn't allow you to manage your own keys. The Orlando release introduces optional key management.
- Key access requires a user session with access to the context/key and doesn't work for other back-end or system user processes.
- Key access can affect application logic and require code changes.
- Key access requires you to perform network and infrastructure maintenance.
- You can't encrypt journals.
- Encryption Support doesn't provide Order Preserving encryption or standard, non-deterministic encryption.

**Encryption methods**

Fields that use Encryption Support may include:

- New or existing Encrypted Text fields.
- String, Date, Date/Time, or URL fields included in encrypted field configuration records.

The Encrypted Field Configurations table [sys_platform_encryption_configuration] contains a record for each field encrypted with Encryption Support. This table enables a security_admin to monitor all fields in the instance that uses Encryption Support. On upgrade, encrypted field configuration records are created for all existing Encrypted Text fields. When a new Encrypted Text field is added, an encrypted field configuration record is created by default.

Encrypted field configurations can encrypt fields using one of the following methods.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single Encryption Context</td>
<td>The field is encrypted with the encryption context defined in the <strong>Encryption context</strong> field. Users who do not have the encryption context cannot view or update field values.</td>
</tr>
<tr>
<td>Method</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Multiple Encryption Contexts</td>
<td>The field is encrypted with the encryption context of the first user to enter data. If the user has two or more encryption contexts, the context defined in the encryption context selector is used. Because the encryption context is set on a per record basis, fields in a list can have different encryption contexts. However, within a single record, the field can be encrypted by only one context. When an Encrypted Text field is created, an encrypted field configuration is created with the multiple encryption contexts method. Encrypted Text fields and fields encrypted with the multiple encryption contexts method behave the same.</td>
</tr>
</tbody>
</table>

**Note:** Mass encryption is not available when using the multiple encryption contexts method.

### Access to encrypted data

A user's encryption context determines access to encrypted data. Security_admin users can grant an encryption context to a user by granting the user an associated role.

To monitor the assignment of roles, the customer or ServiceNow professional services can set up security measures. For example, an email can be sent to an appointed encryption manager whenever a role associated with an encryption context is granted to a user.

**Note:** Impersonation does not change the encryption context available to a user. Even while impersonating, you have only the encryption contexts available to you originally.

<table>
<thead>
<tr>
<th>Access level</th>
<th>Data access to a field using the single encryption context method</th>
<th>Data access to a field using the multiple encryption contexts method</th>
</tr>
</thead>
<tbody>
<tr>
<td>User with no encryption contexts</td>
<td>The form hides the encrypted field. In list view, the field appears blank and cannot be edited, even if the data in the field is decrypted.</td>
<td>The form hides the encrypted field. In list view, the field appears blank and cannot be edited, even if the data in the field is decrypted.</td>
</tr>
</tbody>
</table>
| User with one encryption context    | To use the field, the user must have access to the encryption context defined in the encrypted field configuration. If the user does not have access to the encryption context, the form hides the field. In list view, the field appears blank and cannot be edited.  
  - **If there is no data in the field:** If the user has access to the encryption context, the form shows the field (assuming UI policy does not prevent it). Users with access to the encryption context can view and update the empty field. Data entered in the field is encrypted with the encryption context defined in the encrypted field configuration.  
  - **If there is data in the field:** If the user has access to the encryption context, the user can view and edit data in the field. | The user automatically uses their encryption context with the encrypted field.  
  - **If there is no data in the field:** The form shows the field (assuming UI policy does not prevent it). Users with any encryption context can view and update the empty field. Entering data in the field causes the field to use the currently selected encryption context to encrypt the data.  
  - **If there is data in the field:** If the user has access to the encryption context used to encrypt the field, the user can view and edit the field. |
## ServiceNow Platform Administration

### Limitations

- Only the following field types can be encrypted:
  - String text
  - Date
  - Date/Time
  - Attachments
  - URL

- Because contexts are tied to roles and roles are tied to users, you do not have access to keys from non-user sessions. Anything running as a system user or a scheduled job that doesn't have a user session won't be able to access the key to encrypt or decrypt data.

- Value versus display value:
  - When you use value, you get ciphertext.
  - When you use display value, provided you have the right role, you get cleartext.

Many scripts in the application layers are scripted in such a way that they ignore this distinction and use value. The data won't be encrypted or decrypted if you don't change the scripts to use display value.

### Filtering and searching encrypted fields

When an Encrypted Text field or a field with an encrypted field configuration applied is selected as the left operand in a filter, the following operators are available:

<table>
<thead>
<tr>
<th>Access level</th>
<th>Data access to a field using the single encryption context method</th>
<th>Data access to a field using the multiple encryption contexts method</th>
</tr>
</thead>
<tbody>
<tr>
<td>User with two or more encryption contexts</td>
<td>To use the field, the user must have access to the encryption context defined in the encrypted field configuration. If the user does not have access to the encryption context, the form hides the field. In list view, the field appears blank and cannot be edited.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• If there is no data in the field: If the user has access to the encryption context, the form shows the field (assuming UI policy does not prevent it). Users with access to the encryption context can view and update the empty field. Data entered in the field is encrypted with the encryption context defined in the encrypted field configuration.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• If there is data in the field: If the user has access to the encryption context, the user can view and edit the field. The field always uses the original encryption context to encrypt changes to the field. This behavior prevents users with two or more encryption contexts from changing the encryption context of a field.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>The user can select an encryption context from the encryption context selector in the welcome bar.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• If there is no data in the field: The form shows the field (assuming UI policy does not prevent it). Users with any encryption context can view and update the empty field. Entering data in the field causes the field to use the currently selected encryption context to encrypt the data. The field always uses the original encryption context to encrypt changes to the field. This behavior prevents users with two or more encryption contexts from changing the encryption context of a field.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• If there is data in the field: If the user has access to the encryption context used to encrypt the field, the user can view and edit the field. The field always uses the original encryption context to encrypt changes to the field. This behavior prevents users with multiple encryption contexts from changing the encryption context of a field.</td>
<td></td>
</tr>
</tbody>
</table>
• is
• is not
• is empty
• is not empty

For Date fields, use the date picker to specify the date:

For Date/Time fields, use the date and time picker to specify the date and time:

If a user with one or more encryption contexts filters for equality or searches for a value in a list:
• Only values encrypted with an encryption context available to the user are returned.
• The operators **is empty** and **is not empty** return all matching records. Fields encrypted with an encryption context not available to the current user appear blank.

If a user does not have any encryption contexts, no records are returned.

The **Show Matching** and **Filter Out** options are supported in lists. Only exact matches are returned or filtered out.

**Note:** Adding encrypted fields in condition filters is supported in scripts such as UI policies and business rules.
Exporting data from encrypted fields

When exporting encrypted fields in a list or form to a file format, only fields encrypted by an encryption context available to the current user appear in the exported document.

To disable exports of encrypted data from a list view, add the `glide.encryption.export_encrypted_data.allowed` system property and set the value to `false`.

Activate the Encryption Support plugin

You can activate the Encryption Support plugin (com.glide.encryption) if you have the admin role.

Role required: admin

1. Navigate to System Applications > All Available Applications > All.
2. Find the plugin using the filter criteria and search bar.
   
   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel. For more information, see Request a plugin.
3. Click Install, and then in the Activate Plugin dialog box, click Activate.

   **Note:** When domain separation and delegated admin are enabled in an instance, the administrative user must be in the global domain. Otherwise, the following error appears: Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.

Set up encryption contexts

Create an encryption context that uses an encryption key. Only users who have a role associated with the encryption context can view the data encrypted with that encryption context.

Role required: security_admin

Your instance can generate an encryption key, or you can specify your own key with a certificate authority. See your certificate authority documentation for information on creating an encryption key.

Starting with the London release, the Now Platform no longer supports creating new Triple DES keys for an Encryption Context, but continues to support previously-created Triple DES keys. Previously-created Triple DES keys are listed in the Encryption Contexts with a Type of 3DES.
1. Navigate to **System Security > Field Encryption > Encryption Contexts**.
2. Click **New**.
3. Complete the form.

### Encryption Context form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the encryption context.</td>
</tr>
</tbody>
</table>
| Encryption key  | Key used to encrypt the data. Leave blank to generate a key randomly. Based on the desired type of encryption, enter the exact number of characters:  
  - 16 characters for AES 128-bit  
  - 32 characters for AES 256-bit  
  
  **Warning:** You cannot retrieve this key from the instance. If you need access to the key, save it elsewhere before clicking **Submit**. |
| Application     | Defaults to **Global** and cannot be changed. |
| Type            | Type of encryption used to encrypt your data:  
  - **AES 128-bit**: Advanced Encryption Standard  
  - **AES 256-bit**: Advanced Encryption Standard using 256-bit encryption |

4. Click **Submit**.

The newly-created encryption key is encrypted with a key the system maintains. This key is not stored in the database. This practice prevents other users from copying the key and using it to decrypt data.

5. Navigate to **System Security > Roles** and open the role record to associate with the encryption context, or create a new role.

6. Right-click the form header and select **Configure > Form Layout** to configure the Roles form to add the **Encryption context** field.

7. Select the encryption context to associate with the role (there can be only one encryption context per role).
8. Click **Update**.

You must log out of the instance and log in again to use the encryption context.

**Add an encryption context selector**
Add an encryption context selector to the welcome banner to enable users with multiple encryption contexts to select a context when entering data.

Role required: security_admin

1. Click **System UI > UI Macros**.
2. Open the encryption_select UI macro.
3. Select the **Active** check box.
4. Click **Update**.
5. Click the gear icon in the banner frame to open the System Settings window.
6. On the **General** tab, select the **Show domain picker in header** switch.
7. Reload the page to see the choice list (if you have more than one encryption context).

The encryption context selector appears in the welcome banner only for users who have multiple roles with different encryption contexts.

![Encryption: HR](image)

**Note:** The selector appears only for users who have two or more encryption contexts to choose from. Users with either one or no encryption contexts do not see the selector.

**Encrypt an existing field**
Create an encrypted field configuration to encrypt the value of an existing String, Date, Date/Time, or URL field using Encryption Support.

Role required: security_admin

You can delete encrypted field configurations created to encrypt other field types. Make sure to run a mass decryption before deleting an encrypted field configuration.

1. Navigate to **System Security > Field Encryption > Encrypted Field Configurations**.

The Encrypted Field Configurations table [sys_platform_encryption_configuration] contains a record for each field encrypted with Encryption Support. You can create encrypted field configurations to encrypt existing String, Date, Date/Time, and URL fields.

2. Click **New**.
3. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table that contains the field to be encrypted.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Column</td>
<td>The field to be encrypted. Only String, Date, Date/Time, and URL fields are supported.</td>
</tr>
<tr>
<td></td>
<td>• <strong>String and URL fields</strong>: You can add a new encryption configuration to either a parent table or a child table.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Date and Date/Time fields</strong>: You can create encrypted field configurations to encrypt existing Date and Date/Time fields. You can add a new encryption configuration to a parent table only. You cannot add a new encryption configuration to a child table.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Depending on the number of records affected by the Date and Date/Time fields you are encrypting, it may take up to a few minutes to create the encryption configuration. Make sure that you create the encryption configuration for Date and Date/Time fields when transaction volume on the instance is low.</td>
</tr>
<tr>
<td>Method</td>
<td>• <strong>Single Encryption Context</strong>: Enables data to be encrypted with a single encryption context only. The field is encrypted with the encryption context defined in the <strong>Encryption context</strong> field. Users that do not have the encryption context cannot view or update field values.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Multiple Encryption Contexts</strong>: Enables data to be encrypted with more than one encryption context. The field is encrypted by the encryption context of the first user to enter data. If the user has multiple encryption contexts, the context defined in the encryption context selector is used. Because the encryption context is set on a per record basis, fields in a list can have different encryption contexts. However, within a single record, the field can be encrypted by only one context.</td>
</tr>
<tr>
<td>Encryption context</td>
<td>The encryption context for the encrypted data. Only visible when <strong>Single Encryption Context</strong> is selected in the <strong>Method</strong> field.</td>
</tr>
<tr>
<td></td>
<td>Once an encrypted field configuration is applied to a field using the single encryption context method, you cannot change the encryption context.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Mass encryption is not available when using the <strong>Multiple Encryption Contexts</strong> method.</td>
</tr>
<tr>
<td></td>
<td>After a configuration is created using the single encryption context method, you can update the record to use multiple encryption contexts. However, you cannot change a field using multiple encryption contexts to use a single encryption context.</td>
</tr>
</tbody>
</table>

4. Click **Submit**.

New values added to the encrypted field are encrypted with the corresponding encryption context. If the multiple encryption contexts method is selected in the encrypted field configuration, each record is encrypted with the context of the user that enters the data.

If using the **Single Encryption Context** method and data exists in the field that you want to encrypt, open the encrypted field configuration record and select **Run mass encryption** to encrypt existing values.
Run mass encryption or decryption
You can run mass encryption on encryption configurations. Before deleting an encrypted field configuration, run a mass decryption to decrypt previously encrypted values.

Role required: security_admin
You can also create scheduled jobs for mass encryption and decryption. See Schedule mass encryption, decryption, and rekeying jobs for instructions.

Mass encryption and decryption are available only when an encrypted field configuration uses the single cryptographic module. Mass decryption is available for both the single and multiple encryption context methods.

Note: You should run mass encryption and decryption only during non-peak hours because the operations are resource and time intensive.

1. Navigate to System Security \ Field Encryption \ Encrypted Field Configurations.
2. Open the encrypted field configuration for the field you would like to mass encrypt or decrypt.
3. Under Related Links, select an available option.
   • Schedule Mass Decryption job
   • Schedule Mass Encryption job
4. Confirm your selection in the dialog.

If running a mass encryption, all values are encrypted with the encryption context defined in the encrypted field configuration record. If running a mass decryption, only fields encrypted with an encryption context you have access to are decrypted.

Note: If you attempt to Delete a configuration with encrypted fields, you receive the message Please run a Mass Decryption in every encryption context where applicable before deleting to ensure the data is not encrypted. Press Cancel and run a mass decryption before deleting the configuration.

Encrypt an attachment
You can encrypt attachments when you attach them to records.
1. Log in as a user with at least one encryption context.
2. Navigate to a form that needs an attachment added, such as the Incident or Problem form, and click the attachment icon to open the Attachments dialog box.
3. Select the file to be attached.
   Only users with one or more encryption contexts see the Encrypt check box below the file name.
4. Select the Encrypt check box.
   Important: You must select the Encrypt check box before you upload the attachment. If you don’t, the attachment won’t be encrypted.

Users with more than one encryption context are asked to confirm the encryption context. If you select a different encryption context, the encryption context selector updates to reflect the change.
5. Close the Attachments dialog box to upload the file attachment.
Attached files are listed across the top of the form. A special icon identifies encrypted files. Pointing to the icon shows the name of the encryption context. Note that you can see only encrypted files for which you have the encryption context.
Only users with the same context used to encrypt the attachment can see the attachment in the Activity Formatter. Users without the appropriate context won't see the Activity Formatter entry associated with the encrypted attachment.

**Domain separation and Column Level Encryption Support**

Domain separation is unsupported in Column Level Encryption Support, an application that provides the ability to encrypt data in an instance. The ability to access encrypted data in a domain depends on a user's role and domain assignments. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

**Support level: No support**

- The domain field may exist on data tables but there is no business logic to manage the data.
- This level is not considered domain-separated.

For more information, see [Application support for domain separation](#).

**How domain separation works in Encryption Support**

In Encryption Support, encryption configurations and keys are defined by an encryption context. You assign an encryption context to a role or roles, and then assign roles to specific users. Encryption contexts are user-specific, so when you restrict a user to specific domains, the user can access encrypted data only in the domains to which that user has access.

Domain-specific forms and fields are supported. However, there are some restrictions:

- If an encrypted field appears on multiple forms, regardless of domain, the field is encrypted on all forms in all domains.
- **Basic** domain separation is not supported because it would allow service providers (SPs) to create and manage domain-specific encryption contexts and encryption keys across all domains.
- **Standard** domain separation does not apply to encryption.
- **Enhanced** domain separation is not supported because it would allow domain administrators to create and manage domain-specific encryption contexts and keys for their domain.

**Demonstration plugin for CLE**

The instance provides a demonstration plugin called Encryption Support - Single Context Task Encryption Demo (com.snc.task_encryption.demo) for Column Level Encryption.

The demonstration plugin is meant to illustrate how to use business rules, **UI actions**, and UI policy to support encrypted fields. The plugin enforces a limit of one security context per record. The first person to add encrypted information to a record sets the context.

You should test the demonstration plugin on a non-production instance since it modifies the Task table and adds business rules and a UI policy. After activating the plugin:

1. Create one or more encryption contexts.
2. Configure the Incident form to add the **Social security number**, **Credit card**, and **Encryption context** fields.

The plugin UI actions are:

- **Add Secure Info**: appears on records without encrypted data and allows the user to display the social security numbers and credit card fields.
• **Add Secure Info**: appears on records without encrypted data and prompts the user to select an encryption context (if the user has more than one).

• **Change Encryption**: appears on records with encrypted data and prompts the user to select an encryption context (if the user has more than one).

The plugin business rules are:

• **Form Single Encryption Context**: ensures that each form only has one security context.

• **Update on New Encrypted Attachment**: ensures that each attachment has the same security context as the parent incident.

The plugin UI policies show the encrypted fields when appropriate.

### Database encryption and full-disk encryption

ServiceNow® offers database encryption and full-disk encryption methods for customers with statutory obligations for data protection which may require at-rest protection for all data.

- Database Encryption supports all stored data to be encrypted in real time providing protection for data online and offline with no loss of functionality.
- Full disk encryption protects offline data if there is disk loss or theft.

### Database Encryption

Database Encryption enables all data to be protected with symmetric AES-256 encryption, whether the database is online or offline. From the Now Platform perspective, all data flows in decrypted. This capability is available for all supported releases.

With Database Encryption, all stored data is encrypted and individual records or tables are decrypted in memory while being accessed. New or changed data is encrypted as it is entered into a table and associated activity log files (bin, redo, undo, and error) are also encrypted.

Database Encryption is transparent to users, with no loss of functionality. When using this feature, all instances are encrypted, along with replication traffic and backups. Instance cloning is still available with a minor performance impact for using Database Encryption of up to 5%. Both new and existing instances on supported releases of the Now Platform can take advantage of database encryption.

As illustrated, ServiceNow stores and manages keys using a three-level key hierarchy:
1. A customer specific AES-256 key is created by the database engine and is used to encrypt the data.

2. A second customer specific AES-256 key is created by the database engine and is used to protect the first-level key.

3. A third AES-256 key is created by and stored within FIPS 140 validated key management appliances in the ServiceNow datacenters. This key protects the second-level key and is unique per customer instance.

The Now Platform also supports database encryption with a customer supplied switch, DBE with CCS. This is an encryption solution that encrypts all data-at-rest when not in use in the database. It uses industry standard AES encryption with no impact to functionality. The database encrypts data as it is written to the disk, and decrypts data as it is read from the disk. That means that applications always have the data in an unencrypted state to perform the necessary logic and functions without impact.

If you are using your own keys for database encryption, see Database Encryption with Customer-Controlled Switch (DBE with CCS).

**Full disk encryption**

Full disk encryption may be relevant to heavily regulated organizations, but can add significant cost to a customer’s ServiceNow deployment. Measures in place by ServiceNow to mitigate loss or theft of storage devices may also be a factor in its selection.

From the Now Platform perspective, all data flows in decrypted.

Commercial environments use full disk encryption (FDE) with FIPS 140 validated hardware or storage devices that are in the process of validation along with a ServiceNow dedicated hardware option at extra cost. FDE applies to the hardware itself, and therefore provides encryption at rest for all data stored in every instance assigned to you.
Encryption is applied to the entire storage system within the database server only, because this is the only customer data-storing component. FDE protects only against physical loss or theft of storage devices. When encrypted disk servers are powered on and providing data, the encryption provides no additional protection. For further details on selecting FDE and dedicated hardware options, contact your ServiceNow representative.

**Request database key rotation**

Rotate the database (DBE/TSE) key annually or as needed by submitting a request to support.

Role required: admin

Key rotation occurs at night within 24 hours prior to the expiration date and does not interrupt service for the instance.

**Note:** Currently, key rotation is only available in ServiceNow Commercial, GCC, France, and Singapore environments. Key rotation is supported for standard database rotation (DBE/TSE) and not on DBE with CCS.

Contact Customer Service and Support to request any of the following key rotation actions:

- Enroll to perform annual key rotation on all designated instances
- Obtain a historical report of the last three key rotations containing the following:
  - Instance name
  - Key name and version
  - Dates and times of rotation
- Schedule an early key rotation outside of the annual scheduled rotation.

**Database Encryption with Customer-Controlled Switch (DBE with CCS)**

Database Encryption with Customer-Controlled Switch is an encryption solution that encrypts all data-at-rest when not in use in the database.

**Multiple ServiceNow version support**

**Important:** Database Encryption is a paid infrastructure offering that is release agnostic. It can be applied to any supported release and to new or existing instances.

This solution uses industry standard AES encryption with no impact to functionality. The database encrypts data as it is written to the disk and decrypted by the database as it is read from the disk. That means that applications always have the data in an unencrypted state to perform the necessary logic and functions without impact.

This offering utilizes technology native to the database, often called Tablespace Encryption or Transparent Data Encryption. For more details on the technology, refer to the MariaDB website under Tablespace Encryption.

This offering requires you to create an API endpoint that would provide ServiceNow with your Key Encryption Key (KEK).

**What DBE with CCS protects against**

Database encryption addresses two different threat vectors. In each case, the data is encrypted and is thus of no use to the adversary.

- The threat of an adversary getting into the network, stealing the database files and exfiltrating them.
- The threat of an adversary getting into the datacenter and stealing the drives.
Database encryption does not provide protection at the application level. If application-level encryption is needed, Edge Encryption, Platform Encryption, or Column Level Encryption should be used. Database Encryption can be used with Edge Encryption and/or column-level encryption where higher levels of protection are needed. Database Encryption also does not protect against unauthorized users, either internal or external.

**Encryption components**

Encryption is a primary data security control. It works by scrambling data so that only authorized parties can understand information. In technical terms, it’s the process of converting plaintext to ciphertext.

Encryption requires the use of an encryption “key”–a string of characters used within an encryption algorithm for altering data so that it appears random. Like a physical key, it locks (encrypts) data so that only someone with the correct key can unlock (decrypt) it.

A policy might mandate data custodianship, where only you can access the data and ServiceNow does not have the key. This policy leaves you with two options to fully own key management responsibilities:

- **Edge (client-side) Encryption (EE):** An encrypted field of cipher text resides in the ServiceNow cloud:
  - If you don’t want to manage encryption keys, purchase Platform Encryption or use Encryption Support (Column Level Encryption). See any of the following resources:
    - Edge (client-side) Encryption (EE)
    - Platform Encryption
    - Encryption Support
  - Host your instance on premises.

**Your responsibility as a customer using DBE with CCS**

This offering requires you to create an API endpoint that provides ServiceNow with your Key Encryption Key (KEK). This endpoint is solely your responsibility and serves as the customer-end of the communications channel for transporting the key. The endpoint can include a URL of a server or a service. APIs work using requests and responses.

When the ServiceNow API gateway requests info from your endpoint, it receives a response. In this case, the KEK.

- Supplying your own customer supplied key (CSK) introduces an operational risk to the service. Until you are able to provide the original key used in the original encryption process, the cloud provider is unable to decrypt the data.
- If you lose the key, the data is permanently encrypted. Secure your key and establish Business Continuity/Disaster Recovery (BC/DR) options, should you be unable to access and furnish the key.

Regarding the end point, note the following requirements.

- ServiceNow does not set up your endpoint, nor does ServiceNow own any part of the customer API endpoint.
- There might not be any ServiceNow Professional Services available for setting up the endpoint.
• Your security administrators and engineers need API development expertise. Engage the IT/development resources or find a third-party SI to fulfill this obligation, as you have the sole responsibility for building and maintaining the API endpoint to the specs provided by ServiceNow. See the following Knowledge Base article: KB0789788.

• ServiceNow does not specify how you populate your endpoint with your key material. You are solely responsible for integration. For example, if you have an existing HSM/EKM/PKI that generates key material, you can use them to create and wrap the key to make it available to ServiceNow.

• If you are struggling with setting up the API endpoint, you should use the standard DBE option and then use Platform Encryption, which includes key management.

You can utilize a cloud service to host both the endpoint and populate the key using the AWS or Azure KMS. You can also engage a third-party SI or internal development resources.

**Frequently asked questions**

• What is the difference between ServiceNow database encryption (DBE) and database encryption with a customer-controlled switch (DBE with CCS)?

  With Standard DBE, ServiceNow writes a file alongside the database called “keystore_uri” which defines the location of the key. So the key (also called the KEK, or Key Encryption Key) is within the ServiceNow Hardware Security Module (HSM).

  With DBE with CCS, instead of using the ServiceNow internal HSM, the key (also called the KEK, or Key Encryption Key) location is on your endpoint.

• Do I need to provide the X509 certificates for TLS mutual authentication?

  In a TLS request, the client validates the server’s certificate. Mutual authentication means that the client also provides a certificate that the server validates against its own Trust Store. In the request from the gateway to the customer, the gateway does validate the “server” (customer endpoint) certificate. However, ServiceNow only requires that it is signed by a standard Certificate Authority (CA). You do not need to provide a certificate or CA for your endpoint as ServiceNow does not maintain certifications for customers.

  By requiring a standard CA, a high level of protection is still provided. If an attacker intercepts our request, they could return the wrong key, which would trigger an alert for ServiceNow.

• Can I configure the key_id or instance name types in the GET request "https://<customer.endpoint_host.com>/kek/<instance>/<key_id>?"

  No. The instance name is the actual name as your instance and must be precisely the same to validate with your endpoint. The key_id must be an integer and is treated as a version number.

• Can I use key rotation with this solution?

  Key rotation for DBE with CCS is not supported.

• Is IP address filtering necessary when the GET request is made to the endpoint?

  No. You wrap your key with a public key associated with your instance database. It is only decryptable by the corresponding private key, which only ServiceNow has.

• To reduce any security risk, can I allow only certain IP addresses access to the API exposed for the wrapper service?

  Yes, you can define certain IP addresses that access the API exposed for the wrapper service.

**Other references**

See these references for additional information about DBE with CCS:
How DBE with CCS works
Database encryption with a customer controlled switch requires you to set up an API endpoint and wrap your encryption key, which you then send to ServiceNow.

**Multiple ServiceNow version support**

**Important:** Database Encryption is a paid infrastructure offering that is release agnostic. It can be applied to any supported release and to new or existing instances.

This process is used by ServiceNow to obtain and unwrap a customer supplied key after you have successfully provisioned your encrypted instance.

This procedure explains the process in brief:

1. ServiceNow provides an X-DB-Certificate to you. That certificate represents the database of your instance for which ServiceNow needs the key.
2. You wrap your key with the ServiceNow public key.
3. ServiceNow unwraps your key with a ServiceNow private key.

The following diagram illustrates the flow:
Detailed encryption and decryption steps

The following steps detail how your endpoint and ServiceNow communicate to encrypt and decrypt the database. Familiarize yourself with these concepts:

- **DB Key Encryption Key (KEK)** is a key to encrypt other keys.
- ‘wrappedKey’ is your wrapped customer supplied key. There are actually two unique KEKs involved in ‘wrappedKey’:
  - Your customer supplied KEK.
  - The ServiceNow transport wrapping KEK, which is unique per customer database instance. Multiple databases for the same customer instance do not share a key. It is created using your DBI certificate public key.

TLS 1.2 is an encryption protocol intended to keep data secure when being transferred over a network. It must be enabled on your customer endpoint so ServiceNow can make a TLS 1.2 request.

1. You, as the customer, must set up an endpoint. The endpoint is solely your responsibility. Once your endpoint is set up, work with SNC Provision through a Hi request and send them your endpoint URL.
2. You, as the customer, must download the **X-DB-Certificate** attached to this Knowledge Base Article: [KB0789788](#) and remove the .txt extension.

You use the certificate to validate the connection between the ServiceNow CCS API Gateway and your endpoint. The public key from the certificate is also used to wrap your Key Encryption Key (KEK). The certificate contains `tse_<instance_name>`. As part of the validation, you must append `tse_` to the instance name before your endpoint can compare the certificate to the instance. This comparison verifies that the correct instance is making the request.

The certificate used for the request to the gateway is per-instance. Possession of this certificate authorizes the request of a key for that instance.

3. Populate the trust store with the X-DB-Certificate certificate.

4. Once you have requested the provisioning of your encrypted instance in Hi and supplied the endpoint to `thesnc-provision-dev` (SNC Provision), a datacenter instance sets up:
   - A key pair to authentication with the Gateway
   - An SNC Provision configuration for TSE on that instance.

5. **SNC Provision** sends the certificate and the URL of your endpoint to the **ServiceNow CCS Gateway**, which then makes a TLS 1.2 request to your endpoint. As part of the request, the **CCS Gateway** passes along the certificate as a header.

   A **GET** request is made to "https://<customer.endpoint_host.com>/kek/<instance>/<key_id>" where:
   - `<instance>` is an alpha-numeric string; for example: `my_instance123`.
   - `<key_id>` is an integer (ex. 456) that represents the version.

   with headers:
   - X-DB-Certificate: base 64 encoded X509 certificate in DER format.
   - Note: The base-64 encoding used is the "basic" encoding, not the URL-safe or filename-safe variants.

For more information on the response codes for the request, see [KB0789788](#).

6. Your endpoint validates the certificate in the request header. This validation confirms that the instance whose key is requested is one of your instances. It also verifies that it matches the certificate. Remember that the certificate contains "tse_<instance_name>" to identify your instance. The endpoint actually extracts the CN and Subject Alternative Name values from the certificate. Both items must be set to "tse_<instance>" where `<instance>` is the instance specified in the request. If these values are not set correctly, the request FAILs.

   Because the X-DB-Certificate is signed by the correct Certificate Authority, and represents the correct instance, this request is considered valid. However, certificates are not considered secret. So, to protect against requests from an unauthorized party that may have obtained a copy of the certificate, your customer key must be encrypted with the public key of the certificate. This encryption ensures that your key can only be decrypted by the customer database, which has the private key.

7. You, as the customer, must wrap your key (your KEK) using the RSA public key of the certificate that was passed to the endpoint and using PKCS1 OAEP padding. Your key must be 64 characters of hex (32 bytes hex-encoded). This wrapped key is included in the JSON response as the “wrappedKey”. Then you make this wrapped key available to the endpoint.

   **Important:** You, as the customer, are completely responsible for the wrapping of your key. For an example Java class you can use on your endpoint to wrap your customer supplied key, see the Knowledge Base Article [KB0789788](#). The certificate is also attached to that Knowledge Base Article.
8. The endpoint responds to the GET request with this JSON response:

Response:

- Content type: application/json
- JSON format:

```json
{
    "keyId": 1,
    "wrappedKey": "<customer key encrypted with RSA public key and base-64 encoded>",
    "validUntil": "<iso8601 timestamp>
}
```

The `validUntil` timestamp is the time after which ServiceNow must shut down the database on your instance. Your customer endpoint must always specify a future timestamp on each response to the periodic key poll, to signify that the database should remain running. If the `validUntil` time returned is in the past, that signifies that the database must be shut down immediately. Consider using a date calculated from today, such as seven days from today.

9. After the response is received, “wrappedKey” is sent back to the CCS Gateway. Also included in the response are these items:

- An HTTPS REST response code (200 means successful).
- JSON that includes these items:
  - Your KEK wrapped with the public key from the certificate.
  - The Key ID integer.
  - A valid Until Date (VuD).

10. The ServiceNow CCS Gateway then passes "wrappedKey" back to the original SNC Provision request. Since the key is wrapped using the DBI certificate public key, the gateway cannot see the key.

11. SNC Provision unwraps the returned KEK, stores a SHA256 hash of this KEK, then discards your customer supplied KEK.

- The hash confirms that the customer supplied KEK is valid/unchanged.
- Your customer supplied KEK, once unwrapped, unwraps the keystore key, which is stored temporarily on a tmpfs mount in memory. The service itself uses the keystore key to decrypt the keystore in-memory. When the keystore key is no longer needed, it's removed from the tmpfs mount.

**Warning:** When you as the customer decide to pull the "wrappedKey," ServiceNow looks at the Valid Until Date (VuD) that was sent back to SNC Provision via the Gateway. When the VuD passes, the database will close encrypted and the instance ceases operation.

SNC Provision continually checks for access to your KEK. If the polling for the number of allowable retries fails, the database closes encrypted and the instance ceases operation.

The keystore in memory is wrapped with the encrypted keystore key, and without access to the customer supplied KEK, the DB is encrypted and inaccessible.

Restoring the instance requires restoring the original wrappedKey to the endpoint. This procedure resets the # VuD and requires ServiceNow to rebuild the instance. This process might take several days.
DBE with CCS example GET request and response from the endpoint

In a DBE with CCS (Cascading Controlled Switch) scenario, the ServiceNow Gateway makes a GET request to your endpoint. This example illustrates the steps of the GET request and the JSON response.

Path of the GET request: /kek/csctest/1?sourceDBI=db169154.sjc201.service-now.com%3A3400

Header: X-DB-Certificate: MIIFITCCAwmgAwIBAgIEAck ... NxOpKHJ1 {truncated}

1. The endpoint extracts the instance name and version from the GET request path:
2. On the endpoint, the X-DB-Certificate is decoded and parsed.
3. The endpoint then extracts the CN and Subject Alternative Name values from the certificate. Both must be set to "tse_<instance>" where <instance> is the instance specified in the request. If these values are not set correctly, the request FAILs.
4. Your endpoint then extracts the public key from the certificate, and RSA encrypts your customer key using PKCS1 OAEP padding.
   The request is considered valid because the X-DB-Certificate is signed by the correct Certificate Authority. However, certificates are not considered secret. Therefore, your customer key must be encrypted with the public key of the certificate. The certificate helps protect against requests from an unauthorized party that may have obtained a copy of the certificate. #This procedure ensures that only the database of your instance has the key for decryption.
5. Your endpoint uses Base-64 to encode the encrypted key.
6. You determine the next validUntil date. #Use a date calculated from the current date.
7. The endpoint returns a status code 200 and a JSON body. The JSON body contains the key ID, the encrypted and encoded customer key, and the validUntil (VuD) date. The following code is an example:

```json
{
    "keyId": 1,
    "wrappedKey":"nyxyCw03mh8KPW51XPNHAVmm8R96nmKhmPIWU1NdqY6ebppBP2ecpHysgluxuS1a6v1cTbmPC7SgfCNKnSpBmGoN5jM8rIiRw0Lvz/yboU8q2I/Jw/9l7yy766e5y+rnz1Pckj8x5y9y1gUf/MUyf9B8wH51w5g/11jyGn5c99iF1x3zV29w5hOoN93NhOn5UmlhA0GMBu9Q67ZCw==",
    "validUntil": "2021-02-11T00:50:03Z"
}
```

Edge Encryption

ServiceNow® Edge Encryption™ encrypts sensitive data on your company premises before sending it over the Internet to your ServiceNow instance (encrypted in flight), where it remains encrypted at rest.

Understanding Edge Encryption

Edge Encryption is a network encryption system that resides on your network and that encrypts and decrypts sensitive data as it travels between your data center and the ServiceNow cloud.

What is Edge Encryption

The Edge Encryption feature is an additional cost option that provides you with the ability to control the end-to-end encryption of your data and key management. Edge Encryption uses a proxy application, provided by ServiceNow and installed by you within your own network. This proxy application tokenizes specified data patterns or encrypts string fields, Date fields, Date/Time fields, and attachment data before it is sent from your environment to your instance. The proxy application also decrypts the same data, again only within your own network, using keys stored only within your own network.

The relevant encryption keys and configuration exist only on the Edge proxy within your network and are not visible to ServiceNow. The data is encrypted from the moment it leaves your environment and is only decrypted upon retrieval. At no point is the data accessible in plaintext by ServiceNow systems or personnel.

Who uses Edge Encryption

Only a user logged into the instance through a proxy server on your network can view encrypted data in clear text. Likewise, only a security_admin user logged in to an instance through a proxy server in your network can configure and administer Edge Encryption.

Because the proxy server resides in your network, you own and manage the encryption keys, and they are never sent to the instance. As a result, ServiceNow never shows sensitive data in clear text.

In addition to the Edge proxy configuration and management of rules, you are responsible for the usual requirements of operating a server within your environment (including hosting, routing, backup, DNS configuration, etc.) to enable and support your Edge proxies.

Encryption and tokenization

Edge Encryption supports both encryption (through encryption configurations) and tokenization (through encryption patterns) as a means of protecting your sensitive information.

Encryption configurations

You can encrypt individual fields using encryption configurations. Edge Encryption supports AES 128-bit and AES 256-bit encryption keys. Edge Encryption supports standard, equality-preserving, and order-preserving encryption types.
In addition to attachments, you can encrypt the following field types:

- String
- Date
- Date/Time
- Journal
- Journal Input
- URL

If a Journal field marked for encryption is added to the activity stream, all user input to the field is encrypted in the activity stream.

**Note:** Multi-byte characters within supported field types can be encrypted.

### Encryption patterns

You can use encryption patterns to tokenize strings that match regular patterns such as social security and credit card numbers. While encryption configurations should be the primary method of encryption, use encryption patterns as a supplement to secure sensitive information found outside of encrypted fields.

**Note:** The Edge Encryption proxy server requires a MySQL database in your network only if using order preserving encryption or encryption patterns. Clear text values are stored in the proxy database in your network. For this reason, it is critical that you secure and regularly back up your proxy database. For recommendations, see Edge Encryption components.
Edge Encryption on the Now Platform

Edge Encryption acts as a gateway between your browser and your ServiceNow instance. Traffic from your browser passes through the gateway on its way to the ServiceNow instance. The gateway, in turn, is configured to encrypt outbound data that is marked for encryption. Inbound traffic is decrypted through the gateway, and the end user sees clear text in the browser. The advantage of this implementation from a security control perspective is that the encryption and key management are handled externally from ServiceNow.

Pro's and con's

As with Platform Encryption and Column Level encryption, Edge Encryption imposes some functional limitations within an instance as a result of the additional security. The local Edge proxy does, however, also provide some additional functionality relating to sorting when compared to column-level encryption.

Pros:
• Edge Encryption provides absolute control of who sees your information and prevents data breaches.
• Information remains on your proxy server and never leaves your network unencrypted.
• Information is encrypted in transit, before it even reaches the ServiceNow instance.
• You hold and manage all your own encryption keys. No one else, not even ServiceNow personnel, can access your keys.
• You can choose the strength of the encryption algorithm: AES-128 or AES-256.
• Edge Encryption includes the ability to encrypt String text, Date and Date/Time fields, attachments, URLs, and journals.
• Edge Encryption provides Standard, Equality Preserving, and Order Preserving encryption of data at rest within the database and instance.
• Encryption rules allow you to write custom scripts that tell the proxy server specifically what to encrypt and where to put that encrypted information in the instance. This is useful when the data structure doesn't exactly match the ServiceNow instance.
• Encryption patterns allow you to tokenize information such as passwords.

Cons:
• Edge Encryption requires an extra network hop through the Edge proxies cluster, and extra processing, which can add delay to traffic. The added processing delay of the Edge Encryption application is negligible compared to the network hop.
• Maintaining your own encryption keys can be complex and time-consuming.
• You can maintain a maximum of two keys, with no flexibility to define different keys for different subsets of columns/data, or for different roles, etc.
• Edge Encryption has the side effect that the server or platform can't decrypt the data to perform any manipulation of the decrypted data. As a consequence, functionality and data processing on the Now Platform may be restricted when encrypting columns with Edge Encryption.

What to know before you begin

Because encryption and tokenization change the nature of your data, Edge Encryption can affect other instance processes. Before using Edge Encryption, carefully consider the impact on your instance.

Because the proxy server is installed and maintained in your network, Edge Encryption requires network administration and management. Review the network requirements to ensure a smooth implementation.

Review the following topics to understand the impact of Edge Encryption on your instance:
• Planning for Edge Encryption
• Edge Encryption system requirements
• Sizing your Edge Encryption environment
• Calculate the order-preserving and tokenization database size
• Edge Encryption limitations
• Key management for Edge Encryption
**Edge Encryption components**

Edge Encryption is comprised of the Edge Encryption proxy server that runs on a server in your network, and the Edge Encryption plugin that must be installed on your ServiceNow instance. If using order-preserving encryption types or encryption patterns, a proxy database must also be installed in your network.

**Proxy application**

When going through the Edge Encryption proxy server, the Edge Encryption plugin allows you to specify which fields, patterns, and attachments should be encrypted. You can also manage encryption rules to encrypt specific requests and schedule mass encryption jobs.

**Proxy server**

The Edge Encryption proxy server uses encryption rules to identify in an HTTP request what, if anything, needs to be encrypted and encrypts it before forwarding the request to the instance. For decryption, the Edge Encryption proxy server looks at the HTTP responses for any encrypted data and decrypts it before sending the response back to the client. In order for this to happen, all HTTP requests and responses must go through the Edge Encryption proxy server. This includes any requests originating from a browser, as well as any SOAP or REST requests.

**Proxy database**

If using order preserving encryption or encryption patterns, your proxy servers rely on a MySQL database located in your network. All proxy servers in your network must use the same database.

The proxy database contains these tables.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>db_id</td>
<td>Unique database ID</td>
</tr>
<tr>
<td>edge_token_map</td>
<td>Encryption pattern data</td>
</tr>
<tr>
<td>token_map</td>
<td>Order-preserving encryption data</td>
</tr>
</tbody>
</table>

**Back up your proxy database**

Because encryption patterns rely on tokenization, clear text values are stored in your proxy database. If the database is lost, clear text values cannot be restored. It is critical that you maintain regular backups. To avoid data loss, back up your proxy database according to ServiceNow recommendations.

- Back up your database every 24 hours.
- Retain MySQL database binary log files for at least two days. After a backup has been restored, use the binary log to regenerate any data lost since the most recent backup. Refer to MySQL database backup best practices for your database version.
Edge Encryption clients
Edge Encryption uses three clients to inform the instance that the proxy is running, to synchronize requests between the proxy and the instance, and to forward all end user requests to the instance after any potential encryption.

<table>
<thead>
<tr>
<th>Client</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>heartbeat/keepalive client</td>
<td>In charge of sending a request to the ServiceNow instance every 5 seconds to let the instance know that this proxy is up and running. The requests drive the last_response_on field on the Edge proxy table, and as a consequence drive the state of the proxy. If your system has issues sending the requests, or if the request or request processing is delayed, the instance may mark the proxy as unresponsive, even if the other clients (including the one for user traffic) are up and running. This client also controls the online status of the proxy on the instance. The edgeencryption.proxy.keepalive.interval property controls the polling rate for this client. The default is 5 (seconds).</td>
</tr>
<tr>
<td>polling/sync client</td>
<td>In charge of various requests the proxy sends to the instance to synchronize on the Edge Encryption configuration (for example, which table, column, or attachment to encrypt, keys, jobs, rules, and tokenization patterns). The edgeencryption.config.poll.interval property controls the polling rate for this client. Warning: Do not change this setting. Changing the default setting of the proxy poll interval may result in synchronization delays when updating Edge Encryption settings on the instance.</td>
</tr>
<tr>
<td>default/user traffic client</td>
<td>For everything else, this client handles all end user requests and forwards them to the ServiceNow instance after any potential encryption. This client also handles responses from the instance, forwarding them to the end user after any potential decryption.</td>
</tr>
</tbody>
</table>

Key management for Edge Encryption
You are responsible for providing and managing the encryption keys used by Edge Encryption.

This topic refers to keys for the Edge Encryption product. If you are looking for information on the Key Management Framework, which can be used with Column Level Encryption, see Key Management Framework.

When obtaining and creating encryption keys to support the encryption types used by Edge Encryption, consider the following:

- Whether to use AES 128-bit or AES 256-bit. You must define a default AES 128-bit encryption key, even if it is not used.
- Whether to use file system, Java KeyStore, or Enterprise Key Management (EKM).
- When to rotate encryption keys.
- When and if to use a mass encryption job to re-encrypt data using the new key.

Before removing a key from the proxy configuration files and the keystore, it is critical that you decrypt all data on the instance that uses the key. You can do this by adding a new encryption key and scheduling a mass key rotation job.
Keystores

Edge Encryption supports the following types of key storage.

**File store**

Keys are stored in a file in a file system that is accessible by the Edge Encryption proxy. Encryption keys stored in a file are not encrypted, so it is your responsibility to protect these files.

**Java KeyStore**

Keys are stored in Java's JCEKS KeyStore. A Java KeyStore is protected by a password, so it is more secure than storing keys in a file in the file store. A single Java KeyStore can store multiple keys, and the keys are identified by a key alias, making it easier to manage multiple keys.

**Enterprise Key Management (EKM)**

Keys are stored and retrieved with the SafeNet KeySecure or Unbound Technology key management systems.

The Edge Encryption proxy ships with the Java JCEKS KeyStore file named `keystore.jceks` in the `keystore` directory. This keystore file contains the ServiceNow public key used to validate encryption rules signed by ServiceNow.

**Note:** If using a keystore other than the base system Java JCEKS KeyStore, you must import the ServiceNow public key into your keystore. The public key alias is `servicenow`.

In addition to the encryption keys, the Java JCEKS KeyStore is used to store the RSA key pair for digitally signing the encryption configuration and encryption rules that are stored in the instance, and the digital certificate that the Edge Encryption proxy uses to establish a secure connection with the browsers and any other clients.

SafeNet key versioning for Edge Encryption

Use SafeNet key versioning to simplify changing keys. Instead of creating a new alias for every new key, SafeNet key versioning keeps the same alias and increments the version.

You must set up key versioning in SafeNet before you can configure SafeNet key versioning on the Edge proxy server.

**Note:** Edge proxies installed before the London release support SafeNet keys, but do not support SafeNet key versioning. If you mistakenly use a versioned key on a Kingston or earlier proxy, when you upgrade to a London or later release, the London or later proxy detects this problem, and to prevent potential data loss the proxy does not start.

You must first schedule a mass key rotation job or a single key rotation job to replace the old SafeNet versioned key with a non-versioned key, and then create a new SafeNet versioned key, if needed. This new versioned key is safe to use with the London or later proxy, and you can restart the proxy.

Encryption key configuration

If using SafeNet versioned keys, the Change Default Keys section of the Encryption Key Configuration form includes new fields for the **Key version** of the default 128-bit and 256-bit keys. **Key version** fields are grayed out and cannot be edited.
For procedures, see Configure encryption keys on the instance.

**Versioned keys**

If using SafeNet versioned keys, when you navigate to Edge Encryption Configuration > Encryption Key Configuration > All Keys, versioned keys include the Key version.

A version number does not appear for the initial entries you make in the Change Default Keys section of the Encryption Key Configuration form. When the proxy server requests a key from SafeNet, the system adds a new line for the alias and adds the **Key version**.

In the above example, **AES128key** is listed three times:

- The first listing, with no **Key version** indicated, is the initial entry.
- The second listing, with 1 in the **Key version** column, is the first version of the key returned from SafeNet.
- The third listing, with 2 in the **Key version** column, is the second version of the key returned from SafeNet.
• As other versions of the key are returned from SafeNet, new lines are added to record the **Key version** now in use.

**Encryption configurations and patterns**
With Edge Encryption, you can encrypt fields and tokenize strings.

**Encryption configurations**

You can encrypt individual fields using encryption configurations. Edge Encryption supports AES 128-bit encryption keys. If the Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction Policy files are installed, Edge Encryption supports AES 256-bit encryption keys for each encryption type. Edge Encryption supports the following types of encryption configurations.

**Standard encryption**
The encrypted value of a field is different each time the field is encrypted, even when the field value remains the same. Standard encryption is the most robust form of encryption. Fields using standard encryption cannot be sorted, grouped by, or filtered on.

**Equality-preserving encryption**
The encrypted value of a field is the same when the field value remains the same. Supports equality comparisons and group by operations on a field.

**Note:** When equality-preserving encryption is selected for a field that already contains data, performing a group by action on the field may not group fields with the same value if one is encrypted and the other is not.

**Order-preserving encryption**
Uses tokens and encryption to secure data in your proxy database. Supports equality comparisons, group by operations, and the ability to sort data. The order preserving encryption type is only supported if there is a MySQL database configured for the Edge Encryption proxy server.

**Note:** When using order-preserving encryption and the proxy database is down, updates can be made to fields using order-preserving encryption. However, the sort order will not be correct when trying to sort data based on those fields. Groups also will not work as expected. When the proxy database is again operational, schedule an order token repair job to repair missing tokens.

**Encryption types**
The following encryption types are listed in decreasing security quality.

<table>
<thead>
<tr>
<th>Encryption type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standard AES 256</td>
<td>Fields cannot be filtered, sorted, or compared.</td>
</tr>
<tr>
<td>Standard AES 128</td>
<td>Fields cannot be filtered, sorted, or compared.</td>
</tr>
<tr>
<td>Equality preserving AES 256</td>
<td>Fields can be filtered using equality comparisons.</td>
</tr>
<tr>
<td>Equality preserving AES 128</td>
<td>Fields can be filtered using equality comparisons.</td>
</tr>
<tr>
<td>Order preserving AES 256</td>
<td>Fields can be sorted and equality comparison filtering can be used. Requires the use of a MySQL database in your network.</td>
</tr>
</tbody>
</table>
### Encryption Patterns

You can secure sensitive data found in strings using encryption patterns. Once an encryption pattern is stored and activated, the Edge Encryption proxy server identifies strings that match the pattern in requests. Once located, the clear text string is stored in the proxy database and replaced on the instance with a token. Use encryption patterns to tokenize strings that match regular patterns such as social security and credit card numbers. While we recommend that encryption configurations be the primary method of encryption, use encryption patterns as a supplement to locate and secure sensitive information found outside of encrypted fields.

**Note:** The Edge Encryption proxy server requires a MySQL database in your network only if using order preserving encryption or encryption patterns. Clear text values are stored in the proxy database in your network. For this reason, it is critical that you secure and regularly back up your proxy database. For recommendations, see Edge Encryption components.

**Installed with Edge Encryption**

Edge Encryption installs tables to store encryption-related data, system properties to configure default behavior, and the edge_encryption role to administer Edge Encryption.

**Tables installed with Edge Encryption**

Edge Encryption adds the following tables.

- **Edge Encryption Configuration [sys_encryption_configuration]**
  - Contains encrypted fields and tables for which attachments are encrypted.

- **Edge Encryption Rule [sys_encryption_rule]**
  - Contains a record for each rule. A rule has a name, the condition when it is used, a script, and an order field.

- **Edge Encryption Invalid Insert Log [sys_edge_encryption_invalid_insert_log]**
  - Contains log messages created for attempts to save unencrypted data to an encrypted field.

- **Edge Encryption Proxy [sys_encryption_proxy]**
  - Contains information about the encryption proxy application.

- **Edge Proxy Encryption Type [sys_proxy_encryption_type]**
  - Used for enabling and disabling encryption types on the encryption form.

- **Encryption Job Execution [sys_encryption_job_execution]**
  - Supports mass encryption jobs.

- **Encryption Job Execution Chunk [sys_encryption_job_execution_chunk]**
  - Supports mass encryption jobs.

- **Scheduled Encryption Job [sysauto_encryption_job]**
  - Lists scheduled jobs for encryption, decryption, key rotation, order token repair, and database recovery.

- **Encryption Key Configuration [sys_encryption_key_configuration]**

---

<table>
<thead>
<tr>
<th>Encryption type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Order preserving AES 128</td>
<td>Fields can be sorted and equality comparison filtering can be used. Requires the use of a MySQL database in your network.</td>
</tr>
</tbody>
</table>
Lists default encryption keys.

**Encryption Key [sys_encryption_key]**
Lists available keys and key attributes.

**Proxy Encryption Key [sys_encryption_proxy_key]**
Lists proxy encryption keys.

### Properties installed with Edge Encryption

Edge Encryption adds the following properties.

**Note:** To open the System Properties [sys_properties] table, enter `sys_properties.list` in the navigation filter.

- **glide.edge.pattern.disallowed.chars**
  A list of characters that are not allowed in patterns.
  - **Type:** a string of a comma-separated list of values
  - **Location:** System Properties [sys_properties] table

- **glide.edge.pattern.min.size**
  The minimum pattern size allowed. Allowing smaller patterns means finding more matches, which increases overhead.
  - **Type:** number
  - **Default value:** 5
  - **Location:** System Properties [sys_properties] table

- **sn_edge_encryption.logging.destination**
  Where messages are logged.
  - **Type:** string
  - **Default value:** file
  - **Location:** System Properties [sys_properties] table

- **sn_edge_encryption.logging.verbosity**
  The logging level to use.
  - **Type:** string
  - **Default value:** info
  - **Location:** System Properties [sys_properties] table

- **sn_edge_encryption.encryption.proxy.buildtag**
  The proxy version registered with your instance.
  - **Type:** string
  - **Location:** System Properties [sys_properties] table

- **sn_edge_encryption.cleartext.allowed**
When true, allows clear text to be saved in an encrypted field. This happens when a user is accessing the instance without going through the Edge Encryption proxy. When false, the system prevents clear text from being saved in an encrypted field.

- **Type**: Boolean
- **Default value**: false
- **Location**: System Properties [sys_properties] table

### Role installed with Edge Encryption

**edge_encryption**

Edge Encryption proxies log into the instance as a user, with a user name and password. The user must have this role assigned.

Contains roles: None

### Planning for Edge Encryption

Successful implementation of Edge Encryption requires planning and preparation.

Answer the following questions in the planning stage.

- Which fields are to be encrypted?
- Which encryption types are to be used?
- How many Edge Encryption proxies are needed? See Sizing your Edge Encryption environment for recommendations and considerations.
- If an order preserving encryption type or encryption patterns are to be used, where is the MySQL database located?
- Which key management system is to be used?

System administrators, network administrators, and security team members have different tasks to fulfill for implementing Edge Encryption.

- System administrators need the security-admin role. The system administrator needs to:
  - Download the Edge Encryption proxy application.
  - Set up an Edge Encryption user account for the proxies to use to connect to the instance. The user must be assigned the edge_encryption role.
  - Configure encryption keys, and set the default keys.
  - Configure Edge Encryption on the instance.
  - Schedule encryption jobs.
  - Monitor Edge Encryption.
  - Create and edit encryption rules.
- Your network administrator needs to:
  - Install the Edge Encryption proxy application.
  - Know the network addresses for the proxy servers and the proxy database used for order-preserving encryption and encryption patterns.
  - Install the proxy database to be used for order-preserving encryption and encryption patterns.
  - Start and stop the proxy applications.
  - Perform encryption key management.
  - Determine how to map users to encryption proxy applications. This can be done with DNS settings or routing rules, and is specific to each network.
  - Manage multiple proxy servers.
• Configure load balancer pools and settings.

• Your security administrator must determine the encryption types to be assigned to each field.

**Edge Encryption system requirements**

You can run the Edge Encryption proxy application on servers or virtual machines that run on Microsoft Windows or Linux operating systems. For optimum performance, ensure that your configuration meets these requirements.

**Java requirements**

The host machine installing or running the Edge Encryption proxy server must maintain a supported version of Java:

- Java 8 update 121 (8u121)
- Java 8 update 141 (8u141)
- Java 8 update 151 (8u151) or later

**Note:** Java 8 update 131 (8u131) is not supported.

- Java 11.0.6 or later

**Note:** Before installing the Edge Encryption proxy server, check that the `$JAVA_HOME` variable is pointing to a supported version of Java for each user that will run the proxy server. For example, if installing the proxy server as a local administrator on Windows, check that the `$JAVA_HOME` variable is pointing to the correct version of Java system-wide. If installing on Linux, check that each user that will run the proxy server has this variable correctly defined. If a supported version of Java is not found, the Edge Encryption proxy server will not run.

<table>
<thead>
<tr>
<th>Java Version</th>
<th>Enabling AES 256-bit Encryption</th>
</tr>
</thead>
<tbody>
<tr>
<td>Java 8 update 141 (8u141) or earlier</td>
<td>Install the Java Cryptography Extension (JCE) jurisdiction policy files by copying them into the system Java home directory of each Edge Encryption proxy server host. Add these files to the <code>&lt;Java-home-directory&gt;/jre/lib/security</code> folder before performing a scheduled or manual upgrade. To install the AES 256-bit encryption policy files, see Enable AES 256-bit encryption for Java 8 update 141 (8u141) or earlier.</td>
</tr>
<tr>
<td>Java 8 update 151 (8u151) or later</td>
<td>A <code>java.security</code> file is downloaded with the update. Edit the <code>java.security</code> file to enable AES 256-bit encryption. To edit the <code>java-security</code> file, see Enable AES 256-bit encryption for Java 8 update 151 (8u151) or later. <strong>Note:</strong> If upgrading an Edge Encryption proxy server running on Windows to a new version of Java, you may need to copy the JCE policy files from your previous Java folder to the new Java folder.</td>
</tr>
</tbody>
</table>
Note: Java does not automatically allow unlimited strength keys. You must specifically enable the use of AES 256-bit encryption.

Support for OpenJDK

Starting with the Orlando release, the Now Platform supports the following versions of openJDK:

- OpenJDK version 8
- AdoptOpenJDK version 8
- OpenJDK version 11

Proxy server minimum configuration

A proxy server requires this minimum configuration:

- 4 GB of RAM per proxy server (6 GB is recommended for most deployments).

Note: The proxy server host requires at least 1 GB of RAM more than the proxy server. The proxy server host needs the extra 1 GB for operating system services. For example, if you configure a proxy server to use 4 GB of RAM, you must install at least 5 GB of RAM on the proxy server host.

Because the proxy server requires at least 4 GB of memory, 32-bit JREs and 32-bit operating systems are no longer supported starting with the London release.

- 3 or more GHz CPU (4-core CPU preferred for optimum performance).
- Multiple proxy servers behind a load balancer. The number of proxy servers you need depends on the number of application nodes, the number of simultaneous users, and the number of servers needed for failover. See Sizing your Edge Encryption environment for more information.
- Ability to run concurrently with other services, depending on the server utilization and resource availability.

Proxy server supported systems

The following systems are supported:

<table>
<thead>
<tr>
<th>Supported System</th>
<th>Description</th>
</tr>
</thead>
</table>
| Windows Server 2012, 2012-R2, and 2016 editions | • Virtual machines or physical hardware  
• 64-bit systems |
| Linux | • Virtual machines or physical hardware  
• 64-bit systems  
On 64-bit Linux systems, you must install the 32-bit GNU C library (glibc). The installation command for CentOS is `yum install glibc.i686`. |
Proxy server connection requirements

The proxy server that runs the Edge Encryption application must be able to communicate with machines in your network. Make sure that the proxy server has these network privileges:

<table>
<thead>
<tr>
<th>Network Privilege</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Firewall access</td>
<td>Configure any firewalls between the proxy server and the client devices to allow a connection. If your network uses a DeMilitarized Zone (DMZ) to add an extra layer of security to your Local Area Network (LAN), and if your network security protocols limit port access from within the network to the DMZ, you might have to deploy a proxy server to a machine within the DMZ.</td>
</tr>
<tr>
<td>Network access</td>
<td>Configure each client to enable the proxy server to connect with it. If network security prevents you from configuring new machines that can connect to the clients, install the proxy server on an existing machine with connection privileges.</td>
</tr>
<tr>
<td>Instance access</td>
<td>Ensure that the proxy server has network access to the instance. Make sure that you configure the proxy server network to allow traffic over TCP port 443.</td>
</tr>
<tr>
<td>Network account</td>
<td>Install the proxy server with either a local or domain administrator.</td>
</tr>
</tbody>
</table>

Order-preserving and tokenization database system requirements

Order-preserving encryption and encryption patterns require that you configure an Oracle MySQL database for the Edge Encryption proxy server. Order-preserving encryption allows any comparison operation to be directly applied on encrypted data, without first decrypting the data. Encryption patterns let you replace string patterns with tokens (called tokenization) before they are sent to and stored in the database. Because of the size of the MySQL database, use a dedicated proxy server to run the order-preserving and tokenization database.

The minimum database system requirements include:

<table>
<thead>
<tr>
<th>MySQL Database</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version</td>
<td>MySQL database versions 5.5 to 5.7</td>
</tr>
<tr>
<td>OS</td>
<td>64-bit systems</td>
</tr>
<tr>
<td>CPU</td>
<td>2 or more GHz CPU (4-core CPU preferred for optimum performance)</td>
</tr>
<tr>
<td>RAM</td>
<td>16 GB</td>
</tr>
<tr>
<td>Disk</td>
<td>Storage Area Network (SAN) or local storage (RAID 10 recommended)</td>
</tr>
<tr>
<td>Size</td>
<td>Determined by the number of potential records multiplied by the record size. See Calculate the order-preserving and tokenization database size.</td>
</tr>
</tbody>
</table>
MySQL Database | Requirement
--- | ---
Configuration | High availability cluster. If you are unsure of how to configure your MySQL server, contact MySQL for configuration information.

**Sizing your Edge Encryption environment**

Choosing the number of proxy servers for your environment is an important task. Consider the number of users, redundancy needs, and acceptable latency.

**Redundancy**

Maintain redundant proxy servers in case of hardware failure. Proxy servers should be located behind a load balancer to provide a functional path for all users if a proxy server is unreachable. At a minimum, ensure that two proxy servers are always available.

**Size**

Size refers to the number of proxy servers required to avoid additional latency that the encryption of data produces. Depending on use, you may want to reduce the amount of latency by adding additional proxy servers. For example, if regular mass encryptions are run, add additional proxy servers to handle the load, or run the mass encryptions when the user load is light. In addition, the hardware that the proxy server runs on influences performance and latency. Proxy servers running on hardware with faster CPUs, more CPUs, and more RAM have higher throughput than slower, limited systems.

The following guidelines assume that your proxy server is running on at least the minimum hardware requirements. To determine the number of proxy servers:

- Consider setting up one proxy server for every two application nodes on the instance.
- For redundancy, set up a minimum of two proxy servers behind a load balancer.
- Add an extra proxy server for every 500 simultaneous users.
- Depending on the desired redundancy, add additional proxy servers for failover.

For example, for an instance with 2,000 users, you should have at least five proxy servers behind a load balancer. This calculation includes one proxy server for every 500 users, with an extra proxy server for failover. Determine ahead of time when you will approach a threshold of 500 users and place another proxy server in the load balancer pool.

**Load balancers**

To balance requests and improve server response time, distribute proxy servers in a load balancer pool. Configure load balancers to use the "least connections" method. This method connects requests to the proxy server with the fewest active connections, preventing the overloading of a single proxy.

**CPU utilization**

Because data encryption and tokenization are CPU intensive operations, CPU spikes while encrypting data are normal and expected. When CPU utilization is over 80% for several minutes at a time, it likely means that the proxy server has too much work to do. When this happens, latency increases for the period that the CPU utilization is high. If latency persists, adding another proxy server may help decrease the latency.
Memory

The proxy server must have a minimum of 4 GB of RAM available (6 GB recommended). Set the proxy server initial and upper bound memory limits to the recommended settings.

Calculate the order-preserving and tokenization database size

If using order-preserving encryption or encryption patterns, determine the size of your MySQL database by multiplying the number of potential records by record size.

Use a dedicated machine to run the order-preserving and tokenization database. Do not run the database on the same hardware as the proxy server.

1. Determine the potential number of records that could include fields encrypted with order-preserving encryption.
   a) Multiply the number of encryption configurations using order-preserving encryption by the number of records each configuration is applied to.
   b) To allow for growth, multiply the result by three.

2. Multiply the result of step 1 by 1,536.
   1,536 is the average size of a record in bytes.

3. If using encryption patterns, perform steps 1–2 for tokenized records and add the result to the total.

The calculated value is the recommended size in bytes for your order-preserving and tokenization database.

Edge Encryption limitations

Edge Encryption impacts system functions. Carefully evaluate the impact of encrypting a field.

Field type restrictions

You can encrypt only the following field types:

- String
- Date
- Date/Time
- Journal
- Journal Input
- URL

You cannot encrypt the following field types:

- Choice fields
- Virtual fields
- Fields in system tables, except for certain fields in sys_user
- System fields in tables
- Number fields or fields associated with an auto-numbering scheme
- Any other field type not listed above

Additional restrictions:

- When a Journal field is encrypted, the Post button is disabled, even if there are multiple Journal fields and only one of those fields is encrypted.
- Encrypted fields are not available in Go to and header filter boxes.
- When encrypting fields used as an index, you can use only order-preserving and equality-preserving encryption types. Indexed fields cannot be encrypted using the standard encryption type.

For more information, see Field types.
Filtering and searching restrictions

Standard encryption
When you select a String, Date, Date/Time, or URL field with a standard encrypted field configuration as the left operand in a filter, no filtering options are available.

Equality-preserving encryption
When you select a String, Date, Date/Time, or URL field with an equality-preserving encrypted field configuration as the left operand in a filter, the following operators are available:
- is
- is not
- is empty
- is not empty

Order-preserving encryption
When you select a String field with an order-preserving encrypted field configuration as the left operand in a filter, the following operators are available, in addition to is, is not, is empty, and is not empty:
- greater than
- less than

When you select a Date or Date/Time field with an order-preserving encrypted field configuration as the left operand in a filter, the following operators are available, in addition to is, is not, is empty, and is not empty:
- after
- before
- after or on
- before or on

Date and Date/Time pickers
For Date fields, use the date picker to specify the date:

For Date/Time fields, use the date and time picker to specify the date and time:
List condition filters

The **Show Matching** and **Filter Out** options are supported in lists. Only exact matches are returned or filtered out.

**Note:** Adding encrypted fields in condition filters is supported in scripts such as UI policies and business rules.

Configuration restrictions

Restrictions and behavior of encryption configurations:

- After you add a field to the Edge Encryption Configuration table, you cannot delete the configuration record. If you no longer want a field to be encrypted, deactivate the record in the Edge Encryption Configuration table and schedule an encryption job to decrypt the data.
- If a field in a parent table is marked to be encrypted, the field is also encrypted in all inherited tables. For example, if the **Short description** field in the Task table is encrypted, then the contents of the **Short description** field in the Incident table are encrypted.
- If a field inherited from a parent table is marked to be encrypted, the field in the parent table cannot be encrypted. For example, if the **Short description** in the Incident table is marked to be encrypted, then the **Short description** in the Task table cannot be encrypted. In this example, you can encrypt the **Short description** in the Problem table.
- When a field with an encryption configuration defined is exported to any format, the output includes encrypted values even when exported through the proxy server.
- You cannot import data to a field with an encryption configuration defined.
- You cannot encrypt inherited Date and Date/Time fields. Date or Date/Time fields inherited from a parent table are not listed on the **Column** field drop-down list, and you cannot create Date or Date/Time encryption configurations for those fields.
- You can encrypt a String or URL field only from a parent table or a child table, but not both.

Instance restrictions

Impact of using Edge Encryption on the instance:
• Back-end logic cannot process encrypted data. When the instance contains encrypted data, any business rule, back-end script, or back-end feature that relies on evaluating the data in the encrypted field does not run correctly.

**Note:** Data encrypted with equality-preserving or order-preserving encryption still passes equivalence checks when compared against an identical encrypted value.

• Since email processing goes from the mail systems straight to the instance and cannot pass through the Edge proxy, data sent in or out via email cannot be encrypted or decrypted by the Edge proxy.
  • Data and attachments in inbound emails are not encrypted.
  • Data and attachments in outbound emails remain encrypted and cannot be decrypted.

• Scripts run on the server cannot change encrypted data.

• Global search is not supported. Because global search attempts to search both encrypted and clear text data, the results may not be as expected.

• Encrypted data cannot be copied and pasted into a record where the field is not encrypted.

• Depending on the type of encryption selected, the user interface functionality for the encrypted fields is reduced. For example, being able to compare, group by, sort, and search may be impacted. Generally, the stronger the encryption selected, the more functionality is reduced.

• Except for Java KeyStore, SafeNet, and Unbound Technology, no third-party software or hardware encryption key management is supported.

• Although multiple proxy servers connected to a single instance are supported, encryption proxy cluster management and monitoring are not available. Each proxy must be managed separately.

• System configurations such as workload and the number of encrypted fields can impact the performance of encrypted fields.

• The Edge Encryption proxy server can only connect to a single instance.

• If your instance uses an Oracle database and the String field you are marking to be encrypted is greater than 2925 characters, that field cannot be sorted even when order preserving encryption is selected.

• If your instance uses an Oracle database, Unicode AL32UTF8 is the only supported character set.

• Encrypted data cannot be used in reports.

### Edge Encryption installation

You can install an Edge Encryption proxy manually or using the Edge Encryption interactive installer.

### Java requirements

The host machine installing or running the Edge Encryption proxy server must maintain a supported version of Java:

• Java 8 update 121 (8u121)
• Java 8 update 141 (8u141)
• Java 8 update 151 (8u151) or later

**Note:** Java 8 update 131 (8u131) is not supported.

• Java 11.0.6 or later

**Note:** Before installing the Edge Encryption proxy server, check that the $JAVA_HOME variable is pointing to a supported version of Java for each user that will run the proxy server. For example, if installing the proxy server as a local administrator on Windows, check that the $JAVA_HOME variable is pointing to the correct version of Java system-wide. If installing on Linux, check that each user that will run the proxy server has this variable correctly defined. If a supported version of Java is not found, the Edge Encryption proxy server will not run.
Installing the proxy server

Installing Edge Encryption includes these steps.

- Install the Edge Encryption proxy application on a server in your network using the interactive installer or the manual installer.
- Generate the RSA key pair for digitally signing encryption configurations and encryption rules.
- Install the Java Cryptography Extension (JCE), if you plan to use AES 256 encryption.
- If you are using a secure SSL connection, obtain a server certificate and import it to the Java KeyStore.
- Set up your keystore and encryption key.
- If order preserving encryption types or encryption patterns are to be used, set up a MySQL database on a machine in your network.
- Set the desired properties. Properties are located in the `edgeencryption.properties` configuration file.
- Specify that a proxy server is a trusted source so that Edge Encryption can process requests coming from that proxy server.

Accessing the proxy server

Once installation is complete, point each user's browser to an Edge Encryption proxy using the URL format: `<host>:<port>`. Values are determined by the host and port properties in the `edgeencryption.properties` file.

As an example with the following values:

<table>
<thead>
<tr>
<th>Property</th>
<th>Example value</th>
</tr>
</thead>
<tbody>
<tr>
<td>edgeencryption.proxy.host</td>
<td>hostname.mycompany.com</td>
</tr>
<tr>
<td>edgeencryption.proxy.http.port</td>
<td>8081</td>
</tr>
</tbody>
</table>

A client will access the proxy server using the following address: `http://hostname.mycompany.com:8081/`.

**Note:** DNS settings and routing rules may be used. Host and port values are determined by your network administrator.

Request Edge Encryption

The Edge Encryption plugin (com.glide.edgeencryption) is available as a separate subscription.

To purchase a subscription, contact your ServiceNow account manager. The account manager can arrange to have the plugin activated on your organization's production and subproduction instances, generally within a few days.

If you don't have an account manager, decide to delay activation after purchase, or want to evaluate the product on a subproduction instance without charge, follow these steps.

Role required: none

1. Navigate to System Applications > All Available Applications > All.
2. On the All Applications page, click **Request Plugin** to open the Request form on HI.
3. On Now Support, select the redirect link to access the Now Support Service Portal Service Catalog.

4. On the form, fill in the fields.

**Activate Plugin request form**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target Instance</td>
<td>Instance on which to activate the plugin.</td>
</tr>
<tr>
<td>Plugin Name</td>
<td>Name of the plugin to activate.</td>
</tr>
<tr>
<td>Specify the date and time you would like this plugin to be enabled</td>
<td>The date and time must be at least two business days from the current time.</td>
</tr>
<tr>
<td>Reason/Comments</td>
<td>Information that would be helpful for the ServiceNow personnel who are activating the plugin. For example, if you need the plugin activated at a specific time instead of during one of the default activation windows, specify that in the comments.</td>
</tr>
</tbody>
</table>

5. Click **Submit**.

**Set up an Edge Encryption user account**

The Edge Encryption proxies connect to the instance as a user to obtain and update encryption configuration information. Create a user account for this purpose and give the edge_encryption role to the user.

The Edge Encryption plugin must be installed before you can assign the role.

Role required: admin

1. On your ServiceNow instance, create a user account to be used by the Edge Encryption proxy applications.

2. Assign the edge_encryption role to the user.

**Download the Edge Encryption proxy server**

Download the Edge Encryption proxy server application from your instance, and then copy the file to each computer that is to run the Edge Encryption proxy server.

Before starting this procedure, the Edge Encryption plugin must be installed and activated on your instance.
Note: The Edge Encryption proxy is officially supported only on Oracle JRE.

Role required: security_admin

1. Navigate to Encryption Configuration > Installation & Downloads > Downloads.
2. If using the interactive installer, click Download. If manually installing the proxy server, select the OS version for your proxy server.

Note: Because the proxy server requires at least 4 GB of memory to run, 32-bit JREs and 32-bit operating systems are no longer supported starting with the Quebec release.

3. Copy the installer to each computer that is to run the Edge Encryption proxy server. If manually installing the Edge Encryption proxy server, copy the ZIP file to each computer that is to run the Edge Encryption proxy server.

After downloading the Edge Encryption installer, Install the Edge Encryption proxy server using the interactive installer. If installing manually, Install the Edge Encryption proxy server using the command line installer. Install the Edge Encryption proxy server on a Windows or Linux computer using the interactive installer.

Note: SafeNet KeySecure keystore files are not supported by the Edge Encryption installer. To use a SafeNet KeySecure keystore, Install the Edge Encryption proxy server using the command line installer.

The Edge Encryption plugin must be installed and activated on your instance before you start this procedure. Ensure that the latest version of Java 8 is installed on the machine running the Edge Encryption installer.

The latest version of Java 8 is Java SE 8u171/8u172.
- Java SE 8u171 includes important bug fixes. Oracle strongly recommends that all Java SE 8 users upgrade to this release.
- Java SE 8u172 is a patch-set update, including all of 8u171 plus additional bug fixes.

Role required:
- security_admin on your ServiceNow instance
- local or domain administrator on a Windows host
- service user with full file system access on a Linux host

After installing a new proxy server, you can run the installer again to perform tests to detect issues with an installation or modify current settings. Your options include:

- **Install New**: Install a new proxy server.
- **Verify Installation**: Perform tests to detect and fix issues in a previous installation.
- **Reinstall Existing**: Perform tests to detect and fix issues in a previous installation and view or modify existing settings.

Note: If installing the proxy server on a Linux machine on a privileged port (port 80 or 443), you must run the installer as a root user with full file system access. To restrict file system access after the proxy server is installed, you can use the SetUID feature in the proxy installer. To enable this feature, start the installer as root or sudo root. When prompted by the installer, provide the username and usergroup of an unprivileged user. The proxy server will install with file system privileges of the given user. You can skip this step to continue the default installation with root privileges.
Use the installer to install multiple proxies for your instance on multiple machines, ensuring that the following criteria apply:

- All proxies must have the same encryption keys and the same RSA key pair used to digitally sign encryption configurations and rules.
- The encryption key must be the default key configured on the instance.
- When a proxy database is set up as part of the installation, all proxies must use the same proxy database.

You may need a proxy database for equality-preserving encryption, order-preserving encryption, or tokenization. If you do not use any of these features, you do not need a proxy database.

To use NVDA, an Assistive Technology screen reader designed to read accessibility-enabled Java applications built for keyboard users, see Configure a Windows 64-bit host to use 32-bit NVDA with Java applications.

After installing the Edge Encryption proxy server, set the proxy server initial memory limit and upper bound memory limit.

Install the Edge Encryption proxy server (interactive installer)

Install the Edge Encryption proxy on a Windows or Linux computer.

1. Download the Edge Encryption proxy server installer.
2. Open the Edge Encryption proxy installer.

   **Note:** If installing on a Windows machine, you must run the installer as Administrator.

   a) To run the installer as Administrator on a Windows machine, right-click the Command Prompt and select **Run as administrator**.
   
   b) From the command line, navigate to the directory that contains the downloaded .jar file.
   
   c) Run the following command: `java -jar <file name>.jar`.

3. To install a new proxy server, select **Install New**.
   
   If a proxy is already installed, you can run the installer to:
   
   • **Verify Installation**: Perform tests to detect and fix issues in a previous installation.
   
   • **Reinstall Existing**: Perform tests to detect and fix issues in a previous installation and view or modify existing settings.
4. Configure the **Installation Location** and **Target ServiceNow Instance**.
   a) Click **Browse** to select an installation location or manually enter an installation path.
   b) Enter the URL of the target ServiceNow instance. Include the protocol and port number.
      ```
      https://example.servicenow.com:443
      ```
   c) Enter the user name and password for a user with the edge_encryption role on the target ServiceNow instance.

5. Click **Next**.

6. Configure the **Connection Settings** and **Proxy Settings**.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Proxy Host</td>
<td>Fully qualified domain name of the machine on which you are installing the proxy server.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Click Detect FQDN to look up the machine's fully qualified domain name and auto-populate the Proxy Host field.</td>
</tr>
<tr>
<td></td>
<td>Along with the port, this property defines the URL used by the client to access the proxy server.</td>
</tr>
<tr>
<td>HTTP Port</td>
<td>Port on the proxy for HTTP communication.</td>
</tr>
<tr>
<td>HTTPS Port</td>
<td>Port on the proxy for HTTPS communication.</td>
</tr>
<tr>
<td>Proxy Name</td>
<td>Name of the proxy and the service. The proxy name must be unique.</td>
</tr>
<tr>
<td>Proxy Poll Interval</td>
<td>Poll interval in seconds. With the default setting, it takes 5 seconds for the proxy to learn of encryption configuration changes. Larger values cause the instance to take longer to detect proxies that have come online.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Changing the default setting of the Proxy Poll Interval can result in detection delays when a proxy comes online.</td>
</tr>
<tr>
<td>Proxy Keep-Alive Ping Interval</td>
<td>Time in seconds between pings issued by the proxy to the instance. Pings are issued periodically to verify connectivity between the proxy and the instance. The default value is 10. The minimum value is 5.</td>
</tr>
</tbody>
</table>

7. Click **Install**.
   The Edge Encryption proxy server installs. The installation may take a few minutes.

Configure CyberArk properties protection
   Optionally, configure CyberArk properties protection to securely store Edge Encryption passwords in a centralized and secure digital vault.

You must purchase and configure CyberArk AIM (Application Identity Management) before you can configure CyberArk connection parameters and protected credentials for a proxy server. As part of the installation of the AIM client, the `JavaPasswordSDK.jar` file is installed in the AIM client installation directory. The CyberArk vault is installed on an independent hardened server, and the AIM clients allow secure access to that server.

**Note:** You must install the CyberArk AIM client on every host computer where an Edge proxy is installed.
In the Edge installer, you must specify the location of the `JavaPasswordSDK.jar` file to set up the CyberArk connection to the Edge proxy. You must also enter other values you defined during the AIM client installation.

Setting up CyberArk password storage is optional. If you do not want to set up CyberArk password storage, click Skip through the CyberArk screens.

1. On the CyberArk Connection page of the Edge Encryption installer, enter the CyberArk connection parameters.

   **CyberArk connection parameters**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Path to PasswordSDK.jar</td>
<td>The path to the <code>JavaPasswordSDK.jar</code> file installed on the host Windows machine during CyberArk configuration.</td>
</tr>
<tr>
<td>App ID</td>
<td>The App ID entered during CyberArk configuration.</td>
</tr>
<tr>
<td>Safe Name</td>
<td>The Safe Name entered during CyberArk configuration.</td>
</tr>
</tbody>
</table>

2. Click Next.

3. On the CyberArk Protected Credentials page of the installer, enter the credentials to be protected by CyberArk.
   - To use a single credential name for all protected passwords, select the **Apply one Credential Name to all Credentials** check box, enter the credential name, and click **Apply**.
   - Enter the credential name for one or more of the following fields. Credential names are the usernames entered for the SSH keys during CyberArk configuration.

   **CyberArk protected credentials**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Edge Encryption User</td>
<td>The CyberArk credential name for an Edge Encryption user.</td>
</tr>
<tr>
<td>Signature Key Keystore</td>
<td>The CyberArk credential name for the signature key keystore.</td>
</tr>
<tr>
<td>HTTPS Cert Keystore</td>
<td>The CyberArk credential name for the HTTPS certification keystore.</td>
</tr>
<tr>
<td>Encryption Key Keystore</td>
<td>The CyberArk credential name for the encryption key keystore.</td>
</tr>
<tr>
<td>Database</td>
<td>The CyberArk credential name for the database keystore.</td>
</tr>
<tr>
<td>SafeNet HTTPS Cert Keystore</td>
<td>The CyberArk credential name for the SafeNet HTTPS certification keystore.</td>
</tr>
<tr>
<td>SafeNet Server</td>
<td>The CyberArk credential name for the SafeNet server.</td>
</tr>
<tr>
<td>Forward Proxy</td>
<td>The CyberArk credential name for the forward proxy.</td>
</tr>
</tbody>
</table>

4. Click Next.

Configure the signature key
   Configure the signature key after installing the proxy server through the Edge Encryption proxy installer.

   The signature key signs changes to configurations and properties made by the proxy server. The signature key must be an asymmetric RSA key pair in a JCEKS KeyStore.
**Note:** If installing multiple proxies, each proxy must use the same signature key.

1. On the Signature Key page of the Edge Encryption installer, select the keystore on the host machine to store the signature key.
   - **Create New Java KeyStore:** Enter the directory location, name, and password for the new keystore.
   - **Use Existing Keystore:** Enter the keystore file location and password.

2. Click **Next**.

3. Select or create a signature key.
   - **New Key:** Create a signature key for this proxy.
   - **Use Existing Key:** Use an RSA key-pair from the selected keystore.
   - **Import Existing Key:** Import an RSA key-pair from a different keystore. Browse to the keystore file, enter the password for the keystore, and select the key alias. Provide a new alias for the key.

4. Click **Next**.

**Configure the HTTPS certificate**

To enable clients to connect to the Edge Encryption proxy server using a secure SSL connection, import the HTTPS certificate to the proxy server.

The Edge Encryption proxy provides the HTTPS certificate to clients trying to connect.

1. On the HTTPS Certificate page of the Edge Encryption installer, select the keystore to store the certificate.
   - **Create New Java KeyStore:** Enter the directory location, name, and password for the new keystore.
   - **Use Existing Keystore:** Enter the keystore file location and password.

2. Click **Next**.

3. Select or import a certificate.
   - **Use Existing Certificate:** Use an existing certificate in the selected keystore.
   - **Import from File or KeyStore:** Import a certificate from a different keystore or a .cer file. Browse to the keystore or .cer file, enter the password, and select the alias. You must provide a new alias for the certificate.

4. Click **Next**.

**Configure the AES 128-bit encryption key**

After you configure the HTTPS certificate through the Edge Encryption proxy installer, configure the AES 128-bit encryption key to encrypt your data.

The encryption key is either a plain text file inside the `/keys` directory or a secret key inside a keystore. If you use a keystore for your AES 128-bit and AES 256-bit encryption keys, they must both use the same keystore.
If you are updating an SSL certificate on an Edge proxy server, see Update SSL certificate.

1. Select the encryption key location.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>File Store</td>
<td>Use a file to store a single encryption key. You can use an existing file in the /keys directory, or you can generate a new file. To generate a new file, enter an alias and click <strong>Generate</strong>. A file containing an encryption key is created.</td>
</tr>
</tbody>
</table>

**Note:** This choice designates both the storage location and the encryption key. If you select **File Store**, click **Next** and go to step 5.

<table>
<thead>
<tr>
<th>Create New Java KeyStore</th>
<th>Create a keystore to store the encryption key.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Java KeyStore File</td>
<td>Store the encryption key in an existing Java KeyStore file.</td>
</tr>
</tbody>
</table>

2. Click **Next**.

3. Select or create the encryption key.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>New Key</td>
<td>Create an encryption key and alias.</td>
</tr>
</tbody>
</table>

**Note:** You must use lowercase letters and numbers for the alias name (key name, key alias), per Java KeyStore requirements. To find out more about the keytool utility, see the Java SE Documentation.

<table>
<thead>
<tr>
<th>Use Existing Key</th>
<th>Use an existing encryption key in the selected keystore.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Import Existing Key</td>
<td>Import an encryption key from a different keystore.</td>
</tr>
</tbody>
</table>

4. Click **Next**.
5. Configure the key on the instance according to the requirements defined in your installer.

To configure the key on the instance, navigate to the instance and define a default key. See Configure encryption keys on the instance. Ensure that the key alias, size, and type match the requirements defined in the installer.
6. Once the key is configured on the instance, return to the installer and click **Next**.
Configure the AES 256-bit encryption key

After you configure the AES 128-bit key through the Edge proxy installer, you can optionally configure an AES 256-bit encryption key to encrypt your data.

The encryption key is either a plain text file inside the /keys directory or a secret key inside a keystore. If you use a keystore for your AES 128-bit and AES 256-bit encryption keys, both keys must use the same keystore. If you do not want to configure an AES 256-bit encryption key, click Skip to continue installing the proxy server.

If you are updating an SSL certificate on an Edge proxy server, see Update SSL certificate.

1. Select the encryption key location.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>File Store</td>
<td>Use a file to store a single encryption key. You can use an existing file in the /keys directory, or you can generate a new file. To generate a new file, enter an alias and click Generate. A file containing an encryption key is created.</td>
</tr>
</tbody>
</table>

   **Note:** This choice designates both the storage location and the encryption key. If you select File Store, click Next and go to step 5.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create New Java KeyStore</td>
<td>Create a keystore to store the encryption key.</td>
</tr>
<tr>
<td>Java KeyStore File</td>
<td>Store the encryption key in an existing Java KeyStore file.</td>
</tr>
</tbody>
</table>

2. Click Next.

3. Select or create the encryption key.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>New Key</td>
<td>Create an encryption key and alias.</td>
</tr>
</tbody>
</table>

   **Note:** You must use lowercase letters and numbers for the alias name (key name, key alias), per Java KeyStore requirements. To find out more about the keytool utility, see the Java SE Documentation.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use Existing Key</td>
<td>Use an existing encryption key in the selected keystore.</td>
</tr>
<tr>
<td>Import Existing Key</td>
<td>Import an encryption key from a different keystore.</td>
</tr>
</tbody>
</table>

4. Click Next.

5. Optional: If you want to use AES 256-bit encryption, do the following:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Java 8 update 141 or earlier</td>
<td>Install the Java Cryptography Extension (JCE) and overwrite the policy files in the Java home directory. See Enable AES 256-bit encryption for Java 8 update 141 (8u141) or earlier.</td>
</tr>
<tr>
<td>Java 8 update 151 or later</td>
<td>Edit the java.security policy file to allow the use of unlimited strength keys. See Enable AES 256-bit encryption for Java 8 update 151 (8u151) or later.</td>
</tr>
</tbody>
</table>

6. To use AES 256-bit encryption, you must also configure the AES 256-bit default encryption key on the instance by navigating to the instance and defining a default key.

   See Configure encryption keys on the instance. Ensure that the key alias, size, and type match the requirements defined in the installer.

7. After the key is configured on the instance, return to the installer and click Next.

Update SSL certificate
When updating an SSL certificate on an Edge proxy server, you must delete the old one.

Role required: admin

When updating the SSL certificate on the Edge proxy server, you must also delete the old certificate. If you don't, the old certificate (in the form of an alias in the KeyStore file) continues to be used even though the Edge proxy server is configured to use the new certificate.

1. On the Edge proxy server, list the entries in the Java KeyStore:

   ```
   keytool -list -keystore keystore.jceks -storetype jceks -storepass MY_SUPER_PASSWORD
   ```

2. Remove the old SSL certificate:

   ```
   keytool -delete -alias MY_OLD_ALIAS -keystore keystore.jceks -storetype jceks -storepass MY_SUPER_PASSWORD
   ```

3. Add the new SSL certificate into the Java KeyStore.

Configure the Edge Encryption proxy database

If using order-preserving encryption types or encryption patterns, you can optionally configure the Edge Encryption proxy database properties.

To use order-preserving encryption types or encryption patterns, a MySQL database running in your network is mandatory. This task connects the proxy to the database, but it does not install or configure the database.

**Note:** If using multiple proxy servers, all proxy servers must use the same proxy database. The values entered in the installer must be the same for all proxy servers.

1. Confirm or change the database URL. This URL is the location of the proxy database.
2. In the **Name** field, enter the name of the proxy database. The default value is *edgeencryption*.
3. Enter the username and password for accessing the proxy database.
4. Click **Next**.

Launch the Edge Encryption proxy server

After an Edge Encryption proxy is installed and configured, you can start the proxy from the installer.

1. After configuring keys on the instance and optionally configuring the proxy database, return to the Edge Encryption proxy installer and click **Launch**.
2. If an issue is detected, or to check the status of your proxy server, you can click **Check Status** to verify that the proxy is running.

A message displays the proxy status.

![Proxy status](image)

**Congratulations!**

The Edge Encryption proxy is ready to launch. If you would like to launch it now, hit the “Launch” button. Your instance, through the proxy, is available at:

https://172.16.0.1:1234002

If you encounter any errors, validate your configuration and correct as necessary. If the problem persists, contact ServiceNow support.

![Proxy status](image)

After successfully installing the Edge Encryption proxy server, **Set the proxy server initial memory limit and upper bound memory limit.**

Verify and troubleshoot the Edge Encryption proxy server installation

After your Edge Encryption proxy is installed, you can verify the installation to locate problems or start and stop the proxy.

1. Open the Edge Encryption proxy installer.
2. Select **Verify Installation.**
3. Click **Proxy Directory** and select the proxy directory.
4. **Click Run Tests.**

Test results display.

![Run Tests](image)

**Edge Encryption proxy installation tests**

- Encryptor File Test: Passed
- Connection to ServiceNow Instance Test: Passed
- ServiceNow Instance Authentication Test: Passed
- Valid Proxy Host Test: Passed
- KeyStores are JCEKS: Passed
- Open Signature Keystore Test: Passed
- Open Signature Key Test: Passed
- Signature Key Contains `servicenow` Certificate Test: Passed
- Signature Key is RSA Test: Passed
- Open HTTPS Keystore Test: Passed
- Open HTTPS Certificate Test: Passed

© 2017 ServiceNow. All rights reserved.
5. Click **Next**.

If an issue is encountered, you can move through the installer to correct the configuration. If no issues are encountered, the installer jumps to the **Launch** page. You can check the proxy status, stop the proxy, or start the proxy from the **Launch** page.

### Install the Edge Encryption proxy server using the command line installer

Manually install multiple Edge Encryption proxy servers in your network.

Roles required: security_admin on your ServiceNow instance and local administrator on the host machine.

If order preserving encryption types or encryption patterns are to be used, set up a MySQL database on a machine in your network if not already present.

**Note:** If using Unbound Technology encryption keys with Edge Encryption, install the proxy server using the command line installer on the Unbound client machine. The Edge Encryption proxy server must run on the same machine as the Unbound technology client.

First, set up a single Edge Encryption proxy server. After your first proxy server is successfully running, add additional proxy servers for one instance to ensure an optimal environment. See **Sizing your Edge Encryption environment** to determine the number of additional proxy servers needed.

**Install the Edge Encryption proxy server (command line installer)**

- Install an Edge Encryption proxy on a 64-bit Windows or Linux computer.
- Java 8 is required to run the installer.
- Install the Edge Encryption proxy server on a machine in your network using the appropriate command for your target machine. If installing the Edge Encryption proxy server on a Windows machine, you must additionally install the proxy server as a Windows service.
- When you upgrade the Edge Encryption proxy server, the system backs up the old proxy in the `backup.dist-upgrade-<timestamp>` directory under the current installation directory. The backup directory is generated during the upgrade process and stores the old proxy information.
- When you run an upgrade via the command line, a dist-upgrade.log may be generated in the directory where the command runs. The dist-upgrade.log contains logs for the upgrade process.
- In case of a failed upgrade, the system creates a `failed-backup.dist-upgrade-<timestamp>` directory. In addition, logs/wrapper.log in the original proxy directory may also contain failure information.

1. Create the installation directory.
2. Download the Edge Encryption proxy archive file to the installation directory.
3. Open the terminal and change to the installation directory.

**Note:** If installing on a Windows machine, you must start the Windows Command Prompt with administrator privileges.

4. Run this command for the target machine and change the variables according to your configuration:

```
java -jar edgeencryption-<version>-all.jar -m install -n <ProxyName> --instancehost <host> -p <InstancePort> --protocol https
```

<table>

<td>----------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-n</td>
<td>ProxyName</td>
<td>The name of the encryption proxy instance. Use a unique ProxyName to be able to identify specific proxy instances.</td>
</tr>
<tr>
<td>--instancehost</td>
<td>host</td>
<td>The host name of your ServiceNow instance (for example, mycompany.service-now.com).</td>
</tr>
<tr>
<td>-p</td>
<td>InstancePort</td>
<td>The port of your instance. When the protocol is https, the port is normally 443.</td>
</tr>
<tr>
<td>--protocol</td>
<td>protocol</td>
<td>The protocol used to access your ServiceNow instance (typically https).</td>
</tr>
</tbody>
</table>

**Note:** Do not copy and paste commands from the browser. Occasionally, copy/paste operations cause unexpected characters to be pasted to the target machine and results in the command being executed incorrectly. It is best to type out the command by hand using documentation as a reference.

To see the help screen, execute this command without arguments: `java -jar edgeencryption-<version>-all.jar`

5. If installing on a Windows machine, install the Edge Encryption proxy as a Windows service.
   a) Optionally change the name of the service. Open the `conf/wrapper.conf` file on the new proxy and set the following properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>wrapper.ntservice.name</td>
<td>Unique name of the Edge Encryption proxy service.</td>
</tr>
<tr>
<td>wrapper.ntservice/displayname</td>
<td>Edge Encryption proxy service display name.</td>
</tr>
<tr>
<td>wrapper.ntservice/description (Optional)</td>
<td>Proxy server description.</td>
</tr>
</tbody>
</table>

   If this step is not performed, the Edge Encryption proxy service is installed under the name **Edge Encryption**.

   b) Save and close the file.
   c) Open the Windows Command Prompt and `cd` to `ServerName_port/bin`.
   d) Execute `edgeencryption.bat install`.

The `ProxyName_port` directory is created in the current directory. The `edgeencryption.properties` file is updated with the host, port, and protocol values from the command line.

Create and configure the RSA key pair for the digital signature

Create an RSA key pair that the proxy server can use to create the digital signature for signing changes to the encryption properties and configuration.

To generate and validate the digital signature, an RSA key pair must be generated and stored in the JCEKS Java KeyStore and each proxy must be configured to use this key pair. Generate an encryption key pair using the keytool command.
To use the keytool utility with a proxy installed on SElinux (CentOS), you must enable loading of shared libraries from the proxy java-installation directory. To do this, run the following command as root.

```
chcon -R -t texrel_shlib_t proxy_install_dir/java/jre /lib
```

You must use the Java 1.8 version of the keytool utility. A copy of the utility can be found in `<proxy install dir>/java/jre/bin/keytool`.

1. Change to the KeyStore directory in the proxy download directory.
2. Change the default password.

   The default password is `changeme`.

   ```
   keytool -keystore keystore.jceks -storetype jceks -storepasswd -new <newpassword>
   ```

3. Create an encryption key pair.

   **Note:** Do not enter a password for the key when the keytool utility prompts for one.

   Enter this command on a single line.

   ```
   keytool -genkeypair -alias <key alias> -keyalg rsa -keystore keystore.jceks -storetype jceks -storepass <keystore password> -keysize 2048
   ```

4. Update the encryption proxy property file (`edgeencryption.properties`).
   a) Change to the `<installation directory>/conf/` directory.
   b) Open the `edgeencryption.properties` file.
   c) Enter the properties for the digital signature.

   These properties must be the same for all proxies.

5. Save and close the `edgeencryption.properties` file.

Import and configure the certificate for secure SSL connection

To use a secure SSL connection, import a server certificate and add it to the Java KeyStore.

You must obtain the server certificate before you can add it to the Java KeyStore.

1. Add a server certificate to the Java KeyStore.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you have the RSA private key in the Java Keystore and generated the certificate from that key.</td>
<td>keytool -import -alias keyname -file server.cert -storetype JCEKS -keystore keystore.jceks -storepass pwd</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>If you have a PKCS12 (.pfx) file that contains the RSA key and the</td>
<td>keytool -importkeystore -destkeystore keystore.jceks -deststoretype jceks</td>
</tr>
<tr>
<td>certificate.</td>
<td>-srckeystore &lt;PKCS12 filename&gt; -srcstoretype pkcs12</td>
</tr>
</tbody>
</table>

Make sure that the private key password is the same as the Java KeyStore password.

You can run this command to change the password.

```
keytool -keypasswd -keystore keystore.jceks -alias <key alias>
```

For testing, you can use this command to generate a self-signed certificate.

```
keytool -genkeypair -alias cert -keystore keystore.jceks -storetype jceks -keyalg rsa
```

2. Update the `edgeencryption.properties` file.
   a) Change to the `<installation directory>/conf/` directory.
   b) Open the `edgeencryption.properties` file.
   c) Enter the properties for the SSL certificate.
      
      The certificate must be the same for all proxies connecting to the same instance.

3. Save and close the `edgeencryption.properties` file.

Enable AES 256-bit encryption

256-bit encryption is more secure than 128-bit encryption, and you can optionally configure AES 256-bit encryption on the Edge Encryption proxy server host. How you enable AES 256-bit encryption depends on the Java update installed on each proxy server host.

Edge Encryption supports only AES 128-bit and AES 256-bit keys.

⚠️ **Note:** Java does not automatically allow unlimited strength keys. You must specifically enable the use of AES 256-bit encryption.

Follow the procedure for the Java version that is installed on your proxy server host:

- Enable AES 256-bit encryption for Java 8 update 141 (8u141) or earlier
- Enable AES 256-bit encryption for Java 8 update 151 (8u151) or later

Enable AES 256-bit encryption for Java 8 update 141 (8u141) or earlier

Copy the Java Cryptography Extension (JCE) jurisdiction policy files to the Java home directory of each Edge Encryption proxy server host to enable AES 256-bit encryption for Java update 141 or earlier. 256-bit keys provide greater security than 128-bit keys.

Role required: admin

Your Java home directory includes the AES 128-bit policy files by default. To enable AES 256-bit encryption, you must overwrite the Java home directory policy files with the AES 256-bit policy files. You only need to download the JCE once, but you must update every Edge Encryption proxy server host.

⚠️ **Note:** Java does not automatically allow unlimited strength keys. You must specifically enable the use of AES 256-bit encryption.

1. Download the JCE policy 8 ZIP file from Oracle.
2. Unzip the file.
3. On each proxy server host, copy the `local_policy.jar` and `US_export_policy.jar` files into the `<Java-home-directory>/jre/lib/security` folder.

Enable AES 256-bit encryption for Java 8 update 151 (8u151) or later

Edit the `java.security` policy file to enable AES 256-bit encryption for Java update 151 or later. 256-bit keys provide greater security than 128-bit keys.

Role required: admin

Perform this task in the Java home directory of each Edge Encryption proxy server host on which you want to enable AES 256-bit encryption.

**Note:** Java does not automatically allow unlimited strength keys. You must specifically enable the use of AES 256-bit encryption.

1. Navigate to `<jre_home>/lib/security/java.security` on the proxy server host, where JRE_HOME is an environment variable for both Microsoft Windows and Linux.
2. Open the `java.security` policy file and find the line for the `crypto.policy` parameter, which is commented out by default.
3. Remove the `#` character from the beginning of the `crypto.policy` line to uncomment the line, and then save the file.

**Note:** If you do not uncomment the `crypto.policy` line, Java uses `crypto.policy=limited`, which restricts encryption to AES 128-bit keys.

Set up a key store and encryption keys

Set up the key store and encryption keys used by the Edge Encryption proxy server.

1. Carefully determine the appropriate type of key store to use based on your organization's needs.

<table>
<thead>
<tr>
<th>Supported key store</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>File store</strong></td>
<td>Keys are stored in a file in a file system accessed by the Edge Encryption proxy server. Because encryption keys stored in a file are not encrypted, it is your responsibility to protect these files.</td>
</tr>
<tr>
<td><strong>Java KeyStore</strong></td>
<td>A Java KeyStore:</td>
</tr>
<tr>
<td></td>
<td>• Stores keys in a Java JCEKS KeyStore.</td>
</tr>
<tr>
<td></td>
<td>• Is password protected and more secure than storing keys in a file in the file system.</td>
</tr>
<tr>
<td></td>
<td>• Can store multiple keys. A key alias represents each key, making it easier to manage multiple keys.</td>
</tr>
</tbody>
</table>

The Edge Encryption proxy ships with the Java JCEKS KeyStore file named `keystore.jceks` in the `keystore` directory. This key store file contains the ServiceNow public key used to validate encryption rules signed by ServiceNow.
<table>
<thead>
<tr>
<th>Supported keystore</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enterprise Key Management (EKM)</td>
<td><strong>SafeNet KeySecure</strong></td>
</tr>
<tr>
<td></td>
<td>Keys are stored and retrieved with SafeNet KeySecure key management.</td>
</tr>
<tr>
<td></td>
<td>You must secure a license with Gemalto, download the libraries, and install the SafeNet KeySecure keystore on a host machine in your network before configuring the keystore on the Edge Encryption proxy server.</td>
</tr>
<tr>
<td></td>
<td><strong>Unbound Technology</strong></td>
</tr>
<tr>
<td></td>
<td>The base64-encoded wrapped encryption key is stored as text file on the Edge Encryption proxy server. The Unbound Technology implementation (previously Dyadic Security) maintains control of the wrapping key.</td>
</tr>
<tr>
<td></td>
<td>The Edge Encryption proxy server must run on the same machine as the Unbound technology client.</td>
</tr>
</tbody>
</table>

**Note:** If using a keystore other than the base system Java JCEKS KeyStore, you must import the ServiceNow public key into your keystore. The public key alias is `servicenow`.

2. Set up the keystore and encryption keys in your local network.

Set up a Java KeyStore keystore
You can use a Java KeyStore keystore to store encryption keys.

You must use the Java 1.8 version of the keytool utility. A copy of the utility can be found in `<proxy install dir>/java/jre/bin/keytool`.

The Edge Encryption proxy ships with the Java JCEKS KeyStore file named `keystore.jceks` in the `keystore` directory. This keystore file contains the ServiceNow public key used to validate encryption rules signed by ServiceNow.

1. Set up the keystore properties.
   a) Change to the `<installation directory>/conf/` directory.
   b) Open the `edgeencryption.properties` file.
   c) Enter the properties for the Java KeyStore.

2. Save and close the `edgeencryption.properties` file.

After setting up the Java KeyStore, **Create encryption keys using the Java KeyStore keytool**.

Create encryption keys using the Java KeyStore keytool
You can use the keytool shipped with the encryption proxy distribution to create AES 128-bit and AES 256-bit encryption keys.

You must use the Java 1.8 version of the keytool utility. A copy of the utility can be found in `<proxy install dir>/java/jre/bin/keytool`.

To find out more about the keytool utility, see the [Java SE Documentation](https://docs.oracle.com/javase/8/docs/technotes/tools/unix/keytool.html).
Note: The Java KeyStore requires that the alias name (key name, key alias) use lowercase letters and numbers.

1. Change to the keystore directory, `<installation directory>/keystore/`.
2. To create the encryption key, run one of the following commands.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AES 128</td>
<td><code>keytool -genseckey -alias 128bitkey -keyalg aes -keysize 128 -keystore keystore.jceks -storetype jceks</code></td>
</tr>
<tr>
<td>AES 256</td>
<td><code>keytool -genseckey -alias 256bitkey -keyalg aes -keysize 256 -keystore keystore.jceks -storetype jceks</code></td>
</tr>
</tbody>
</table>

You add the alias on the instance when you assign default keys.

Note: The key password must be the same as the keystore password.

Set up a SafeNet KeySecure keystore

If you are using a SafeNet keystore, copy a set of libraries into the proxy distribution directory.

You must install and set up the SafeNet keystore before performing this step. Secure a license with Gemalto in order to download the libraries.

Note: On Linux, file paths use a forward slash (/).

1. Copy these files to the `<installation directory>/lib` directory:
   - `ingrianNAE=<version>.jar`
   - `ingrianlog4j-api=<version>.jar`
   - `ingrianlog4j-core=<version>.jar`

2. Change to the `<installation directory>/conf/` directory, and open the `edgeencryption.properties` file.
3. Enter the properties for the SafeNet keystore.

An example for a SafeNet keystore using username and password authentication.

```
edgeencryption.nae.retries = 3
edgeencryption.nae.enabled = true
edgeencryption.nae.server = url
edgeencryption.nae.port = 9000
edgeencryption.nae.protocol = ssl
edgeencryption.nae.keystore.path = keystore/safenet_truststore
edgeencryption.nae.keystore.password = password
edgeencryption.nae.user = safenet_user
```
edgeencryption.nae.password = safenet_password

An example for a SafeNet keystore using client certificate authentication. This authentication method eliminates the need to store the SafeNet server username and password in the properties file.

edgeencryption.nae.retries = 3
edgeencryption.nae.enabled = true
edgeencryption.nae.server = url
edgeencryption.nae.port = 9000
edgeencryption.nae.protocol = ssl
edgeencryption.nae.keystore.path = keystore/safenet_clientcert
edgeencryption.nae.keystore.password = password
edgeencryption.nae.client.certificate = cert_name

4. Add or create a key in the SafeNet keystore.
   You add the key name (alias) on the instance when you assign default keys.

5. Save and close the edgeencryption.properties file.

Upgrade from Kingston or lower to London or higher

If you use a SafeNet NAE server for key storage with Edge, before upgrading the proxy from Kingston or lower to London or higher, you must copy Gemalto SafeNet client ProtectApp JAR files and add new properties.

Note: On Linux, file paths use a forward slash (/).

1. Copy the following files from `<installation directory>/lib` to a directory path that is completely outside of the proxy installation directory path:
   • ingrianNAE-<version>.jar
   • ingrianlog4j-api-<version>.jar
   • ingrianlog4j-core-<version>.jar

2. On the current version (not upgraded) of the proxy, update the `<installation directory>/conf/edgeencryption.properties` file by adding the following two properties:
   • edgeencryption.ekm.provider.classname = com.snc.edgeencryption.encryption.CloudEdgeNaeKeyProvider
   • edgeencryption.thirdparty.vendor.library.path = <directory path to the directory where you copied the jar files in step 1>

3. Save the changes.

4. Proceed with the upgrade to London or higher.

Set up Unbound Technology keys

To use Unbound Technology (previously Dyadic Security) keys with Edge Encryption, store the base64-encoded wrapped encryption key as text file on the Edge Encryption proxy server and provide the wrapping key key alias. The Unbound Technology implementation maintains control of the wrapping key.

Role required: security_admin

In your Unbound Technology implementation, identify both the wrapping key and the wrapped key. Use the RSA/ECB/OAEPTWTHSHIA-256ANDMGF1PADDING algorithm for wrapping and padding. Export the wrapped key in base64-encoded text format. Save the file using the key alias as the name with no file extension.
Note: If using Unbound Technology encryption keys with Edge Encryption, install the proxy server using the command line installer on the Unbound client machine. The Edge Encryption proxy server must run on the same machine as the Unbound technology client.

1. Add the wrapped encryption key in base64-encoded text format to the `<proxy-installation-directory>/keys` directory. The name of the file must be the key alias with no file extension.

2. Update the `edgeencryption.properties` file.
   a) Open the `edgeencryption.properties` file.
   b) Enter the File store properties. Set the value of `edgeencryption.keyfile.directory` to `keys`. This property directs the proxy server to look for the encryption key in the `<Java-home-directory>/keys` directory.
   c) Uncomment the properties for the Dyadic provider configuration. Set the value of `edgeencryption.ekm.provider.rsa.wrapping.key.alias` to the wrapping key alias in your Unbound implementation.
   d) Save and close the file.

Add the encryption key alias to the instance. The encryption key alias is the file name of the wrapped encryption key added to the `<proxy-installation-directory>/keys` directory. For example, if the file in the directory is named `myunboundkey`, add this name to the `key alias` field. See Configure encryption keys on the instance.

Create an encryption key stored in a file

You can use a simple text file as a keystore. Each file holds a single encryption key.

Note: The name of the key file must match the key alias specified in the encryption keys table in the instance. See Configure encryption keys on the instance.

1. Create a file in the `/keys` folder of the proxy server installation directory.

2. Add the encryption key to the file.

   
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AES 128</td>
<td>Place the encryption key, exactly 16 bytes, into the file.</td>
</tr>
<tr>
<td>AES 256</td>
<td>Place the encryption key, exactly 32 bytes, into the file.</td>
</tr>
</tbody>
</table>

3. Update the `edgeencryption.properties` file.
   a) Change to the `<installation directory>/conf/` directory.
   b) Open the `edgeencryption.properties` file.
   c) Enter the properties for the file store.
   d) Save and close the file.

Configure encryption keys on the instance

Edge Encryption provides the tools to manage encryption keys without taking the proxy offline.

Role required: security_admin

Before setting up new encryption keys on the instance:

1. Create the encryption key.
2. Make the new key available to all encryption proxies. Either copy the file or Java KeyStore file to each proxy, or ensure that each proxy has access to the Java KeyStore or Enterprise Key Management (EKM) device.

Key aliases must be unique. Each key alias must have the same key size and type on each proxy, or the key cannot be assigned as the default.

1. Navigate to **Edge Encryption Configuration > Encryption Key Configuration > Set Up Keys**.
2. On the Add New Keys section of the form, complete the following steps to add a new key.

   a) Double-click in the row that says **Insert a new row...**.
   b) In the edit box, enter a name for the key, then click the check mark.
   c) In the same row, double-click in the **Key size** column.
   d) In the select box, select a key size, either **128 bits** or **256 bits**, then click the check mark.
   e) In the same row, double-click in the **Type** column.
   f) In the select box, select a key type, either **File**, **Keystore**, **SafeNet**, or **Unbound**, then click the check mark.
   g) When you are done adding keys, click **Next Step**.
   h) You must specify an alias, key size, and key type for each key before moving on.

3. On the Keys Status section of the form, check the **State** of the key and ensure that it is **Available**. This may take a few minutes. When the key is **Available**, click **Next Step**.

   a) Double-click in the row that says **Retrieve latest key versions** link in the Related Links to retrieve the latest version of each key from the Edge proxy.

   b) In the edit box, enter a name for the key, then click the check mark.
   c) In the same row, double-click in the **Key size** column.
   d) In the select box, select a key size, either **128 bits** or **256 bits**, then click the check mark.
   e) In the same row, double-click in the **Type** column.
   f) In the select box, select a key type, either **File**, **Keystore**, **SafeNet**, or **Unbound**, then click the check mark.
   g) When you are done adding keys, click **Next Step**.
   h) You must specify an alias, key size, and key type for each key before moving on.

The instance tracks the status of every encryption key available to any proxy. When a key is available on all proxies, its state becomes **Available**. If the state does not change after a few minutes, check to ensure that the
key is available on all proxies. If the state remains **Unavailable**, one or more of the proxies does not have the key.

### Encryption key states

<table>
<thead>
<tr>
<th>Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Available</td>
<td>All online proxies have the key.</td>
</tr>
<tr>
<td>Unavailable</td>
<td>This is a new key and the proxies have not yet loaded the key, or at least one proxy failed to load the key.</td>
</tr>
</tbody>
</table>

4. On the Change Default Keys section of the form, do one of the following:
   - Type in the key alias.
   - Click the magnifying glass icon and select an alias.

   **Note:** If using SafeNet versioned keys, an additional field appears for the **Key version**. The **Key version** is grayed out and cannot be edited.

   **Note:** If using SafeNet versioned keys, choose only the most recent key version. If you choose an earlier version, the following message appears when you click **Update** or **Next Step**:

   One of the default keys chosen is not the latest version available for the key. Please use the latest version.

   **Note:** If using SafeNet versioned keys, and if the default keys are not the latest versions of the SafeNet keys, an **Update default keys to latest version** link appears in the Related Links. Click the link to update the default keys to use the latest version.

   Click **Next Step**.

5. On the Schedule Key Rotation section of the form, schedule a mass key rotation job or single key rotation job to encrypt existing data using the new encryption key.

   If you do not run a mass key rotation job or single key rotation job, existing data remains encrypted with the old key until the data is accessed again.

Configure additional properties in the Edge Encryption properties file

After installing the Edge Encryption proxy server in your network and setting up your keystore and keys, configure the additional Edge Encryption properties.

1. Open the `<installation directory>/conf/edgeencryption.properties` file and configure the following Edge Encryption proxy server properties:
   - Target (instance) properties
   - User account properties
   - Proxy properties
   - If using order preserving encryption types or encryption patterns, configure the **Proxy database properties**
   - Clear text and static IV properties

2. Save and close the file.
If your network uses a web proxy, you can set up the Edge Encryption proxy to use the web proxy.

If your network does not use a web proxy, leave the web proxy properties in the configuration file commented out.

The Edge Encryption proxy server supports HTTP connection to and basic authentication with the web proxy.

1. Change to the `<installation directory>/conf/` directory.
2. Open the `edgeencryption.properties` file.
3. Configure the web proxy properties.
4. Save and close the `edgeencryption.properties` file.
5. If the web proxy is using a customer-specific server certificate, add this certificate to the JVM used by the Edge Encryption proxy server to establish trust between the web proxy and the Edge Encryption proxy server.
   a) cd to `<Java home directory>/jre/lib/security/cacerts`
   b) Execute the command:
      
      ```
      keytool -keystore cacerts -importcert -alias <chooseAlias> -file <certificateFile>
      ```

Set the proxy server initial memory limit and upper bound memory limit

Set the initial memory limit and upper bound memory limit to specify how much memory the proxy server can consume. Set these limits to avoid performance issues in your Edge Encryption implementation.

As a guideline, set both the initial memory limit and the upper bound memory limit to the same value. On any machine, allocate 2 GB of the physical memory to the operating system (OS). Then allocate the rest of the physical memory to the heap using the initial memory limit and upper bound memory limit properties. For example, on a machine with 8 GB of memory, allocate 2 GB to the OS, and allocate the remaining 6 GB (6144 m) to the initial and upper bound memory.

**Important:** If your Edge Encryption proxy server is running, you must stop and restart the proxy server after updating these properties.

1. In your proxy server directory, open `<install dir>/conf/wrapper.conf`.
2. To set the initial memory limit, add the following line at the end of the file:

   ```
   wrapper.java.additional.<number>=-Xms<min_memory_in_MB>m
   ```

   Set `<number>` to the next available `<number>` in the sequence of `wrapper.java.additional.<number>` properties defined in the `wrapper.conf` file.

   For example, you have the following list of `wrapper.java.additional.<number>` properties:

   ```
   wrapper.java.additional.1=
   wrapper.java.additional.2=
   ```

   The maximum `<number>` in the above list is 2. When you add the `wrapper.java.additional.<number>=-Xms<min_memory_in_MB>m` line, set `<number>` to 3, the next available number.

   **Important:** Do not leave gaps in the numbering sequence.

   Set `<min_memory_in_MB>` to the number of megabytes of memory remaining after allocating 2 GB of memory to the OS.
3. Set the upper bound memory limit.

Because an upper bound memory limit is not set in the base system, the proxy server can use all available memory. If other services are running on the server, you may want to set the upper bound memory limit.

Add the following line at the end of the file:

```java
wrapper.java.additional.<number>=-Xmx<max_memory_in_MB>m
```

Set `<number>` to the next available `<number>` in the sequence of `wrapper.java.additional.<number>` properties defined in the `wrapper.conf` file.

For example, you have the following list of `wrapper.java.additional.<number>` properties:

```java
wrapper.java.additional.1=
wrapper.java.additional.2=
```

The maximum `<number>` in the above list is 2. When you add the `wrapper.java.additional.<number>=-Xmx<max_memory_in_MB>m` line, set `<number>` to 3, the next available number.

**Note:** Do not leave gaps in the numbering sequence.

Set `<max_memory_in_MB>` to the number of megabytes of memory remaining after allocating 2 GB of memory to the OS.

4. Save and close the file.

**Example: Setting proxy server initial and upper bound memory limits**

```java
wrapper.java.additional.1 = -Djava.io.tmpdir=./tmp
wrapper.java.additional.2 = -Dcloudedge.home.dist=..
# must ensure UTF8 encoding when running on Windows
wrapper.java.additional.3 = -Dfile.encoding=UTF8
# additional properties for heap settings
wrapper.java.additional.4 = -Xms6144m
wrapper.java.additional.5 = -Xmx6144m
```

Start the Edge Encryption proxy.

Start the Edge Encryption proxy

After an Edge Encryption proxy is installed and configured, you can start the proxy from the command line.

Before starting the encryption proxy, verify the following:

- The Edge Encryption plugin is activated on the instance.
- The `edgeencryption.properties` file on this machine has been configured.
- If using an order preserving encryption type or encryption patterns, the proxy database is running.
1. Run the proxy server.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>On a Linux machine</td>
<td>a. cd to ServerName_port</td>
</tr>
<tr>
<td></td>
<td>b. Execute ./startup.sh</td>
</tr>
<tr>
<td>On a Windows machine</td>
<td>Perform the following steps from the command line as admin:</td>
</tr>
<tr>
<td></td>
<td>a. cd to ServerName_port/bin</td>
</tr>
<tr>
<td></td>
<td>b. Execute edgeencryption.bat start</td>
</tr>
</tbody>
</table>

2. Check the log on the proxy server to verify that the proxy is running.

Obfuscate passwords in the properties file
You can obfuscate passwords in the edgeencryption.properties file to share the properties file without revealing clear text passwords.

Make sure that the Edge Encryption proxy server is set up and successfully running before you set this property.
Before setting this property, Stop the Edge Encryption proxy.

Setting this property may make it difficult to debug connection and access issues during initial startup. Only set this property in production environments after the proxy has been set up and tested successfully.

1. Change to the <installation directory>/conf/ directory.
2. In the conf directory, create a text file containing a complex string or phrase that can be used as a passphrase which the proxy uses to obfuscate the passwords in the edgeencryption.properties file. This passphrase should be a random and complex phrase not related to the passwords themselves.
3. Open the edgeencryption.properties file.
4. Set the password encryption property.
5. Save and close the edgeencryption.properties file.

After setting this property, you can Start the Edge Encryption proxy.
Manually add an additional proxy
After the first Edge Encryption proxy is properly configured and tested, you can set up additional proxies on a Linux or Windows machine. Installing multiple proxies on the same machine is not recommended.

Add additional proxy servers on additional machines to ensure an optimal environment. See Sizing your Edge Encryption environment to determine the number of additional proxies needed.

Note: Make sure that all proxies have the same encryption keys and the same RSA key pair used to digitally sign encryption configuration and encryption rules. If a proxy database was set up as part of the installation, all proxies must use the same proxy database.

1. Install the proxy using the appropriate command. See Install the Edge Encryption proxy server (interactive installer).
2. Copy all the encryption keys and the edgeencryption.properties file from the first proxy to the new proxy.

Encryption keys may be located in the proxy keystore, in the /keys directory, or in a SafeNet KeySecure keystore.
3. Open the `edgeencryption.properties` file on the new proxy.
4. Change the following properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>edgeencryption.proxy.name</code></td>
<td>Unique name of the proxy server</td>
</tr>
<tr>
<td><code>edgeencryption.proxy.host</code></td>
<td>The server name, IP address, or fully-qualified domain name of the computer running the proxy.</td>
</tr>
<tr>
<td><code>edgeencryption.proxy.http.port</code></td>
<td>Port on the proxy for HTTP communication. Must be unique across all processes on the machine.</td>
</tr>
<tr>
<td><code>edgeencryption.proxy.https.port</code></td>
<td>Port on the proxy for HTTPS communication. Must be unique across processes on the machine.</td>
</tr>
</tbody>
</table>

5. If installing the proxy server on a Windows machine, you must change the name of the service. Open the `conf/wrapper.conf` file on the new proxy and add the following properties.

   **Note:** You must perform this step before launching the proxy server.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>wrapper.ntservice.name</code></td>
<td>Unique name of the Edge Encryption proxy service.</td>
</tr>
<tr>
<td><code>wrapper.ntservice.displayname</code></td>
<td>Edge Encryption proxy service display name.</td>
</tr>
<tr>
<td><code>wrapper.ntservice.description</code> (Optional)</td>
<td>Proxy server description.</td>
</tr>
</tbody>
</table>

6. Save and close the file.
7. Launch the proxy using the appropriate command. See [Start the Edge Encryption proxy](#)

**Authenticate an Edge Encryption proxy server**

Specify that a proxy server is a trusted source so that Edge Encryption can process requests coming from that proxy server.

If a proxy server is not authenticated, the console log includes the following message:

```
WARN This Edge Encryption proxy has not yet been authenticated by the instance.
Please navigate to the matching Proxy record on your ServiceNow instance and authenticate it.
```

If you attempt to access the proxy, you receive the following message: **This site can't be reached.**

To maintain the proxy in an operational state during the upgrade process, authentication is not required until after the proxy update is successful.

Role required: admin

1. Navigate to **Edge Encryption Configuration > Proxies.**
2. Select the proxy and click **Authenticate.**

The proxy moves from **Unauthenticated** to **Pending** to **Authenticated.** The status changes from **Unauthenticated** to **Pending** when you start the authentication. When authentication is complete, the status changes from **Pending** to **Authenticated,** and you can access the proxy and Edge Encryption can accept requests from the proxy.

   **Note:** If you stop and restart the proxy, the proxy remains **Authenticated** and restarts successfully.
Stop the Edge Encryption proxy
You can stop an Edge Encryption proxy from the command line.

1. Stop the proxy server.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>On a Linux machine</td>
<td>Execute <code>./shutdown.sh</code></td>
</tr>
<tr>
<td>On a Windows machine</td>
<td>Execute <code>edgeencryption.bat stop</code> To remove the Windows service, execute <code>edgeencryption.bat remove</code></td>
</tr>
</tbody>
</table>

2. Check the log on the proxy server to verify that the proxy has stopped.

Uninstall the Edge Encryption proxy on Linux
You can uninstall the Edge Encryption proxy. If you are upgrading the proxy, it is not necessary to shut down and uninstall the current version.

You must have access to the computer running the Edge Encryption proxy.

Before shutting down the Edge Encryption proxy, ensure that no users are connected to the instance using the proxy.

The encryption proxy running on Linux operates as a single process. You can end this process to accommodate such tasks as redeploying the encryption proxy to another host machine, updating the proxy version, updating the Java version, or changing the unique name of the encryption proxy when deploying the encryption proxy on multiple proxy servers.

1. You may want to save the `edgeencryption.properties` file before deleting the distribution directory.
2. Execute the `shutdown.sh` shell script.
3. Check the log on the proxy server to verify that the proxy server is shut down.
4. Delete the files in the distribution folder.

Uninstall the Edge Encryption proxy on Windows
You can uninstall the Edge Encryption proxy. If you are upgrading the proxy, it is not necessary to shut down and uninstall the current version.

You must have access to the computer running the Edge Encryption proxy.

Before shutting down the Edge Encryption proxy, ensure that no users are connected to the instance using the proxy.

1. You may want to save the `edgeencryption.properties` file before deleting the distribution directory.
2. Execute `edgeencryption.bat stop`
3. Execute `edgeencryption.bat remove`
4. Check the log on the proxy server to verify that the proxy server is shutdown.
5. Delete the files in the distribution folder.

Set up multiple provider SSO with Edge Encryption
If implementing multiple provider single sign-on (SSO) with Edge Encryption enabled, some users may need to log in to your instance through the Edge Encryption proxy server, while other users may not. Set up multiple provider SSO to enable logging in through the Edge Encryption proxy server URL or the instance URL.

- Role required: admin
- Enable the Edge Encryption plugin (com.glide.edgeencryption) and ensure that one or more proxy servers are set up in your network.
- Determine the URL for the Edge Encryption proxy server that users will log in through using multiple provider SSO. To determine the URL of an Edge Encryption proxy server, see Edge Encryption installation.
• If routing all users through the Edge Encryption proxy server, set up your identity provider record and define the proxy server URL in the ServiceNow Homepage, Entity ID / Issuer, and Audience URI fields.
• To route some users through the proxy server and some users to the instance, create two identity provider records. Both records use the same value in the Identity Provider URL field. However, one of the records routes through the proxy server, while the other routes to the instance.

1. Enable the duplication of identity provider URLs in identity provider records.
   A unique constraint prevents duplication of the identity provider URL in two different identity provider records. You can enable duplication of the identity provider URL in multiple IdP records by setting a field to false.
   a) Navigate to System Definition > Dictionary.
   b) Open the definition record for the idp field of in the Identity Providers table [saml2_update1_properties].
   c) Configure the form to add the Unique field.
   d) Ensure that the value of the Unique field is set to false.

2. Navigate to Multi-Provider SSO > Identity Providers.
3. Create two identity provider records for the same identity provider: one using the instance URL and one using the Edge Encryption proxy server URL.
   To create an identity provider record, see Create and update identity providers.
   a) For the Edge Encryption proxy server URL, complete the form using these values.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identity Provider URL</td>
<td>Imported from IdP metadata.</td>
</tr>
<tr>
<td>ServiceNow Homepage</td>
<td>The URL for your proxy server homepage. For example: https://&lt;proxy hostname&gt;:&lt;port&gt;/navpage.do</td>
</tr>
<tr>
<td>Entity ID / Issuer</td>
<td>https://&lt;proxy hostname&gt;:&lt;port&gt;</td>
</tr>
<tr>
<td>Audience URI</td>
<td>https://&lt;proxy hostname&gt;:&lt;port&gt;</td>
</tr>
</tbody>
</table>

b) Click Submit.

c) For the instance URL, complete the form using these values.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identity Provider URL</td>
<td>Imported from IdP metadata.</td>
</tr>
<tr>
<td>ServiceNow Homepage</td>
<td>https://&lt;instance&gt;.service-now.com/navpage.do</td>
</tr>
<tr>
<td>Entity ID / Issuer</td>
<td>https://&lt;instance&gt;.service-now.com/navpage.do</td>
</tr>
<tr>
<td>Audience URI</td>
<td>https://&lt;instance&gt;.service-now.com/navpage.do</td>
</tr>
</tbody>
</table>

d) Click Submit.
4. Optional: If using more than one identity provider, modify the MultiSSO installation exit.
   a) Navigate to **System Definition > Installation Exits**.
      The system displays the current list of installation exits.
   b) Open the **MultiSSO** installation exit.
   c) Locate the following statement in the **Script** field.

   ```javascript
   var samlResponseTxt = request.getParameter("SAMLResponse");
   if (!GlideSession.get().isLoggedIn() &&
       GlideStringUtil.notNil(samlResponseTxt)) {
       var idpRecord = this.getIdPRecord(request);
       if (idpRecord) {
         SSO_Helper.debug("IdP found based on SAML response: " +
                         idpRecord.getUniqueValue());
         return new SSO_Helper(idpRecord.getUniqueValue(), false, null, true);
       }
   }
   
   d) Replace the statement with the following code.

   ```javascript
   var samlResponseTxt = request.getParameter("SAMLResponse");
   if (!GlideSession.get().isLoggedIn() &&
       GlideStringUtil.notNil(samlResponseTxt)) {
       /* // You have two profiles that use the same IdP entity id it
          cannot use
       // the IdP issuer / entity id from the response otherwise it may
          result in the
       // wrong IdP profile. IdP initiated login will not work
       var idpRecord = this.getIdPRecord(request);
       if (idpRecord) {
         SSO_Helper.debug("IdP found based on SAML response: " +
                         idpRecord.getUniqueValue());
         return new SSO_Helper(idpRecord.getUniqueValue(), false, null, true);
       }*/
       return new SSO_Helper(null, true);
   }
   
   {Note: IdP initiated login does not work in this configuration.}
   
   e) Click **Update**.
5. Optional: If using more than one company, Configure users for Multi-Provider SSO. Update the sys_id of the identity provider record depending on the user.

- To configure a user to log in through the Edge Encryption proxy server, use the sys_id of the identity provider record that uses the Edge Encryption proxy server URL.
- To configure a user to log in to the instance, use the sys_id of the identity provider record that uses the instance URL.

### Login URLs

<table>
<thead>
<tr>
<th>URL</th>
<th>Login destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>https://&lt;instance name&gt;.service-now.com/login_with_sso.do?glide_sso_id=&lt;sys_id of IdP record for the instance URL&gt;</td>
<td>Logs in through the instance.</td>
</tr>
</tbody>
</table>

### Edge Encryption proxy server properties

The `edgeencryption.properties` configuration file located in the `<installation directory>/conf/` folder contains properties used to configure your environment.

You must restart the proxy server after making changes to any proxy server properties. Changes on the instance and changes to the `log4j.properties` do not require a proxy restart.

### Target (instance) properties

**edgeencryption.target.host**

Host name for the instance. Must be the same for all encryption proxies connecting to the same instance. This property is set when the proxy is installed. For example, `instancename.service-now.com`

**edgeencryption.target.port**

Instance port. Must be the same for all encryption proxies connecting to the same instance. This property is set when the proxy is installed.

**edgeencryption.target.protocol**

Instance protocol. Must be the same for all encryption proxies connecting to the same instance. This property is set when the proxy is installed. Options include:

- http
- https

### User account properties

**edgeencryption.target.username**

User name that the proxy uses to log in to the instance. The user must have the edge_encryption role. See Set up an Edge Encryption user account.
edgeencryption.target.password
Password that the proxy uses to log in to the instance.

Proxy properties

edgeencryption.proxy.host
Server name, IP address, or fully qualified domain name of the computer running the proxy. Along with the port, this property defines the URL used by the client to access the proxy server.

dgeencryption.proxy.name
Proxy name. Must be unique for each proxy.

dgeencryption.proxy.http.port
Port on the proxy for HTTP communication.

dgeencryption.proxy.https.port
Port on the proxy for HTTPS communication.

SSL certificate properties

Restart your proxy if you change the value of any SSL certificate property. The system uses the HTTPS keypair on startup to establish the proxy server connection and determine how the proxy answers client requests.

edgeencryption.proxy.https.cert.alias
Alias of the certificate provided by the proxy server to connecting clients.

edgeencryption.proxy.https.keystore.path
Path to the keystore that contains the HTTPS certificate.

edgeencryption.proxy.https.keystore.password
Password for the keystore that contains the HTTPS certificate.

Proxy configuration locked property

edgeencryption.proxy.locked
When true, the proxy does not accept encryption configuration changes or encryption rule changes from the instance. Set this property on the production instance after all encryption configurations and rules are final.

Proxy database properties

edgeencryption.db.url
Proxy database location. Must be the same for all encryption proxies connecting to the same instance.

dgeencryption.db.user
User name for accessing the proxy database. Must be the same for all encryption proxies connecting to the same instance.

dgeencryption.db.password
Password to access the proxy database. Must be the same for all encryption proxies connecting to the same instance.

**edgeencryption.db.name**
Proxy database name. Must be the same for all encryption proxies connecting to the same instance.
- Default value: edgeencryption

**edgeencryption.db.bootstrap.file**
Bootstrap file for the proxy database. The file is relative to the sql/ directory. Must be the same for all encryption proxies connecting to the same instance.

⚠️ **Warning:** Under normal circumstances, do not change this parameter.

**Digital signature properties**

**edgeencryption.proxy.signature.keystore.path**
Path and Java KeyStore file name.

**edgeencryption.proxy.signature.keystore.password**
Password. The default password is <changeme>. Change the password after installing the Java KeyStore.

**edgeencryption.proxy.signature.keystore.keyalias**
The key alias given as the -alias argument when the RSA key pair is generated.

**NAE device keystore properties**

**edgeencryption.nae.retries**
Number of retries to make.

**edgeencryption.nae.enabled**
Setting indicates whether an NAE device is available.

**edgeencryption.nae.server**
Name of the NAE server.

**edgeencryption.nae.port**
Port used by the NAE server.

**edgeencryption.nae.protocol**
Protocol used by the NAE server.

**edgeencryption.nae.keystore.path**
Path to the keystore on the NAE server.

**edgeencryption.nae.keystore.password**
NAE keystore password.

**edgeencryption.nae.username**
User name to use to authenticate with the NAE device.

**edgeencryption.nae.password**
Password to use to authenticate with the NAE device.
**edgeencryption.nae.client.certificate**
Certificate located in the keystore on the NAE server. Set this property to authenticate using a certificate instead of a username and password.

**Clear text and static IV properties**

**edgeencryption.customer.assigned.known.cleartext**
Clear text to let the instance verify that all proxies are using the same keys. At startup, the proxy encrypts the clear text and sends the encrypted text to the instance. The instance does not know the clear text, nor are keys sent to the instance. This property must be the same for all proxies.

**edgeencryption.encrytter.static.iv**
Static IV (initialization vector) used in equality-preserving and order-preserving encryption. This property must be the same for all proxies and must be exactly 16 bytes (16 ASCII characters).

**Password property**

**edgeencryption.encrytter.properties.password**
Name of the file in the conf folder that contains a string used within a secure process to obfuscate passwords in the edgeencryption.properties file.

If this property is not set, passwords in your properties file appear in clear text. Leave this property blank until after the proxy configuration has been set up and tested.

**Web proxy properties**

**edgeencryption.webproxy.host**
Web proxy name or IP address.

**edgeencryption.webproxy.port**
Port on the web proxy.

**edgeencryption.webproxy.user**
User name used to connect to the web proxy. If your web proxy does not use authentication, leave this property commented out.

**edgeencryption.webproxy.password**
Password to use to connect to the web proxy. If your web proxy does not use authentication, leave this property commented out.

**Java KeyStore properties**

**edgeencryption.keystore.path**
Path to the Java KeyStore. If using a file store or a SafeNet KeySecure keystore, leave this property commented out.
Example:

```yaml
edgeencryption.keystore.path = keystore/keystore.jceks
```

**edgeencryption.keystore.password**

Password the proxy uses to connect to the Java KeyStore. If using a file store or a SafeNet KeySecure keystore, leave this property commented out.

### File store property

**edgeencryption.keyfile.directory**

The directory specifies where key files are stored. If using the Java KeyStore or a SafeNet KeySecure keystore, leave this property commented out.

Example:

```yaml
edgeencryption.keyfile.directory=keys
```

If using Unbound Technology keys, uncomment this property and set the value to the keys directory.

### Unbound Technology provider properties

**edgeencryption.ekm.provider.classname**

Internal class name for the implementation.

⚠️ **Warning:** Do not change this property.

**edgeencryption.thirdparty.vendor.library.path**

Path to the Unbound API JAR file on the Unbound client machine.

**edgeencryption.ekm.provider.rsa.wrapping.key.alias**

Wrapping key alias in the Unbound Technology implementation. Must be the same for all proxies.

### General configuration properties

**edgeencryption.config.poll.interval**

Poll interval in seconds. The default setting means that it takes 5 seconds for the proxy to learn of encryption configuration changes. Larger values cause the instance to take longer to detect an offline proxy.

⚠️ **Warning:** Do not change this property. Changing the default setting of the Proxy Poll Interval can result in detection delays when a proxy comes online.

**edgeencryption.rules.dir**

Folder where the encryption rules are stored on the proxy.

**edgeencryption.encryption.order_preserving.cache.enable**

Setting determines whether caching is used to support order-preserving encryption types.
edgeencryption.encryption.order_preserving.cache.size
Maximum cache size, in bytes.

edgeencryption.jobs.concurrency
Maximum number of mass encryption jobs that can run concurrently on this proxy.

edgeencryption.jobs.requests_per_second
Number of http job requests per second that can be sent to the instance by this proxy.

edgeencryption.attachments.request.timeout.seconds
Attachment upload request timeout in seconds.

edgeencryption.request.buffer.size
Size of an encryption request. If an encryption request is larger than this size, the excess is saved to disk.

Warning: Do not change this property.

edgeencryption.httpclient.request.buffer.size
Size of the client request. If the client request is larger than this size, the excess is saved to disk.

Warning: Do not change this property.

edgeencryption.proxy.idle.timeout
Time in seconds after which a transaction times out.
• Default value: 300 (seconds)

edgeencryption.proxy.keepalive.interval
Time in seconds between pings issued by the proxy to the instance. Pings are issued periodically to verify connectivity between the proxy and the instance.
• Default value: 10 (seconds)
• Minimum value: 5 (seconds)

edgeencryption.register.retry.count
Maximum number of times the proxy pings the instance to try to register.
• Default value: 0 (no limit)

edgeencryption.tokenization.exclusion.list
Encryption patterns cannot tokenize strings found in these fields.

Proxy server performance properties

Proxy server performance properties are not present in the configuration file by default. To change the default values, you must add the properties and restart the proxy server. For more information, see Edge Encryption diagnostics and performance.

edgeencryption.stat.collection.enabled
Enables the collection of statistics used by the Edge Encryption proxy server performance dashboard.
• Default value: true

Add this property and set the value to false to disable the collection of statistics used by the Edge Encryption proxy server performance dashboard.

**edgeencryption.stat.collection.interval**

Interval length in seconds during which the Edge Encryption proxy server collects statistics. The value cannot be less than 30 seconds.

• Default value: 30 (seconds)

## Deprecated proxy encryption properties

**edgeencryption.encrypter.default.key128**

Specifies the name of the current AES 128 key. An AES 128 key must be available even if it is not used. Must be the same for all proxies.

Perform maintenance of these keys on the instance.

**edgeencryption.encrypter.default.key256**

Specifies the name of the current AES 256 key. Must be the same for all proxies.

Perform maintenance of these keys on the instance.

**edgeencryption.encrypter.key**

Specifies the key name for each key and is used to specify the default keys. This is the key alias integrated with the metadata that is included with each encrypted item and, therefore, is stored on the instance. The key name must use lowercase letters.

**edgeencryption.encrypter.type**

Specifies the type of encryption keystore system.

**edgeencryption.encrypter.file**

 Specifies the path and file name of the text file associated with the key.

**edgeencryption.encrypter.password**

Specifies the password for accessing the keystore.

---

### CyberArk integration with the Edge proxy server

Use CyberArk to store passwords in a centralized and secure digital vault to secure passwords that were previously stored in clear text and secured by file access, or that were previously encrypted via a second file.

CyberArk AIM (Application Identity Management) prevents unauthorized access by eliminating hard-coded and visible passwords. AIM stores passwords in a digital vault on an independent hardened server, where the passwords are represented as digital credentials. The AIM clients (the Edge proxy servers) use CyberArk digital credentials and access the independent server to retrieve the secured passwords. No passwords are stored on the Edge proxy servers or in the instance.

### CyberArk digital vault credentials

You must purchase and configure CyberArk before you can set up CyberArk integration with the Edge proxy server.

To add a credential to CyberArk (which is read by the Edge proxy), set the **Platform Name** of the credential to **Unix via SSH** and make sure you either create a **Custom** credential **Name** or write down the **Auto-generated**
credential **Name**. When you configure the Edge proxy to use this credential, the proxy server matches this credential **Name** to the setting in the proxy.

Each credential entry holds a **Password** that is being secured, as well as a credential **Name** used by an application to access that password.

**Note:** CyberArk credentials are not encryption keys.

**Adding CyberArk during an Edge proxy installation**

The proxy installer includes a new configuration page for a CyberArk integration. This page is optional if you do not want to include CyberArk when installing your proxy with the proxy installer. You can also manually set up and configure CyberArk integration in the configuration file.
The proxy installer also includes a new page for CyberArk protected credentials. This page allows configurations of different properties using a single credential name or multiple credential names. This page is optional if you do not want to include CyberArk when installing your proxy with the proxy installer.
**CyberArk password protection**

Any password field in the Edge proxy installer that has a CyberArk credential configured in the CyberArk vault and specified on the CyberArk Protected Credentials page of the installer is grayed out and contains the message *Protected by CyberArk.*
Using a load balancer with the Edge proxy server

You can use a load balancer to balance the load across the proxy servers in your Edge Encryption proxy setup. If the load balancer and proxy servers are using different ports, specify the host name and HTTPS port of the load balancer to enable users to view responses on their browser.

**Important:** All production environments should include at least two Edge Encryption proxy servers for redundancy.

Edge request processing without a load balancer

If you are not using a load balancer, a request is processed as described below.

1. The user issues a request from a browser.
2. The browser sends the request to the Edge proxy server.
3. The proxy server sends the request to the ServiceNow instance.
4. The ServiceNow instance returns the response to the proxy server.
5. The proxy server adds its own port number in the response header before returning the response to the user's browser.

The request is completed successfully because the user can view the response from the proxy server at the port number specified in the response header.
Edge request processing with a load balancer

However, if you are using a load balancer, the user’s browser communicates directly with the load balancer, not with the proxy server. A request is processed as described below.

**Note:** The following example uses 1025 as the proxy server port number.

1. The user issues a request from a browser.
2. The browser sends the request to a load balancer Virtual IP (VIP), also known as a Virtual Server.
3. The VIP is configured to point to the proxy server (for example, 10.2.200.148:1025), so the load balancer forwards the request to the proxy server.
4. The proxy server sends the request to the ServiceNow instance.
5. The ServiceNow instance returns the response to the proxy server.
6. The proxy server rewrites the location header in the response with values configured in the properties for risk-servicenow.dev.echonet:1025.
   - **Host:** edgencryption.proxy.host
   - **HTTP port:** edgencryption.proxy.http.port
   - **HTTPS port:** edgencryption.proxy.https.port
7. The proxy server forwards the response to the load balancer with the location header pointing to the proxy server port.

The outcome depends on whether the load balancer and proxy servers are using the same port.
- If the load balancer and proxy servers are using the same port, the request succeeds because the user receives the response from the same port identified in the response header.
- If the load balancer and proxy servers are using different ports, the request fails because the user's browser communicates only with the load balancer, but the response is on the proxy server.

Solution

You could resolve the issue by simply using the load balancer and all Edge proxy servers on the same port, but this is not an ideal solution. A better solution is to enable the system to know which port the load balancer uses.

The following properties enable the Edge proxy server to reroute response messages to the load balancer if the proxy server and load balancer are using different ports.

- **edgeencryption.proxy.rewrite.location.host** specifies the host name used to access ServiceNow through the load balancer.
- **edgeencryption.proxy.rewrite.location.https.port** specifies the HTTPS port used to access ServiceNow through the load balancer.

Configure the load balancer

If the load balancer and proxy servers are using different ports, specify the host name and HTTPS port of the load balancer to enable users to view responses on their browser.

Roles required:

- local or domain administrator on a Windows host
• service user with full file system access on a Linux host

1. Login to the proxy server host as admin, domain admin, or a service user.
2. Navigate to the installation directory for the Edge proxy and select `conf/edgeencryption.properties`.
3. Set the following properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| `edgeencryption.proxy.rewrite.location.host` | If your Edge configuration includes a load balancer to balance the load among proxy servers, rewrites responses to the load balancer so requests can be completed.  
• If there is a load balancer in the proxy setup, specify the host name used to access ServiceNow through the load balancer.  
• **Optional:** If there is no load balancer in the proxy setup, can be set to the host name used by the proxy server. |
| `edgeencryption.proxy.rewrite.location.https.port` | If your Edge configuration includes a load balancer to balance the load among proxy servers, specifies the HTTPS port used to access ServiceNow through the load balancer.  
• If there is a load balancer in the configuration, specify the HTTPS port used to access ServiceNow through the load balancer.  
• **Optional:** If there is no load balancer in the configuration, can be set to the HTTPS port used by the proxy server. |

4. Save the file.

Requests can be completed because users can now view responses on their browser.

**Edge Encryption upgrades**

Both instance upgrades and proxy server upgrades require special consideration in an Edge Encryption environment.

**Instance upgrades**

Instance upgrades in an Edge Encryption environment require caution to ensure that Edge controls work properly after the instance upgrade.

During an instance upgrade, you should not add, edit, or delete the following:

• Edge Encryption configurations
• Edge Encryption rules
• Edge Encryption tokenization patterns
• Edge Encryption scheduled jobs
• Edge Encryption key configurations
• Edge Encryption scheduled upgrades
• Edge Encryption exclude list IP configurations
Any scheduled job running during the instance upgrade will not complete. To complete the interrupted job, rerun the job once the instance is upgraded. When you reschedule the job, the processing that occurred before the instance upgrade is not lost, and the job continues to process only the data that has not yet been processed.

**Proxy server upgrades**

Schedule a proxy upgrade to enable the instance to upgrade the Edge Encryption proxy server, or manually upgrade the proxy server at any time.

⚠️ **Warning:** For an upgrade on Windows, you may encounter file lock issues and the upgrade may fail. For the upgrade to succeed, you should not have any files open under the installation directory. Also, there should be no existing shell in the installation directory. In particular, if you start the proxy from the command line (via `bin\edgeencryption.bat install/start`) while in the installation directory, you should close that shell or move it out of the installation directory afterward. No files under the installation directory should be opened by an editor or by any other application.

**Third party libraries**

Third party libraries, such as Gemalto, are lost during instance and proxy server upgrades if they are kept in the same directory. You can perform the following to prevent the loss of third party libraries during upgrades:

1. Manually add the following property to `edgeencryption.properties`:
   ```
   edgeencryption.ekm.provider.classname = com.snc.edgeencryption.encryption.CloudEdgeNaeKeyProvider
   ```

2. Add the `edgeencryption.thirdparty.vendor.library.path` vendor library location property and set it to `/path/to/jars`.
   
   For example:
   ```
   edgeencryption.thirdparty.vendor.library.path = /app/servicenow/libs
   ```

3. Copy the SafeNet JARs into that path.

After you install the third party libraries outside of the Edge Encryption installation, they are no longer lost during upgrades.

**Scheduled upgrades**

Schedule an upgrade to allow the instance to upgrade the proxy server at the scheduled time. This functionality is available by default after upgrading. A scheduled upgrade includes these events:

1. The proxy server checks with the instance to see if there is a new version available for upgrade. New versions generally become available when the instance is upgraded.

2. The administrator receives a notification upon logging in when a new version of the proxy server is available.

3. The administrator can Schedule an Edge Encryption proxy server upgrade for each proxy server.

ℹ️ **Note:** Only users with the security_admin role can create an upgrade schedule through the proxy server.
4. Once the upgrade is scheduled, the proxy server automatically upgrades at the scheduled time. During the upgrade, the proxy server is offline for only a short time.

**Note:** Because the proxy server restarts during the upgrade, it is offline for a short time. The amount of time is determined by your environment and how long it takes to stop and restart the proxy service.

5. During the scheduled upgrade, a new proxy directory is created and your configuration files are copied to the new directory. New properties are written to your existing properties file. The following files or directories in your old proxy directory are copied to the new proxy directory:
   - /conf directory
   - /keys directory
   - /keystore directory
   - java/jre/lib/security/cacerts file

As a result, your keys, keystores, settings, and certificates are preserved.

**Note:** Only the above files are copied to the new proxy directory. Any other customized files in the proxy server directory are not preserved during a scheduled upgrade. The upgrade log file can be found in the original proxy directory in the following folder: `<original-proxy-directory>/tmp/upgrade-wrapper/bin`.

### Prerequisites for scheduled upgrades

Before scheduling an upgrade for an Edge Encryption proxy, ensure the following:

1. The `JAVA_HOME` environment variable points to a java installation on the machine that is outside the Edge Encryption proxy’s directory structure.

2. The `JAVA_HOME` environment variable points to a java installation that is at version 1.8_u144 or higher.

3. The `-Djava.io.tmpdir` parameter in the wrapper.conf file of the Edge Encryption proxy points to a directory that is OUTSIDE the Edge Encryption proxy’s directory structure, and the proxy has read/write/execute permissions on the directory. Optionally, you could comment out the parameter entirely so that Java uses its default tmp location.

If you are using Safenet keys, add the following properties to the `edgeencryption.properties` file:

- `edgeencryption.ekm.provider.classname = com.snc.edgeencryption.encryption.CloudEdgeNaeKeyProvider`
- `edgeencryption.thirdparty.vendor.library.path = /path/to/jars`

The `/path/to/jars` has to be outside of the Edge install directory and needs to contain the libraries downloaded from Gemalto:

- `ingrian-log4j-api-2.0-rc1.jar`
- `ingrian-log4j-core-2.0-rc1.jar`
- `ingrian-nae-8.2.0.000.jar`
Manual upgrades

Instead of creating an upgrade schedule, you can manually upgrade each proxy server through the command line. See Manually upgrade an Edge Encryption proxy server running on Linux or Manually upgrade an Edge Encryption proxy server running on Windows.

Proxy build status

You can easily identify whether a proxy server is out of date by navigating to Edge Encryption Configuration > Proxies > All. The status of your proxy build is indicated in the Proxy build column by the following colors:

Green
Your proxy server is up-to-date.

Yellow
Your proxy server is out-of-date and an upgrade is needed.

Orange
Upgrade failed. Your proxy server reverts to the old version to ensure that there is no downtime.

Troubleshoot a failed scheduled proxy upgrade

When a scheduled proxy upgrade fails, the proxy server reverts to the version you are upgrading from. All original data, keys, and configuration files are preserved. This process may take several minutes. Contact Customer Service and Support to ensure a successful upgrade.

To determine the reason for the failure, you can check the Failure Reason in the upgrade schedule. In addition, the installation directory for the failed upgrade is maintained so that log files are available for troubleshooting.
Note: Before deleting any extra proxy directories, always confirm which directory is current by reviewing the log files. If the log files have recent activity, the proxy might be connected to your instance.

If a scheduled proxy upgrade fails repeatedly, you can manually upgrade your proxy server. See Manually upgrade an Edge Encryption proxy server running on Linux and Manually upgrade an Edge Encryption proxy server running on Windows.

Java minimum requirements

The host machine installing or running the Edge Encryption proxy server must maintain a supported version of Java:

- Java 8 update 121 (8u121)
- Java 8 update 141 (8u141)
- Java 8 update 151 (8u151) or later

Note: Java 8 update 131 (8u131) is not supported.

- Java 11.0.6 or later

Note: Before installing the Edge Encryption proxy server, check that the $JAVA_HOME variable is pointing to a supported version of Java for each user that will run the proxy server. For example, if installing the proxy server as a local administrator on Windows, check that the $JAVA_HOME variable is pointing to the correct version of Java system-wide. If installing on Linux, check that each user that will run the proxy server has this variable correctly defined. If a supported version of Java is not found, the Edge Encryption proxy server will not run.

If using AES 256-bit encryption with Java 8 update 141 (8u141) or lower, you must install the Java Cryptography Extension (JCE) jurisdiction policy files by copying them into the system Java home directory of each Edge Encryption proxy server host. Add these files to the <Java-home-directory>/jre/lib/security folder before performing a scheduled or manual upgrade. To install the AES 256-bit encryption policy files, see Enable AES 256-bit encryption for Java 8 update 141 (8u141) or lower.

Mixed proxy-version environments

Although an environment running old versions of the proxy server with up-to-date versions of the proxy server is not recommended, it is supported if all proxy servers are within the same version family as your instance. For example, if you have an instance on the Quebec release, your environment supports proxy servers from any Quebec patch or hot fix. However, the following limitations apply.

- If one proxy server supports functionality that another proxy does not support, you will see inconsistent behavior, depending on which proxy server is used.
- If a proxy server is out-of-date, it may not include recent security enhancements.

If a proxy server from a previous release is registered with a newer release of the instance, you will receive regular notifications that the proxy server is out-of-date. To ensure an optimal and secure environment, ServiceNow recommends always upgrading your proxy server to the most recent version of the software supported by your instance.

Schedule an Edge Encryption proxy server upgrade

Create an upgrade schedule to enable the instance to upgrade an out-of-date proxy server.

To schedule an upgrade, you must be logged in to your instance through the proxy server.
If using AES 256-bit encryption with Java 8 update 141 (8u141) or lower, you must install the Java Cryptography Extension (JCE) jurisdiction policy files by copying them into the system Java home directory of each Edge Encryption proxy server host. Add these files to the `<Java-home-directory>/jre/lib/security` folder before performing a scheduled or manual upgrade. To install the AES 256-bit encryption policy files, seeEnable AES 256-bit encryption for Java 8 update 141 (8u141) or lower.

Role required: security_admin

Once the upgrade is scheduled, the proxy server automatically upgrades at the scheduled time. During the upgrade, the proxy server is offline for only a short time.

**Note:** Because the proxy server restarts during the upgrade, it is offline for a short time. The amount of time is determined by your environment and how long it takes to stop and restart the proxy service.

During the scheduled upgrade, a new proxy directory is created and your configuration files are copied to the new directory. New properties are written to your existing properties file. The following files or directories in your old proxy directory are copied to the new proxy directory.

- `/conf` directory
- `/keys` directory
- `/keystore` directory
- `java/jre/lib/security/cacerts` file

As a result, your keys, keystores, settings, and certificates are preserved.

**Note:** Only the above files are copied to the new proxy directory. Any other customized files in the proxy server directory will not be preserved during a scheduled upgrade. The upgrade log file can be found in the original proxy directory in the following folder: `<original-proxy-directory>/tmp/upgrade-wrapper/bin`.

If multiple proxy servers are out-of-date, you must schedule an upgrade for each proxy server individually.

**Note:** Avoid hosting multiple proxy servers on the same machine. However, if your environment includes this configuration, do not schedule upgrades to multiple proxies on the same machine at the same time.

1. Navigate to **Edge Encryption Configuration > Proxies > Upgrade Schedules**.
2. Click **New**.
3. Complete the form.

### Edge Encryption Proxy Upgrade Schedule form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Proxy server</td>
<td>Proxy server being upgraded.</td>
</tr>
<tr>
<td>Target version</td>
<td>Version to which you are upgrading your proxy server. This value is read-only and set to the most up-to-date proxy version available for your instance.</td>
</tr>
<tr>
<td>Scheduled Start Time</td>
<td>Date and time on which to start the upgrade.</td>
</tr>
<tr>
<td>Active</td>
<td>Whether the scheduled upgrade is active. If this field is not selected, the upgrade will not perform on the scheduled date and time.</td>
</tr>
</tbody>
</table>
Field | Description
--- | ---
Status | The status of the upgrade. This value is read-only. Possible statuses include:
• Pending
• Running
• Complete
• Failed

4. Click **Submit**.

After an upgrade is executed, you can review the upgrade details to learn more about it. If your upgrade failed, review the **Failure Reason** to determine next steps.

**Upgrade details**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>From Version</td>
<td>The version that the server was upgraded from.</td>
</tr>
<tr>
<td>To Version</td>
<td>The version that the server was upgraded to.</td>
</tr>
<tr>
<td>Actual Start Time</td>
<td>Time that the upgrade began.</td>
</tr>
<tr>
<td>End Time</td>
<td>Time that the upgrade ended.</td>
</tr>
<tr>
<td>Failure Reason</td>
<td>Reason that the upgrade failed.</td>
</tr>
</tbody>
</table>

**Manually upgrade an Edge Encryption proxy server running on Linux**

Update a proxy running on Linux.

If using AES 256-bit encryption with Java 8 update 141 (8u141) or lower, you must install the Java Cryptography Extension (JCE) jurisdiction policy files by copying them into the system Java home directory of each Edge Encryption proxy server host. Add these files to the `<Java-home-directory>)/jre/lib/security` folder before performing a scheduled or manual upgrade. To install the AES 256-bit encryption policy files, see **Enable AES 256-bit encryption for Java 8 update 141 (8u141) or lower**.

Role required: **security_admin** or local administrator on the host machine

1. Copy the Edge Encryption update-archive file to the installation directory.
2. Change to the installation directory.
3. Run the following command:

   ```
   java -jar edgeencryption-dist-<version>-linux-x86-64.jar -m dist-upgrade -c <proxy directory>
   ```

   **Option** | **Description**
   --- | ---
   proxy directory | The directory in the installation directory where the proxy was initially installed. This directory is created by the install.

   If you want to see the help screen, execute this command without arguments: `java -jar edgeencryption-dist-<version>-linux-x86-64.jar`

A new proxy directory is created with a current timestamp. A backup of the old proxy directory is maintained as `backup.dist-upgrade_timestamp` in the new proxy installation directory. The old proxy shuts down and the new proxy starts up. Any open connections/transactions on the old proxy server are terminated.
4. Check the proxy log in the new directory and the instance to verify that the new proxy is running.

**Manually upgrade an Edge Encryption proxy server running on Windows**

Update a proxy running on Windows.

If using AES 256-bit encryption with Java 8 update 141 (8u141) or lower, you must install the Java Cryptography Extension (JCE) jurisdiction policy files by copying them into the system Java home directory of each Edge Encryption proxy server host. Add these files to the `<Java-home-directory>/jre/lib/security` folder before performing a scheduled or manual upgrade. To install the AES 256-bit encryption policy files, see Enable AES 256-bit encryption for Java 8 update 141 (8u141) or lower.

Role required: security_admin or local administrator on the host machine

1. Download the Edge Encryption proxy-update archive file to the installation directory.
2. Start the Windows cmd terminal program with administrator privileges.
3. Change to the installation directory.
4. Run the following command:

   ```
   java -jar edgeencryption-dist-<version>-all.jar -m dist-upgrade -c <proxy directory>
   ```

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>proxy directory</td>
<td>The directory in the installation directory where the proxy was initially installed. This directory is created by the install.</td>
</tr>
</tbody>
</table>

If you want to see the help screen, execute this command without arguments: `java -jar edgeencryption-dist-<version>-all.jar`

A new proxy directory is created with a current timestamp. A backup of the old proxy directory is maintained as `backup.dist-upgrade_timestamp` in the new proxy installation directory. The old proxy shuts down and the new proxy starts up. Any open connections/transactions on the old proxy server are terminated.

5. Check the proxy log in the new directory and the instance to verify that the proxy has been updated and is running.

**Roll back an Edge Encryption proxy server upgrade**

If a proxy upgrade is unsuccessful, you can go back to the earlier version.

If an upgrade fails when using the scheduled upgrade feature in the Quebec release, the proxy server will automatically roll back to the old version. The old proxy server is stored unmodified in a backup directory.

If you would like to roll back a manual upgrade, you can follow these steps.

1. Shut down the proxy.
2. Delete the new proxy directory.
3. Rename the backup directory to the proxy name.
   - The backup directory is in the proxy installation directory with the name `<proxy name>_backup`
4. Start the proxy.
5. Check the proxy log and the instance to verify that the proxy is online.

**Edge Encryption configuration**

After the Edge Encryption proxy server is installed and running, manage Edge Encryption through the proxy server.

You must complete all the steps in Edge Encryption installation before creating encryption configurations and encryption patterns on the instance.
Note: To access the Edge Encryption configuration, you must log in through the proxy server and elevate to the security_admin role.

**Rotate encryption keys**
Perform encryption key rotation from the instance. Add a new key, change the default key assignment, and then schedule a mass key rotation or a single key rotation.

Before setting an encryption key as the default key, make the key available to each proxy. This ensures that the proxies have the key to encrypt data when the key is assigned as the default key. All proxies must have access to a key before that key can be assigned as the default key.

**Warning:** Before deleting a key from the proxy, set up and run a mass key rotation job to ensure that no data on the instance uses the key. If any information is still encrypted with that key, you cannot decrypt the information after you delete the key.

**Edge filtering and sorting behavior**
Whenever you change default keys, be sure to perform a key rotation (either mass or single key rotation). Otherwise, you may receive unexpected results when sorting and filtering records. For example, consider the following scenario:

1. You create encrypted records using one encryption key.
2. You create a new key and set it as default.
3. You create a new set of encrypted records using the new encryption key.

If you filter by any encrypted field when connected through the Edge proxy, all records may not be filtered out correctly, or records may appear unexpectedly. The filter works only for records encrypted using the current default key. The records encrypted using the previous default key still appear in the list view.

If you sort by any encrypted field when connected through the Edge proxy, you see two groups of records with the same human readable text in the encrypted field.

**Schedule a single key rotation job**
Schedule a job to find data encrypted using a specified key alias and then re-encrypt the data with the current default encryption key. The data is decrypted before it is re-encrypted with the default key.

Role required: security_admin

Before scheduling this job, update the default key in Edge Encryption Configuration > Encryption Key Configuration > Set Default Keys.

1. Navigate to Edge Encryption Configuration > Maintenance > Schedule Single Key Rotation.
2. Fill in the fields on the form as appropriate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a descriptive name.</td>
</tr>
<tr>
<td>Job Type</td>
<td>Select <strong>Single Key Rotation</strong>.</td>
</tr>
<tr>
<td>Key</td>
<td>Enter the key to be retired. Verify that this key is no longer the default key in Edge Encryption Configuration &gt; Encryption Key Configuration &gt; Set Default Keys.</td>
</tr>
<tr>
<td>Estimate record count</td>
<td>Total estimated number of records to process. Not available when running a single key rotation.</td>
</tr>
<tr>
<td>Field</td>
<td>Value</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Process Historical Records</td>
<td>Select to process historical records in the Audit table if the field is audited. When encrypting historical records for a field in the Audit table, both new values and old values are encrypted. This field is read only and active. To learn more about audited fields, see Auditing.</td>
</tr>
<tr>
<td>Estimate Maximum Audit Record Count</td>
<td>Estimated maximum number of audited records to process. Not available when running a single key rotation.</td>
</tr>
<tr>
<td>Active</td>
<td>Clear this check box if you want to deactivate this job.</td>
</tr>
<tr>
<td>Run</td>
<td>Select the period between job executions.</td>
</tr>
<tr>
<td>Starting</td>
<td>Enter the date and time to run the job for the first time.</td>
</tr>
</tbody>
</table>

3. Click the menu icon in the form header and select **Save**.

**Estimate Record Count** is not supported when processing audited fields.

Schedule a mass key rotation job

Schedule a job to find data encrypted with any previous key, and then re-encrypt the data with the current default encryption keys. The data is decrypted before it is re-encrypted with the current default key.

Role required: security_admin

1. Navigate to **Edge Encryption Configuration > Maintenance > Schedule Mass Key Rotation**.
2. Fill in the fields on the form as appropriate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a descriptive name.</td>
</tr>
<tr>
<td>Job Type</td>
<td>Select <strong>Mass Key Rotation</strong>.</td>
</tr>
<tr>
<td>Estimate record count</td>
<td>Total estimated number of records to process. Not available when running a mass key rotation.</td>
</tr>
<tr>
<td>Process Historical Records</td>
<td>Select to process historical records in the Audit table if the field is audited. When encrypting historical records for a field in the Audit table, both new values and old values are encrypted. This field is read only and active. To learn more about audited fields, see Auditing.</td>
</tr>
<tr>
<td>Estimate Maximum Audit Record Count</td>
<td>Estimated maximum number of audited records to process. Not available when running a mass key rotation.</td>
</tr>
<tr>
<td>Active</td>
<td>Clear this check box to deactivate this job.</td>
</tr>
<tr>
<td>Run</td>
<td>Select the period between job executions.</td>
</tr>
<tr>
<td>Starting</td>
<td>Enter the date and time to run the job for the first time.</td>
</tr>
</tbody>
</table>

3. Click the menu icon in the form header and select **Save**.

**Estimate Record Count** is not supported when processing audited fields.

Schedule an attachment key rotation job
Schedule a job to find attachments encrypted using a specified key alias, and then re-encrypt the attachments with the current default encryption key. The attachment is decrypted before it is re-encrypted with the default key.

Role required: security_admin

1. Navigate to Edge Encryption Configuration > Maintenance > Schedule Attachment Key Rotation.
2. Fill in the fields on the form as appropriate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a descriptive name.</td>
</tr>
<tr>
<td>Job Type</td>
<td>Select Attachment Key Rotation.</td>
</tr>
<tr>
<td>Active</td>
<td>Clear the check mark if you want to deactivate this job.</td>
</tr>
<tr>
<td>Table</td>
<td>Select a table.</td>
</tr>
<tr>
<td>Run</td>
<td>Select the period between job executions.</td>
</tr>
<tr>
<td>Starting</td>
<td>Enter the date and time to run the job for the first time.</td>
</tr>
</tbody>
</table>

3. Click the menu icon in the form header and select Save.
4. To see an estimated count of records to be updated, click Estimated Record Count.
5. To run the job immediately, click Execute Now.

Encrypt fields using encryption configurations
Encrypt fields by creating encryption configurations.

To configure Edge Encryption, you must be connected to the instance through the proxy. Test all changes on a non-production instance before making the changes to the production instance.

Define encryption keys
After setting up one or more proxies and configuring a default encryption key, the instance verifies that the keys are available to all proxies. You cannot make an encryption key the default key unless all proxies have the key. Once a default key is defined, you can create encryption configurations.

Assign fields and attachments to be encrypted
Assigning fields and attachments to be encrypted means assigning an encryption type to the field or attachment. Before marking a field as encrypted, evaluate these issues.

- Determine what system features might be impacted.
- Examine all scripts for use of the field.
- Make any desired adjustments to the field size. After a field has been configured for encryption, the field size cannot be changed.

Marking a field to be encrypted expands the field size to store the encrypted data. The process of expanding the field size can take a long time, depending on the number of records in the table.

Create an encryption configuration
Select the fields to be encrypted and identify the encryption type.

Role required: security_admin

2. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table that contains the field to be encrypted.</td>
</tr>
<tr>
<td>Type</td>
<td>Whether to encrypt a table column or attachments for the table. Select <strong>Column</strong>.</td>
</tr>
<tr>
<td>Column</td>
<td>The field to be encrypted. Appears only when the <strong>Type</strong> is <strong>Column</strong>.</td>
</tr>
<tr>
<td></td>
<td>Only String, Date, Date/Time, Journal, Journal Input, and URL fields are supported.</td>
</tr>
<tr>
<td></td>
<td>• <strong>String and URL fields:</strong> You can add an encryption configuration to either a parent table or a child table.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Date and Date/Time fields:</strong> You can add an encryption configuration to a parent table only. You cannot add a new encryption configuration to a child table.</td>
</tr>
<tr>
<td>Encryption type</td>
<td>The encryption type to use.</td>
</tr>
</tbody>
</table>

**Note:** Depending on the number of records affected by the Date and Date/Time fields you are encrypting, it may take up to a few minutes to create the encryption configuration. Make sure that you create the encryption configuration for Date and Date/Time fields when transaction volume on the instance is low.

| note: A specific table and field combination can have only one active configuration at a time. |

3. Click **Submit**.

After you add the encryption configuration record, you can create an encryption job to encrypt existing data. If you do not run an encryption job, Edge encrypts the existing data the next time the data changes.

Deactivate an encryption configuration

After configuring a field or a table's attachments to be encrypted, you can stop encryption by deactivating the encryption configuration. After deactivating encryption, you can run a Decryption job for fields or an Attachment Decryption job for attachments to remove the encrypted data from the instance.

Role required: security_admin

**Warning:** Deactivating an encryption configuration does not delete the encryption record and the encryption type cannot be changed.

1. Navigate to **Edge Encryption Configuration > Edge Encryption Configurations > All**.
   The **Edge Encryption Configurations** list is shown.
2. Click on the encryption configuration to be deactivated.
   The **Edge Encryption Configuration** form is shown.
3. Click on the **Active** box.
   The **Active** box is clear.
4. Click **Update**.
   
The *Edge Encryption Configurations* list is shown.

You can run a Decryption or Attachment Decryption job to decrypt data on the instance. If you do not run a job, the encrypted data is decrypted the next time it is changed.

**Schedule an encryption job**

You can schedule a job to find and encrypt any unencrypted data in a specified field, using the default encryption key configured for the field. If you do not create an encryption job after configuring a field for encryption, only new values are encrypted.

Role required: security_admin

1. Navigate to *Edge Encryption Configuration > Encryption Configurations > All*.

2. Click the field that you want to schedule an encryption job for.

   The *Scheduled Encryption Job* form is shown with all fields populated. The bottom of the form shows records for any previous job executions.

4. Fill in the fields on the form, as appropriate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a descriptive name.</td>
</tr>
<tr>
<td>Active</td>
<td>Clear this check box if you want to deactivate this job.</td>
</tr>
<tr>
<td>Job Type</td>
<td>Select <strong>Encryption</strong>.</td>
</tr>
<tr>
<td>Table</td>
<td>Select a table.</td>
</tr>
<tr>
<td>Column</td>
<td>Select a column.</td>
</tr>
<tr>
<td>Estimated record count</td>
<td>Total estimated number of records to process. Populates after selecting <strong>Estimate Record Count</strong>.</td>
</tr>
<tr>
<td>Process Historical Records</td>
<td>Select to process historical records in the Audit table if the field is audited. When encrypting historical records for a field in the Audit table, both new values and old values are encrypted. To learn more about audited fields, see <strong>Auditing</strong>.</td>
</tr>
<tr>
<td>Estimate Maximum Audit Record Count</td>
<td>Estimated maximum number of audited records to process. Populates after selecting <strong>Estimate Record Count</strong>. This field is only visible when <strong>Process Historical Records</strong> is selected.</td>
</tr>
<tr>
<td>Run</td>
<td>Select the period between job executions.</td>
</tr>
<tr>
<td>Starting</td>
<td>Enter the date and time to run the job for the first time.</td>
</tr>
</tbody>
</table>

5. Click the menu icon in the form header and select **Save**.

6. To see an estimated count of records to be updated, click **Estimate Record Count**.

7. To run the job immediately, click **Execute Now**.

You can schedule a job to decrypt data in an encrypted field, to store clear data in the instance.

**Note:** You must mark the encryption record for the field as inactive (clear the **Active** box) in order to run the decryption job.

**Important:** Access is required to encrypted data prior to running a mass decryption. If your instance contains encrypted column and/or attachments with encryption contexts, Key Management Framework, or Platform Encryption, first assign the encryption contexts or cryptographic modules to the instance user that is configured in the Edge Encryption config file.

Role required: **security_admin**

1. Navigate to **Edge Encryption Configuration > Encryption Configurations > All.**
2. Click the field that you want to decrypt.
3. Under **Related Links**, click **Schedule Mass Decryption Job.**

   The **Scheduled Encryption Job** form is shown with all fields populated. The bottom of the form shows records for previous job executions.

4. Fill in the fields on the form, as appropriate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a descriptive name.</td>
</tr>
<tr>
<td>Job Type</td>
<td>Select <strong>Decryption.</strong></td>
</tr>
<tr>
<td>Active</td>
<td>Clear this check box if you want to deactivate this job.</td>
</tr>
<tr>

<td>Estimated record count</td>
<td>Total estimated number of records to process. Populates after selecting <strong>Estimate Record Count.</strong></td>
</tr>
<tr>
<td>Process Historical Records</td>
<td>Select to process historical records in the Audit table if the field is audited. When encrypting historical records for a field in the Audit table, both new values and old values are encrypted. To learn more about audited fields, see Auditing.</td>
</tr>
<tr>
<td>Estimate Maximum Audit Record Count</td>
<td>Estimated maximum number of audited records to process. Populates after selecting <strong>Estimate Record Count.</strong> This field is only visible when <strong>Process Historical Records</strong> is selected.</td>
</tr>
<tr>
<td>Run</td>
<td>Select the period between job executions.</td>
</tr>
<tr>
<td>Starting</td>
<td>Enter the date and time to run the job for the first time.</td>
</tr>
</tbody>
</table>

5. Click the menu icon in the form header and select **Save.**
6. To see an estimated count of records to be updated, click **Estimate Record Count.**
7. To run the job immediately, click **Execute Now.**
Encrypt attachments using standard encryption

You can encrypt attachments for specific tables.

All attachments to a table use the same encryption type. Encrypted attachments are not searched when performing a text search. Only the standard encryption types are allowed for attachments. The order preserving or equality preserving encryption types are not allowed.

For a session bypassing the Edge Encryption proxy:

- On a record with attachment encryption activated:
  - The user can see that there are attachments and the attachment names.
  - The user cannot add new attachments.
- On a record without attachment encryption activated:
  - The user can open and download existing attachments.
  - The user can add new attachments.

For a session using the encryption proxy, the user can open and download existing attachments and add new attachments.

Configure attachment encryption

Select the tables whose attachments are to be encrypted and identify the encryption type.

Role required: security_admin

2. Fill in the fields on the form, as appropriate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>Select a table whose attachments are to be encrypted.</td>
</tr>
<tr>
<td>Type</td>
<td>Whether to encrypt a table column or attachments for the table. Select Attachment.</td>
</tr>
<tr>
<td>Column</td>
<td>The table field to be encrypted. This field appears when the Type is Column, and not when Type is Attachment.</td>
</tr>
<tr>
<td>Encryption type</td>
<td>The encryption type to use. For attachments, only Standard AES128 and Standard AES256 are allowed.</td>
</tr>
</tbody>
</table>

3. Click Submit.

After the encryption record has been added, you can create an attachment encryption job to encrypt existing attachments. If you do not run an attachment encryption job, the system encrypts new attachments when you attach them.

Schedule an attachment encryption job

You can schedule a job to find and encrypt any unencrypted attachments for a specified table, using the default encryption key configured for the table.

Role required: security_admin

1. Navigate to Edge Encryption Configuration > Encryption Configurations > All.
2. Click the table you want to schedule an encryption job for.

The Scheduled Encryption Job form is shown with all fields populated. The bottom of the form shows records for previous job executions.

4. Fill in the fields on the form, as appropriate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a descriptive name.</td>
</tr>
<tr>
<td>Active</td>
<td>Clear this check box if you want to deactivate this job.</td>
</tr>
<tr>
<td>Job Type</td>
<td>Select Attachment Encryption.</td>
</tr>
<tr>
<td>Table</td>
<td>Select a table.</td>
</tr>
<tr>
<td>Run</td>
<td>Select the period between job executions.</td>
</tr>
<tr>
<td>Starting</td>
<td>Enter the date and time to run the job for the first time.</td>
</tr>
</tbody>
</table>

5. Click the menu icon in the form header and select Save.
6. To see an estimated count of records to be updated, click Estimate Record Count.
7. To run the job immediately, click Execute Now.

Schedule an attachment decryption job

You can schedule a job to decrypt any encrypted attachments for a specified table, to store clear attachments in the instance.

Note: You must mark the encryption record for the table as inactive (clear the Active box) before the decryption job runs, otherwise, nothing happens.

Role required: security_admin

1. Navigate to Edge Encryption Configuration > Encryption Configurations > All.
2. Click the table with the attachments that you want to decrypt.

The Scheduled Encryption Job form is shown with all fields populated. The bottom of the form shows records for previous job executions.

4. Fill in the fields on the form, as appropriate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a descriptive name.</td>
</tr>
<tr>
<td>Job Type</td>
<td>Select Attachment Decryption.</td>
</tr>
<tr>
<td>Active</td>
<td>Clear the check mark if you want to deactivate this job.</td>
</tr>
<tr>
<td>Table</td>
<td>Select a table.</td>
</tr>
<tr>
<td>Run</td>
<td>Select the period between job executions.</td>
</tr>
<tr>
<td>Starting</td>
<td>Enter the date and time to run the job for the first time.</td>
</tr>
</tbody>
</table>

5. Click the menu icon in the form header and select Save.
6. To see an estimated count of records to be updated, click Estimate Record Count.
7. To run the job immediately, click Execute Now.
Change a field or attachment’s encryption type
You can change a field or attachment’s encryption type by selecting a new encryption type in the existing encryption configuration record. A specific table and field combination can only have one active configuration at a time.

Role required: security_admin

1. Navigate to Edge Encryption Configuration > Encryption Configurations > All. The Edge Encryption Configurations list is shown.
2. Open the record for the encryption configuration to be changed.
3. Click the Encryption type dropdown and select a new encryption type.

   ![Note: For attachments, only Standard AES128 and Standard AES256 are allowed.]

4. If needed, run an encryption or attachment encryption job. It is not necessary to run an encryption job. If you do not run an encryption job, the field or attachment is encrypted using the new encryption type the next time the field or attachment is changed.

Tokenize strings using encryption patterns
You can replace string patterns with tokens before they are sent to and stored in the instance.

To use encryption patterns, you must install and set up a MySQL database in your network. This is the same database used for order-preserving encryption. To create or edit encryption patterns, you must be connected to the instance through the proxy.

Role required: security_admin

You can use base system patterns, or create your own patterns. Base system patterns are advanced patterns. Encryption patterns include the following limitations.

• A pattern of all alpha characters is not allowed.
• The minimum pattern size is five characters. You can change this setting using a system property.
• The * and + quantifiers are forbidden in encryption patterns.
• Encryption patterns match complete words, not parts of strings embedded in a larger string. Words are defined by spaces and characters not available for inclusion in a pattern.
• If the same string is sent to the instance multiple times, it is replaced with the same token.
• Text search on exact matches is supported. The query string is exchanged with a token when sent to the instance, the search is performed on tokens, and when the search results are returned to the proxy server, the tokens are replaced with the clear text. Features such as stemming are not supported.

When using patterns, the clear text never leaves your network. When the proxy server matches a pattern in a request going to the instance, the proxy replaces the string with a token of the same size. The token is sent to instance instead of the clear text string. When the response is sent from the instance to the proxy server, the proxy replaces the token with the string. When viewed through the proxy server, the string displays as clear text.

   ![Note: Encrypted fields are not checked for encryption patterns.]

1. Navigate to Edge Encryption Configuration > Encryption Patterns > Create New. Alternatively, you can navigate to Advanced Patterns to activate or edit a preconfigured pattern.
2. Enter the pattern name.
3. Define the **Edge pattern input type**.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Basic</strong></td>
<td>A series of character types. In the Basic Pattern Input tab, click Add and select a character type. The Sample pattern displays the pattern as characters are added. Click New Block to move the next character to the next line. This enables you to group characters in a long pattern. Click X to delete the last character in the pattern.</td>
</tr>
<tr>
<td><strong>Advanced</strong></td>
<td>A Java RegEx expression. If advanced is selected, you cannot change the input type back to basic. In the Sample match field, enter a sample pattern to test the RegEx expression. In the Pattern field, enter a Java RegEx expression. Click Validate to verify that the expression matches the sample pattern.</td>
</tr>
</tbody>
</table>

The input type defines how you are going to enter the pattern. It does not impact how the pattern is used.

4. Click **Submit**.

**Repair or recover order-preserving encrypted data**

If you have the security-admin role, you can schedule jobs performed by the Edge Encryption proxy to repair or recover fields that use order preserving encryption.

You can schedule jobs to:

- Repair order tokens.
- Recreate the proxy database.

Running these jobs can be a time-consuming operation which might impact the performance of the Edge Encryption proxy. Schedule these jobs at a time when no users or a minimum set of users are using the system, such as midnight on the weekend.

**Schedule an order token repair job**

You can schedule a job to find and repair fields where the order token is missing.

Role required: security_admin

Use these jobs to repair individual fields in a table or to repair all fields using order preserving encryption. Run this job when the proxy database has been offline while the instance has been running, which results in order preserving fields that are missing order tokens.

1. Navigate to **Edge Encryption Configuration > Maintenance > Schedule Order Token Repair**.
2. Fill in the fields on the form, as appropriate.
Schedule a proxy-database recovery job

Run this job when the proxy database has lost data. This job finds all records that have been encrypted with a token (order preserving encryption type) and sends them to the proxy so that the proxy database can be rebuilt.

Role required: security_admin

1. Navigate to **Edge Encryption Configuration > Maintenance > Schedule Database Recovery**.
2. Fill in the fields on the form, as appropriate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a descriptive name for this job.</td>
</tr>
<tr>
<td>Job Type</td>
<td>Select <strong>Database Recovery</strong>.</td>
</tr>
<tr>
<td>Active</td>
<td>Clear this check box if you want to deactivate this job.</td>
</tr>
<tr>
<td>Run</td>
<td>Select the period between job executions.</td>
</tr>
<tr>
<td>Starting</td>
<td>Enter the date and time to run this job for the first time.</td>
</tr>
</tbody>
</table>

3. Click the menu icon in the form header and select **Save**.
4. To see an estimated count of records to be updated, click **Estimated Record Count**.

Prevent an IP address in your network from sending requests to your instance

Because the Edge Encryption proxy server resides in your network, it may be subject to vulnerability scans by your network software. To prevent IP scanner or other requests from being forwarded to your ServiceNow instance, you can add IP addresses, IP ranges, or network masks to a deny list. Any connection to the proxy server from a deny listed address is terminated and is not forwarded to your instance.

Role required: security_admin

To place an IP address on a deny list, you must be logged in to your instance through the proxy server.

**Important:** Ensure that you understand your network topology before adding IP addresses in your network to a deny list. If an IP address is added to the deny list, any user with that IP address will be blocked from accessing the Edge Encryption proxy server.

1. Navigate to **Edge Encryption Configuration > Maintenance > Denylist IP Addresses**.
2. Click **New**.
3. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Proxy server</td>
<td>The Edge Encryption proxy server that is prevented from forwarding requests from addresses on the deny list.</td>
</tr>
</tbody>
</table>
4. Click **Submit**.
5. Repeat these steps for all other proxies for which an IP address should be denied.

The Edge Encryption proxy server terminates any connection from IP addresses, ranges, or network masks on the deny list and cannot forward the request to the instance. **Encrypt data from a record producer**

Record producers allow end users to create task-based records, such as incident records, from the Service Catalog and Service Portal. If a record producer attempts to insert data into a field marked for encryption, an invalid insert message displays and the data is not saved to the field. To configure your Edge Encryption proxy server to allow inserts from a record producer, create encryption rules from the record producer record.

**Role required: security_admin**

Encrypting data from a record producer requires an encryption configuration defined for the target field. Check that you have created an encryption configuration for the target field and table before creating an encryption rule from a record producer. See **Create an encryption configuration**. To encrypt attachments from a record producer, **Configure attachment encryption**.

1. Log in to your instance through the Edge Encryption proxy server.
2. Navigate to **Service Catalog > Catalog Definitions > Record Producers**.
3. Create a record producer record or open an existing record producer record.
4. Under **Related Links**, select **Create Edge Encryption Rule**.

Two inactive encryption rules are automatically created to encrypt data sent from the record producer to the field marked for encryption.

<table>
<thead>
<tr>
<th>Encryption rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;RecordProducerName&gt;</code></td>
<td>Rule created to process POST parameters from the Service Catalog and map variables to fields in the instance.</td>
</tr>
<tr>
<td><code>&lt;RecordProducerName&gt;Json</code></td>
<td>Rule created to process a JSON payload from the Service Portal and map variables to fields in the instance.</td>
</tr>
</tbody>
</table>

5. Activate the necessary encryption rules created by the record producer.
   a) Navigate to **Edge Encryption Configuration > Rules > All**.
   b) Depending on where the record producer will be used, open the associated encryption rule created by the record producer and select the **Active** flag.

If using the record producer in the Service Catalog, activate the `<RecordProducerName>` encryption rule. If using the record producer in the Service Portal, activate the `<RecordProducerName>Json` encryption rule.
6. Optional: Examine the Encryption rule Action field and add any necessary field names or statements.

If a record producer directly maps a variable to a field in a table, the encryption rule automatically maps the variable to the correct field. However, if a variable is indirectly mapped through various scripts on the platform, you may need to update the rules to map each variable to the correct field.

The below encryption rule was created from the Report Outage record producer and processes POST parameters from the Service Catalog to map variables to fields in the instance. Replace 'FILL ME IN' with the target field.
The below encryption rule was created from the Report Outage record producer and processes a JSON payload from the Service Portal to map variables to fields in the instance. Add additional statements to map any scripted variables to the target fields.
Edge Encryption Rule

ReportOutage.js

<table>
<thead>
<tr>
<th>Name</th>
<th>ReportOutage.js</th>
<th>Request type</th>
<th>HTTP Post</th>
</tr>
</thead>
<tbody>
<tr>
<td>Condition</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Action</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Order</td>
<td></td>
<td></td>
<td>100</td>
</tr>
</tbody>
</table>

```javascript
function ReportOutageJsonCondition(request) {
  return true;
}
```

```javascript
function ReportOutageJsonAction(request) {
  var tableName = 'INCIDENT';
  var isCurrentConfiguration = request.getParameter('variable1');
  if (isCurrentConfiguration) {
    return false;
  }
  return true;
}
```
When the payload from the record producer is examined, the error_message element contains the value for the short_description field. By adding the following statement, you can map the scripted variable error_message to the short_description field.

```javascript
if (jsonElement.getName() == 'error_message')
    jsonElement.valueFor(tableName, 'short_description');
```

The value of the Action field becomes:

```javascript
function ReportOutageJsonAction(request) {
    var tableName = 'incident';
    // Some fields are set in script, additional parameter lines may need to be added
    // current.comments is accessed via script from notes; // assignment to current.comments does NOT replace existing values
    // current.short_description is accessed via script from short_description;
    // current.description is accessed via script from current.short_description;
    // current.caller_id is accessed via script from gs.getUserID();
    var jsonContent = request.getAsJsonContent();
    for (var jsonElementItr = jsonContent.getIterator('variables'); jsonElementItr.hasNext();)
    {
        var jsonElement = jsonElementItr.next();
        if (jsonElement.getName() == 'error_message')
            jsonElement.valueFor(tableName, 'short_description');
        else {
            jsonElement.valueFor(tableName, jsonElement.getName());
        }
    }
}
```

The two encryption rules enable the record producer to insert values into fields marked for encryption from either the Service Catalog or Service Portal.

**Define a custom encryption rule**

It may be necessary to identify and encrypt sensitive information in HTTP requests on the way to your instance. You can write encryption rules to identify, interpret, and encrypt data in such requests, mapping fields in the request to table-field names on your instance.

**What is an encryption rule**

Encryption rules are scripts executed on the Edge Encryption proxy server to map fields in a request to fields in a table on your ServiceNow instance. An encryption rule tells the Edge Encryption proxy server how to encrypt data in custom payloads.

**Note:** Encryption rules only support ECMAScript 3 and below.

**When to use custom rules**

A set of encryption rules is included as part of the Edge Encryption plugin. These rules handle core platform use cases such as editing a field from the list edit form, updating a record from the record form, managing direct web services, and processing data from the REST API. Applications created using standard forms and lists should work without custom encryption rules.

If you develop scripted processors, scripted web services, scripted REST APIs, UIs, or Ajax scripts that contain data that should be encrypted, you must write encryption rules to find and map the data to Glide table-field names.
Format of an encryption rule

Rules include three parts:

- **Condition**: Identifies the type of request.
- **Action**: Maps fields in the request to fields in a table, encrypting values that map to fields with encryption configurations defined.
- **Order**: Priority of the rule. The lowest priority rule with a satisfied condition is the only rule that runs. Like business rules, rules run from lowest to highest.

Except for attachment requests, when an HTTP request hits the Edge Encryption proxy server, the Edge Encryption proxy server evaluates all encryption rule conditions in priority order until either all conditions return false, or one condition returns true. When a condition returns true, the action is executed on the request and the result is forwarded to the instance. No other conditions are evaluated. As a result, encryption rule conditions should be as specific as possible. A generic rule might evaluate as true for a request meant to be processed by another rule, causing the request to be processed by the wrong action. If a generic condition is unavoidable, the rule should be marked with a high-order value so that more specific rules are evaluated first.

Guidelines for creating encryption rules

Creating efficient, optimized encryption rules can reduce processing time for script validation.

**Overall guideline**: When rules get very long, do your best to minimize the number of blocks and break the rules apart whenever possible. Ideally, custom rules should apply to specific use cases, rather than encompassing several cases, with `if`s or switch statements in the action script.

1. Split rules whenever possible. For example,
   - Create different rules for different tables and ensure that each rule runs only on its respective table.
   - Create different rules for each record producer you are targeting, or at least for each subset of record producers. Instead of one rule targeting dozens of `sys_ids`, you could create several different rules targeting smaller subsets of record producers, or even create one rule per `sys_id`.

   **Note**: Creating multiple rules requires more maintenance. The trade-off is that multiple, simpler rules can be validated more efficiently than longer, more complex rules.

2. Minimize the number of blocks. Because the processing engine scans each block while evaluating scripts, a large number of blocks causes delays in validation. For example,
   - Replace all `if` blocks with an array lookup, and replace all blocks in the array lookup with just one `if` block.
   - Combine `if` blocks whenever it is possible to group them.

Encryption rule APIs

Encryption rules are written in JavaScript and utilize Edge Encryption APIs to locate and encrypt sensitive information in the body of a request. The API uses expressions similar to xPath to navigate through both JSON and XML content.

Edge Encryption APIs process the request off the stream as it is being written to the output stream. Stream parsing allows encryption rules to be network performant. However, fetching and parsing content from the body multiple times could lead to unexpected results. To account for this, requests should be processed by the action in a single pass.
When creating encryption rules, you cannot use Glide APIs, script includes, business rules, or any global parameters such as `current`. Because the rules are created for HTTP objects, a global `request` object is available.

When creating encryption rules, you cannot use APIs from the white list manager or scoped applications.

**Error handling**

If an encryption rule condition or action throws an exception, check the proxy log for troubleshooting information.

**Inspect the client request**

Before creating a custom encryption rule, you must determine the format of the client request entering the Edge Encryption proxy server.

Because encryption rules iterate over client requests and determine what, if anything, needs to be encrypted, you must understand the type of request you are creating a rule for. The format of the client request determines the structure of your encryption rule and the APIs available for use in the rule.

1. Inspect the client request.

   Depending on the source of the request, the following tools are available to inspect the request and determine the format.

<table>
<thead>
<tr>
<th>Source of request</th>
<th>Available tools</th>
</tr>
</thead>
<tbody>
<tr>
<td>Client browser</td>
<td>Use the developer console in your browser to inspect the client request. Useful tools include:</td>
</tr>
<tr>
<td></td>
<td>• Firefox Network Monitor</td>
</tr>
<tr>
<td></td>
<td>• Chrome Network Panel</td>
</tr>
<tr>
<td>Third-party/external source</td>
<td>Use an HTTP protocol analyzer to inspect the request. Useful tools include:</td>
</tr>
<tr>
<td></td>
<td>• Wireshark</td>
</tr>
<tr>
<td></td>
<td>• HTTP Scoop</td>
</tr>
<tr>
<td></td>
<td>Alternatively, you can often use documentation for the external source to determine the format of the request.</td>
</tr>
</tbody>
</table>
2. From the client request, inspect the packet and determine:
   • The client request method
   • The URL path of the request
   • The URL parameters
   • The POST parameters, if any
   • The format of the request body, if included

Inspecting the request provides an understanding of the fields you need to filter for and iterate over in your encryption rule. To understand the fields in the request object, see request.

Create an encryption rule
Encryption rules are used by the proxy to find content in HTTP requests that should be encrypted.

Role required: security_admin

Before creating an encryption rule, you must Inspect the client request to determine the format.

To create or edit encryption rules, you must be connected to the instance through an encryption proxy.

1. Navigate to Edge Encryption Configuration > Rules > Create New.
2. In the Name box, enter a name.
3. In the Request Type, select an HTTP method.
   • HTTP Post
   • HTTP Get
   • HTTP Put
   • HTTP Patch
   • HTTP Delete

   **Note:** Pre-Jakarta instances allow only HTTP Get and HTTP Post methods.

4. In the Condition box, enter a JavaScript statement defining when the rule should run.
5. In the Action box, enter a JavaScript function to be executed when the condition is true.
6. In the Order box, enter the relative priority of the rule.
7. Click Submit, or save the form.

Encryption rule conditions
Encryption rule conditions determine if the rule should be executed.

An encryption rule condition must return true if the rule is to handle the HTTP request; otherwise, it must return false.

As you build your condition, keep in mind that only one rule is executed per request. As a result, the condition must be as general or specific as needed to run under the intended circumstances.
Note: Be careful when performing checks on content in the condition. Excessive checks can be expensive for the proxy server and may cause increased latency when handling complex requests.

The condition can use the method type, content type, URL path, or any URL query string parameters to determine if the rule should handle the request. The condition has access to these fields via the request object. Be sure that, prior to creating an encryption rule condition, you have inspected the client request and understand the conditions needed to trigger the rule.

Note: To build efficient rules, consider easy ways to rule out requests that you do not want to be evaluated by a rule. Build your condition to return false for those requests first. This method increases performance and quickly routes the request to the correct rule faster.

Encryption rule objects and APIs are available to encryption rule conditions.

Example using path and postParams

```javascript
/*This condition checks if the request coming in has a path ending in "/sample_processor.do" and if a post parameter exists in that request called myPostParam */

function SampleCondition(request) {
  if (endsWith(request.path, "/sample_processor.do") && request.postParams.myPostParam) {
    return true;
  }
  return false;
}
```

Example using urlParams and contentType

```javascript
/* This condition checks if a url parameter exists in the query called myUrlParam and if the content type contains 'xml' (if so, you can expect the body to be an XML payload). Then, it checks if the xml payload contains myXmlTag */

function SampleCondition2(request) {
  if (request.urlParams.myUrlParam && request.contentType.indexOf('xml') > -1 && request.xmlContains('myXmlTag')) {
    return true;
  }
  return false;
}
```

Encryption rule actions

An encryption rule maps fields in a client request to fields in a table on your instance and identifies fields marked for encryption.

An encryption rule action only runs when the encryption rule condition returns true. An encryption rule identifies the data to be encrypted in your request payload. Because the rule iterates over the content in the request object, you must understand the form and structure of your request body and determine what in the request needs to be encrypted. The data to be encrypted might be located within:

- A POST or URL parameter.
- JSON or XML content within a POST or URL parameter.
- A JSON payload.
Before writing an encryption rule action, be sure to:

- Inspect the client request.
- Identify where the sensitive data is located in the request object.
- Determine the field and table name to insert data into, or understand how to dynamically pull this from the request.

Encryption rule objects and APIs are available to encryption rule actions and conditions.

Encryption rule objects and APIs
Use encryption rule APIs to parse and encrypt values in requests moving through the Edge Encryption proxy server to the instance.

The APIs available for your encryption rule depend on the format of the request object. For example, if the contentType parameter of the request object is XML, you can use the XML APIs to parse and encrypt values in the payload. After you determine the type of object in your request, you can build an encryption rule using the available APIs.

Encryption rule APIs are available in both encryption rule condition and action scripts.

request
The request object is a global object available in Edge Encryption rule action and condition scripts.

The request object is a JavaScript object that represents the client request coming in to the Edge Encryption proxy server. You must build your encryption rule to parse the request object, map request object values to fields in a table on the instance, and encrypt any sensitive data in the request object.

The request object includes the following attributes and data from the client request:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>The path portion of the URL</td>
</tr>
<tr>
<td>requestMethod</td>
<td>GET, POST, PUT, PATCH, DELETE.</td>
</tr>
<tr>
<td>contentType</td>
<td>The Content-Type header field.</td>
</tr>
<tr>
<td>urlParams</td>
<td>The parameters in the query string. This can also be evaluated to a String.</td>
</tr>
<tr>
<td>postParams</td>
<td>If this is a form post, this contains the post parameters.</td>
</tr>
</tbody>
</table>

request - getAsJsonContent()

Returns the request as an iterable object of type JsonNode.

This method is available only in an Edge Encryption rule if the request body is a valid JSON payload. If you are not sure what format the request body includes, check the contentType field on the request object.

Once the request is returned as a JsonNode object, you can use the JSON APIs to iterate over the object and encrypt fields.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JsonNode</td>
<td>The request as an iterable JsonNode.</td>
</tr>
</tbody>
</table>

request - `getAsXmlContent()`

Returns the request content as an iterable object of type `XMLContent`.

This method is available only in an Edge Encryption rule if the request body is a valid XML payload. If you are not sure what format the request body includes, check the `contentType` field on the `request` object.

Once the request is returned as an `XMLContent` object, you can use the XML APIs to iterate over the object and encrypt fields.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLContent</td>
<td>The request as an iterable object of type <code>XMLContent</code>.</td>
</tr>
</tbody>
</table>

request - `XMLContains(String path)`

Returns true if the given path exists in the XML DOM.

This method is available only if the request body is a valid XML payload. If you are not sure what format the request body includes, check the `contentType` field on the `request` object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>String</td>
<td>XPath statement you are searching for.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Whether the given path exists in the XML DOM.</td>
</tr>
</tbody>
</table>

POST and URL parameter APIs

POST and URL parameters can be accessed as properties of the `request` object using `request.postParams` and `request.urlParams`.

Any single parameter can be accessed as a property of the `postParams` and `urlParams` parent objects by calling `request.postParams.myParam`. Any parameter accessed this way is an object of the underlying class `ParameterValue`. Any APIs in this class can be called on any parameter.

After inspecting the client request, it may be necessary to access and encrypt parameter values from the request object. Depending on the data in the client request, you can encrypt values and map them to fields on the instance in multiple ways.
Encrypt the value of a known table and field

If you know the name of the instance table and field that will hold the encrypted data, you can explicitly define them in the encryption rule. For example, you may know that the request will be processed on the instance to create an incident and you want to encrypt the text parameter in the description field. In this case, you can create the following action.

```javascript
function SampleAction1() {
    request.postParams.text.valueFor('incident', 'description');
}
```

Encrypt the value of a dynamically defined table and field

If, conversely, you do not know the name of the field that the encrypted data will populate, you can dynamically define them using tableName and fieldName.

The below example processes a generic request that might store data in different task tables (such as incident, problem, and change_request) on the instance.

```javascript
function SampleAction2() {
    var tableName = request.urlParams.table;
    for (var parameter in request.postParams) {
        var currentParam = request.postParams[parameter];
        var fieldName = currentParam.toString();
        if (fieldName == 'text') {
            currentParam.valueFor(tableName, 'description')
        } else {
            currentParam.valueFor(tableName, fieldName);
        }
    }
}
```

This action:
- Gets the destination table from the URL parameters.
- Iterates over the URL parameters.
- Asks the Edge Encryption proxy server to encrypt any URL parameter with a name that matches a field marked for encryption.
- Looks for a specific parameter called text and asks the Edge Encryption proxy to encrypt the value based on the encryption configuration for the description field on the incident table.

In this example, the valueFor() method is not actually performing any encryption. Rather, the method asks the Edge Encryption proxy server to check whether the table/field pair in the request object is marked for encryption with an encryption configuration and, if applicable, encrypt it.

Encrypt JSON or XML within a parameter

A POST or URL parameter might include JSON or XML content. In this case, you can process the content within the parameter, iterate over the values, and encrypt required fields. In this example, the tableName is still accessed from a POST parameter, but the value of the field is the JSON object data.

```javascript
function SampleAction3() {
    var tableName = request.postParams.table;
    var data = request.postParams.data;
    var dataIterator = data.getAsJsonContent().iterator();
```
while (dataIterator.hasNext()) {
    var jsonElement = dataIterator.next();
    var fieldName = jsonElement.getName();
    if (fieldName == 'text') {
        jsonElement.valueFor(tableName, 'description');
    } else {
        jsonElement.valueFor(tableName, fieldName);
    }
}

An example of an encryption rule action that processes XML within a POST parameter.

function SampleAction4() {
    var tableName = request.postParams.table;
    var data = request.postParams.data;
    var dataIterator = data.getAsXmlContent().getIteratorOverAllChildren();
    while (dataIterator.hasNext()) {
        var jsonElement = dataIterator.next();
        var fieldName = jsonElement.getName();
        if (fieldName == 'text') {
            jsonElement.valueFor(tableName, 'description');
        } else {
            jsonElement.valueFor(tableName, fieldName);
        }
    }
}

Encrypt a query

You might encounter an encoded query within a parameter in the client request that contains sensitive data. To match a field in a query to an encrypted value in the instance database, you must create an encryption rule that asks the proxy to check whether a field in the query is marked for encryption. The `encodedQueryFor()` method parses an encoded query on a given table, and checks if any fields in the query have encryption configurations.

In this example, the rule iterates over the parameters looking for the `filter` parameter, which is expected to be a Glide encoded query.

function SampleAction5() {
    var tableName = request.urlParams.table;
    for (var parameter in request.postParams) {
        var currentParam = request.postParams[parameter];
        var fieldName = currentParam.toString();
        if (fieldName == 'filter') {
            currentParam.encodedQueryFor(tableName);
        } else {
            currentParam.valueFor(tableName, fieldName);
        }
    }
}

For example, if the value of `filter` is: `short_description=My sensitive information^number=INC000056^category=Outage`, the query would become `short_description=<Encrypted(My sensitive information)>^number=INC000056^category=Outage` on the instance.
Converts the POST or URL parameter value to a string.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The parameter value as a string.</td>
</tr>
</tbody>
</table>

**ParameterValue - getAsJsonContent()**

Returns the request as an iterable object of type `JsonNode`.

This method is available only in an Edge Encryption rule if the request body is a valid JSON payload. If you are not sure what format the request body includes, check the `contentType` field on the `request` object.

Once the request is returned as a `JsonNode` object, you can use the JSON APIs to iterate over the object and encrypt fields.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JsonNode</td>
<td>The request as an iterable <code>JsonNode</code>.</td>
</tr>
</tbody>
</table>

**ParameterValue - getAsXmlContent()**

Returns the request content as an iterable object of type `XMLContent`.

This method is available only in an Edge Encryption rule. This method assumes that the request body is a valid XML payload. You can check the `contentType` to make sure.

Once the request is returned as an `XMLContent` object, you can use the XML APIs to iterate over the object and encrypt fields.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLContent</td>
<td>The request as an iterable object of type <code>XMLContent</code>.</td>
</tr>
</tbody>
</table>
ParameterValue - encodedQueryFor(String tableName)
Specifies that the value of the element is an encoded query on the specified table.

Calling this function on a parameter tells the proxy that the value of the parameter is an encoded query for the specified table. The proxy parses the encoded query and encrypts the fields in the encoded query that must be encrypted.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>The table that you expect the query to run on.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

ParameterValue - valueFor(String tableName, String fieldName)
Specifies that the value of the element maps to the specified field in the specified table.

Calling this method on an element value tells the proxy that the value for this element maps to the specified field in the specified table. The proxy then checks if the field must be encrypted.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>The table name.</td>
</tr>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The field name.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

XML APIs
XML APIs can be used after calling getAsXmlContent() on either the request object or a ParameterValue property.

When using XML APIs to write your encryption rule, you can follow a general format:

1. Call getAsXmlContent() on the request object or ParameterValue property. This returns an iterable object of the XMLContent underlying class.

2. Call getIterator() or getIterator(String xPath) on the XMLContent object. This returns an XMLElementIterator object that can be used to iterate over XML elements.

3. Call the hasNext() method on the XMLElementIterator object to determine whether another element is available.

4. Call next() on the XMLElementIterator object to return the next XML element. You cannot call next() without first calling hasNext().
5. Call `valueFor(String tableName, String fieldName)` on the XML element. This method tells the proxy that the value for this element maps to the specified field in the specified table. The proxy then checks if the field must be encrypted.

Note: To determine if you want to call `valueFor(String tableName, String fieldName)` on an XML element, you can use the `getName()` method to return the name of the element.

Mapping to a known table-field on the instance

In this example, the XML payload will be processed on the instance to insert records in the incident table. The description field will populate short_description on the incident.

```
<data>
  <record>
    <name>'Test Record 1'</name>
    <description>'Test Record 1 Description'</description>
    <tag>critical</tag>
  </record>
  <record>
    <name>'Test Record 2'</name>
    <description>'Test Record 2 Description'</description>
    <tag>security</tag>
  </record>
</data>
```

The following encryption rule action can apply:

```
function sampleXmlAction1() {
  var xmlContent = request.getAsXmlContent();
  // This loop iterates over all description tags that match the given path
  var xmlElementIterator = xmlContent.getIterator('data/record/description');
  while (xmlElementIterator.hasNext()) {
    var xmlElement = xmlElementIterator.next();
    xmlElement.valueFor('incident', 'short_description');
  }
}
```

This action iterates through the `description` tags and asks the proxy server to encrypt the values and insert them into `incident.short_description` on the instance.

Note: This rule finds all `description` tags within all `record` tags in the XML payload. If there is only one occurrence of a tag to encrypt, the rule still uses the xPath and iterator structure. However, it iterates only once in the loop.

Mapping to an unknown table-field on the instance

In this example, the rule iterates over the `record` tags, but does not know what tags to expect within the `record` tag. The only known is that the tags within the `record` tags match the names of the columns specified in the table URL parameter.
The rule also specifies that, if the table is incident, then the data in the **description** tag should be encrypted and stored in the **short_description** field on the instance.

```javascript
function sampleXmlAction2() {
    var xmlContent = request.getAsXmlContent();
    var tableName = request.urlParam.table;
    // This first iterator will iterate over all record elements
    var xmlElementIterator = xmlContent.getIterator('data/record');
    while (xmlElementIterator.hasNext()) {
        encryptFieldsInRecord(xmlElementIterator.next());
    }
}

function encryptFieldsInRecord(xmlElement) {
    // Then, iterate over all tags representing fields in the table
    var fieldIterator = xmlElement.getIteratorOverAllChildren();
    while (fieldIterator.hasNext()) {
        var field = fieldIterator.next();
        var fieldName = childElement.getName();
        // If table is incident, then description is encrypted for the
        // short_description field
        if (tableName == 'incident' && fieldName == 'description') {
            field.valueFor(tableName, 'short_description');
        // If table is not incident, ask the proxy to check if the given
        field is encrypted for the given table
        } else {
            field.valueFor(tableName, fieldName);
        }
    }
}
```

In the `encryptFieldsInRecord()` function, the `valueFor()` method is called on a table and a field that are dynamically assigned based on the request. Even though the table and field names can change, the rule asks the proxy to check whether the field in the table must be encrypted based on the encryption configurations defined.

If the field is not configured for encryption, or if the tag does not match a field in the table, the proxy skips that tag. If the tag matches a field marked for encryption, then the Edge Encryption proxy server encrypts the value.

**Using an encoded query**

In this example, all tags have the **filter** attribute, which indicates whether the tag contains an encoded query.

```xml
<data>
    <record>
        <name filter="false">'Test Record 1'</name>
        <description filter="false">'Test Record 1 Description'</description>
        <query filter="true">category=1^name=edge</query>
    </record>
    <record>
        <name filter="false">'Test Record 2'</name>
        <description filter="false">'Test Record 2 Description'</description>
        <query filter="true">category=2^severity=3</query>
    </record>
</data>
```

The following encryption rule action can apply:

```javascript
function sampleXmlAction3() {
    var xmlContent = request.getAsXmlContent();
    var xmlElement = xmlContent.getIterator('data/record');
    while (xmlElement.hasNext()) {
        encryptFieldsInRecord(xmlElement.next());
    }
}
```
var tableName = request.urlParam.table;

// This first iterator will iterate over all record elements
var xmlElementIterator = xmlContent.getIterator('data/record');
while (xmlElementIterator.hasNext()) {
    encryptFieldsInRecord(xmlElementIterator.next());
}
}

function encryptFieldsInRecord(xmlElement) {
    // this time we want to iterate over all tags representing fields in the table
    var fieldIterator = xmlElement.getIteratorOverAllChildren();
    while (fieldIterator.hasNext()) {
        var field = fieldIterator.next();
        var fieldname = childElement.getName();
        // let's look at the filter attribute, if true, then encrypt as encoded query
        if (field.getAttributeValue('filter') == 'true') {
            field.encodedQueryFor(tableName);
        } else {
            // if it is false then check if the field should be encrypted
            field.valueFor(tableName, fieldName);
        }
    }
}

If the filter attribute value is true, the rule asks the proxy server to encrypt the values in the encoded query. If false, the rule asks the proxy to check whether the field should be encrypted.

XMLContent
A global object that provides methods to iterate over the XML content.
You can access an XMLContent object by calling getAsXmlContent() on a request object.

You access XML data in a POST or URL parameter by calling request.postParams.<parameter name>.getAsXmlContent() or request.urlParams.<parameter name>.getAsXmlContent().

XMLContent - getIterator()
Returns an XMLElementIterator object for the XML content.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLElementIterator</td>
<td>An object that can be used to iterate over elements in the XMLContent object.</td>
</tr>
</tbody>
</table>

XMLContent - getIterator(String xPath)
Returns an XMLElementIterator object for the XML content based on the specified parameter.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xPath</td>
<td>String</td>
<td>An XPath-like expression that specifies where in the XMLContent object to start.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLElementIterator</td>
<td>An object that can be used to iterate over elements in the XMLContent object.</td>
</tr>
</tbody>
</table>

**XMLElementIterator**

Provides methods for iterating over XML elements.

You get an XMLElementIterator object by calling the `getIterator()` method of the XMLContent class.

**XMLElementIterator - hasNext()**

Determines if there is another element available.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if another element is available.</td>
</tr>
</tbody>
</table>

**XMLElementIterator - next()**

Returns the next element in the iterator.

You cannot call `next()` without first calling `hasNext()`.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLElement</td>
<td>The next XML element.</td>
</tr>
</tbody>
</table>
XMLElement

Provides methods for iterating through XML elements and mapping values to fields in a table.

You get an XMLElement object by calling the next() method of an XMLElementIterator object.

XMLElement - getIterator(String xPath)

Returns an XMLElementIterator object for the XML element based on the specified parameter.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xPath</td>
<td>String</td>
<td>An xPath-like expression that specifies where in the XMLElement object to start.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLElementIterator</td>
<td>An object that can be used to iterate over elements in the XMLElement object.</td>
</tr>
</tbody>
</table>

XMLElement - getIteratorOverAllChildren()

Returns an XMLElementIterator object that includes all sub-elements for the XML element based on the specified parameter.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLElementIterator</td>
<td>An object that can be used to iterate over elements in the XMLElement object.</td>
</tr>
</tbody>
</table>

XMLElement - valueFor(String tableName, String fieldName)

Specifies that the value of the element maps to the specified field in the specified table.

Calling this method on an element value tells the proxy that the value for this element maps to the specified field in the specified table. The proxy then checks if the field must be encrypted. If the table and field names are unknown, you can call the valueFor() method on a table and a field that are dynamically assigned based on the request.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>The table name.</td>
</tr>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The field name.</td>
</tr>
</tbody>
</table>
XMLElement - encodedQueryFor(String tableName)

Specifies that the value of the element is an encoded query for the specified table.

Calling this function on an element tells the proxy that the value of the element is an encoded query for the specified table. The proxy parses the encoded query and encrypts the fields in the encoded query that must be encrypted.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>The table that you expect the query to run on.</td>
</tr>
</tbody>
</table>

XMLElement - getName()

Returns the element name.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

XMLElement - getAttributeValue(String attribute)

Returns the value of the specified attribute.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attribute</td>
<td>String</td>
<td>Attribute name.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The attribute value.</td>
</tr>
</tbody>
</table>

**JSON APIs**

JSON APIs can be used after calling `getAsJsonContent()` on either the request object or a `ParameterValue` property.

When using JSON APIs to write your encryption rule, you can follow a general format:

1. Call `getAsJsonContent()` on the request object. This returns an iterable object of the `JsonNode` underlying class.
2. Call `getIterator()` or `getIterator(String xPath)` on the `JsonNode` object. This returns a `JsonNodeIterator` object that can be used to iterate over nodes in the JSON object.
3. Call the `hasNext()` method on the `JsonNodeIterator` object to determine whether another element is available.
4. Call `next()` on the `JsonNodeIterator` object to return the next JSON element. You cannot call `next()` without first calling `hasNext()`.
5. Call `valueFor(String tableName, String fieldName)` on the JSON element. This method tells the proxy that the value for this element maps to the specified field in the specified table. The proxy then checks whether the field must be encrypted.

**Note:** To determine if you want to call `valueFor(String tableName, String fieldName)` on a JSON element, you can use the `getName()` method to return the name of the element.

**Mapping to a known table-field on the instance**

In this example, the JSON payload is processed on the instance to insert records in the incident table. The description field populates short_description on the incident.

```json
{
  data: {
    records: [
      {
        "name": "Test Record 1",
        "description": "Test Record 1 Description",
        "tag": "security"
      },
      {
        "name": "Test Record 1",
        "description": "Test Record 1 Description",
        "tag": "security"
      }],
    "query": "assigned_to=3D4860165813e63a00d00abd322244b092^category=vulnerability"
  },
  "source": "10.11.13.14"
}
```
The following rule can apply:

```javascript
function sampleJsonAction1() {
    var jsonContent = request.getAsJsonContent();
    // This loop iterates over all description elements in the records array
    var jsonNodeIterator = jsonContent.getIterator('/data/records/description');
    while (jsonNodeIterator.hasNext()) {
        var jsonNode = jsonNodeIterator.next();
        jsonNode.valueFor('incident', 'short_decription');
    }
}
```

This action iterates through the `description` nodes and asks the proxy server to encrypt the values and insert them into `incident.short_description` on the instance.

**Note:** This rule finds all `description` nodes within the JSON payload. If there is only one occurrence of a node to encrypt, the rule still uses the XPath and iterator structure. However, it iterates only once in the loop.

### Mapping to an unknown table-field on the instance

In this example, the rule iterates over `records`, but is not sure what nodes to expect. The only known is that for each object within `records`, the nodes match the names of the columns specified in the table URL parameter.

The rule also specifies that, if the table is incident, then the data in the `description` node should be encrypted and stored in the `short_description` field on the instance.

```javascript
function sampleJsonAction2() {
    var jsonContent = request.getAsJsonContent();
    var tableName = request.urlParam.table;
    // This first iterator will iterate over all record elements
    var jsonNodeIterator = jsonContent.getIterator('data/records');
    while (jsonNodeIterator.hasNext()) {
        encryptFieldsInRecord(jsonNodeIterator.next());
    }
}

function encryptFieldsInRecord(jsonNode) {
    // this time we want to iterate over all nodes
    var fieldIterator = jsonNode.iterator();
    while (fieldIterator.hasNext()) {
        var field = fieldIterator.next();
        var fieldname = childElement.getName();
        if (fieldname == 'description') {
            field.valueFor(tableName, 'short_description');
        } else {
            field.valueFor(tableName, fieldname);
        }
    }
}
```

In the `encryptFieldsInRecord()` function, the `valueFor()` method is called on a table and a field that are dynamically assigned based on the request. Even though the table and field names can change, the rule asks the proxy to check whether the field in the table must be encrypted based on the encryption configurations defined.

If the field is not configured for encryption, or if the node name does not match a field in the table, the proxy skips that node. If the node name matches a field marked for encryption, then the proxy encrypts the value.
Using an encoded query

```javascript
function sampleJsonAction3() {
    var jsonContent = request.getAsJsonContent();
    var tableName = request.urlParam.table;
    // This first iterator will iterate over all record elements
    var jsonNodeIterator = jsonContent.getIterator('data');
    while (jsonNodeIterator.hasNext()) {
        var jsonNode = jsonNodeIterator.next();
        if (jsonNode.getName() == 'records')
            encryptRecords(jsonNodeIterator.next());
        else if (jsonNode.getName() == 'query')
            jsonNode.encodedQueryFor(tableName);
    }
}
function encryptRecords(jsonNode) {
    //we iterate over all fields in the node
    var recordIterator = jsonNode.iterator();
    while (recordIterator.hasNext()) {
        encryptFieldsInRecord(recordIterator.next());
    }
}
function encryptFieldsInRecord(jsonNode) {
    //this time we want to iterate over all nodes
    var fieldIterator = jsonNode.iterator();
    while (fieldIterator.hasNext()) {
        var field = fieldIterator.next();
        var fieldName = childElement.getName();
        field.valueFor(tableName, fieldName);
    }
}
```

In this example, the rule iterates over `data`. As it finds `records`, it performs the same logic as in the second example, iterating over fields in each node. When it finds the `query` node, it calls `encodedQueryFor()` to encrypt values that should be encrypted in the query.

**JsonNode**

A global object that provides methods to iterate over the JSON content.

You can access a `JsonNode` object by calling `getAsJsonContent()` on a request object.

You access JSON content from a POST or URL parameter by calling `request.postParms.<parameter name>.getAsJsonContent()` or `request.urlParms.<parameter name>.getAsJsonContent()`.

**JsonNode - getIterator(String xPath)**

Returns a `JsonNodeIterator` object for the JSON content.

This method can only be used on the root node, but can be used to traverse deep into the JSON object. Subsequent traversals must use the `iterator()` method.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xPath</td>
<td>String</td>
<td>An xPath expression.</td>
</tr>
</tbody>
</table>
### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JsonNodeIterator</td>
<td>An object that can iterate over nodes in the JSON object.</td>
</tr>
</tbody>
</table>

**JsonNode - iterator()**

Returns a `JsonNodeIterator` object that iterates over all child nodes of the current node.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JsonNodeIterator</td>
<td>An object that can iterate over nodes in the JSON object.</td>
</tr>
</tbody>
</table>

**JsonNode - getAsString()**

Returns the current node value as a string.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The current node value.</td>
</tr>
</tbody>
</table>

**JsonNode - getAsString(String propertyName)**

Returns the string value of the specified property.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>propertyName</td>
<td>String</td>
<td>Name of the property.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The property value.</td>
</tr>
</tbody>
</table>

**JsonNode - getName()**
Returns the name of the current JSON node.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Name of the current JSON node.</td>
</tr>
</tbody>
</table>

JsonNode - valueFor(String tableName, String fieldName)

Specifies that the JSON property maps to the specified field in the specified table.

Calling this method on a JSON property tells the proxy that the value for this property maps to the specified field in the specified table. The proxy then decides if the field must be encrypted. If the table and field names are unknown, you can call the `valueFor()` method on a table and a field that are dynamically assigned based on the request.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>The table name.</td>
</tr>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The field name.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

JsonNode - encodedQueryFor(String tableName)

Specifies that the value of the JSON property is an encoded query for the specified table.

Calling this function on a JSON node tells the proxy that the value is an encoded query for the specified table. The proxy parses the encoded query and encrypts the values for fields in the encoded query that must be encrypted.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>The table that you expect the query to run on.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
JsonNodeIterator

You get a JsonNodeIterator object by calling the getIterator() or iterator() methods of the JsonNode class.

JsonNodeIterator - hasNext()

Determines if there is another property available.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if another property is available.</td>
</tr>
</tbody>
</table>

JsonNodeIterator - next()

Returns the next property in the iterator.

You cannot call next() without first calling hasNext().

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JsonNode</td>
<td>The next JsonNode.</td>
</tr>
</tbody>
</table>

print(String message)

Prints a message to the wrapper log file: <proxy server directory>/logs/wrapper_<date>.log.

This method is available only in an Edge Encryption rule action script.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>The message to be written to the wrapper log file.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
The Edge Encryption proxy validates encryption rule scripts before saving the rule. Many JavaScript keywords are not allowed in encryption rule scripts.

### Prohibited keywords

<table>
<thead>
<tr>
<th>Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DIR</strong></td>
</tr>
<tr>
<td><strong>FILE</strong></td>
</tr>
<tr>
<td><strong>LINE</strong></td>
</tr>
<tr>
<td><strong>parent</strong></td>
</tr>
<tr>
<td><strong>proto</strong></td>
</tr>
<tr>
<td>Error</td>
</tr>
<tr>
<td>eval</td>
</tr>
<tr>
<td>getClass</td>
</tr>
<tr>
<td>getPrototypeOf</td>
</tr>
<tr>
<td>Java</td>
</tr>
<tr>
<td>javax</td>
</tr>
<tr>
<td>javafx</td>
</tr>
<tr>
<td>JavaImporter</td>
</tr>
<tr>
<td>load</td>
</tr>
<tr>
<td>loadWithNewGlobal</td>
</tr>
<tr>

</tr>
<tr>
<td>this</td>
</tr>
<tr>
<td>throw</td>
</tr>
</tbody>
</table>

### Edge Encryption dictionary attributes

You can add Edge Encryption dictionary attributes to tables and fields.

To set an Edge Encryption dictionary attribute to true, you must enter `attribute=true` in the **Attributes** field.

To add a dictionary attribute to a record, see [Dictionary attributes](#).

**Edge Encryption Excluded [edge_encryption_excluded]**

When set to true, the field or table cannot be encrypted.

- Value: true/false
- Target element: field or table
• Default value: false

**Edge Encryption Enabled [edge_encryption_enabled]**

When set to true, the field is eligible for encryption through an encryption configuration. Because this attribute is used by the system and cannot be modified, it is not always displayed to the user.

*Note:* This attribute does not indicate that a field is encrypted, nor does it trigger any encryption logic on the field. Rather, the attribute determines the possibility of the field being encrypted by a user.

• Value: true/false
• Target element: field
• Default value: true for String fields

**Edge Encryption Clear Text Allowed [edge_encryption_clear_text_allowed]**

When set to true, allows server-side scripts to append non-encrypted data to an encrypted string within the field for user actions performed through the proxy server, or any server-side automated scripts, such as scheduled jobs.

• Value: true/false
• Target element: field
• Default value: false

**Domain separation and Edge Encryption**

Domain separation is unsupported in Edge Encryption. This application provides the ability to encrypt data from within the customer's environment through the use of specific configurations, rules, and keys defined on the Edge Encryption proxy. The Edge Encryption proxy is not domain aware and cannot support domain-specific settings. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

**Support level: No support**

• The domain field may exist on data tables but there is no business logic to manage the data.
• This level is not considered domain-separated.

For more information, see Application support for domain separation.

**How domain separation works in Edge Encryption**

Edge Encryption can be used where domain-specific keys, configurations, and rules are not required.

*Note:* It is not recommended to install Edge Encryption on domain instances at all even for internal service provider usage.

**Data integration with Edge Encryption**

To integrate third-party data with an instance using Edge Encryption, you must route the data through the Edge Encryption proxy server using supported integrations. Supported integrations use base system encryption rules that map data in each payload to fields in a table.
Upload data to fields marked for encryption

Edge Encryption does not support importing data from or exporting data to Excel, CSV, XML, or other file types to or from fields with encryption configurations defined.

**ODBC driver**

Encrypt requests and query data through the Edge Encryption proxy server using the ODBC driver.

Learn more: [Edge Encryption ODBC driver integration](#)

**MID Server**

You can configure the MID Server to route data through an Edge Encryption proxy server. However, some restrictions apply.

Learn more: [Edge Encryption MID Server integration](#)

**REST/SOAP web services**

Use REST/SOAP web services to update or retrieve record data through the Edge Encryption proxy server.

Learn more: [Web services](#)

**JSONv2 web service**

Use JSONv2 web service APIs to update or retrieve record data through the Edge Encryption proxy server. Base system encryption rules support data retrieval and data modification APIs.

- To insert a single record using the data modification API, use the `insert()` or `insertMultiple()` methods.
- To insert multiple records using the data modification API, use the `insertMultiple()` method.

Learn more: [JSONv2 Web Service](#)

To encrypt data from custom third-party integrations not listed above, create custom encryption rules. See [Define a custom encryption rule](#).

Upload attachments to records marked for encryption

Attachments can be uploaded to tables with attachment encryption configured using REST and SOAP web services.

**Edge Encryption ODBC driver integration**

Configure your ODBC driver to query data encrypted by Edge Encryption. The Edge Encryption proxy server encrypts ODBC driver requests to the ServiceNow instance when Edge Encryption is integrated with the ODBC driver.

Encrypted responses from the instance are decrypted through the Edge Encryption proxy server before passing to the ODBC driver in your network.
For a successful integration, the ODBC driver must trust the Edge Encryption proxy server certificate. If the Edge Encryption proxy server certificate is signed by a Certificate Authority trusted by the ODBC driver, the Edge Encryption proxy server is automatically trusted. However, if a Certificate Authority trusted by the ODBC driver has not signed the Edge Encryption proxy server certificate, you must import the self-signed certificate to the ODBC truststore.

Import a self-signed certificate to the ODBC truststore
If a Certificate Authority trusted by the ODBC driver has not signed the Edge Encryption proxy server certificate, you must import a self-signed certificate to the ODBC truststore. You can export the certificate from the Edge Encryption proxy server and import it into the ODBC truststore.

To determine whether a Certificate Authority trusted by the ODBC driver has signed the Edge Encryption proxy server certificate, run the following command in the keystore directory in the proxy home directory to view a list of Certificate Authorities trusted by the ODBC driver:

```
keytool -keystore "<ODBC directory>\ip\Java\jre\lib\security\cacerts" -list
```

1. Change to the keystore directory in the proxy home directory.
2. Check the keystore for the self-signed certificate.
   a) To check the keystore for the certificate, you can run the following command to list all the items in the keystore.

```
keytool -list -keystore keystore.jceks -storetype jceks -v
```
   b) Locate the key alias in the list of items.
3. Using the key alias, export the certificate to a .cer file.

```
keytool -export -alias <key alias> -keystore keystore.jceks -storetype jceks -rfc -file <file name>.cer
```
4. Change to your ODBC truststore directory: ODBC\ip\Java\jre\lib\security\cacerts.
5. Import the certificate to your ODBC truststore.

```
keytool -keystore cacerts -importcert -alias $<key alias> -file <file name>.cer
```

Set the ODBC driver properties

Set the ODBC driver properties to route requests through the Edge Encryption proxy server.

1. In Windows, navigate to Start > Programs > ServiceNow ODBC Management Console.
2. Expand the console tree root to: ServiceNow ODBC Manager\Manager\<installation location>\Services\ServiceNow_ODBC\Data Source Settings\ServiceNow\IP Parameters.
3. Double-click the DataSourceIPProperties attribute.
4. Change the **Value** to the URL of your Edge Encryption proxy server, such as `https://<IP address>:<port>`
5. Click OK.

The ODBC driver is now configured to route requests to the instance through the Edge Encryption proxy server.

**Edge Encryption MID Server integration**

Configure the MID Server to route data through an Edge Encryption proxy server.

When integrated with the MID Server, the Edge Encryption proxy server acts as the MID Server’s endpoint. The Edge Encryption proxy server then encrypts and decrypts data passing between the ServiceNow instance and the MID Server.

**Limitations when integrating with the MID Server**

When MID Server data is configured to pass through the Edge Encryption proxy server, the following limitations apply:

- Encryption of ECC Queue fields is not supported.
- Encrypted data cannot be used with Discovery or Service Mapping.

**Point the MID Server to the Edge Encryption proxy server**

To pass data from the MID Server through the Edge Encryption proxy server, update the MID Server configuration file to point the MID Server to the Edge Encryption proxy server.

When configuring the MID Server to pass through the Edge Encryption proxy server, you cannot use the web proxy properties in the MID Server configuration file to route traffic through the Edge Encryption proxy server to your instance. Instead, you must set the Edge Encryption proxy server as the MID Server’s endpoint.

1. Navigate to your local MID Server directory and open the `config.xml` file.
2. Find the element `<parameter name="url" value="https://YOUR_INSTANCE.service-now.com" />` and change the value property to the URL of your Edge Encryption proxy server. For example, `http://hostname.mycompany.com:8081`.
   This step directs the MID Server to pass traffic to the Edge Encryption proxy server instead of the instance. The Edge Encryption proxy server in turn encrypts any necessary fields and passes the payload to the instance.
3. Save and close the file.
4. If running, restart the MID Server.

**Edge Encryption diagnostics and performance**

Monitor Edge Encryption proxy server performance trends and drill into errors generated by the Edge Encryption proxy server.

### Edge proxy performance

View key Edge Encryption proxy server performance trends using the Edge Proxy graph set on the ServiceNow Performance homepage. Monitored trends include:

- Maximum and average response times between the client, proxy server, and instance.
- CPU, disk space, and memory usage of the host machine.
- Maximum and average network latency between the proxy server and the ServiceNow instance.

**Note:** Edge Encryption proxy servers with duplicate names do not report performance trends.
Graph Set

Monitorable Items

Edge Proxy

Proxy Server

Edge Processing (Max)

Processing Time (Ms)

0 250 500 750 1000

15:20 15:30 15:40 15:50

Total Time  Proxy Response  Proxy–Instance Round Trip

Edge Processing (Average)

Processing Time (Ms)

0 200 400 600

15:20 15:30 15:40 15:50

Total Time  Proxy Response  Proxy–Instance Round Trip

Edge Proxy Performance (Max)

Percent

0 50 100 150

15:20 15:30 15:40 15:50

CPU Usage  Memory Usage  Disk Usage

Edge Proxy Performance (Average)
Maximum and average time in milliseconds to process a request. These data points are general trends over time.

- **Total Time**: Time for the proxy server to receive a request from a client and send a response. This data point is the sum of the subsequent data points.
- **Proxy Response**: Time for the proxy server to process a response from the instance.
- **Proxy-Instance Round Trip**: Time for the proxy server to send a request to the instance and receive a response. Includes network latency between the proxy server and the instance and time spent by the instance to process the request.
- **Rules**: Time for the proxy server to evaluate a request using defined encryption rules.
- **Proxy Request**: Time for the proxy server to process a client request and forward it to the instance.

**Edge Proxy Performance (Max and Average)**

Maximum and average percentage of resources used on the host machine.

- CPU Usage
- Memory Usage
- Disk Usage

**Edge Proxy Latency**

Maximum and average network latency in milliseconds at a given point in time. Latency is determined by round-trip time for a proxy server to send a simple ping to the instance and receive a response.

**Proxy Error Reports**

Navigate to **Edge Encryption Configuration > Diagnostics and Troubleshooting > Proxy Error Reports** to view all proxy server errors collected over the past seven days.
Errors are collected over a one-minute period. Each minute, an error report is generated. The vertical axis displays the number of error reports over the last seven days that include each error. For example, even if the DEFAULT_ERROR_CODE error is thrown multiple times over a one-minute report period, the DEFAULT_ERROR_CODE bar will only reach one on the **Number of Error Reports** axis.

From this view, you can:

- Click each proxy error code bar to see the report on a single error for each proxy server. From this view, you can click the bar again to view the error text in the Edge Encryption Proxy Stat table [edge_encryption_stat]. Follow links in the error text to see more information and possible remediation steps.
- Click **Other** to see page two of the error report.

**Note:** If you have more than one proxy server with the same name, a single DUPLICATE_PROXY_NAME error appears in the Proxy Error Report. No other errors are reported for proxy servers with duplicate names. If you encounter this error, make sure that all proxy servers have unique names.

### Additional monitoring resources

The instance tracks all encryption proxies. Each Edge Encryption proxy server registers when it starts up. The instance is notified when:

- A new Edge Encryption proxy server starts up.
- An Edge Encryption proxy server is intentionally shut down.

If an Edge Encryption proxy server attempts to register with an instance that does not have Edge Encryption installed, the proxy does not start.
All encryption configuration files are audited. Deleted records are audited on all encryption configuration files. Audit records are put in the sys_audit table. To view the history of a specific configuration record, view the record, and click History > List in the menu. The Mass Encryption Job is not audited.

Use the following additional resources to monitor you proxy servers.

<table>
<thead>
<tr>
<th>Table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invalid Insert Attempts</td>
<td>List of attempts to save the following data to encrypted fields:</td>
</tr>
</tbody>
</table>
| [sys_edge_encryption_invalid_insert_log] | • Unencrypted data.  
|                                | • Data that did not come from an Edge Encryption proxy.                       |
|                               | The instance rejects and then logs any attempts to save this data. If you have the security-admin role, you can view the logs in the Invalid Insert Attempts list. |
| Job Failures                  | A list of jobs that did not execute successfully.                           |
| [sys_encryption_job_execution] |                                                                             |
| System logs                   | The instance periodically checks for messages from each registered proxy server. If a proxy server has not sent a message in the required time frame, an error is logged. The log message contains information about the encryption proxy and the last time the proxy pinged the instance. If the instance determines that none of the encryption proxies are online, it logs a message. These messages are added to the system log. |

**Disable or reduce Edge Proxy statistic collection**

Prevent the Edge Encryption proxy server from sending Edge Proxy Graph Set statistics to the ServiceNow Performance homepage, or reduce the frequency of statistic collection.

Role required: admin or security_admin

By adding properties in the edgeencryption.properties configuration file, you can:

- Disable the Edge Proxy graph set.
- Change the interval during which statistics are collected by the Edge Encryption proxy server. By default, statistics are collected every 30 seconds.

1. In your proxy server installation directory, open the edgeencryption.properties configuration file located in the <installation directory>/conf/ folder.
2. Add one of the Edge Encryption proxy server properties.
3. Restart the proxy server.

**Data Classification**

Group data by type, using pre-defined or user-defined data classifications. If you have an assigned data classification administrator or auditor role, you can administer different data classes or visually analyze the current state of different types of data within the instance.

Data Classification enables support for:

- Visibility into the types of data hosted on a Now Platform instances.
- Compliance with privacy laws, and meeting regulation requirements for industries such as financial services and medical device manufacturing.
Data classifications

Data classification is a standalone process in which you manually apply data classifications to existing dictionary entries in any table.

- You classify data as you find appropriate for your business and you can alter the available data classes as necessary.
- When you classify data, you can use the pre-defined data classifications, or create your own. Although use of pre-defined data classifications is optional, it is advisable do so as a starting point. These pre-defined data classifications are included in demo data that you can install in your instance. To learn more, see Install Data Classification plugin demo data and Components installed with Data Classification demo data.
- If you create your own data classifications, you can also design a tiered hierarchical system with parent and child data classifications.

Overview dashboard

Use the Overview dashboard to understand how your current data tables map to different data classifications. You can also analyze how your global, regional, international users may require different approaches to data classification, regarding the use or access to data. You can also customize the Overview dashboard content and layout to fit your needs.

To learn how to use the available scripted and REST APIs to apply the classification metadata within existing processes, workflows, and applications, see the following:

- Data Classification - REST API
- DCManager - Global
- ScopedDCManager - Scoped

Note: Data Classification supports domain separation, and the data_classification table itself is process separated.

Use cases

General Data Protection Regulation (GDPR) is a European Union regulation whose purpose is to provide individuals with control over their own personal data. You can use data classifications, such as Personally Identifiable Information, to identify where personal data is being stored in your instance. By applying the appropriate security mechanisms to protect that personal data from leaking out, your organization satisfies GDPR requirements.

If you store customer information in the Now Platform, use the Personally Identifiable Information (PII) classification code where needed to track data subject to regulation by local privacy laws. When you install demo data, it automatically applies this classification code to certain security-sensitive fields in the User [sys_user] table. To learn more, see:

- Components installed with Data Classification demo data
- Assign data classifications to dictionary entries

You can apply a Restricted data classification to Employee table columns that store sensitive employee information such as Social Security Numbers (SSN). Administrators and auditors can then use the Overview dashboard to confirm
that you have assigned data classifications to the correct columns. They can also view the classification details for restricted types of information.

**Install Data Classification plugin demo data**

When you upgrade to or install Quebec (and above), the Data Classification (com.glide.data_classification) plugin is automatically activated. However, you should manually install the demo data that comes with the plugin. It includes several important pre-defined data classifications, and it also assigns one of them to specific User [sys_user] table columns in your instance.

Role required: admin

Regardless of whether you install demo data, the activated Data Classification plugin adds the following user roles in your instance:

- **data_classification_admin**: Can administer all aspects of the Data Classification application, including data classification setup and assignment.
- **data_classification_auditor**: Can audit Data Classification code assignments made to user tables and columns.

1. Navigate to **System Applications > All Available Applications > All**.
2. Find the Data Classification plugin using the filter criteria and search bar.
   - An Installed message appears after you locate the plugin.
3. Click the icon with three vertical dots, then select **Repair** to access the Activate Plugin dialog.

   ![Activate Plugin dialog](image)

   The following dialog box appears:

   ![Activate Plugin dialog contents](image)

4. Select **Load demo data**, and then click **Repair**.
Components installed with Data Classification demo data

When you install the demo data included in the Data Classification (com.glide.data_classification) plugin, several types of components are installed in your instance. These components include pre-defined data classifications and code assignments for specific User [sys_user] columns.

Data Classifications installed

<table>
<thead>
<tr>
<th>Data Classification</th>

<td>Personally identifiable information</td>
</tr>
</tbody>
</table>
Create data classifications

Create your own user-defined data classifications in the Data Classification [data_classification] table that you can then assign to specific columns in specific tables.

Role required: data_classification_admin, admin

1. Navigate to System Security > Data classification > Data classes.
2. Fill in the fields on the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Classification Name</td>
<td>Name of the data classification.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the data classification.</td>
</tr>
<tr>
<td>Parent</td>
<td>Name of the parent data classification that this data classification is subordinate to. Leave the field empty if this data classification is not a parent to child data classifications.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope for this data classification.</td>
</tr>
</tbody>
</table>

3. If this data classification should be a parent to child data classifications, click New.

   If you do not want to create child data classifications, skip this step.
4. Fill in the fields on the form.

<table>
<thead>
<tr>
<th>Title</th>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Classification Name</td>
<td>Name of the child data classification.</td>
</tr>
<tr>
<td></td>
<td>Description</td>
<td>Description of the child data classification.</td>
</tr>
<tr>
<td></td>
<td>Parent</td>
<td>Name of the parent data classification that this data classification is subordinate to. Leave the field empty if this data classification is not a parent to child data classifications.</td>
</tr>
<tr>
<td></td>
<td>Application</td>
<td>Application scope for this child data classification.</td>
</tr>
</tbody>
</table>

5. Click Submit.

Assign data classifications to dictionary entries

Assign data classifications to specific table columns in the Dictionary [sys_dictionary] table. When you assign data classifications, it creates entries in the Dictionary-Data Class [m2m_dictionary_dataclass] table, which you can then review in the Overview dashboard.

Role required: data_classification_admin, admin

1. In the Navigator pane, type sys_dictionary.list.
2. In Dictionary Entries, select each of the elements you want to assign specific data classifications to.
3. After selecting the elements, click Actions on selected rows, and then select Classify.

   Note: To clear previously assigned data classifications for selected dictionary elements, you can select Clear classification.
4. When the Assign to data class dialog appears, select the data classifications you want to assign to your selected dictionary elements, then click **Classify**.

You can select multiple data classifications as needed.

**Analyze data classifications using the Overview dashboard**

The Overview dashboard reports the current state of data classifications within your instance, and how your users are distributed by location. If you have a data classification administrator or auditor role, you can visualize the current sensitivity of instance data, which helps increase security and compliance with privacy laws. By using the Location field in user records, administrators map users across different regions that have differing privacy regulations.
Tables and columns tab

Breakdown of classified data

- Personally identifiable information = 14 (77.78%)
- Internal = 2 (11.11%)
- Confidential = 1 (5.56%)
- Restricted = 1
Users tab

Domain separation and Data Classification

Domain separation is supported for Data Classification. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

Support level: Enhanced

- Includes Basic and Standard levels
- Data-driven process enables service provider customers to modify business logic that is based on defined use cases. These configurations are UI-based and fail-safe so that configurations by one customer cannot affect another.
- Tenants of the instance must be able to configure minimum viable product (MVP) business logic and data parameters for themselves. This logic and parameters would be expected for the application's normal function.

Use case: Tenant-customers of a shared environment must be able to modify the impact, urgency, or priority matrix to set priority within their domain.

To learn more, see Application support for domain separation.

How domain separation works in Data Classification

For domain separation, the application uses process separation for the Data Classification [sys_data_classification] table. For the Dictionary-Data Class [m2m_dictionary_dataclass] table, it uses data separation. For learn more about data and process separation, see Domain separation explained.

Auditing

Track record changes on auditing-enabled tables. By default, the system tracks changes to the incident, change, and problem tables, among others.

Enabling auditing tracks the creation, update, and deletion of all records in the table. If you want to audit individual fields in a table, you can hide fields you do not want to track using a dictionary attribute.

Auditing information is kept in these tables:
- The Audit table.
- The History sets table.

CAUTION: Auditing certain system tables that receive a large amount of traffic, such as Workflow Contexts [wf_context], can impact performance and is not recommended. The em_alert table itself can have audit=true, but the fields are not audited unless you explicitly set audit=true for a field.

Auditing parent and child tables

Tables do not derive the audit flags from parent or child audited tables.
- For example, if you enable auditing for the cmdb_ci table, only CIs stored in that base table are audited.
- Likewise, if you enable auditing for the cmdb_ci_computer table, only the computer CI records are audited, including any fields on the cmdb_ci_computer table that are derived from the cmdb_ci table.
Auditing system tables

By default, the system does not audit the deletion of a record from system tables. To audit a system table, add it to the list of tables in the glide.ui.audit_deleted_tables property list.

Auditing deletions from a form or list

By default, the system audits deletions of individual records from a form. To prevent auditing, set the table's dictionary attribute no_audit_delete.

The system audits deletions from a list when audit is selected on the table dictionary, and the table is not listed in the glide.db.audit.ignore.delete property.

Note: By default, the glide.db.audit.ignore.delete property is not present in the System Property [sys_properties] table. To change the property, and its associated values, you must first manually add it. However, when manually added, it overwrites the following default values:

```plaintext
glide.db.audit.ignore.delete =
  sys_mutex, sys_db_cache, sys_lucene_block, sys_lucene_file, sys_lucene_directory, sys_user_preference,
  cmdb_ci_windows_service, cmdb_sam_sw_install, cmdb_software_instance,
  cmdb_sam_sw_usage, sam_sw_counter_detail
```

To learn more about adding system properties, see Add a system property.

Information audited

Auditing tracks the following record changes:

- Unique Record Identifier (sys_id) of the record that changed
- Field that changed
- New field value
- Old field value
- Number of times this record and field have been updated
- Date and time when the change occurred
- User who made the change
- Reason for the change (if any reason is associated with the change)
- Internal checkpoint ID for the record, if the record has multiple versions.

Information exempted from auditing

Some updates are not audited despite enabling auditing on a table. It is why you may see 132 updates in a record's history, but only seven audited ones.

Auditing excludes the following information:

- Updates made by an upgrade.
- Updates made through import sets.
- Records in parent or child tables.
- Fields with the no_audit dictionary attribute.
- System tables not listed in the glide.ui.audit_deleted_tables property list.
- Fields that begin with the sys_ prefix (system fields), except the sys_class_name and sys_domain_id columns.
- UI Pages can sometimes trigger updates to a record without creating an audit log.
Anytime an inactivity monitor touches a record. It prevents you seeing possibly hundreds of updates listed against an incident, with the noise drowning out the useful data.

**Auditing a table**

For instructions on how to audit a table, see Enable auditing for a table.

By default, the system tracks all fields in an audited table. You can audit a subset of fields in a table in one of two ways:

- You can enable auditing for the entire table, then exclude those fields you do not want to include. It is appropriate when you want to audit most, but not all, fields, and is referred to as an **exclusion listing**. For more information, see Include a field from being audited (exclusion listing).
- You can enable auditing for the table, but only for specified fields. It is appropriate when you want to audit only a small number of the table’s fields and is referred to as **inclusion listing**. For information on how to include a field using inclusion listing, see Include a table field in auditing (inclusion listing).

**Sys Audit and Audit Relationship Change tables**

The Now Platform tracks inserts and updates to audited records in the Sys Audit (sys_audit) and Audit Relationship Change (sys_audit_relation) tables.

The Now Platform tracks audit tables. To track tables, select the **Audit** check box in the dictionary record to set the value to true. By default, it does not audit records from system tables, such as update sets tables.

**Note:** To prevent performance issues and infinite loops, the system skips any business rule or workflow triggered by inserts to the Sys Audit table.

**Sys audit table columns**

The following columns appear in the sys_audit table records:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table name</td>
<td>Table that the audit record is for (for example, &quot;incident&quot;)</td>
</tr>
<tr>
<td>Field name</td>
<td>Column in the table that the audit record is for (for example, &quot;assigned_to&quot;)</td>
</tr>
<tr>
<td>Document key</td>
<td>Sys_id (Unique Record Identifier) for the originating record associated with the audit record.</td>
</tr>
<tr>
<td>Old value</td>
<td>Old value of the field change represented by this sys_audit record.</td>
</tr>
<tr>
<td></td>
<td>• Reference fields: Unique sys_id value of the changed record.</td>
</tr>
<tr>
<td></td>
<td>• Date and time fields: Value in Coordinated Universal Time (UTC) as stored in the database.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>New value</td>
<td>New value of the field change represented by this sys_audit record.</td>
</tr>
<tr>
<td></td>
<td>• Reference fields: Unique sys_id value of the changed record.</td>
</tr>
<tr>
<td></td>
<td>• Date and time fields: Value in Coordinated Universal Time (UTC) as stored in the database.</td>
</tr>
</tbody>
</table>

How the Audit Relationship Change (sys_audit_relation) table works

The Sys Audit [sys_audit] table tracks activity in tables that are flagged for auditing. This activity includes journal field entries and history sets. The Audit Relationship Change [sys_audit_relation] table tracks relationship changes between sys_audit table records and the source tables that the audited records originate from. It also tracks when a record might have been deleted.

• Whenever you audit any record in a table, a relationship is created between the various originating tables to the store that records data. This relationship information is saved in the sys_history_set, sys_history_line, and sys_journal tables.
• If you delete a field that is related to an audited table record, the sys_audit_relation table records the deletion. In other words, anytime you change an audited record, it first deletes past elements, and then creates a relationship in the sys_audit_relation table with new document IDs.

Enable auditing for a table

You can enable table auditing to track changes to all or some of the table's fields.

Role required: admin

1. Navigate to System Definition > Dictionary.
   The system displays the list of dictionary entries. The list includes a row for each table as well as a row for each column (field) in the table.
2. In the list of dictionary entries, find the row corresponding to the table you want to audit, for example cmdb_ci_computer. You can distinguish the row for the table itself – versus a row for a column in the table – by finding the row with the correct table name, an empty entry for Column name, and a Type of Collection.
3. Select the dictionary entry for the table.
   The system displays the dictionary entry form.
4. Check the Audit check box.
5. Click Update.

If you want to audit only a few fields in the table Enable inclusion list auditing for a table. If you want to audit most – but exclude some – fields, Exclude a field from being audited (exclusion listing).

Enable inclusion list auditing for a table

Enable a table to audit only those fields you explicitly designate. This is useful when you want to audit only a small number of fields in an audited table.

Role required: admin

The table must be enabled for auditing.

1. Navigate to System Definition > Dictionary.
The system displays the list of dictionary entries. The list includes a row for each table as well as a row for each column (field) in the table.

2. If necessary, customize the list view to show the Attributes column.

3. In the list of dictionary entries, find the row corresponding to the table you want to audit, for example cmdb_ci_computer. You can distinguish the row for the table itself – versus a row for a column in the table – by finding the row with the correct table name, an empty entry for Column name, and a type of collection.

4. In the Attributes field for that row, enter audit_type=whitelist.

Designate which fields you want to audit in this table.

**Exclude a field from being audited (exclusion listing)**

Prevent the Now Platform from tracking a subset of fields in an audited table by excluding those fields from an audit.

Role required: admin

To exclude a field in a table from being audited, you must have first enable auditing for that table.

Add a set of fields to an exclusion list when you want to audit most of the fields in an auditable table. If you want to audit only a few fields, follow the inclusion listing procedure instead.

**Note:** Disabling auditing on journal-based fields can impact the functionality of features, such as the Activity Formatter. For more information, see KB0743142.

1. Navigate to System Definition > Dictionary.
2. If necessary, customize the list view to show the Attributes column.
3. Navigate to the row corresponding to the table and field (column) you want to exclude from auditing.
4. In the Attributes column for that row, enter no_audit.

**Include a table field in auditing (inclusion listing)**

Track a subset of fields in an audited table by add those fields to an inclusion listing.

Role required: admin

To add fields in a table to an inclusion list, you must have first enabled auditing for that table and enabled inclusion list auditing for that table.

Add a set of fields to an inclusion list when you want to audit only a small number of an audited table’s fields. If you need to audit most fields, and exclude only a few, follow the exclusion list procedure instead.

1. Navigate to System Definition > Dictionary.
2. If necessary, customize the list view to include showing the Attributes column.
3. Navigate to the table and field (column) you want to the inclusion list.
4. In the Attributes field, enter audit=true.

**Enable auditing for a system table**

Deletions from tables with a sys_ prefix are not audited by default. To track deletions from these tables, add the table name to the glide.ui.audit_deleted_tables property. Enabling the Restore Deleted Records plugin adds several default values to this property.

Role required: admin

1. Navigate to System Properties > UI Properties.
2. Locate the List of system tables (beginning with "sys_", comma separated) that will have the delete audited property.
3. Add or remove table names. Table names should be separated by commas, without any spaces.
4. Click **Save**.

**Note:** For more information about auditing, see Understanding the sys audit Table.

### History sets

The system automatically generates History Set records as needed from the Audit table when a user either creates a record or views its history.

If a record is in an audited table, its history set is generated when the record is inserted or when a user views the record.

**Note:** Do not use history sets to generate reports.

Several fields of information are captured in the History Set record, displayed in the list view.

<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>List View Record Fields</strong></td>
<td></td>
</tr>
<tr>
<td>ID</td>
<td>Document ID for the record whose history is being recorded.</td>
</tr>
<tr>
<td>Table</td>
<td>Audited table for the record whose history is being recorded.</td>
</tr>
<tr>
<td>Load Time</td>
<td>Amount of time it took to generate the history set.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Audit History Record Fields</strong></td>
<td></td>
</tr>
<tr>
<td>Label</td>
<td>Label of the field that was changed.</td>
</tr>
<tr>
<td>Old</td>
<td>Value before the change.</td>
</tr>
<tr>
<td>New</td>
<td>Value after the change.</td>
</tr>
<tr>
<td>Type</td>
<td>Indicates if the entry is for a normal field, an email record, or a relationship change record.</td>
</tr>
<tr>
<td>Update Number</td>
<td>Number of times this field has been changed. A value of -1 indicates when the record was created or deleted.</td>
</tr>
</tbody>
</table>
### History Sets in a Calendar View

Once History Sets are active, the History context menu choice populates using information from the history set, rather than from the `sys_audit` table. From the user's perspective, the same historical data is available in the same user interface, but how the information is stored is different.

Since the History view includes a calendar view, but does not use the normal list interface to filter and interact with the history records, it allows:

- Searching and filtering historic data.
- Exporting historic data.

### Viewing history sets

There are two ways of viewing the history set, accessible through the Context Menu action **History**.

### Differences Between Audit and History Sets

The Audit `[sys_audit]`, History Sets `[sys_history_set]`, and History `[sys_history_line]` tables store the same data, but they serve different purposes and manage data differently.

### Audit `[sys_audit]` table

The Audit `[sys_audit]` table is where the system stores historical information for all records. These records are intended to be kept forever so that administrators can always track the history of audited records. As the number of auditing records grows over time, it becomes more inefficient to directly query the Audit table for historical information. It is much more efficient to run queries only on the smaller subset records you actually want to view historical information for.
History Set [sys_history_set] table

The History Set [sys_history_set] table identifies which particular records from an audited table have historical information. The History [sys_history_line] table stores the actual changes to field values that occurred.

- The system automatically generates History Set and History records as needed from the Audit table when a user either creates a record or requests its history.
- Rather than containing a complete history of all changes in the system, History Set and History records only contain a recent subset of historical information for records where users have created or requested such information.
- In addition to audit data, history sets also include the information that is set during record insert, including journal field entries. Journal field entries you create before creating a record are handled in the same manner as journal entries created at the time of record creation. These journal entries appear in history sets with the same creation time and created by data as the associated record itself.

The system limits History Set and History records by:

- Having the table cleaner delete History Set records that have not been updated in 30 days.
- Using table rotation to rotate between four History tables every seven days. The system drops History records that are older than 28 days.

Should someone need historical information again at a later date, the system can regenerate it from auditing source records.

After the system generates History Set records, the context menu choice History uses the History Set rather than Audit records. From the user's perspective, the same historical data is available in the same user interface, but the way the information is stored is different.

Control access to history

You can give a role access to view audit history by setting a system property.

Role required: admin

1. Navigate to System Properties > System.
2. In the property List of roles (comma-separated) that can access the history of a record, enter the user roles you want to access history.
3. Click Save.

Any changes to a field are omitted if a user without read-access views the history of a record.

Change the number of history entries

By default, the history displays a maximum of 250 history entries, but you can change this value.

Role required: admin

1. Navigate to System Properties > System.
2. In the property Maximum number of field entries displayed in record history, default is 250, enter a new maximum number of entries.
History List

The history list displays each change as its own row in the change list.

<table>

View History List

Click on a row item to view additional details about the change.
View List Change

Requirements

To view a history list, the following requirements must be met.

- **Auditing**: Auditing for the table must be enabled to view a history list.
- **ACLs**: By default, the List history option is only available to users with the admin user role. To enable this option to non-admins, create a custom ACL rule granting read access to the Record History [sys_history_set] table.
- **Roles**: At least one of the roles that the user has must be included in the glide.history.role property, which includes the itil role by default.

History Calendar

The history calendar shows you the days where the record was changed, who made the change, and when.
The History Calendar is sorted by update number. Each user is assigned a color so you can tell at a glance how many
times a record was changed by a specific user. For example:

Changes made by system administrator

Changes made by ITIL user

To highlight changes to a particular field, select the field from the **Highlight changes to field** selection box.
Picking a field from this selection box changes the calendar to highlight the times that field was changed. Hover over
the text of one of a highlighted change to see the change in value.
If you hover over the icon within an entry, a popup displays all the value changes. This is the same information that is displayed in the top part of the form.
<table>

### Incident History Detail

**Details for INC0000039**

- **Created**: 2012-04-05 17:42:29 by admin
- **Last updated**: 2012-06-15 12:56:26 by itil
- **Update count**: 3 (1 audited)

- **Created by**: System Administrator (70 Days 1 Week)
- **Updated by**: ITIL User (2 Minutes)

**Field** | **Value**
---|---
Active | true
Approval | Not Yet Requested
Assignment group | Network
Caller | Bud Richman
Category | Network
Configuration item | MailServerUS

**Additional comments**: Routing from San Diego to the Oregon mail server appears to be getting packet lost!

- **Contact type**: Phone
- **Escalation**: Normal
- **Impact**: 3 - Low
- **Incident state**: New
- **Incident type**: Routing
- **Knowledge**: false
- **Location**: Salem OR
- **Made SLA**: false
- **Notify**: Do Not Notify
- **Number**: INC0000039
- **Opened**: 2012-04-05 17:41:01
- **Opened by**: Bud Richman
- **Priority**: 4 - Low
- **Severity**: 3 - Low
- **Short description**: Routing to oregon mail server
- **SLA due**: 2012-04-26 17:41:01
- **State**: New
- **Task type**: Incident
- **Domain**: global
- **Urgency**: 3 - Low
You can click on the day number to get a view of the changes for that day. You can also click on the week number to the left to get a the week view. You can scroll to and from month to month to see changes.

**History Timeline**

You can view a timeline of changes for a CI and for its related records, relationships, baselines, and proposed changes for the CI. Timelines are available for CIs in the Configuration Item [cmdb_ci] table or a descendant of this table, if auditing is enabled for the tables.

Role required: The ACL for this view is based on the roles defined in the `glide.history.role` system property, which by default is set to `itil`. Also, the user must have read access to the History Set [sys_history_set] table, which by default is granted to admin.

You can open a timeline when you view the history of a CI. You can specify the time period, time range, and properties that are displayed in the timeline. You can view either what has changed in a particular change set, or view the entire CI to better troubleshoot any issues. You can also display a timeline of changes to the CI's related records, and export and compare snapshots of the CI at any point in time.

CI changes are represented by bubbles in different shapes and colors along the timeline. The shape of each bubble represents a different type of change and the color of each bubble specifies whether the change is valid or invalid. CI baselines are represented by black circles that you can hover over to display more details. Click the ? icon to display bubble shape and color definitions, and point to a bubble to display details about the change set.

A change to a relationship is considered valid only if it was applied through change management. If the change was applied via the Proposed Changes framework, it is valid. For additional validation steps, see Create or edit a planned validation script.

---

**History Timeline view**

© 2021 ServiceNow, Inc. All rights reserved.
Timeline bubbles

**Note:** Proposed changes that do not have a planned start date are placed at future points of time.

**Timeline navigator**

Use the handles on both ends of the timeline navigator to extend or to shorten the time period that is shown.

You can scroll to a different period of time by clicking on the bottom part of the timeline navigator and then dragging the navigator to the left or right.

**Zoom**

By default, the timeline for the last month is shown. Next to the **Zoom** label above the timeline, you can select another time interval. You can select intervals from a minute to the entire period of data.

If there are many changes of the CI during the time period, the bubbles displayed might get too crowded. You can zoom in or out to spread the bubbles in either method:

- Change the time interval on the timeline. As you shorten the time interval, you zoom in, and as you lengthen the time interval, you zoom out.
- Select the section of the timeline that you want to zoom into.

**Property filter**

You can filter the bubbles that are displayed. By default, all bubbles are displayed, representing changes to all of the CI's properties. You can limit the view to display only the bubbles in which selected properties have changed and exclude bubbles in which only unselected properties changed.

The **Detail** and **Summary** views highlight properties within your filter scope that have changed. The changed properties are highlighted in light blue.

In the **Summary** view, you can choose to include all the properties of the CI, or only properties that have changed. If you choose to display all properties in the summary view, then changed properties are listed before unchanged properties.
Summary view

The **Summary** view displays snapshots of the CI's represented by each bubble. Each snapshot displays the changes to the CI's fields and relationships according to the change set. It displays old and new values before and after the change, and any relationships that were added or deleted.

Use the > and < buttons on both sides of the snapshot display to scroll through the next and previous change set records in a chronological order.

Detail view

The **Detail** view displays snapshots of the CI that correspond with the bubbles. Each snapshot includes the fields that are within the property filter scope, displaying the properties that have changed with a light blue background. Click on a bubble to display its corresponding snapshot of the CI. The data that is displayed is read-only.

Use the > and < buttons on both sides to scroll through the next and previous change set records in a chronological order.

**View timeline of changes to related records**

On the timeline of changes for a CI record, you can also view a timeline of changes for the CI's related records.

- Role required: admin
- Target table: the CI record must be in the Configuration Item [cmdb_ci] table or a descendant of this table.
- Auditing: must be enabled for the table containing the CI.

1. Open the timeline for the CI.
2. Click the **Related Records** icon and select related records from the **List of Related Records** to view. Click the Related Records icon again to display the related records timeline.

The timeline of changes to the CI's related records is displayed right above the CI's timeline. If you uncheck all related records, the related records timeline is hidden.

Hover over a change bubble on the related records timeline to display details about the change, such as date and number of changed properties. As you change the time interval in focus, or zoom in or out, it affects both the CI timeline and the related records timeline simultaneously.

**Export a snapshot of a CI**

You can export a snapshot of a CI from its timeline.

The CI must be in the Configuration Item [cmdb_ci] table or a descendant of this table. Auditing must be enabled for the table containing the CI.

Role required: admin

You can export a snapshot of the CI to an XML, PDF (Portal), or PDF (Landscape) format.

1. Open the timeline for the CI.
2. Select the bubble representing the time for which you want to export a snapshot of the CI.
3. Click the export icon ( ).
4. Select the file format to use for the export.
   You can download the file to your system for viewing.

**Compare CI snapshots**

You can compare the properties and relationships of a CI at two different points in its timeline.

The CI must be in the Configuration Item [cmdb_ci] table or a descendant of this table. Auditing must be enabled for the table containing the CI.
Role required: admin

1. Open the timeline for the CI.
2. Click Compare.
3. Select a Start date and an End date.
4. Click Compare.

Tracking changes to reference fields

Administrators can track changes to reference field display values.

Since reference fields only store an ID value, the system can normally only audit changes when the ID value changes. By default, the system does not audit changes when a reference field display value changes.

Consider the following situation. A user changes her name from Jane Smith to Jane Miller. Since the user name is the display value for the User table, any previous reference to Jane Smith instead refers to Jane Miller. If the administrator just updates the name of the existing user record, audit and history records will only display the new name Jane Miller. By default, the system does not provide a way to distinguish between changes made under the original user name versus those made with the new user name.

If your auditing policy requires tracking user name changes, you can:

- Create a new user record for the new name and deactivate the previous user record. The system preserves audit records for the old user name and creates future audit records with the new user name.
- Create custom fields and a business rule to save the previous name and the date of the name change. The system can use this information to construct the proper names in audit and history records.

Tracking inserts

By default, the system does not create Audit records for inserts because in a typical instance, inserts can account for over 80% of the size of the Audit table.

Not tracking inserts allows for better performance and a much smaller Audit table. Administrators can enable auditing of inserts by setting the `glide.sys.audit_inserts` property to `true`.

Tracking CI Relationships

Changes to a CI relationship (CI Relations, CI/User Relations, or CI/Group Relations) appear in the history of the items on both sides of the changed relationship regardless of whether the change was manual or a result of Discovery.

For example, if the computer alpha has a used by CI Relation with the computer beta, then the history for alpha has a record of when the relationship with beta was established, and likewise, the history for beta has a record of when the relationship with alpha was established. This example illustrates the history displayed when some CI Relations are established, and then one of the relations is removed:
CI Relationship History

The created bullet indicates the date that the CI, user, or group was created. The last activity bullet refers to when the relationships were last changed. If you don’t want to show CI relationship history for any or all CI relationship types, you can turn it off by disabling auditing on the CI relationship tables (CI Relationship [cmdb_rel_ci], CI/User Relationship Type [cmdb_rel_user_type], or Group Relationship [cmdb_rel_group]).

System logs

The System Logs module provides a variety of logs that you can use to troubleshoot and debug transactions and events that take place within the instance.

Access the following logs from the System Logs module:

<table>
<thead>
<tr>
<th>Log</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transactions</td>
<td>All application activity for an instance.</td>
</tr>
<tr>
<td>Email and Push</td>
<td>All email notifications and Push messages sent from all instances within the system.</td>
</tr>
<tr>
<td>Events</td>
<td>All system events that occur within the system.</td>
</tr>
<tr>
<td>Import</td>
<td>Data import activity within the platform.</td>
</tr>
<tr>
<td>Log</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Table Changes</td>
<td>Changes made to all tables in the system.</td>
</tr>
<tr>
<td>Outbound HTTP Requests</td>
<td>All outbound web services requests such as REST and SOAP requests.</td>
</tr>
<tr>
<td>Signature Images</td>
<td>Electronic signatures for the HR signature pad.</td>
</tr>
<tr>
<td>System</td>
<td>Warnings and errors for instance processes, records, and non-critical events, such as memory usage on the server machine.</td>
</tr>
</tbody>
</table>

Use the Log File Browser to search and download logs. You can also search archived logs in the log history.

**Other logs**

Your instance offers other logs in addition to those in the System Logs module. For example, the System Diagnostics module provides upgrade history and slow query logs, which you can use to gain insight into how queries are affecting platform performance. The Customer updates table records every change that is made in the system.

**System log**

View warnings and errors for instance processes, records, and non-critical events, such as memory usage on the server machine.

The following information is tracked in the system log:

- Workflows
- Configuration
- Chats sessions
- Transactions for each view of each page in the system, including load times for network, server, and browser
- Inbound and outbound email
- Events triggered in the system
- Imports and integrations
- System warnings, errors, and script logs
- Upgrade information for any plugin activations, update sets, or system upgrades

Log entries appear for the current day only. To view other log files, use the log file browser. This log provides the following information for all occurrences:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created</td>
<td>Date and time of the logging activity for the locale of the machine running the instance.</td>
</tr>
<tr>
<td>Level</td>
<td>Type of message. The levels are Debug, Error, Warning, and Information.</td>
</tr>
<tr>
<td></td>
<td>• A warning is an error that has been handled and recovered.</td>
</tr>
<tr>
<td></td>
<td>• An error is something that must be fixed.</td>
</tr>
<tr>
<td>Message</td>
<td>System-generated message regarding the nature of the occurrence.</td>
</tr>
</tbody>
</table>
Workflow logging

- Each activity executed, including:
  - Date and time started
  - Date and time ended
  - State, for example, Finished, Cancelled, Timed Out, Error
  - Result
  - Fault description, if there was an error
- Transition history, including:
  - Time of transition
  - Activity transitioned from
  - Activity transitioned to
  - Which transition was triggered
- Workflow log, including any log statements added to the workflow

Configuration information

- Action taken, including insert, update, and delete
- Category of change
- Comments recorded with the change
- Name of the change
- XML difference of the change
- Update set the change is associated to
- Date and time of the change
- User who made the change
- Table where the change was made
- Name of the object being changed
- Type of object being changed
- View the change was made in, for changes to forms or lists

Transaction logs

The transaction log records all browser activity for an instance. To aid in debugging of system issues, you can filter transaction logs by application scope, limiting transactions that appear to only those transactions originating in specific scopes.

The transaction log provides the following information for all activities.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created</td>
<td>Date and time of the application action for the locale of the machine running the instance.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Type</td>
<td>Type of recorded transaction.</td>
</tr>
<tr>
<td>Created by</td>
<td>User who created this activity.</td>
</tr>
<tr>
<td>Origin application</td>
<td>Application scope the transaction originated in. Global appears if the transaction originated in the global scope.</td>
</tr>
<tr>
<td>Response time</td>
<td>Round trip response time for the application request, in milliseconds.</td>
</tr>
<tr>
<td>Network time</td>
<td>Latency time of the network response after the application request is made, in milliseconds.</td>
</tr>
<tr>
<td>Output length</td>
<td>Size of the output string sent by the instance to the application, in bytes.</td>
</tr>
<tr>
<td>SQL count</td>
<td>Number of SQL server commands executed for this activity.</td>
</tr>
<tr>
<td>Business rule count</td>
<td>Number of business rules executed for this activity.</td>
</tr>
<tr>
<td>Business rule time</td>
<td>Elapsed time for the execution of the business rules for this activity.</td>
</tr>
<tr>
<td>URL</td>
<td>Application or module connected to by the client application.</td>
</tr>
<tr>
<td>System ID</td>
<td>System generated identifier of the client instance making the request. This ID is used for cluster environments in which several instances (nodes) communicate with the database.</td>
</tr>
<tr>
<td>IP address</td>
<td>IP address of the client making the request.</td>
</tr>
<tr>
<td>GZipped</td>
<td>Indication of whether a compressed Web page was requested by the application.</td>
</tr>
<tr>
<td>Protocol</td>
<td>HTTP protocol used by the application for this instance.</td>
</tr>
</tbody>
</table>

Client transaction timings

The Client Transaction Timings plugin enhances the system logs by providing additional information about the durations of transactions taking place between the client and the server.

You can track down performance issues to their source by viewing where the time is being consumed, and how time was spent during a transaction.

This plugin requires the Response Time Indicator to be enabled, and collects information from the following browsers:
- Firefox
- Internet Explorer
- Chrome

Client Transactions Information

Installing the plugin adds the **Client Transactions** module to the **System Logs** application. It provides a list of every logged transaction between client and server within the last day:
Client Transactions Information

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created</td>
<td>Moment the transaction was recorded.</td>
</tr>
<tr>
<td>Response Time</td>
<td>Number of ms spent by the server in fulfilling the transaction.</td>
</tr>
<tr>
<td>Business Rule Time</td>
<td>Number of ms spent by business rules triggered by the transaction.</td>
</tr>
<tr>
<td>SQL Time</td>
<td>Number of ms spent by the SQL database.</td>
</tr>
<tr>
<td>Client Response Time</td>
<td></td>
</tr>
<tr>
<td>(Load_completion_time) - (start_time). It is inclusive of server time.</td>
<td></td>
</tr>
<tr>
<td>Client Network Time</td>
<td>Number of ms spent by the network the client is connecting through.</td>
</tr>
<tr>
<td>Browser Time</td>
<td>Number of ms spent by the browser during the transaction.</td>
</tr>
<tr>
<td>Client Script Time</td>
<td>The number of ms spent executing client scripts.</td>
</tr>
<tr>
<td>UI Policy Time</td>
<td>Number of ms spent executing ui policy.</td>
</tr>
<tr>
<td>Type</td>
<td>Type of transaction:</td>
</tr>
<tr>
<td></td>
<td>- Form</td>
</tr>
<tr>
<td></td>
<td>- List</td>
</tr>
<tr>
<td></td>
<td>- Other</td>
</tr>
<tr>
<td>Table</td>
<td>Name of table that appeared. For example, incident, change_request.</td>
</tr>
<tr>
<td>View</td>
<td>View for this form/list.</td>
</tr>
</tbody>
</table>

Client Detailed Information

A more detailed breakdown of the client timings for all Form rendering (but not list rendering) is also tracked. To see details, drill into a particular client transaction record and observe the related list at the base of the screen.

Client Detailed Information

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Order</td>
<td>Order during the load in which this operation occurred.</td>
</tr>
<tr>
<td>Type</td>
<td>Type of operation.</td>
</tr>
<tr>
<td>Name</td>
<td>Descriptive name of this particular operation</td>
</tr>
<tr>
<td>Duration</td>
<td>Number of ms this operation took to complete.</td>
</tr>
</tbody>
</table>
Push logs

Consult the push log to track the status of push notifications that are queued to send from your system.

To view the push log, navigate to System Logs > Push Notifications. Users are required to have the push_admin or admin role to view the push log.

Push log fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Claim</td>
<td>Identification number that is generated by the scheduled job that sends the push notification. This number is applied to the Claim field to ensure consistency across multiple push scheduled jobs.</td>
</tr>
<tr>
<td>Payload</td>
<td>Content of the push notification.</td>
</tr>
<tr>
<td>Queue count</td>
<td>Number of times that the system tried to send the push notification. The status of the push notification relates to its queue count.</td>
</tr>
<tr>
<td></td>
<td>• If the queue count is 0 for longer than expected, then there are no scheduled jobs that are trying to send the push notification.</td>
</tr>
<tr>
<td></td>
<td>• If the queue count is greater than 0 and the Type is success, then you can infer that this is how many times the system tried to send the push notification before finally sending.</td>
</tr>
<tr>
<td></td>
<td>• If the queue count reaches 10, the system stops trying to send the push notification. The Type changes to failure.</td>
</tr>
<tr>
<td>Request ID</td>
<td>Unique identification number for the push notification. Similar to the message ID for an email, the request ID is used as a correlation token for the push notification.</td>
</tr>
<tr>
<td>Type</td>
<td>Status to indicate whether the push notification has been sent. The Type column can have these values:</td>
</tr>
<tr>
<td></td>
<td>• failure: The message could not be sent.</td>
</tr>
<tr>
<td></td>
<td>• pending: The message is queued for processing.</td>
</tr>
<tr>
<td></td>
<td>• success: The message was successfully sent, although not necessarily received by the mobile device.</td>
</tr>
</tbody>
</table>

System email log and mailboxes

The system email log records all emails that the instance creates or receives. System mailboxes are filtered views of this log.

Every notification email that the instance creates or receives is recorded in an Email [sys_email] record. You can navigate to a log of these records at System Logs > Emails.

The System Mailboxes are filtered views of the Emails [sys_email] table. The instance assigns an email record to a system mailbox depending on the values of the Type and State fields. For more information, see System mailboxes.

The following fields can be included in the layout of the system log and any of the system mailboxes:
## Email log

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mailbox</td>
<td>The system mailbox that lists this email record. The instance sets the value of this field according to the values of the <strong>Type</strong> and <strong>State</strong> fields.</td>
</tr>
<tr>
<td>State</td>
<td>The current state of the email (Error, Ignored, Processed, or Ready).</td>
</tr>
<tr>
<td>Receive type</td>
<td>The type of inbound email (None, Forward, New, or Reply).</td>
</tr>
<tr>
<td>Type</td>
<td>The status of the email. Choices are:</td>
</tr>
<tr>
<td></td>
<td>• received: The server received this email.</td>
</tr>
<tr>
<td></td>
<td>• received - ignored: The server received this email, but it was ignored by the instance for inbound email action purposes. Typically, these emails are either spam or auto-replies. See the <strong>Error String</strong> field for details.</td>
</tr>
<tr>
<td></td>
<td>• send - failed: The server has attempted to send the email and failed. See the <strong>Error String</strong> field for details.</td>
</tr>
<tr>
<td></td>
<td>• send - ignored: The server skipped sending this email. Typically, this is for an email which was generated but lacked a recipient email address or is a duplicate email. See the <strong>Error String</strong> field for details.</td>
</tr>
<tr>
<td></td>
<td>• send - ready: The email is ready to be sent, but has not been sent out by the mail server. Typically, an email remains in this state for only a short time.</td>
</tr>
<tr>
<td></td>
<td>• sent: The email was sent by the instance without any errors or issues.</td>
</tr>
<tr>
<td>Target</td>
<td>A Document ID reference to the record if the email is generated by an insert, update, or delete of a particular record.</td>
</tr>
<tr>
<td>User</td>
<td>The name of the user, from the user record, of the instance from which the email notification was sent.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>This is a string field.</td>
</tr>
<tr>
<td>Notification Type</td>
<td>The type of notification. Choices are:</td>
</tr>
<tr>
<td></td>
<td>• None</td>
</tr>
<tr>
<td></td>
<td>• SMS</td>
</tr>
<tr>
<td></td>
<td>• SMTP</td>
</tr>
<tr>
<td>UID</td>
<td>The unique ID of the email stored on the server.</td>
</tr>
<tr>
<td>Created</td>
<td>The date and time of the email activity for the locale of the machine running the instance.</td>
</tr>
<tr>
<td>Deleted</td>
<td>For inbound email, indicates whether the email was deleted from the email server.</td>
</tr>
<tr>
<td>Weight</td>
<td>The weight of the email, which determines the sending priority relative to other notifications on the same table.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Importance</td>
<td>An indication that the email was sent with a changed level of importance, such as Urgent.</td>
</tr>
<tr>
<td>Originating Event and Notification</td>
<td>For emails generated by notifications, an embedded list that stores the event and notification that created the email.</td>
</tr>
<tr>
<td>Subject</td>
<td>The email subject. For notifications, you create the subject text in System Notification &gt; Email &gt; Notifications.</td>
</tr>
<tr>
<td>Error String</td>
<td>The error string captured from the email server to determine why the email was not sent. This is logged only if the email is send-failed.</td>
</tr>
<tr>
<td>Recipients</td>
<td>The email addresses of the recipients.</td>
</tr>
<tr>
<td>Body</td>
<td>The body of the email, displayed in raw HTML markup. Use the related link Preview HTML Body to see the body text as rendered HTML.</td>
</tr>
<tr>
<td>Content type</td>
<td>The email content type.</td>
</tr>
<tr>
<td>Headers</td>
<td>Any headers embedded in the email.</td>
</tr>
</tbody>
</table>

**Event logs**

The event log records all system events that occur within the Now Platform.

This log provides the following information for all events that occur:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created</td>
<td>Date and time of the event for the locale of the machine running the instance.</td>
</tr>
<tr>
<td>Name</td>
<td>Name of the event as listed in the Event Registry.</td>
</tr>
<tr>
<td>URI</td>
<td>HTTP query that generated the event.</td>
</tr>
<tr>
<td>Parm1</td>
<td>Event-specific value that depends on the event and the recipient.</td>
</tr>
<tr>
<td>Parm2</td>
<td>Event-specific value that depends on the event and the recipient.</td>
</tr>
<tr>
<td>Table</td>
<td>Database table acted on for this event.</td>
</tr>
<tr>
<td>Processed</td>
<td>Date and time the event was processed. This time reflects the locale of the machine running the instance.</td>
</tr>
<tr>
<td>Processing time</td>
<td>Time taken to process this event, in milliseconds.</td>
</tr>
<tr>
<td>Queue</td>
<td>Processor queue name.</td>
</tr>
</tbody>
</table>
Import logs

The import log displays information in a verbose format about any data import activity within the platform.

For a more detailed view of the import sets that produced a particular log, see Import Sets > Transform History.

This log provides the following information for all imports:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created</td>
<td>Date and time of the import for the locale of the machine running the instance.</td>
</tr>
<tr>
<td>Level</td>
<td>Type of message displayed. For import files, the level is Information.</td>
</tr>
<tr>
<td>Message</td>
<td>System-generated message regarding the status of the import.</td>
</tr>
<tr>
<td>Source</td>
<td>Name of the external source of the import, such as an integration.</td>
</tr>
</tbody>
</table>

System Diagnostics module

The System Diagnostics application provides logs that relate to the platform.

These logs are available:

- **Upgrade History**: tracks every upgrade to an instance.
- **Slow Queries**: provides insight into how queries affect platform performance. See Slow Query Logs.

Customer updates table

Every change that is made in the system is recorded on the Customer Updates [sys_update_xml] table chronologically.

To navigate to this table, enter `sys_update_xml.list` into the navigation filter. For information about update sets, see System update sets.

The following information is stored about each update:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A name that identifies the updated record.</td>
</tr>
<tr>
<td>Created</td>
<td>The date and time the customer update record was created.</td>
</tr>
<tr>
<td>Created By</td>
<td>The user who performed the change.</td>
</tr>
<tr>
<td>Type</td>
<td>The type of the update.</td>
</tr>
<tr>
<td>Updated</td>
<td>The date and time the customer update record was updated.</td>
</tr>
<tr>
<td>Updated By</td>
<td>The user who performed the update.</td>
</tr>
<tr>
<td>Updates</td>
<td>The number of times the record has been updated.</td>
</tr>
</tbody>
</table>
### Log history

The system uses table rotation and table extension to archive older logs.

By default, the system uses the following schedule to archive common logs:

#### Common log archive schedule

<table>
<thead>
<tr>
<th>Table</th>
<th>Archive schedule</th>
<th>Rotations</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Event [ecc_event]</td>
<td>Every day</td>
<td>7</td>
<td>Rotation</td>
</tr>
<tr>
<td>Queue [ecc_queue]</td>
<td>Every day</td>
<td>7</td>
<td>Rotation</td>
</tr>
<tr>
<td>Event [sysevent]</td>
<td>Every day</td>
<td>7</td>
<td>Rotation</td>
</tr>
<tr>
<td>Log [syslog]</td>
<td>Every week</td>
<td>8</td>
<td>Rotation</td>
</tr>
<tr>
<td>Transaction Log [syslog_transaction]</td>
<td>Every week</td>
<td>8</td>
<td>Rotation</td>
</tr>
<tr>
<td>Email [sys_email]</td>
<td>Every 30 days</td>
<td>8</td>
<td>Extension</td>
</tr>
</tbody>
</table>

#### Use the log file browser

The instance provides the utilities log file browser and log file download.

Use **System Logs > Log File Browser** to view any system log entry. You can search for log files by using the following filters:

#### Log file browser

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start time</td>
<td>Start date and time of the range you want to search, for the locale of the machine running the instance.</td>
</tr>
<tr>
<td>Session ID</td>
<td>System-generated hexadecimal string that identifies the session that generated the log entry.</td>
</tr>
<tr>
<td>End time</td>
<td>End date and time of the range you want to search, for the locale of the machine running the instance.</td>
</tr>
<tr>
<td>Message</td>
<td>System-generated description of the occurrence.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>Level</td>
<td>Type of message displayed. The levels are Debug, Error, Warning, and Information. A warning is an error that has been handled and recovered. An error is something that must be fixed.</td>
</tr>
<tr>
<td>Thread name</td>
<td>System-generated identifier of the thread that created the log file.</td>
</tr>
<tr>
<td>Max rows</td>
<td>Maximum number of records returned for a particular filter.</td>
</tr>
</tbody>
</table>

The instance creates compressed archives of system logs every two days and purges log archives after 21 days. You can download log file archives and view them with System Logs > Log File Download. Select a log archive from the list, and then click Download log under Related Links to open or save the archive.

**Note:** Log files are only available for the node you are currently logged into. To see the currently logged into node, navigate to System Diagnostics > Stats.

**Antivirus Scanning**

Use Antivirus Scanning to help protect your instance against virus infections that can be introduced by file attachments to your system records, such as incidents, problems, and stories.

**Security scan**

Antivirus Scanning scans file attachments stored in your attachment [sys_attachment] table to help protect users from uploading and downloading infected files. All the document types supported by the Platform are scanned by Antivirus Scanning.

The Antivirus Protection plugin (com.glide.snap) is activated and enabled by default on your instance. As an administrator, you can deactivate and reactivate the Antivirus Scanning feature across your instance at the switch of a toggle, set configuration options, and review antivirus activity on the instance.

**Note:**
- Antivirus Scanning is also available for customers in the Government Community Cloud (GCC) and commercial environment. Users must set the (com.glide.snap.fed_enable_scan) property to True to start using the feature.
- Edge-encrypted files are excluded from this scan.
- Any file above 100 MB file size is not scanned.
- Inbound emails are scanned for viruses by system email filters, not by Antivirus Scanning.

**Scanning scenarios**

Review these upload and download scenarios to understand how the system identifies potential security threats from files attached to your records.

**Scenario 1 - Upload a file**

1. A user unknowingly uploads an infected file to a record.
2. The system scans the file and moves it to quarantine.
3. The file appears in the Attachments window, where it is marked as unavailable.
4. The user selects the file and this error message appears: The file Infected_testing.txt did not pass the security scan. Please remove the file from record INC0000059 and try again.
5. The system sends an email notification to the user and the antivirus administrator.
6. The user closes the Attachments window and is returned to the record, where the infected file displays as unavailable.

Scenario 2 - Download a file

1. A user opens a record to download a file that is attached to it.
2. Unaware that the file is infected, the user selects it for download.
3. The system scans the file, moves it to quarantine, and displays this message.

4. The user closes the message and the screen refreshes showing that the file is unavailable.
5. The system sends an email notification to the user and the antivirus administrator.

Scenario 3 - Download a ZIP file

1. A user opens a record and downloads a ZIP file that is attached to it.
2. The system scans the ZIP files individually.
3. One file does not pass the security scan and is marked as unavailable. The remaining files are zipped and downloaded successfully.
4. The user opens the ZIP file and sees an “error.txt” file in addition to the successfully downloaded file. This file contains an error message specifying which file did not pass scanning and was therefore not included in the ZIP.

5. The user opens the record again, and sees that the unavailable file has been moved into the Potential security risks section in the Attachments window and cannot be downloaded.

![Diagram of Attachments window with Potential security risks section highlighted.]

**Configure Antivirus Scanning**

Configure Antivirus Scanning across your instance and at the table level.

Role required: antivirus_admin or admin

Antivirus Scanning is active by default in your instance, where it automatically scans attachments to identify any files that are infected by viruses. You can also deactivate it in your instance if required. Configure the feature by ensuring the scan is enabled across your instance, and by identifying any tables that you want to exclude from the scan.

1. Navigate to Antivirus > Configuration.
2. As you configure the feature, consider the following.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable Antivirus scanning</td>
<td>As antivirus scanning is active and enabled on your instance by default, its toggle is set to the on position and appears green in color. To disable the scanning across your instance, you can switch the toggle to the off position so it is no longer green.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Allow attachments to be downloaded when Antivirus scanner is unavailable</td>
<td>If this option is set to the on position, antivirus scanning is bypassed if the scanner times out and a response cannot be obtained. In this situation, the file download proceeds without completing the scan. If the option is set to off, the file download is prohibited until the scan can complete successfully.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>List of Tables Excluded</th>
<th>Any file attachments associated with a table in this list are excluded from antivirus scanning. Proceed to Step 4 if you want to define the tables the system excludes from scanning.</th>
</tr>
</thead>
</table>

3. Click **Save**.

4. Exclude tables from the Antivirus scan by adding them to the **List of Tables Excluded**.
   a) Navigate to **System Definition # Dictionary**
   b) Search for the table you want to exclude from the scan and select the table with Type set to collection.
   c) In the **Attributes** tab, click **New**.
   d) Add **Exclude_from_antivirus_scan** in the Attributes field and enter **True** in the **Value** field.
   e) Click **Submit**.

Antivirus Scanning is enabled in your instance, and the **List of Tables Excluded** on the Antivirus Configuration page is populated with all of the tables that you excluded from the scan.

**Dictionary attributes for Antivirus Scanning**

Dictionary attributes alter the behavior of the table or element that the dictionary record describes. As an administrator, you can set the values of dictionary attributes to modify the behavior of the default Antivirus Scanning configuration.

<table>
<thead>
<tr>
<th>Dictionary attributes for Antivirus Scanning</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Value</td>
</tr>
<tr>
<td>Exclude_from_antivirus_scan</td>
<td>true/false</td>
</tr>
<tr>
<td>Supress_antivirus_email_notification</td>
<td>true/false</td>
</tr>
<tr>
<td>Supress_antivirus_ui_notification</td>
<td>true/false</td>
</tr>
</tbody>
</table>

**Review quarantined files**

Review quarantined file attachments and take further action as needed.

Role required: antivirus_admin or admin
Monitor your quarantined file entries in the Antivirus Quarantine page at regular intervals to perform any of the following actions.

1. Navigate to **Antivirus > Quarantine**.
2. Select the **Actions on selected rows** check box next to each quarantined entry on which you want to perform any of these actions.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Delete</strong></td>
<td>Select this action to delete the quarantined file if it is not required any more by users.</td>
</tr>
<tr>
<td><strong>Restore</strong></td>
<td>Select this action to restore the file based on your assessment of its status or on the user request. However, scan the file with your third-party antivirus product before you restore it to mitigate any virus threats. Once restored, the file is available for download to the user.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Download</td>
<td>Select this action to download the file to your local system for further scanning and analysis, if desired.</td>
</tr>
</tbody>
</table>

The system asks for confirmation and performs the selected action per your input.

**Review antivirus activity**

Review the Antivirus Activities log that tracks all activities that occur on potentially-infected files from the point that they are discovered and placed into quarantine.

Role required: antivirus_admin or admin
This log functions as a report that captures antivirus activity, such as discovery, deletion, and other possible quarantined file events.

1. Navigate to **Antivirus > Activity**.
2. Review the log of quarantined files.

You can view the actions performed (highlighted in red) on each quarantined file.

Determine which records you want to delete, restore, download, or keep in the log. See **Review quarantined files**.
Virtual Private Network (VPN)

Use a virtual private network (VPN) to integrate your instance with external data sources over the Internet.

When configuring an integration that uses an encrypted protocol, such as Lightweight Directory Access Protocol (LDAP) or HTTPS, it is good practice to use the Internet as a transport mechanism.

However, there may be security or network architecture requirements that dictate the use of a site-to-site Internet Protocol Security (IPSEC) Virtual Private Network (VPN) connection between the datacenters and your business networks. The VPN supports the necessary encrypted communication between the instance and your network.

This video describes how to locate the IP addresses for each of your company's instances.

VPN connections

The ServiceNow VPN infrastructure uses pairs of Cisco adaptive security appliance (ASA) devices that serve as VPN termination points.

The VPN between the instance and your network utilizes your existing networking hardware to support communications. It is not necessary to install a piece of hardware. Because each customer has a unique configuration, the instance has a flexible VPN solution. The instance has built tunnels to Checkpoint, Juniper, Nortel, and other IPSEC VPN-capable devices.

The VPN connections between the instance and your network are created to support the encrypted flow of traffic into your network. Frequently, integrations that use the VPN do not have encryption as part of the underlying protocol. For example, LDAP over the VPN versus LDAPS over the Internet and HTTP over the VPN versus HTTPS over the Internet.

The network does not allow any inbound-to-ServiceNow integration or end-user-to-ServiceNow traffic to traverse a VPN connection. This restricted communication includes end-user access to the platform, administration of the platform, web services integrations, and other integrations that are configured to use a MID Server. All such inbound communication to the instance must be performed over the Internet using HTTPS. This configuration provides an encrypted communication channel. The encryption channel, along with IP access control, meets the security requirements for this traffic flow.

Addresses for VPN communication

To prevent conflict or overlap with internal ServiceNow networks or with another internal IP address schemes in your network, all tunneled traffic in the encryption domain must use non-RFC-1918 addresses on both sides of the tunnel.

ServiceNow provides a single IP address for the source of queries into your network. You must provide Network Address Translation (NAT), non-RFC-1918 addresses for each host that is integrating with your instance. These public addresses need to be owned by your organization. Third-party addresses cannot be used inside tunnels. Additionally, the encryption domain must not contain the IP address of the VPN peer.
Redundant tunnels

There are two ways to build redundancy for your tunnels:

- Using the same encryption domain behind both of your peers. This is the preferred method.
- Using a different encryption domain behind each peer.

With the first method, you need to provide the same NAT address behind each of your peers to create a connection path using that address to your server. The path to your server could be the same physical machine or a mirror which provides identical services. With this method, your instance would use the same IP address to connect to your servers regardless of whether your primary or secondary tunnel is active. If you have more than one server, follow this same scheme for your additional servers. This method provides the most transparency to your users and is recommended.

The second method requires configuration in your instance to provide the redundancy. When the tunnel is used for LDAP, for example, you could provide redundant LDAP servers in your instance. Note that this method requires the connection to the first configured LDAP server to timeout before the instance attempts to connect to the secondary server. Because of this additional time delay, this solution should only be implemented if the first option is unattainable. Also note that not all services can be configured for redundantly in your instance. If you are using a VPN tunnel for something other than LDAP and redundancy is required, check that your configuration can support multiple addresses, or see the first option above.

Alternatives to using a VPN

These alternatives provide a simpler way to connect your instance to the resources in the ServiceNow data centers and provide better encryption. Additionally, you can avoid any issues that VPN downtime might cause, such as making your instance unavailable to users if there is an issue with the VPN tunnel.

Single sign-on and MID server

Consider using a combination of Single Sign-On (SSO) for authentication and the MID Server for user data synchronization, rather than using a VPN to connect your LDAP server to your instance. For integrations other than LDAP, consider using certificate-based encryption.

You can use the LDAP listener on a MID server to synchronize your user table in near real time. The advantage of this approach is that there are no firewall holes, routes, VPN tunnels, or other special network settings to configure and maintain. The SSO/MID-Server solution is the most flexible, secure, and cost-effective method to achieve the complete LDAP integration.

LDAP over SSL

Another alternative to using a VPN tunnel is to configure LDAP Over SSL (LDAPS) directly over the Internet. You can configure a read-only domain controller and lock the instance down in your DMZ using only the instance's source addresses and the destination ports of your choice. Since the ports for LDAP are configurable in your instance, you can perform a port address translation (PAT) if desired. With LDAPS, you control the certificate that is uploaded over an encrypted channel to the instance, (see Upload a certificate to an instance). The packets cannot be encrypted or decrypted without the certificate.

The advantage of this approach is that it provides a stronger encryption and decryption mechanism. A VPN can only encrypt and decrypt the traffic between the two peers sitting on the Internet with a coordinated pre-shared key, similar to a password. LDAPS provides a longer encrypted path, end-to-end, at the application layer and with a certificate that is far more complicated than a pre-shared key that the IPSec tunnel uses.
VPN setup

From the time that a VPN request is submitted, it typically takes one week or less to complete the VPN build. To support the redundancy requirements of your instance and your organization, a minimum of two and a maximum of four VPNs are provisioned (from the active site to your active site or the active site to your DR site, and so on).

It is good practice for the encryption domain to be as specific as possible. Ideally, the encryption domain would include only the specific hosts that are required for the integrations. A large encryption domain can create opportunities for routing discrepancies (VPN versus Internet).

To create the VPN, the instance does the following:

1. Provides the VPN peer and host addresses from each data center.
2. Builds the necessary VPN connectivity from two data centers into your network. To support redundancy and disaster recovery (DR) requirements, the VPNs can be provisioned from two data centers into two networks.

The instance does not support building multiple VPN tunnels into a customer network for the purpose of connecting to multiple geographic regions or subsidiaries. You should perform any inter-site routing, traffic distribution, or traffic shaping within your own internal network, rather than having multiple VPN tunnels.

Request a VPN service

For all VPN requests, including provisioning, modifications, or general questions, use the Service Catalog VPN Request form.

1. Open HI.
2. Navigate to Self-Service > Service Requests > VPN Requests.
3. Select the appropriate VPN request type.
4. Answer the questions. Questions vary depending on the request type selected.
5. Click Submit.

Once your request is submitted, ServiceNow will work with your network engineer(s) to test and validate that the VPN is successfully passing traffic. To ensure that your questions are answered in a timely manner, please address VPN-related questions during this process.

Create an address for VPN communication

To prevent conflict or overlap with internal ServiceNow networks or with another customer's internal IP address schemes, the instance requires that all tunneled traffic in the encryption domain use non-RFC-1918 addresses on both sides of the tunnel.

The instance provides a single IP address for the source of queries into your network.

- Provide Network Address Translation (NAT), non-RFC-1918 addresses for each host that is integrating with the instance.

Domain separation for service providers

With the ServiceNow Platform, service providers (SPs) can provide their customers with faster onboarding, meet compliance, and protect their data using domain separation. Separate client data, processes, and reports into logical groupings called domains. SPs control who sees and accesses what content.

Watch this short video for an overview of domain separation.

What's new in Quebec for service providers

See what's new in the Quebec release with domain separation for service providers.

New in Quebec

Domain Separated Tables
See at a glance which tables are domain-separated in your instance.

Domain Override Viewer
See and manage all your process overrides at once across the entire instance.

IntegrationHub Remote Process Sync
When integrations require the transform and mapping of data across different tables between two instances, ServiceNow remote system administrators can now use generic record management actions to integrate any two tables. See also the IntegrationHub Release Notes.

Subscription Management Domain Specific Reporting
System administrators with a new dashboard can enable program and account management with greater detail on license and subscription unit consumption, making cost recovery easier.

ITOM: Global MID-Server for Cloud Provisioning and Governance (CPG)
Service providers can provision a single MID-server to handle certain cloud actions in CPG without having to managing multiple, discrete MID-servers. See also the ITOM Optimization release notes.

Platform User Interface (UI) Builder
With the UI Builder with domain separation, support system administrators and delegated developers can build modern user interfaces and actions in a visual design studio without costly customizations. See also the UI Builder release notes.

Quebec release notes
ServiceNow domain separation product enhancements and updates in the Quebec release

Understanding domain separation
With domain separation you can separate data, processes, and administrative tasks into logically defined domains.

Domain separation is best for those customers who:

- Need to enforce absolute data segregation between business entities (data separation).
- Customize business process definitions and user interfaces for each domain (delegated administration).
- Maintain some global processes and global reporting in a single instance.
- Separate data between service providers, customers, partners, or sub-organizations.
- Have minor or moderate process differences among customers.
Domain separation compared to separate instances

While domain separation provides multi-tenancy support, multi-tenancy is still contained within a single instance. Some global properties, data, and processes are shared across all domains. For example, having the system Remember me on the login page of the system is global and cannot be specified per domain.

If you need complete and total separation of all system properties and do not require global reporting or global processes, then separate instances are the best option.

Data separation

Members of a domain see only the data contained within their domain or the child domains that are lower in the domain hierarchy. By default, all users and all records are members of the global domain unless an administrator assigns them to a particular domain. Once you assign a user or a record to a domain, the instance compares the user's domain to the record's domain to determine whether the user can view the record.

ServiceNow applications are defined with the following incremental support levels. These levels are based on the perspective of actual use cases and personas.

**Data Separation:** Tenants see only data that they have permissions to see. Tenants can be granted access to other tenant data, but cannot query tenant data if they don't have access.

**UI Separation:** Supports a tenant-specific experience for UI elements such as views, lists, labels, and so on.

**Business Logic Separation:** You can create tenant-specific system policies such as email notifications, business rules, client scripts, UI policy, and UI actions.

**Hierarchical Modeling:** Nested-multi-tenancy so parent tenants can access child tenant resources. Business logic for parent tenants runs automatically for child tenants, and can be overridden at any level.

**Cross-Tenant Intelligence (Domain Scope):** Handles automatically the data, metadata, business logic, and processing context for tenants that have access to additional tenant data.

In general, data defined at a higher level in the domain hierarchy is not visible at lower levels in the hierarchy.
Domain path migration

Domain paths are used for all customers. Domain numbering is not used. Customer Service and Support can assist in the upgrade.

Alternatives to domain separation

Separate instances are a common alternative to domain separation. This provides a great degree of flexibility in meeting the requirements for customers and stakeholders with little to no impact on others.
Warning: Before activating domain separation, consult your representative to verify that it is suitable for your environment. Domain separation adds a level of administration overhead. Although it can be disabled, it cannot be removed from an instance.

Domain assignment

By default, domain separation adds a domain field to tables and their extensions.

You can also extend domain separation to any new tables you create by adding a `sys_domain` field to the table's dictionary definition. By default, the system only domain-separates platform and baseline application tables where appropriate.

Warning: ServiceNow does not recommend domain-separating platform tables (any table with the `sys_` prefix such as the Dictionary Entry [sys_dictionary] and Dictionary Entry Override [sys_dictionary_override] tables) because it can produce unexpected results.

Each record is assigned a single domain. That domain is stored in the `sys_domain` field. Several tables, by default, have the `sys_domain` column and are already domain separated.

The value of the `sys_domain` field contains the domain assigned to the record by any of the following:

- Company to which the user belongs
• Business rule when creating record
• Module used when creating record
• Form template used when creating record
• Domain of the parent record
• Domain assigned to User record
• Domain of the user who creates it

The system prevents the following tables from being domain separated:

• Access Control [sys_security_acl]
• Script Include [sys_script_include]
• System Property [sys_properties]
• Security Exclusion/Inclusion List Entities [sys_security_restricted_list]
• Dictionary Entry [sys_dictionary]
• Dictionary Entry Override [sys_dictionary_override]

Assigning users to companies

Administrators can quickly assign users to a domain by assigning them to a company. After users are assigned to a domain, records automatically inherit the user's domain.

For example, assigning Bow Ruggeri to the ACME company automatically assigns him to the ACME domain. Assigning Don Goodliffe to the Initech company automatically assigns him to the Initech domain. Any records they create are automatically added to the appropriate domain.

Adding a user to a domain by setting the company

Using business rules to assign domains

Administrators can use a business rule to automatically set a domain value when creating a record. The business rule must set a value in the sys_domain field. Administrators must ensure there is a sys_domain column available for the record’s table. To learn more see Domain separation recommended practices for service providers.
Using modules to assign domains

Administrators can use the **sysparm_domain** URL parameter to automatically assign new records to a particular domain from a module. Administrators must create a module with an **Argument** value of: `sysparm_domain=sys_ID of domain`.

Using form templates to assign domains

Administrators can use a form template to automatically assign new records to a particular domain. Administrators must add the **sys_domain** field to the form and select a domain value. For example, setting the **sys_domain** field to **TOP/ACME domain** automatically assigns all records from this template to the TOP/ACME domain.

Domain inheritance on tables

By default, related records inherit the domain of the parent record. For example:

- A change task record inherits the domain of the parent change request record.
- A problem record inherits the domain of the parent incident record.

Automatic domain assignment based on user domains

If no other domain conditions apply, a record automatically inherits the domain of the user who creates it.

Visibility domains and Contains domains

Visibility domains control what a specific user can see, while "contains" domains control what an entire domain of users can see.

Visibility domains

The "Visibility domains" element is in a related list on the user record that determines whether users from one domain can access records from another domain. Granting users a visibility domain grants all the rights they would normally have to the record based on ACL (access control list) rule permissions.

A visibility domain:

- Is a user-to-domain relationship and is explicitly granted.
- Is not a child domain.
- Is not controlled by the selection in the domain picker. Once users are granted access to a visibility domain, they always see data in that domain and its child domains.

> **Note:** Using visibility domains excessively is not recommended. Although visibility is one method to allow users to access records, it's best to use contains domains for more robust control.

Contains domains

Normally parent-child relationships define the domain hierarchy. A contains domain lets you relate domains on an as-needed basis, independent of parent-child relationships. However, contains domains grant visibility only to domain data. Processes remain unaffected by contains relationships.
A contains domain:

- Is a many-to-many, domain-to-domain relationship.
- May have child domains. When a domain is selected, you can see the data from that domain and its children.
- Is controlled by the selection in the domain picker.

**Note:** When you open the domain record, the scope is set to that record's domain, so you can see only child domains. Choose **Toggle Domain Scope** from the menu to populate the related list.

Contains domain example

When a user's home domain is A, and the A domain contains domains B and C, they all become peer domains. That means the user sees data from domains A, B, and C while in their home domain A. If users change domains with the domain picker to Domain B, they see only data in Domain B. When users interact with a record from Domain B or Domain C directly, they see only data for that domain.

Visibility domain example

Using domain visibility, if Don Goodliffe is in the Database domain, and Bow Ruggeri is in the Network domain, and no incidents are in the global domain, then Don cannot access Bow’s incidents because of data separation.
Inheriting visibility domains based on group membership

If you set the domain table to the Group [sys_user_group] table, users can inherit visibility domains based on their group membership.

Domain scope

Domain scope defines what users can and cannot access.

Every user has two domain scopes when establishing a session in a domain-separated instance.

- **Session scope** is set upon session establishment to the domain listed in the user's user record. Users can manually change their session domain scope from the domain picker.
- **Record scope** uses the domain of the record and is active when viewing the form of any record.

By default, the record scope takes precedence over the session scope so that users in higher level domains adhere to each record's data and process constraints. However, these users can choose to expand or collapse the domain scope to show or hide data from other domains. For example, a user in the Service Provider (SP) domain also has visibility into child domains such as the ACME domain. When looking at an incident record from the ACME domain, the user can choose to expand the domain scope to show values from the SP domain or collapse the domain scope to show only record values that match the record's ACME domain.

**Note:** Users always have access to data from domains that have been explicitly granted to them by domain visibility.

Users with the domain_expand_scope user role can select the domain scope from the **Toggle Domain Scope** UI action on the form. When record scope is in effect, click the UI action to expand to session scope and display all data available based to the user's domain and child domains. When session scope is in effect, click the UI action to collapse to record scope and display only data that matches the current record's domain.

**Note:** A record does not display the UI action to toggle the domain scope if the record is in the global domain or if the user's domain matches the record's domain.

Record value selection from other domains

Users who can see multiple domains have the option to select record values from a domain that is different than the record's domain.

For example, service desk agents working for a service provider might want to assign certain incidents to themselves to resolve issues on behalf of their customers. When they do this, the incident **Assigned to** field might contain a user from the SP domain, even though the incident record itself is associated with a child domain such as ACME.

Selecting a record value from another domain does not change the record's domain. The record retains its original domain. When a user views a record with values from multiple domains, the user's domain visibility determines what they see.
Record value selection

<table>
<thead>
<tr>
<th>When these conditions are met</th>
<th>The user has access to these UI elements</th>
</tr>
</thead>
</table>
| The user has access to the domain of the current record referenced in a field. | The user can:  
  - See reference field display value. For example, sees the user name in the **Assigned to** field.  
  - See the related record from reference icon. For example, sees the user record for the user in the **Assigned to** field.  
  - Select values from any visible domain. For example, can select users from either the SP and ACME domains. |
| The user does not have access to the domain of the current record referenced in a field. | The user can:  
  - Not see reference field display values. (This is the case if domain separation was activated in Madrid or later releases and the user doesn't have access to the domain of that record.)  
  - Only select values from the record's domain. For example, can only select users from the ACME domain. |

Domains and associated companies

With domain separation you can cascade changes you make to a company record to the domain and other records associated to the company.

By default, the system automatically assigns users to the same domain as their company. For example, all users of the ACME company automatically become members of the TOP/ACME domain.

**Note:** Users with the admin role can change their own user records and therefore change domains. Service Providers may want to either disable delegated administration or set up an approval process to verify that the user needs the admin role.

When you change a company's domain, the instance automatically changes the domain of the following associated records to match the company's new domain.

- Locations
- Departments
- Groups
- Users

**Note:** The instance does not automatically change the domain of any record where you have selected the Managed domain checkbox.

Domain deactivation and associated companies

When you deactivate a domain, the instance also automatically completes the following actions.

- Deactivates all companies in the domain.
• Prevents all users assigned to the inactive company from logging in.

**Note:** When a user from an inactive company attempts to log in, the user sees an error message.

For example, if you deactivate the ACME domain from the sample data, the instance also deactivates the ACME company, and the three sample users are locked out.

![Login error message example](image)

**Concepts for service providers**

These concepts work with the existing ServiceNow platform capabilities to help you solve for common use cases.

**Global queue**

The global queue concept provides a single virtual view of tasks that reside in multiple instances. The concept creates a custom application using remote tables to provide a fulfiller view of work that resides in multiple instances without having to replicate tasks or data. The concept can also be used to create a single view of an employee's requests in multi-instance environments.
Overview

Service Providers with agents working on tasks from multiple systems tend to integrate the data back to a central instance, or a “swivel chair” between instances. While this method might be appropriate in some cases, it can be expensive and time-consuming to build and maintain. This method also opens the provider up to potential auditing and data requirement considerations such as General Data Protection Regulation (GDPR) in all of the instances where the data now lives.

Global queue is an alternative: With this method, agents can see data assigned to them from a single instance without sovereign data persisting on the instance they are logged into. For example, in cases where clients have data residency requirements, but allow access by agents from other countries, the provider could use a “follow-the-sun” Help Desk using global queue.

Learn more about the Global Queue v.2 Proof of Concept on the ServiceNow Knowledge site.

Note: In the Quebec release forward, the Global Queue Proof of Concept has been upgraded to Global Queue v. 2.

Service provider connector
The service provider connector application is a reference design for creating a ServiceNow Store application for your customers to use to integrate with your systems. Service provider applications help you speed on-boarding and create standardized integrations.
Benefits of service connectors

When service providers (vendors, suppliers, partners) publish connectors, customer on-boarding is faster, which means faster billing. Integrated instances increase productivity, greater visibility in the ServiceNow ecosystem, and partner program benefits. Specific benefits are:

- Eliminates custom integrations, including the cost of services required to deliver and maintain them.
- Services are provider-defined within their ServiceNow instances and remove the need for the complexity and cost of custom integrations.
- Workflows and catalog requests can be synchronized, with the customer’s processes and approvals preceding the provider’s processes, so customers can follow their own processes.
- Any data created or modified (e.g. CIs) for the customer on the provider’s instance can be synchronized back into the customer’s instance for their visibility and use in processes.

Key features

User Interface

A service connector should include the following UI components at a minimum:

- Reports/Dashboards – Reports and dashboards pre-defined by persona help with visibility.
- Menu and modules – The customer should be able to find the application via descriptive Menu **Provider XYZ Services**.
- Roles – Every connector requires user and admin roles to ensure access can be controlled by the customer. For example, “x_snc_xyz_user” or “x_snc_xyz_admin”.
- On-boarding – Rapid on-boarding is essential to a good customer experience and should be included via playbook, guided setup, or catalog item in such a way that no professional services are required for the customer to go live. (Professional services are available, but on-boarding can be achieved without it).
- Configuration – Data points should be built into processes to account for most of the normal process configuration a customer needs to achieve. This eliminates professional services as much as possible.
- Documentation – Thorough documentation increases customer satisfaction and ease of use.
- Support integration or contact info – The customer needs an easy way to stay in contact with the service provider for any issues, questions, or requests.

Tasks

- The **eBonding** of tasks such as incidents, case, changes, problems, and so on, should be predefined in the connector. These integrations are built using Flow Designer and IntegrationHub to ensure the highest level of resiliency and performance.
CMDB

- Core data synchronize such as the CIs required for proper ITIL processes should be kept in sync between provider and customer instances.

Workflows

- All workflows should be designed in Flow Designer to ensure resiliency and performance.

Catalogs

- The provider’s catalog that the customer requests from should be included in the application as a record-producing catalog. The request generated by the item in the customer’s instance should be eBonded with the provider’s instances. The provider’s workflows keep the request updated and synchronize back to the customer’s instance.

Customer Processes

- Any mechanisms for syncing requests with the provider’s instance should allow for customer processes to interact with the requests before they are sent to the provider’s instance. During provider processing, approvals can be sent to the customer’s instance as needed.

Integration

- Integrations should be built using Flow Designer and IntegrationHub to ensure the highest level of resiliency and performance.

Possible components you can include in a Service Connector

Instance data replication (IDR): when replication is the goal

- Can be used for process integration, but can be too rigid depending on the complexity integration logic based on state transition
- To learn more, see Instance Data Replication

IntegrationHub: When process integration is the goal

- Easier to inject in the middle of a process, as part of complex or conditional step in the middle of a flow
- To learn more, see IntegrationHub

Global Work Queue (Virtual): when task federation is the goal, and storing data externally is not acceptable

- Used where agents are working across multiple ServiceNow instances and need to see all open work assigned to them
- Rows returned should be limited to less than 1000
- To learn more, see Global work queue

Remote Tables: when external data usage without storage is the goal

- Used to connect an instance to third-party sources, or to another instance, to retrieve external data and optionally cache it in the memory. The data is treated as a table in the instance for read-only purposes such as group, sort, aggregate, and filter.
- To learn more, see Retrieving external data using remote tables and scripts

Flow Designer: when process design is the goal

- Used for automating processes in a single design environment. Process owners can use natural language to automate approvals, tasks, notifications, and record operations without coding.
• To learn more, see Flow Designer

Learn more about the Service Connector proof of concept on the ServiceNow Knowledge site.

Installed with domain separation

Several platform components are added or modified with domain separation.

Roles

**Application support for domain separation**

Many ServiceNow applications support domain separation in the base system but not all. Some supported applications include limitations on the data and administrative settings that can be domain-separated. These definitions delineate the domain separation support levels from the perspective of actual use cases and the people who use them.

**Domain separation support levels**

ServiceNow applications that support domain separation may support the separation of data and data routing only, have advanced business logic separation, or support tenant (customer) level administration of the application. ServiceNow applications are defined with the following incremental support levels.
<table>
<thead>
<tr>
<th>Basic</th>
<th>Standard</th>
<th>Enhanced</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Data is domain-separated</td>
<td>• Application properties are domain-aware as needed</td>
<td>• Data-driven process enables failsafe configuration by tenants through the UI to drive business logic</td>
</tr>
<tr>
<td>• Logic exists to ensure proper data routing, caching, rollups, and aggregations</td>
<td>• Business logic can be domain-separated by the instance owner per tenant</td>
<td></td>
</tr>
<tr>
<td>• Global configuration operational for multiple tenants</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

No support

• The domain field may exist on data tables, but no logic exists to manage data.
• This level is not considered domain-separated.

Basic

• Business logic: Ensure data goes into the proper domain for the application’s service provider (SP) use cases.
• In the application, the user interface, cache keys, reporting, rollups, aggregations, and so on, all use domain at production run time.
• The owner of the instance needs to be able to set up the application to function across multiple tenants.

Use case: When an SP uses chat to respond to a tenant-customer’s message, the client must be able to see the SP’s response.

Standard

• Includes Basic level support.
• Business logic: Processes can be created or modified per customer by the service provider (SP). The use cases reflect proper use of the application by multiple SP customers in a single instance.
• The owner of the instance needs to be able to configure the minimum viable product (MVP) business logic and data parameters per tenant as expected for the specific application.

Use case: An admin needs to be able to make comments mandatory when a record closes for one tenant but not for another.

Enhanced

• Includes Basic and Standard levels
• Data-driven process enables service provider customers to modify business logic that is based on defined use cases. These configurations are UI-based and fail-safe so that configurations by one customer cannot affect another.
• Tenants of the instance need to be able to configure minimum viable product (MVP) business logic and data parameters for themselves. This logic and parameters would be expected for the application's normal function.

Use case: Tenant-customers of a shared environment need to be able to make changes to the impact, urgency, or priority matrix to set priority within their domain.

Note: Effective Domain (*)

• In some cases, a platform feature or application may effectively support SP use cases even without the domain framework. If so, the use cases must detail its support of domain separation. An asterisk (*) after the support level indicates this kind of configuration.

Domain separation recommended practices for service providers

You can create, implement, and maintain domain separation for your applications and services.

Domain basics

With domain separation (also known as ServiceNow Multitenant Platform Architecture), you can segregate the application data, user interface, and business logic in a single customer instance that supports hierarchical modeling with cross-tenant intelligence. Business logic describes how the domain separation is configured and what rules are affecting the configuration.

Before you set off on the domain separation journey, here are some good practices to follow. Select topics as you want or follow them in order by clicking the links below the image.
Domain separation explained

With domain separation, you can segregate application data, UI, and business logic, such as rules or workflows, in a single customer instance. Separating these elements into logically defined domains supports specific hierarchies for all customers using your applications.

Domain basics

Domain separation, also known as ServiceNow multitenant platform architecture, adds considerable overhead to the management of an instance. If you use domain separation correctly though, it can improve efficiency, add greater security, and increase the performance of your customers' instances.

You can't separate some global standards and properties, such as system properties and table schema, per tenant.

Before you start separating domains, read the following guidelines.

What you can do with domain separation

- Data separation: Enables tenants of the domain to see only data that they have permissions to see. Tenants can be granted access to other tenant data but can't query tenant data that they don't have access to.
  - When you update data records, they do not generate Update Set records.
  - Users, including the customer accounts that are used for integrations, see only the data in the domains they have permission to access.
  - Customers, agents, and fulfillers see data that pertains to the customers and organizations that they support.
- UI separation: Supports a tenant-specific experience for UI elements such as views, lists, labels, and so on.
  - You can override the browser-based user interface, including application menus, lists, forms, homepages, and dashboards. You can also customize them for a specific domain or set of domains while preserving your basic process logic.
  - Service providers can alter the displayed branding and UI elements to meet individual customer needs.
- Business logic separation: Creates tenant-specific system policies such as email notifications, business rules, client scripts, UI policy, and UI actions.
- Hierarchical modeling: Nests your multiple tenants so that parent tenants can access child tenant resources.
  - Business logic for parent tenants runs automatically for child tenants, which you can override at any level.
- Cross-tenant intelligence: Automatically handles data, metadata, business logic, and processing context for tenants with access to additional tenant data.

Domain separation at a glance

The following graphic shows the division of data, process, and UI separation. These concepts are discussed in depth in the Recommended Practices section.
Domain Separation

Ability to establish sub-tenants (logically defined domains) within a single ServiceNow instance

Data Separation

Process Separation

UI Separation

Global Standards, Centralized Administration, and Reporting

Domain architecture

User records are assigned a domain value that represents the user’s home domain. Users have no access to data in parent domains, peer domains, or domains in other branches of the hierarchy.

See Contains queries and domain access for advanced options to grant additional domain visibility.

The following diagram shows how the architecture process flows down to the child domains.
Domain separation value proposition
With domain separation, service providers can have a multitenant instance architecture that delivers offerings efficiently and securely to their clients. Strong universal process standards, data-driven process design, strict governance, and centralized administration help to maximize these benefits.
**Benefits of domain separation**

The tenants of a domain benefit from a quick return on investment, lower administrative overhead, and leverage of business services provided by instance owners.

Here is a quick view of these benefits.

</tbody>
</table>

**Definition of domain separation**

With domain separation (also known as the ServiceNow® Multitenant Platform Architecture), you can segregate application data, UI, and business logic in a single customer instance that supports hierarchical modeling with cross-tenant (customer) intelligence.

**Properties of domain separation**

Domain-separated ServiceNow applications are defined with the following properties:

**Data separation**

Enables customers to see only the data that they have permissions to see. Customers can be granted access to other customer data but cannot query customer data if they don't have access.

**UI separation**

Supports a customer-specific experience for UI elements such as views, lists, labels, and so on.

**Business logic separation**

Supports customer-specific system policies such as email notifications, business rules, client scripts, UI policy, and UI actions.

**Hierarchical modeling**

Supports nested-multitenancy so parent tenants (customers) can access child customer resources. The business logic for parent customers runs automatically for child customers and can be overridden at any level.

**Cross-customer intelligence (domain scope)**

Handles automatically the data, metadata, business logic, and processing context for tenants that have access to additional tenant data.
How domain separation works
A common analogy for understanding how domain separation works is by looking at a comparison of a single-family home (single-tenant) versus an apartment complex (domain-separated).

**Single-family home vs. apartment complex**

With a house, you pay more but you get more control. You can knock down walls, paint, add a room or pool, and so on.

With an apartment complex, someone else decides all of those things for you. Sometimes, you can't even paint the walls that you live within.

**Single versus multiple tenants**

**Single-tenant instance**

You're a ServiceNow customer, you bought the licenses, and it's up to you to decide what services you want. You can upgrade when you want, see previews of all the great new features, and configure your instance right away. Being a single tenant has these benefits and restrictions:

- You have higher upfront costs and administrative overhead, but you have more freedom to remodel and expand.
- You have higher costs to obtain and maintain the instance and supply administration staff. Although you are free to build out the environment as required, you must comply with the ServiceNow recommended practices and standards.

**Multiple-tenant instance**

Someone else owns the instance, possibly a service provider with multiple customers. They upgrade when they want and put new services on the instance when they want. If you are a customer of a service provider, you are most likely on their instance because you wanted what they offer. Multiple tenants have these benefits and restrictions:

- A centralized staff administers configurations, integrations, and upgrades.
- The instance owner provides added services.
- Domain tenants have lower upfront costs to use the ServiceNow platform, have lower monthly costs because they are sharing it with many tenants, and do not have to employ a staff to administer the environment.
- Benefits shared from requests or changes that are initiated by other tenants.

**Analogy summary**

<table>

</tbody>
</table>
Domain separation hierarchies

Create a hierarchy when defining a domain architecture to track your processes and workflows.

Sample domain separation hierarchies

The following diagram suggests a good starting point for defining domain architecture. It demonstrates the relationship between the TOP and lower domains and how the process, data, and business rules impact parent and child domains.

- In the following example, TOP is a process domain. It should never contain users. TOP should contain the new processes that instance owners develop and the overrides to these processes from the global domain.
- Only the service provider (SP) has access to the default domain. This domain never contains active users. It contains only the lost data that you need to reassign to the correct domain.

**Note:** When data is not assigned to a specific domain, it goes to the default domain. It is temporarily "lost" and needs to be assigned to its correct domain.

- Tasks and users without a domain are placed in the default domain automatically when you create or update domains. You can override this behavior by either clearing the Default option on this record or selecting the Default option on another domain record. If you have not set a default domain yet, tasks and users with no domain are placed in the global domain.
- Don't move data between domains when you are using the instance.
- If any data ends up in the default domain, that means you have a configuration or procedural problem to address.

- You don't see the word "Global" in this diagram because there is no global domain; "Global" is the absence of a domain on a record.
- For example, a table that has no domain field means that the table contains all global records. A table that has a domain field means that any record without a domain is a global domain.
- The word "Global" is in the domain field. It is placed there automatically when the record has no domain.
- Global records are available to all users of the instance unless they are restricted by security configurations.
- Use the default domain to make sure that records do not end up in the global domain on tables that should never have global records.
- Instance owners must then triage the records in the default domain and move them to the correct domain.
Domain hierarchies

- Parent/child – Process and data affected
  - Design that is based on a process flow. Remember that the parent domains can access all data in the child domains.
• "Contains" domain – Only data is affected. For example, making SP in the diagram contain TOP does not make processes in SP run in the TOP domain and downward.
  • Grants data access rights to individuals in groups that require dedicated access to certain domains.
  • Contains causes or conditions to be added to DB queries that can cause performance issues with large domain and data sets.

• Visibility – Hierarchy that is always visible to users once you provide access. Only the data is affected, not the processes.
  • Grants data access of a domain to another domain that did not have that access when the parent and child hierarchy was built.
  • Enables users to see all the data in the domains that they are granted visibility to, all the time, regardless of the record they are working on.

**Note:** Use sparingly, as it can allow complete access that you may not intend.

Many SPs have customers who implicitly state that access to their domains must be tightly regulated, which constrains the use of “Contains” at the TOP domain. The following diagram explains how to mitigate that regulation by dividing domains into Restricted and Unrestricted domains.
Unrestricted and restricted use cases for domain separation

Here is how to handle such cases:

- Under TOP, create two domains, Unrestricted and Restricted.
  - For customers who do not have SP visibility restraints, place those customers and their domains under Unrestricted.
  - For customers who do have that requirement, place them and their domains under Restricted.
- System admins can then use “Contains” and “Visibility” functions in an efficient, targeted manner.
  - Apply "Contains" to Unrestricted, so a single “Contains” can grant visibility to most customers.
  - Apply domain visibility using ”domain visibility groups” to specific domains as needed.

Tasks and users without a domain are placed in this domain when created or updated. You can override this behavior by:

1. Clearing the Default option on this record.
2. Selecting the Default option on another domain record.

If no domain is set as default, tasks and users that have no domain are placed in the Global domain.
The following diagram delineates how to choose which hierarchy model is right for you. You can choose separate hierarchies, hybrid, or shared hierarchies depending on which processes and functionality you want in your domain structures.

Customer Decision Trees

Partner Sales uses tree to determine if a new customer should directly interact with managed instance or dedicated instance.

Customer installs the service providers CONNECTOR directly off the Store which allows customer to connect to the service providers managed instance for consumption of service(s).

Customer wants NOW for reasons other than the providers services.

See Dedicated vs. Shared tree for detail on this step.

Provider sells NOW licenses, sells/outsources professional services, and deploys CONNECTOR on the customer’s instance.

Provider sells fully managed service delivered in domain-separated instance. Customer doesn’t want ServiceNow platform, but does want its user experience for service(s) purchased.
Context and domain separation

The context of a user's session determines the processes, data, and user interface (UI) as the user browses through list views, home pages, reports, and knowledge articles. The context is determined by the processes that you create, the business rules that you set, your workflows, and other factors.

User session context

Many factors determine the context of a user session, such as user profiles, groups, company criteria, and so on. In the following diagram, you see that the incidents that a company has created are part of the context.

The user in this example has a home domain of Cloud Dimensions.

1. The branding reflects the settings in the Cloud Dimensions domain and company record.
2. The application navigator shows the items that are inherited from higher-level domains as well as the modules that are defined in the Cloud Dimensions domain.
3. The home pages and list data reflect the data that is visible to the user. This data is based on the user’s session context. In this case, the user in the Cloud Dimensions domain can see the data in Cloud Dimensions, child domains, and the global domain.

**User session context starts in the home domain**

In the following diagram, you can see the elements of the context.

![Diagram showing user session context](image)

The system administrator sets users' home domains on their user records. Typically, a user’s home domain is set to the same domain as their company’s domain. When the user logs in, the domain picker sets automatically to the user’s home domain. Users can return to their home domain at any time by clicking the arrow icon on the domain picker.

The domain picker's list includes domains within the user’s session context. Users may further limit their session context by selecting child domains with the picker.

The context of the user session includes the user’s home domain and any child domains. This set of domains in the user’s session context is appended automatically to every query that is sent to the database. That way, the results are limited to just the data in these domains and global data. This process is embedded in the compiled code that is not accessible.

Service accounts that are used for integrations also have user session context. There is user context and records context, each with its own data in its own domain. These contexts affect the integrations. Database queries (records) are limited in the same way as interactive users (users), meaning that they work as normal but are limited by whatever constraints the developer has configured.

You can learn about additional ways to add domains to a user’s session context in Service provider reference architecture.
Record context

As a user drills into individual records, record context is activated. The record context determines the UI elements and processes to apply to the record.

A record’s domain dictates the process, data, and the availability of UI elements within the record.

Note:

• Record context persists even if the user's domain changes.
• Users can view records concurrently in multiple browser tabs, while maintaining their own record context.
Segregating and securing data with domain separation

You can segregate and secure data on the ServiceNow platform in multiple ways, depending on your customer's needs.

Segregating data in multiple ways

The following diagram shows four ways that you can segregate data. You can use separate instances, domain separation, contextual security and business rules, and the reference architecture itself as ways to segregate data.

You can segregate data in these four ways:

1. Customizing the reference architecture with qualifiers and filters so that departments and groups within a company can focus on their own work. By segregating the data between these departments or groups, a department or group can't see another department or group's records.

2. Adding contextual security and Before Query business rules as additional layers of security to guard against data breaches. See Context and domain separation and Before Query business rules to learn more about domain separation and business rules.

3. Adding another level of security in a company by using domain separation. The data from every database query is limited to the data that is visible in a domain before contextual security and business rules are executed.

4. Using separate instances to segregate the data at the database and application layer.
Separate instances, domain separation, contextual security and business rules, and the reference architecture are ways to segregate data. These four ways relate to each other as indicated by the Comprehensiveness of need arrow in the diagram. How each layer interacts with the other layers depends on how you set up your domain separation configuration.

Not all organizations require domain separation. You might find other alternatives, such as separate instances or a single instance without a domain. To learn more about these alternatives, see Evaluating the need for domain separation.

Alternatives to domain separation

You can use a separate instance as an alternative to domain separation for your customers. A separate instance allows you the flexibility to meet the requirements for data separation within the groups and departments in an organization with little to no impact on others.

Separate instances

Pros and cons of separate instances

<table>
<thead>
<tr>
<th>Separate instance</th>
<th>Single instance - without domain</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Pros</strong></td>
<td><strong>Pros</strong></td>
</tr>
<tr>
<td>Built to suit each customer/organization</td>
<td>May address simple scenarios</td>
</tr>
<tr>
<td>Minimize impact of customization on others</td>
<td>Cost</td>
</tr>
<tr>
<td>Release schedule coordination</td>
<td><strong>Cons</strong></td>
</tr>
<tr>
<td>Clean separation</td>
<td>Extensive modifications to baseline code</td>
</tr>
<tr>
<td>Choose DATACENTER region</td>
<td>Modified base system code skipped during upgrades</td>
</tr>
<tr>
<td><strong>Cons</strong></td>
<td>Must address all secondary and supporting tables as well</td>
</tr>
<tr>
<td>Cost</td>
<td>Extensive testing required</td>
</tr>
<tr>
<td>Alignment of instances</td>
<td>No ServiceNow product team to evolve your custom code</td>
</tr>
<tr>
<td>Testing effort for upgrades</td>
<td></td>
</tr>
<tr>
<td>Duplication of effort</td>
<td></td>
</tr>
<tr>
<td>Integrations required</td>
<td></td>
</tr>
</tbody>
</table>

You can time upgrades and releases separately for each instance. However, if you choose to use separate instances, you need to do a lot of coordination with other people who are administering instances. By configuring an instance with contextual security, form views, reference qualifiers, filters, and robust conditions, you don't have to use domain separation in your company.

With a separate instance, you may address data and process separation but your instance owners must maintain and keep up with the extensive customizations that is required for separate instances.

Evaluating the need for domain separation

You may find that domain separation doesn't always work for your customers' organizations. It's best that you base your decision to go with domain separation by looking at your customers' needs.
Reasons for domain separation

These factors may help you decide to choose domain separation for your customers' organizations:

- Your customers have moderate alignment of processes and general platform requirements.
- Your customers plan to work on tasks as fulfillers rather than as requesters.
- Your customers have a contractual agreement that requires that data records be isolated, but your instance owner has determined that the requirement may be addressed somewhere else in the configuration.
- Your company's instance owners have entire entities that operate as physically separate organizations and do not share data, but full reporting is still required. Separate domains would allow data visibility when configured correctly.

Reasons for no domain separation

These factors can point to reasons why your customers' organizations might not want to set up domain separation:

- Your customers want to administer their environment, have full ownership of it, and set the roadmap for expansion.
- Your customers require that the data and process at the physical or database level be completely isolated.

Note:

Domain-separated instances contain a shared database so this undermines the isolation requirement.

- Departments in your customers' organization want to isolate records. (Access controls may suffice.)
- Your customers all want their own processes, business rules, and workflows.
- The corporate culture is one of non-collaboration between your customers' organizations.
- Your customers interact with the platform as end users only.
Benefits of domain separation

Domain separation may work better for your customers' organizations than any other method for separating the data between groups and departments.

Domain separation benefits at a glance

You can enable domain separation with a ServiceNow plugin that has functionality built into the core platform. The separate domains configuration is managed by a product manager who is supported by a development team. Enhancements and fixes for domain separation functionality are included with ServiceNow releases and ready to be used by customers. For assistance with domain separation, your instance owners can use Customer Service and Support resources, such as the Service Portal.
How a database query works with domain separation

Using database queries with domain separation in your customers' applications help them protect their data. These queries then speed up the configuration and build processes.

How domain separation protects data

In the following figure, the Incident table [incident] has a domain field that is inherited from the incident's task. When you see this domain field, you know that the records in the table can have domain assignments.

When users log in, their home domain appears with the set of domains they may access. This is known as the user’s session context. For more information about session contexts, see Context and domain separation.
1. In a browser, the user from one of the companies, Acme, selects the Open Incidents module to view all incidents where active=true.

2. The active=true filter is submitted to the application.

3. The application then sends a query to the database by appending a WHERE clause to active=true. The WHERE clause limits the incident records that are returned to those records that are in the user's domain or the domains that the user may access. Only the records in these domains are returned to the application for processing.
4. Contextual security is applied, further limiting the data that is returned to the user. The incident records appear in the Open Incidents list.

**Note:**

When you apply contextual security, you create limits to the data that are returned to the user. These limits protect other content that you may not want users to see.

To learn more about contextual security, see *Context and domain separation.*

**Note:** This processing logic applies for all queries to the database, including those queries that are triggered using integrations.

### Domain separation levels of support

You can choose from three high-level categorizations for domain separation of an application for your customers' organizations. Applications that support domain separation may support the separation of data and data routing only, have advanced business logic separation, or support tenant (customer) level administration of the application. These definitions delineate the support levels from the perspective of actual use cases and the people who implement them.

### Incremental ServiceNow support levels

<table>
<thead>
<tr>
<th>Level</th>
<th>Type</th>
<th>Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>No support</td>
<td></td>
<td>• The domain field may exist on data tables, but no business logic exists to manage the data.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• This level is not considered domain-separated.</td>
</tr>
<tr>
<td>Level</td>
<td>Type</td>
<td>Summary</td>
</tr>
<tr>
<td>---------</td>
<td>-------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Basic</td>
<td>Customer data management</td>
<td>• Business logic: Ensures that data goes into the proper domain for the application’s service provider use cases.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• In the application, user interface, cache keys, reporting, rollups, aggregations, and so on, all consider the properties of the domain at run time.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Your instance owners need to be able to set up the application to function normally across multiple tenants.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Use case: When a service provider uses chat to respond to a customer’s message, the client must be able to see the response.</td>
</tr>
<tr>
<td>Standard</td>
<td>Customer process management</td>
<td>• Includes the Basic level</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Business logic: Processes can be created or modified per customer by the service provider. The use cases reflect how the application is used by multiple service provider customers in a single instance.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Your instance owners need to be able to configure minimum viable product (MVP) business logic and data parameters per customer for the specific application.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Use case: Admin needs to be able to make comments required when a record closes for one customer, but not for another customer.</td>
</tr>
<tr>
<td>Enhanced</td>
<td>Customer self-managed configuration</td>
<td>• Includes Basic and Standard levels</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Enables service provider customers to modify business logic that is based on defined use cases. These configurations are UI-based and fail-safe so that configurations by one customer cannot affect another customer.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The instance customers need to be able to configure MVP business logic and data parameters themselves.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Use case: Customer of a shared environment needs to be able to make changes according to impact, urgency, or priority within a domain.</td>
</tr>
</tbody>
</table>
Effective domain*

In some cases, a platform feature or application may support service provider use cases even if the domain framework is not being used. The use cases must be detailed to support domain separation. An asterisk (*) after the support level indicates this kind of configuration.

Use case: Before the New York release, Service Catalog had no domain support but the instance owners could configure separate catalogs and items for each tenant in a domain-separated instance by using user criteria. The result was that each tenant could use Service Catalog at a Standard level.

To view all applications listed by their support level see Application support for domain separation.

Summary

Domain separation is a framework that you must use to make your applications aware of its customers.

Consider the domain framework capabilities, your applications' business use cases, what the personas are, and how they use the application before you can use the framework to make your application supportable.

Service provider reference architecture

Your customers can access service provider (SP) services by using a portal that is designed for them to reach their domain-separated instance.

Basic attributes of service provider reference architecture

- You do not assign fulfillers to a domain. Instead, you share them across domains. This makes it harder to audit how many fulfillers you have per domain.
- You can share and leverage domain administration. This means that there is no overhead and you can optimize licenses.
- The number of users on the instance can change when you get a new customer. A new customer can result in tens or even hundreds of thousands of new users on the system. The number of total users is virtually unlimited in one shared environment.
The portal for SP services is dedicated or shared to the SP shared instance. Service providers use ServiceNow shared instances to manage their service delivery.
Reference hierarchy for domain-separated instances

- **SP Contains TOP**
  - Service provider (SP)
    - Domain contains TOP for complete data access.
  - TOP
    - Top-level, process flows down
    - Overrides from global processes are done here.

- **Parent/Child**
  - SP “Contains” TOP
    - For complete data access
  - Initex
    - Can access only from global and itself
  - Oceanic Airlines
    - Can access only from global and itself
  - ACME
    - Can access only from global and itself
  - Cisco
    - Example 3rd-party vendor
You can use decision trees and a comparison chart to determine if a new customer should be added to a shared instance or to their own dedicated instance.

**Decision trees**

Use these decision trees to help your customers decide whether to use a managed or dedicated instance.
Customer decision tree
## SP reference architecture comparison

<table>
<thead>
<tr>
<th>Standalone (SA)</th>
<th>Multi-Tenant (MT)</th>
<th>Hybrid (MT+SA)</th>
<th>SIAM (Multi-Vendor)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Platform as a Service</strong></td>
<td><strong>Enterprise scale</strong></td>
<td><strong>Processes simplified</strong></td>
<td><strong>Cost reduction</strong></td>
</tr>
<tr>
<td>Customer wants full power of platform to solve own needs outside those offered by SP.</td>
<td>Large customer: Transactions or data amount stored cause for multiple nodes or dedicated hardware.</td>
<td>Global governance &amp; admin for business use case &amp; process can be developed &amp; maintained on the instance. Best when used w/ minor-to-moderate process differences among customers or sub-entities.</td>
<td>Lower administration, transaction, &amp; onboarding costs, &amp; ongoing operational costs for resources &amp; licensing. Faster onboarding = more revenue.</td>
</tr>
</tbody>
</table>
Service provider reference architecture for dedicated instances
Service provider (SP) customers can access SP services by using a portal to a dedicated instance. SPs use these dedicated instances to manage their service delivery.

Dedicated instances

- SP customers access SP services via a portal to a dedicated instance
- SP uses dedicated instance(s) to manage their service delivery

Legend:
- Centralized governance at the SP for instances managed by the SP
- Administration owned by the SP or customer for dedicated instances
- SP & customer fulfillers on each instance
- Customer requesters on each instance

Attributes

- Dedicated instances require that you have separate administration and dedicated teams. You need multiple licenses for the administrators and developers who log in to multiple instances.
- Each instance has a finite number of requesters and fulfillers. When you get a new customer, you must procure an instance that is based on the size and scale of your customer’s company.
Dedicated instance

Legend:
- Centralized governance at the SP for instances managed by the SP
- Administration owned by the SP or customer for dedicated instances
- SP & customer fulfillers on each instance
- Customer requesters on each instance

- SP customers access SP services via a portal to a dedicated instance
- SP uses dedicated instance[s] to manage their service delivery
Dedicated vs. shared instance
### SP reference architecture comparison

**Service provider reference architecture for hybrid**

Use the hybrid service provider (SP) reference architecture for a customized solution. Your customers require a dedicated instance for a specific service. They can still use the shared SP instance for other services, but it requires integration of each instance.

### Hybrid architecture

Your customer may be responsible for delivering this additional service directly. You’ll need to build a hybrid solution of several attributes for your customer to provide.
Attributes

- You can share and leverage the administration of the instance. This means that there is no overhead, and you can optimize licenses.
- If there is a new instance for a decentralized environment, the program team is responsible and funded accordingly as dedicated administrator users for that instance. In a centralized environment where all instances stem from a blueprint, you'll need duplicate administration licenses.
- You do not assign fulfillers to a domain. Instead, you can share them across domains.
- If a customer is sharing both a shared environment and a dedicated environment, they require a filler in both environments. This means more work for each team because the processes for shared and dedicated instances require different work for each instance.
- The number of users on the instance can change when you get a new customer. A new customer can result in tens or even hundreds of thousands of new users on the system. The number of total users is virtually unlimited in one shared environment.
Each instance has a finite number of requesters and fillers. When you get a new customer, you must procure an instance that is based on the size and scale of your customer's company.

</tbody>
</table>

**SP reference architecture comparison**

*Service provider reference architecture for Service Integration Management (SIAM)*

The Service Integration Management Service Integration and Management (SIAM) for service provider (SP) architecture integrates services for a unified customer experience.

**Attributes of SIAM architecture**

- Customers access SP services on a dedicated or shared portal to the SP shared instance.
- SPs use ServiceNow shared instances to manage their service delivery.
SP Reference Architecture – SIAM

- Customer is contracting with best in class service providers for individual services but key operational data needs to be shared across multiple SPs.
- SIAM provides service integration layer for unified customer experience.
- Customer fulfillers operate out of the dedicated instances.

Often de-centralized as each supplier has their own governance programs. However, either a guardian provider or the customer SHOULD force a unified governance committee.

Administration is distributed to each supplier’s own ITSM platform. Integrations/eBonds must be governed for process interactions.

Requesters are generally at the central instance but fulfillers fulfill out of their own supplier instances with the eBonds connecting the flow.

SIAM architecture at a glance
Domain separation terms

With a ServiceNow instance, you can improve efficiency, add greater security, and increase performance for your customer organizations. It’s helpful to understand some of the most common terms as you create your configurations.

Managed domain

In a managed domain, the Managed domain field allows domain administrators to manually select a domain for the user, group, department, location, or CI record, rather than using the domain that is assigned automatically from the company record.

If you want to change those properties, you can override them to further customize the functions of the applications in each of your domains.
Process tables

In process tables, if you see a value in the **Overrides [sys_overrides]** field, a process override record exists. That means that delegated administration, which is how administrators can set domain-specific policies, is in effect. Admins in the global domain can use the **Expand/Collapse Domain Scope** related link to see override records.

When you view process tables from a domain, you see only the relevant process records for the selected domain. When you view a process table from the global domain, the **Expand Domain Scope** related link is displayed to let you see all process records, including overrides. To view only the relevant process records for global again, use the **Collapse Domain Scope** related link.

The domain scope feature is used only for process tables and causes the visibility of data on the table to shift in the opposite direction. For example, a record in the parent domain can be seen in the child, but a parent cannot see a child record. This allows the process to flow down to child domains.
Types of domains

Different types of domains can help you organize your processes and data and how they function in the application or feature.

Customer Domain

In the customer's domain is the user interface, as well as the process that controls how the data is used.

The ACME domain in the following image is a customer domain.

Process Domain

You create processes for how the data is used and what it does in the domain. These processes must have these attributes:

- Specific processes and UI settings for a set of domains
- No core data of any kind (such as specific user data).
• The TOP domain in the following image is a process domain.

**Data Domain**

The data domain holds data that is relevant to multiple customers. That data can be shared without sharing the actual customer domains. Each customer has its own data domain and can access it.

**Note:**

This kind of domain is not common and can cause performance issues if overused. Consult with an SP architect before use.

Example: The domain may hold tasks that ACME, Cisco, and the SP all need to interact with.

The Default domain in the following image is a data domain.

**User Data**

User record data never belongs in the global domain or any of the process domains. Users are primarily created in customer domains and can on occasion be created in data domains.

Admin accounts are special as they should not be used as everyday users of the instance and should be in the global domain to facilitate administrative functions.
Domain hierarchy

Lists, admin, global process

Lists

From the global domain, if you right-click any choice field’s label, select **Configure Choices**, and then add a new choice, the choice pushes automatically to all domain-specific lists for that field. If the new option is marked as **Selected**, it is added as active. If the new option is marked as **Available**, it is added as inactive.

Instance Administration
The instance owner’s administrators must handle all normal process creation, modification, and maintenance in a domain-separated instance. Individual domain managers can maintain some parts of data-driven processes. The types of domain managers maintain user administration, support group memberships, and locations, or manage applications that are designed with tenant administration in mind.

**Global process/parameters**

You can create and maintain the process that affect the global domain as well as set the parameters. These properties are common for all users of a domain-separated instance.

Examples: System properties, dictionary overrides, `sys_documentation` (field labels), the data model (classes, CI types, and so on), tables and fields `[sys_dictionary]` (access can be restricted), indexing (text indexes as well as database), ACLs, installation exits, inbound actions, public pages, and interceptors.

**Creating custom tables in separate domains**

You may need to create custom tables in separate domains because you may want a table to function one way for one customer and another way for another customer.

**Separating a table into domains**

There are four basic sequences to creating separate domains in a table.

1. **Create a `sys_domain` field**

If the Domain Separation plugin hasn't created a separate domain in a table, it's best not to try to force your customization. Use these points as a guideline.

- Create a new field and leave it as a string.
  - Column Name: `sys_domain`
  - Other attributes are defined automatically

  The `sys_domain_path` is created automatically.

The column name `sys_domain` is reserved in the ServiceNow platform, which means that the system recognizes it and automatically applies the appropriate field type and attributes for you. This automatic configuration also creates a corresponding `sys_domain_path` field.

**Note:**

- Set the column name to `sys_domain` rather than using the label.
- Domain separation is not appropriate for every table. If a table is part of the base instance and that table doesn't have a `sys_domain` field, you should leave it that way.

A `sys_domain` field is created automatically when you create a string field with the name “sys_domain.”
2. Add a business rule to set the domain

Your custom tables need business rules to make the table function as it should.

Without business rules
The domain is set to the current domain of the user who creates the record.

With business rules
The domain is not left blank, but is assigned using scripted logic, typically based on the Company field.

The first rule is the **Domain – Set Domain – Task** business rule, which attempts to set the domain of the record based on the record’s company’s domain.

If this rule doesn't find a domain, the **Domain – Default – Task** business rule executes and sets the domain of the record to the default domain.

Then, if the domain of a task record changes, the **Domain – Cascade Domain – Task** business rule changes the domain on all records that are related to the task, such as workflows, metrics, SLAs, and attachments.
3. Add a business rule if Step 2 failed

If the initial business rule fails to set a domain and the domain is still empty or global, a second business rule runs. The second rule examines the `task_for` field that is based on the caller or `requested_for` field. The rule is checking to see if you can set the domain of the record based on the user’s domain. If not, the business rule sets the domain to the default domain. The following image demonstrates these rules.

![Business Rule Table]

- **Name:** Domain – Set Domain  
  **Order:** 100

  **Description:** Business Rule executes before an insert or update on the Task [task] table.

  **Condition:** `current.company.changes() && !current.company.nil()`

  **Script:** `current.sys_domain = current.company.sys_domain;`

- **Name:** Domain – Set Domain - Default  
  **Order:** 9,000

  **Description:** Business Rule executes AFTER Domain – Set Domain – Task.

  **Condition:** `current.sys_domain == 'global' || current.sys_domain.nil()`

  **Script:**

  ```
  /* essentially
   * If (task_for is set)
   * set the domain to the user’s domain
   * ELSE set the domain to the default domain
   */
  ```

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
4. **Add a business rule to cascade the associated records**

Tasks can have many related tables that work together for business objectives. These related records include workflow, SLA, approvals, attachments, and email. If the domain of a task changes, the related records domain must change, too, so they remain visible to the users in the new domain.

This Cascade rule is commonly triggered when you clear records out of the default domain. The following image is an example of a **cascade** business rule.

![Cascade Rule Example](image)

<table>
<thead>
<tr>
<th>Name:</th>
<th>Domain – Cascade Domain - Task</th>
<th>Order:</th>
<th>10,000</th>
</tr>
</thead>

* Keep domains in sync w/related records for:
* workflow context
* workflow executing activities
* workflow history
* task SLAs and related workflows
* approver tables and related workflows
*/ | * group approvals and related workflows
* attachments
* emails
* / |        |

**Customizing domain properties and themes**

You can customize your customers' company properties and themes within the domains that you have configured. Customization makes their instances fit in with their companies' overall look and feel.

**Customizing company themes and logos**

On the company record, you can customize specific design themes and logos for each company.

**Customize the domain**

By default, when you have the service provider plugin installed, the standard business rules contained in the core tables cause the record's domain to be set to the domain of the company that is associated with the record. The company can control the tables such as Task, User, Group, Location, Department, and so on.

With all of these tables, except the Task table, you can override the domain that a record is created in. This gives you more customization options.

**Managing domain separation for specific uses**

You can set up separate domains for email notifications and customize the properties of catalog, tables, users, groups, and views. This enables you to provide more specific behavior in each domain, giving your customers more flexibility.
Emails

You can use separate domains for email notifications and overrides. When you use separate domains for notifications, you can do an override that is based on the domain of just the attached record, not the user’s whole domain.

Service Catalog

The Service Catalog is now domain-separated so that your customers can see and access the catalog. Items are processed as OR conditions when multiple items are used. Service providers should administer the categories and items themselves so they fit their own criteria specifically.

Users and groups

Only use admin accounts in the global domain because admins need access to all domains. Do all your application testing from an actual domain, not in the global domain. Overrides don't process properly in the global domain. Admins should also be given user accounts in production if they are to use the application.

Working with fields

There are several points to consider when you work with fields. Pay close attention to these fields because they can have many variations that affect your configurations.

Lists

There are personal, global, and domain lists, as well as multiple views of each.

Forms

There are global and domain lists as well as multiple views of each.

One database

Any fields that you create exist for all users, in one database. Consider the global impact before you create one.

- ACL scripts cannot keep a field from being viewed in a list because they do not run. You can add a READ ACL to hide a field from users if the ACL is only role-based.

Creating tables

When you create a table, you should add a `sys_domain` or an `sys_overrides` field. Any table that contains data that your instance users need to access, needs the `sys_domain` field. Tables that extend or support processes and that need to flow down to children domains also need the `sys_domain` field.

Configuring domain separation with the domain picker

Use the domain picker wisely, and remember the 80/15/5 approach so that you do not customize too much and impact the performance of your instance.

Verify your domain before making changes

The domain picker gathers all the domains into a list for you to choose from.
If your session times out and even if you don't get logged out, your session falls back to the domain on your user record. You also lose any elevated roles at the same time. In this case, your domain picker could still show the last domain that you selected if the top frame of the list hasn't been reloaded. For this reason, you should reload your list completely if you have been away from the instance for any time.

**Configuring at the TOP domain or the global domain**

Domain separation works best when you are providing services to customers that are mostly standard in their configuration and user and group definition. The more that you customize and create "one-off" solutions, the more you create a margin for error. When you create your processes and business logic, any variations should be in properties that work automatically for each customer. While processes can still be adjusted as needed, use great care when you decide when, and to what degree, to create a unique configuration for a single customer.

You'll need to use an "80-15-5" approach in configuring your domains to avoid too large a margin for customization, and therefore error.

- **Recommended approach for configuration:**
  - 80% or more **Standard**
  - 15% or more **Parametric**
  - Less than 5% **Configuration**

- Determine if a suggested change should be a global or a configurable property.
• Do not overbuild by adding more and more customization that needs to be managed. Instead, do the following:
  • Start with the base system features and verify any gaps before you make any changes.
  • Look for no-code solutions.
  • Use server-side scripts, build modular APIs, and build in domain-separated properties.
  • If you must use client scripting, use only ServiceNow APIs. Limit "synchronous" calls (those that go back and forth from client to server, also called AJAX).
  • Write all scripts logically to keep them simple and effective. Enforce peer reviews of code changes and make sure everyone is following the Domain separation recommended practices for service providers in this section.

Domain separation performance considerations
As you configure domain separation in your application and services, make sure that you consider the number and properties of domains you create. Too many property-heavy domains can impact the performance of your instance.

Limiting property-heavy domains
You can create as many domains as needed, but make sure that you don't create unnecessary domains on the instance. Weighing too many domains on the instance with a lot of properties can impact the performance of your instance.

The number of domains is not what impacts performance but rather what’s in them. Too many properties can slow down the domain picker, which then slows down the overall user experience of your customers. If you are loading the domain picker and already have a large number of domains with a lot of properties, the domain picker has to load all the domains before it gives you control in the session. This process could lead to an outage where you can't access anything on the instance until the domain picker finishes. Before you create new domains, navigate to the domain hierarchy under Domain Admin > Domain Map and make sure that you actually need to create a new domain or whether an existing domain hierarchy can work.

Using the UI16 domain picker
The domain reference picker is available in UI16. With the reference picker, you do not load all the domains at once, but rather the domain is searched as you begin to enter the name of your domain into the domain picker.

Enable the domain reference picker in UI16 by following these steps:
1. In the application navigator, enter sys_properties.list.
2. Set the glide.ui.domain_reference_picker.enabled property to true.
3. Refresh the browser.

Note: Do not upload a large number of domains (over 30) via integration or import sets without doing some testing first or you might bring down your instance.

Setting up domain hierarchies
You can avoid slowdowns and performance impacts in your instance by knowing how domain hierarchies work and by setting them up properly.

Based on the domain hierarchy, users have access to the data in their home domain and any child domains. The process flows down to the child domains and the data rises up.

Make changes to the existing domain hierarchy only when needed. When you update the parent of a domain, the system re-establishes the parent domain with all its child domains that change the domain hierarchy. When the domain hierarchy updates, the system triggers a cascade update on all tables that relate to domains for the records that are created on that domain. As a result, a large number of supporting tables have to be updated too.
For the same reasons, even if you must change the domain hierarchy, never do a mass update. Imagine the number of queries that the system has to run to change the domain hierarchy. Always do an update in small batches. Before you start the next batch of updates, make sure that Domain Work Request (DWR) records are processed. DWRs are reports that display whether there are errors after you’ve changed the domain hierarchy.

**Tracking DWR records**

In the syslog_domain table, look for an information entry for **DWR execution completed.** to confirm that DWR is completed.

---

<table>
<thead>
<tr>
<th>Level</th>
<th>Message</th>
<th>Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>Information</td>
<td>DomainWorkRequestExecutor worker thread pool is shut down. Total time taken for executing the threadpool: 0:00:20</td>
<td>com.glide.domain.par</td>
</tr>
<tr>

<td>DWR execution completed</td>
<td>com.glide.domain.par</td>
</tr>
<tr>
<td>Information</td>
<td>DomainPathUpdater is finished! Total time taken for migration: 0:00:20</td>
<td>com.glide.domain.par</td>
</tr>
<tr>
<td>Information</td>
<td>All DWRs have been processed. Producer will shutdown consumers and exit.</td>
<td>com.glide.domain.par</td>
</tr>
</tbody>
</table>

---

**Domain Work Requests screen**

**Checking domain logs for errors and warnings**

Check the domain logs to find errors or warnings in your domain path processes and hierarchy configurations.

You can find the domain logs in the Domain Log [syslog_domain] table. When the domain hierarchy updates, the system triggers a scheduled job to recalculate the domain paths. The domain logs table captures the results.

Look for any errors and warnings in this table. After reviewing this table, you need to resolve these errors and run the domain path validator again.

In this example of a log, the system has detected ten orphan records in the sys_ui_list table. The errors in these records must be fixed before the domain path can run successfully.
To learn more about domain-separation errors, see Troubleshoot domain separation errors.

**Importance of the Default domain**

Organizing your domains is a crucial part of the domain separation process. If you don't set a default domain, new tasks and user records go to the global domain. Anyone can see the records in the global domain, which means that data can be seen when it isn't supposed to. When you set the default domain, its records are not visible to any user other than an admin.

You should always set one default domain for the domain records on your instance. The default domain is where the system automatically assigns task and user records that are not already assigned to a domain.

When you create a default domain from the Domain Administration screen, add the name Default in the Name field to differentiate it from other domains. Check the Default option as follows:

Maintain regularly the records that you create in the default domain and move them to the correct domains. If records show up often in the default domain, you may need to investigate why. Ideally, you should make sure that all records are created in their appropriate domains (not global or default domains).

**Contains queries and domain access**

Use a "contains" query only in special cases, such as when users or groups need to see data from a domain that they don't have access to, but you don't want to move those users to a domain. Creating domain "contains" and user or group access for a domain should be an exception, only when absolutely needed.

"Contains" is a domain-to-domain relationship that is many-to-many, and has no effect on the flow of process. If you create a large number of domain "contains" relationships or provide broad access, you will generate queries with too
many OR conditions. OR conditions are slow and impact the performance of your instance. Instead of using too many
"contains" relationships, set up your domain hierarchy as follows:

```sql
SELECT ... FROM task task0 ignore index(number) WHERE task0.`sys_class_name` = 'incident' AND (task0.`sys_domain_path` LIKE '%/!' OR task0.`sys_domain_path` LIKE '%/$!/!!/%' OR task0.`sys_domain_path` LIKE '%/$!/!!/$!/!!&/%') ORDER BY task0.`number` DESC limit 0,20
```

**Sample query**

Before you move users to a domain, make sure that they really should have access to that domain. Weigh the benefits
and limitations. The query above is for just one contains relationship. If you have a domain that contains another
domain, and that domain is the parent of a number of other domains, you will have many more OR conditions. Be
careful when you create a domain map so that you do not impact the performance of your instance.

**Domain paths query method**

You can create effective queries with domain paths.

Use domain paths instead of domain spooling (sys_domain) or domain numbering. Queries that use domain paths
are much faster than spooling or numbering.

Domain paths is the default query method for instances that have enabled domain separation.

If you want to verify the query method on your instance, look for the following system properties in the admin
dashboard:

- **If domain path is enabled:** In the System Properties table, you see `glide.sys.domain.provider=domain_paths` and `glide.sys.domain.paths.installed=true`.
- **If domain path is not enabled:** In the System Properties table, you see `glide.sys.domain.provider` != `domain_paths`, `glide.sys.domain.paths.installed=false`.

**Slow queries and SQL debugging**

Debugging SQL and slow queries can help you resolve slowness issues in an instance.

When you debug an instance, you can either enable SQL debugging to look for slow queries or you can look for slow
queries by checking the Slow Queries [sys_query_pattern] table by navigating to System Diagnostics > Stats >
Slow Queries. This table stores all the slow queries in the instance.

When you search the table, look for queries that contain `domain_path` to determine if any slow queries are due to
the domain path in your instance.

If you do find slow queries, try to analyze why they are slow.
Common reasons for slow queries

- A query has too many OR conditions (for more information, see Contains queries and domain access). In the domain hierarchy, place the user or a domain at a hierarchy level where contains or visibility is not
• The query method is not the domain path query method (for more information, see Domain paths query method): If you are not using the domain path query method, contact Customer Service and Support.

• A query needs a database to be indexed so you can see what is in the database quickly. If you can identify the slow query, run the "explain plan" to see if there are options for indexing available. The "explain plan" is a function of SQL that shows the query and what is going on with it.

**Before Query business rules**

You can use a Before Query business rule to help support data segregation on an instance. ServiceNow applications that support domain separation may support the separation of data and data routing only, have advanced business logic separation, or support tenant (customer) level administration of the application.

A Before Query business rule is supplementary code that you use to support data segregation within domain-separated environments.

**Warning:** Do not use the Before Query business rule in place of the Domain Separation plugin. This business rule does not prevent data leakage as securely as the plugin.

**Using the Before Query business rule for data segregation**

You can use the Before Query business rule with data segregation in these situations:

• When domain separation is not supported by a ServiceNow application and you must grant or restrict table or row access to one or more non-internal customers outside of the service provider organization.

**Note:** Before you begin developing, contact ServiceNow Customer Support about the application roadmap for that product; domain support improvements may be planned for upcoming releases.

• When a table is domain-separated but access to its rows must be granted or restricted based on certain conditions that apply only to a set of domains in the system.

  • For example, a customer in the X domain has multiple vendors supporting that domain and those vendors are granted access to see only the records that are assigned to them

**Points to consider before creating Before Query business rules**

You can script Before Query business rules to prevent parent and child table access based on a combination of user information, group memberships, companies, roles, or record-specific field conditions.

• Before Query business rules are put into separate domains and created to apply globally, to a specific branch of a domain hierarchy.

  • Where you can, create Before Query business rules at the lowest possible part of the domain hierarchy so that the rule runs only for users that it applies to.

  • Know that there are scenarios in the system where business rules may not run or where a user-triggered interaction may not trigger a business rule to run. For example, a business rule won't run when you have transform maps with Run business rules turned off, or you have scripts with the workflow disabled.

  • Always populate the condition field to specify when the rule runs. For example, you can specify if the business rule applies only to certain vendors in a domain.

**Warning:** When designing and coding business rules (especially Query business rules), limit OR clauses and searches in non-indexed fields. Too many OR clauses and searches in non-indexed fields can slow queries or affect how your instance performs.
• Use Before Query business rules only when necessary. Too many Before Query rules can affect how your instance performs.

• Before Query business rules run before access control lists (ACLs) and perform better in general. This is true especially when you limit the returned results to those users in service provider (SP) environments who have access to several domains in the system.

• Filtering the data is transparent (unlike with ACLs) to users who do not see the message Data Security restricts... when interacting with data.

When not to use Before Query business rules and ACLs

Be careful when you use Before Query business rules and ACLs to segregate customer data. By using both business rules and ACLs, you create customizations that you then must maintain. Customizations can potentially cause performance issues. Your development teams should create processes to make sure that they don’t break the system.

Domain separation provides both scalability and governance with the current domain path query method (v3), which is a widely supported framework. The ServiceNow Platform and App teams are responsible for maintaining the framework, taking the burden off the customer.

For companies with many customers in many instances, excessive use of Before queries and ACLs may cause the database queries not to perform well.

How domain separation is enabled

You can enable domain separation with a ServiceNow plugin. A product manager, supported by a development team, manages the functionality. Enhancements and fixes for domain separation functionality are included with ServiceNow releases. Instance owners can consult Customer Service and Support resources, such as the Service Portal, at https://support.servicenow.com for assistance with domain separation.

Avoiding domain path in scripts

Domain paths can cause the values of your script to change or even break, so don't use them in scripts.

Your script should not depend on the domain path because if you ever change the domain hierarchy, the domain path recalculates and its value changes. When this happens, your scripts are useless or can throw errors or break. The best strategy is not to write your scripts based on domain paths.

Use the sys_domain field in your scripts rather than depending on the domain path. If you ever change the domain hierarchy, the domain path recalculates and its value changes, which can cause your scripts to be useless, throw errors, or break. Look for base system business rules, which use the sys_domain field, to get some ideas before creating your own scripts.

The ServiceNow platform does not capture the sys_domain_path values in an update set in order to avoid issues with differences in the domain hierarchy for each instance. Therefore, you should validate the domain hierarchy after you import an update set to ensure that the domain path values for your records are correct.

To learn more about domain path, see Request domain separation and Domain Separation Center.
Domain assignments

How you assign a domain impacts the value of the `sys_domain` field. The assignments contain designs and business properties that affect how the application functions in each domain.

Value of the `sys_domain` field

The value of the `sys_domain` field contains the domain that is assigned to the record by any of the following:

- Company to which the user belongs
- Business rule that is used when creating the record
- Module that is used when creating the record
- Form template that is used when creating the record
- Domain of the parent record
- Domain that is assigned to the User record
- Domain of the user who creates it

Make sure that your domain assignment strategies and designs are well documented and tested so that you are creating records as those strategies and designs are inserted into the correct domain. That way you can see that the properties of each domain should you need to duplicate or modify them.

Domain separation and the Customer Service Management (CSM) plugin

For the best outcome, be aware of how the properties in the CSM plugin work. When the plugin is enabled, you can see the status of your records in your domains.

Instance owners should contact Customer Service and Support to enable this property:

- `csm_auto_account_domain_generation`

**Note:** This base system property is located in the system properties table and is available after CSM plugins are enabled.

What the property does

Whenever a new account in the Customer Service application is created, a domain is created and placed under the TOP domain. If the parent field on the account form is populated, and a new record is inserted, it creates that account as a subdomain of the parent.

What happens if this property is not true and the domain is enabled

New account records in a domain-separated environment are automatically placed in the default domain.

In the following image, you can see the status of the records with the plugin enabled.
Domain separation setup and administration

Setting up domain separation involves requesting activation of a plugin, setting options, and assigning users and records to domains.

Do the following to set up domain separation:

1. Request domain separation
2. Create a domain
3. Add a domain field to a table

You can also perform these basic administrative tasks on domains:

- Enable or disable a domain
- View domain relationships
- Expand domain scope
- Create a domain-specific choice list

See Advanced domain separation administration for a list of tasks to perform after you set up domain separation and perform basic administration.

Request domain separation

All domain support features are activated with a plugin called Domain Support - Domain Extensions Installer. Administrators can request activation of this plugin.

To purchase a subscription, contact your ServiceNow account manager. The account manager can arrange to have the plugin activated on your organization's production and sub-production instances, generally within a few days.

If you do not have an account manager, decide to delay activation after purchase, or want to evaluate the product on a sub-production instance without charge, follow these steps.

Role required: admin

If the Domain Support - Domain Extensions Installer plugin is already active, content in the Domain Support - Domain Extensions Installer plugin will not be installed to avoid potential conflict with an existing implementation.

Domain separation replaces Company Separation. Starting with the Helsinki release, the Company Separation plugin can no longer be activated. However, if company separation is already active when you activate domain separation, both plugins are active at the same time. You can control the company separation activation status with the glide.db.separation.field property.
Note: Domain paths are used for all customers on Helsinki and later. Domain numbering is no longer used. Customer Service and Support can assist in the upgrade.

1. Navigate to System Applications > All Available Applications > All.
2. On the All Applications page, click **Request Plugin** to open the Request form on HI.
3. On Now Support, select the redirect link to access the Now Support Service Portal Service Catalog.

<table>
<thead>
<tr>
<th>Activate Plugin</th>
</tr>
</thead>
<tbody>
<tr>
<td>In order to enhance the user experience, we have redesigned Activate a Plugin service catalog. Please use the new HI Service Portal 'Activate a Plugin' service catalog item. You can also use Manage Instances page on Service Portal to Activate a Plugin.</td>
</tr>
<tr>
<td>Take me to the HI Service Portal Activate a Plugin Service Catalog.</td>
</tr>
</tbody>
</table>

4. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target Instance</td>
<td>Instance on which to activate the plugin.</td>
</tr>
<tr>
<td>Plugin Name</td>
<td>Name of the plugin to activate.</td>
</tr>
<tr>
<td>Specify the date and time you would like this plugin to be enabled</td>
<td>The date and time must be at least two business days from the current time.</td>
</tr>
<tr>
<td>Reason/Comments</td>
<td>Information that would be helpful for the ServiceNow personnel who are activating the plugin. For example, if you need the plugin activated at a specific time instead of during one of the default activation windows, specify that in the comments.</td>
</tr>
</tbody>
</table>

5. Click Submit.

Activating the Domain Extension Installer plugin enables these features:

- Domain separation is based on the Domain [sys_domain] table.
- Delegated administration lets each domain have separate policy.
- All records are part of the global domain.
- The current user's domain determines the domain to use when viewing or operating on a record in a different domain.
Domain separation plugin

The Domain Support - Domain Extensions Installer plugin activates several domain separation features and properties at once. This plugin is typically referred to as the Domain Separation plugin.

Recommended practice for activating the Domain Separation plugin

As part of domain separation development, administrators must request activation of this plugin. For best results, activate the Domain Separation plugin at the start of the development process, preferably before any other plugin is enabled.

If you enable the plugin towards the end of ServiceNow implementation or once an instance has gone live, your application is at risk in both performance and process. On established instances, depending on how things were structured in development, the risk to the platform and its usability could be high. To learn more about domain separation process, see Understanding domain separation.

One risk can happen with the Task table: When the Domain Separation plugin is enabled, the `Domain (sys_domain)` column is added to the table and every existing record is automatically placed in `global`. The instance owner would need to script all these records into the correct domains, which mean there would have to be an established parent/child hierarchy. These types of scripted actions risk data corruption or loss, and possible production down time as large amounts of data would have to be moved. Much of the platform’s code such as business rules, client scripts, form views, workflows, and so on, would be placed into `global` and affected as well.

While that might be acceptable in the ServiceNow base system, if a customer creates code or modifies ServiceNow code, there is risk to platform performance and usability. This is like trying to rewire the main power poles fed into a house while the power is still turned on. Instance owners could severely delay their implementation or experience lengthy down-times in the aftermath of this type of approach.

Features of the Domain Separation plugin

These features are enabled when you activate the plugin:

- Domain separation is based on the Domain `sys_domain` table.
- Delegated administration lets each domain have separate policy.
- All records are part of the global domain.
- The current user's domain determines the domain to use when viewing or operating on a record in a different domain.

Domain system properties and user preferences

Administrators have access to properties and user preferences that control domain scope.

Properties

New activations of domain separation automatically restrict domain scope to the record's domain for all related data or processes. When the user views a record in a form, the record's related data (such as reference picker and related list data) and applied processes (such as business rules and client scripts) are restricted to the record's domain scope. If there are records in multiple tabs, each tab has its own domain scope based on the record opened within that tab. The following properties restrict domain scope to either the record’s domain and the user’s current session domain.
Domain system properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Details</th>
</tr>
</thead>
</table>
| glide.sys.domain.use_record_domain_for_processes | Restricts domain scope to the record's domain for all processes. This property does not apply to business rules. Business rules are always processed from the domain record.                                                                                           * Type: true | false  
  * Default value: true  
  * Location: System Property [sys_properties] table                                                                                                                                                                                                                                           |
| glide.sys.domain.use_record_domain_for_data     | Restricts domain scope to the record's domain for all data.                                                                                                                                                                                                                                                                                                                                                                                                               |
  * Type: true | false  
  * Default value: true in new domain activations from Fuji onwards (upgrades from instances older than Fuji do not have this property in the table)  
  * Location: System Property [sys_properties] table                                                                                                                                                                                                                                           |

When either the **glide.sys.domain.use_record_domain_for_processes** or the **glide.sys.domain.use_record_domain_for_data** property is set to **true**, the following properties are not used, regardless of their setting:

- glide.sys.domain.use_record_domain
- glide.sys.domain.use_record_domain_for_client_scripts
- glide.sys.domain.domain_change_notify
- glide.sys.domain.no_change_roles

For a full list of properties see *Available system properties*.

**Domain scope for business rules executed on the domain table**

In new activations of domain separation starting with the Jakarta release, the session domain determines the business rules executed on the domain table. In previous versions, business rules executed on the domain table were set based on the newly created domain’s hierarchy. This behavior is modified by the **glide.sys.domain.skip_domain_insert_businessrules** property. Setting this property to true significantly improves domain insert performance.

**Domain scope properties for business rules executed on the domain table**

<table>
<thead>
<tr>
<th>Property</th>
<th>Details</th>
</tr>
</thead>
</table>
| glide.sys.domain.skip_domain_insert_businessrules | Specifies the domain scope for business rules executed on the domain table. In new activations of domain separation, the property default is true and business rules are determined by the session domain. In existing implementations, the property default is false and the business rules are determined by the newly created domain’s hierarchy.  
  * Type: true | false  
  * Default value: True in new domain activations starting with Jakarta. False in existing implementations.                                                                                                                                                                                                                                           |
### User preferences

In addition, user administrators can set the following user preference globally or on a per-user basis:

**Domain scope user preferences**

<table>
<thead>
<tr>
<th>Preference</th>
<th>Category</th>
<th>Updated By</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.domain.session_scope</td>
<td>Domain</td>
<td>Admin Only</td>
<td>When true, sets the default scope to the user's session domain rather than the record's domain. When false, the default scope is the record's domain. Users with the domain_expand_scope user role can still change the domain scope as needed.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Type: true</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Default value: false</td>
</tr>
<tr>
<td>glide.domain.session_scope_notification</td>
<td></td>
<td>Admin Only</td>
<td>When true, displays a visual cue that record values include an expanded domain scope. When false, the notification is hidden.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Type: true</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Default value: true</td>
</tr>
</tbody>
</table>

### Create a domain

You can create a domain by creating a record in the [domain] table.

Role required: admin

When creating a new domain, keep the following in mind:

- Only one domain can be the default domain.
Only one domain can be the primary domain.

1. Navigate to **Domain Admin > Domains**.
2. Click **New**.
3. Fill in the necessary fields (see table).
4. Click **Submit**.

![Domain Admin new domain form](image)

### Domain form fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a unique name for the domain.</td>
</tr>
<tr>
<td>Type</td>
<td>Select a domain type that describes the domain. By default the domain types are <strong>Vendor</strong>, <strong>Customer</strong>, and <strong>MSP</strong>. You can also add your own choices.</td>
</tr>
<tr>
<td>Primary</td>
<td>Select the check box if this domain is to be the top-level domain in the hierarchy. The top-level domain only has child domains and no parent domains.</td>
</tr>
<tr>
<td>Default</td>
<td>Select if this domain is to be the default domain for your hierarchy.</td>
</tr>
<tr>
<td>Parent</td>
<td>Select the name of the domain higher in the hierarchy that contains this domain. This field must have a value for the domain to appear in the domain map.</td>
</tr>
<tr>
<td>Active</td>
<td>Select the check box to make the domain available for use. You must select this option for this domain to appear in the domain map.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>------------------------------</td>
</tr>
<tr>
<td>Description</td>
<td>Enter a description for the domain.</td>
</tr>
</tbody>
</table>

Each domain record can also have several related records:

- Companies
- Contains Domains
- Contained By

To change the domain hierarchy, go to the Contains Domains related list and select the domain records that is the child (contained) domains of the contains relationship.

**Make a domain the default**

The default domain is the domain to which the system automatically assigns task and user records that are not already assigned to a domain.

Role required: admin

1. Navigate to **Domain Admin > Domains**.
2. Open the domain you want to be the default domain. For example, Default.
3. Configure the form layout to add the **Default** field.
4. Select the **Default** check box.
5. Click **Update**.
<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>WSP 1</td>
</tr>
<tr>
<td>Primary</td>
<td></td>
</tr>
<tr>
<td>Default</td>
<td></td>
</tr>
<tr>
<td>Description</td>
<td>Tasks and users without a domain are placed in this domain when created/updated. This behavior can be overridden by: 1) Unchecking the Default field on this record, or 2) Checking the Default field on another domain record. If no domain is set as Default, tasks and users with no domain are placed in the global domain.</td>
</tr>
</tbody>
</table>

**No records to display**
**Note:** If you do not set a default domain, then new tasks and user records are placed in the global domain.

**Manually manage the domain for particular records**

By default, the system automatically assigns a domain based on the user's company record. In some cases, however, domain administrators want to manually manage which domain a particular record belongs to.

Role required: admin

The **Managed domain** field allows domain administrators to manually select a domain for the user, group, department, location, or CI record, rather than using the domain assigned automatically from the company record. The **Managed domain** field is available on these record types.

- User records
- Group records
- Department records
- Location records
- CI records

1. Navigate to the record you want to manually manage.
2. Select the **Managed** domain check box.
3. From the **Domain** field, select the domain for the record.
4. Click **Update**.

Clearing the **Managed domain** check box hides **Domain** field and the record uses the domain value from the record's company.

**Domain Separated Tables**

You can see at a glance which tables are domain-separated in your instance with the Domain Separated Tables feature.

**Overview**

Use the Domain Separated Tables feature to see which tables are domain-separated. You must activate the **Domain separation plugin** (Domain Support - Domain Extensions Installer), which requires the "maint" role. Start typing "domain" to see the feature appear in the left navigation pane.
You can filter this view to display or remove column names to look for certain properties or attributes that are included in your tables. There are two table types that display on the list:

- Tables that have an explicit `sys_domain` column present, where the Column name displays `sys_domain` value in the list.
- Tables that are using the `domain_master` attribute to derive domain separation from a referenced table, where the Attributes column includes the `domain_master=ref-table` value.

When you use the Show Matching or Filter Out selections on the Column name menu, you can view these two types of tables.
Domain Override Viewer

With the Domain Override Viewer, you can see and manage all your process overrides at once across the entire instance.

Overview

Rather than creating an elaborate search for overrides in your scripts, you can use the Domain Override Viewer to find them quickly.

To launch this feature, begin typing its name in the navigation pane.

The table selector in the Domain Override Viewer displays a list of only the tables that contain record overrides, along with a count of overrides in that table. After you select a table, a list of all parent records with overrides is returned. You can quickly view all parent records, the domain of the parent record, and a count of overrides for each record.

Selecting View Overrides loads a new tab where all overrides, including the parent record, display in the standard list view.
## Domain Override Viewer

Select a table below to display all records with overrides. Select View Overrides on a record to view all of its overrides. Note: Only tables and records with overrides are listed

Please select one table from the dropdown list.

- **Business Rule (sys_script)** - override count: 445
- **Decision (sys_decision_question)** - override count: 1
- **Rule (sysrule)** - override count: 1
- **UI Action (sys_ui_action)** - override count: 10

</table>
To learn more, see Create domain-separated property overrides.

Enable or disable a domain

When you activate or deactivate a domain, the activation status cascades to companies within the domain.

Role required: admin

When you activate a company record, domain separation automatically activates the company's associated domain. For example, if you activate the ACME company, then you also activate the TOP/ACME domain.

1. Navigate to the domain record.
2. Clear or select the **Active** check box.
3. Click **Update**.

⚠️ **Warning:** Do not delete domains. Deactivate domains that you no longer need instead of deleting them.

Add a domain field to a table

Administrators can domain-separate a custom table by adding a `sys_domain` field to it. However, it is not recommended to add domains to base system tables.

Role required: admin

1. Navigate to the table's list view. For example, type `<table name>.list` in the navigation filter.
2. Right-click the list header and select **Configure > List Layout**.
3. In the **Create new field** section, enter `sys_domain` as the **Name** and **Domain ID** as the **Type**.
4. Click **Add**.
5. Click **Save**.

ℹ️ **Note:** Any other means of creating a field adds a `u_` prefix to the column name. But with the domain field, the system automatically creates the field without the `u_` prefix. You can use the following functionality as a shortcut: Whenever you create a `sys_domain` field, name it `sys_domain` and leave the field type as is. The system automatically sets the field type to **Domain ID** and the field label to **Domain**, saving you a few clicks.

Adding domains to base system tables requires prohibitively thorough testing, updates and adding new logic. In addition in many cases, the source code is not accessible to the customer.

View domain relationships

The domain map offers domain administrators a read-only representation of the active domains on the instance and how they relate to each other.

Role required: admin

All domain maps must have one domain set as the primary domain. In addition, each domain in the domain map must meet these criteria:

- The **Parent** field must be filled in (the primary domain is the only exception to this).
- The **Active** check box must be selected.

The domain map does not draw domain relationships for domains that fail to meet the mapping criteria.

1. Navigate to **Domain Admin > Domain Map**.
2. Click the plus (+) or minus (-) icons on the domain headers to show or hide sub domains.
Select a primary domain
The primary domain indicates the top-level domain in the domain map.

Role required: admin

The primary domain cannot have a parent domain and must have at least one child domain. There can only be one primary domain at a time. If you select another domain as the primary domain, it overrides the previous primary domain.

1. Navigate to Domain Admin > Domains.
2. Select the domain you want to be the primary domain. For example, TOP.
3. Select the Primary check box.
4. Click **Update**.
### Domain

</table>

### Contained By

<table>
<thead>
<tr>
<th>Contains = TOP</th>
<th>Domain</th>
</tr>
</thead>
</table>

Actions on selected rows...
Create Contains relationships between domains
Creating a "contains" relationship between domains changes the domain hierarchy.

Role required: admin

Domains in a contains relationship inherit the settings of the containing domain. The containing domain allows users to see data in the contained domain as well as any of its children. Processes are unaffected by a contains relationship.

1. Navigate to the domain table.
2. Select the domain record that is the parent (container) domain of the new contains relationship.
3. Toggle the domain scope to switch between the session scope and record scope, if necessary.
4. From the Contains Domains related list, click Edit.
5. Select the domain records that is the child (contained) domains of the contains relationship. Only child domains appear by default when the domain picker is set to Global. Toggle the domain scope to see all domains in slushbucket.
6. Click Save, and then click Update.

Expand domain scope
By default, when a user in the global domain views a table containing a sys_overrides column, the user sees records from only the global domain. When an admin in the global domain views a process table, that admin sees only records that are in that process table.

Role required: admin

1. Change the glide.sys.restrict_global_domain_processes property to true.
2. To view records from all domains, click Expand Domain Scope under Related Links.
3. To return to viewing records from the global domain only, click Collapse Domain Scope.

Add domains to a visibility domains list
Adding a visibility domain allows a user or group to see and potentially edit records from another domain regardless of the user or group's normal domain membership.

Role required: admin

Assigning visibility domains to all members of a group is preferred over granting them to individual users.

Note: Adding a visibility domain does not change a table or record's access control rule requirements.

1. Navigate to the group table.
2. Select the group you want to provide with visibility domains.
3. Add the Visibility domains related list to the form.
4. From the Visibility domains related list, click Edit.
5. Select the domain records you want the group or domain to see.
6. Click **Save**, and then click **Update**.

---

**Grant visibility domains to an individual user**

While it is possible to add visibility domains for specific users on the User form, it’s best to add them only via groups. This controls permissions and access should individuals change departments or leave the company.

Role required: **admin**

1. Navigate to **User Administration > User**.
2. Select the user you want to provide with visibility domains.
3. Add the **Visibility domains** related list to the form.
4. From the Visibility Domains related list, click **Edit**.
5. Select the domains whose records you want the user to see.
6. Click **Save**, and then click **Update**.

---

**The Visibility domain embedded list contains the following fields.**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Domain</td>
<td>Domain that is visible to the group or user.</td>
</tr>
<tr>
<td>Inherited</td>
<td>Domain is inherited from domain visibility or a parent domain.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Granted By</td>
<td>Name of the group that granted domain visibility.</td>
</tr>
<tr>
<td>Parent visibility</td>
<td>Name of the parent domain and used for grouping records. If the parent record is deleted, then all records with the same parent are deleted as well.</td>
</tr>
</tbody>
</table>

Create a domain-specific choice list

Administrators can configure choice lists to contain entries specific to a particular domain.

Role required: admin

1. Select the domain from domain picker where the choice should be added.
2. Right-click the choice field you want to customize and select **Configure Choices**.
3. Update or add choices.
4. Push changes through the normal change process such as update sets.

**Note:** Administrators should ensure that choices are unique across domains to prevent administrative confusion in the global domain.

If an administrator adds a new choice from the global domain, then users from domains lower in the hierarchy see the new choice at the end of their current choice lists. If the new choice is not active at the global level, then it is available to the domain users via **Configure Choices** but does not show as an active choice.

Advanced domain separation administration

Administrators can view information about domain separation, identify potential issues, and change configuration settings.

You can perform these advanced administrative tasks on domains:

- Use domain selection menus
- View domain relationships

**Use domain selection menus**

The instance offers domain selection via two menu formats.

- Domain selector: provides a simple drop-down list of available domains.
- Domain reference picker: enables a reference field that offers filtering and an auto-complete, type-ahead entry feature. Use this format for longer lists.

The placement of these pickers and the procedure to show or hide them differ depending on the user interface version.

Enable domain selection menus in UI16

Displaying the domain picker in UI16 enables the domain selector by default. After enabling the domain selector, you can add a system property to enable the domain reference picker.

Role required: admin

1. Click the gear icon in the header.
2. On the General tab, click the **Show domain picker in header** switch.

The domain selector appears in the UI16 header.
3. Optional: Enable the domain reference picker.

Note: Enabling the domain reference picker removes the global option from the list. To return to your home domain, click the return arrow next to the reference field. Admin users can click the return arrow to return to the global domain.

a) Enter `sys_properties.list` in the application navigator.
b) If not already present, add the `glide.ui.domain_reference_picker.enabled` property and set the value to `true`.
c) Refresh the browser.

The domain reference picker appears in the UI16 header.

Enable domain selection menus in UI15
Enable the domain selector or the domain reference picker. Use the domain reference picker with auto-complete for long lists that require excessive scrolling.

Role required: admin

On UI15, you must enable a UI macro.

1. Navigate to **System UI > UI Macros**.
2. Select a macro depending on the type of menu you want to enable.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>domain_select</code></td>
<td>Enables the domain selector</td>
</tr>
<tr>
<td><code>domain_reference_picker</code></td>
<td>Enables the domain reference picker</td>
</tr>
</tbody>
</table>

3. Select the **Active** check box, and click **Update**.

Note: If using the domain reference picker, the `domain_select` macro must be set to `false`. If using the domain selector, the `domain_reference_picker` macro must be set to `false`.

4. Refresh the browser.
5. Click the gear icon in the banner frame to show the **Domain** field (UI15).
The domain selector for UI15
Restrict access to the domain picker

Use a system property to restrict access to the domain picker in UI16.

Role required: admin

By default, users with the ITIL role, and roles that include the ITIL role (such as the administrator), can access the domain picker in UI16. You can grant other roles access by adding them to the property or restrict roles by removing them.

2. Add this property: glide.ui.domain_picker.role
3. Configure the property value as a comma-separated list of roles that you want to access the domain picker.

Restrict access to domain selection by role (UI15)

You can include a comma-separated list of roles in domain-related UI macros to restrict access to domain selection by user role.

Role required: admin

This procedure is valid for the pre-UI16 interface. Starting with UI16, you must use a system property to control access to the domain picker. See Restrict access to the domain picker.

1. Navigate to System UI > UI Macros.
2. Select either of the two domain-related UI macros: domain_select or domain_reference_picker.
3. Locate one of the following lines of code:
   - domain_select:
     ```javascript
     var ds = new DomainSelectControl("gsft_domain","itil","Domain","Domain");
     ```
   - domain_reference_picker:
     ```javascript
     var dp = new DomainPicker("${jvar_id}","itil","DomainReference","Domain");
     ```

4. Replace the parameter `itil` with a comma-separated list of roles to control who sees the domain selection menu.

View domain relationships
The domain map offers domain administrators a read-only representation of the active domains on the instance and how they relate to each other.

Role required: admin

All domain maps must have one domain set as the primary domain. In addition, each domain in the domain map must meet these criteria:

- The **Parent** field must be filled in (the primary domain is the only exception to this).
- The **Active** check box must be selected.

The domain map does not draw domain relationships for domains that fail to meet the mapping criteria.

1. Navigate to **Domain Admin > Domain Map**.
2. Click the plus (+) or minus (-) icons on the domain headers to show or hide sub domains.

Domain separation application properties
The Domain Separation plugin has two new tables to give service providers more flexibility in customizing their applications that use domain separation. These tables are the System Application Property table [sys_application_property] and the System Application Property Value table [sys_application_property_value].

New tables offer more options

With service provider (SP) applications, certain actions can vary depending on the domain. However, the ServiceNow® base system System Properties [sys_properties] table is not domain-separated, so it doesn't satisfy the requirements for applications that use domain separation.

Each SP customer may want to customize their applications differently. Previously, features that could be customized were defined as only one global value. Application developers need a more flexible table. Now you can modify your application without having to create code every time you want to add or change the functionality.

How overrides work in the new tables

Developers typically use the ServiceNow System Property [sys_properties] table to create various functions in applications. If you wanted to develop an application to behave differently in different domains, you'd have to customize it yourself.

In the Paris release, the new Application Property [sys_application_property] table simplifies that customization. Instead of going directly to the System Property table for a value, the application property table goes to the System Application table first. This new table now stores the logic that you require to configure your application. If it finds a property in the new table, it uses that content. If there is no information in that table, it moves on to the base system properties table.
When you configure support for domain separation, you can add domain logic to this new Application Properties table. This table can contain properties that don't exist in the System Properties table. Or you can add properties to the configuration table that can override any property that you select in the System Properties table.

For example, let's say that you want to configure an application with a First day of the week feature. Sometimes, you might want the first day of the week to be Sunday. In other cases, you might want the first day of the week to be Monday. In the base system table, there might be only one Day 1 option, which is Sunday. With the new table, you can store another property, making Day 1, Sunday, and a child domain, Monday.

This figure shows how the system draws properties from the Application Property table before going to the System Property [sys_properties]

How scoped apps work in the new table

The new Application Properties table is supported from scoped applications. The application property name, similar to the system property name, is unique, which means that it is prefixed with the scope name if it is not global. The scope of an application impacts your configuration. The scope may determine which Day 1 is defined as Sunday and which as Monday. You can use the same property but customize it so that Day 1, Sunday is the parent domain and
Day 1, Monday is the child domain. In the new table, there is both a domain column and a scope column, so you can set these properties for each.

You can use the Expand Domain Scope view in the `sys_application_property_value` table to show all overrides, as shown in the following image.

![Application Property Values](image)

**Note:**

If those tables are not available, make sure that you have activated the Domain Extension Installer (com.glide.domain.msp_extensions.installer) plugin.

### New application property tables

The new System Application Property `[sys_application_property]` table contains these fields:
• sys_application_property table
  • name
  • description
  • type (choice of string, true|false, integer, time zone, color, and so on)
  • default_value
  • property (ref to sys_properties)
  • usage_notes
  • read_roles
  • write_roles
  • unique key: (name)

The new System Application Property Value [sys_application_property_value] table contains these fields:
• sys_application_property_value table
  • sys_application_property (ref to sys_application_property)
  • sys_domain
  • sys_overrides
  • value
  • unique key: (sys_application_property, sys_domain)

**New APIs**

The new APIs are also supported in scoped apps. Domain-separated application properties have distinct APIs. The GlideApplicationProperty API has two new scriptable methods, available in both global and scoped applications. See GlideApplicationProperty - Scoped, Global to learn more about these new APIs.

**Domain Migration Tool**

Use the Domain Migration Tool to move a customer from a domain-separated environment to their own dedicated instance. After migration, the new instance is not domain separated.

**Domain Migration Tool plugin**

The Domain Migration Tool plugin (com.glide.domain.migration_tool) simplifies the task of moving a customer from a domain-separated environment to a more flexible dedicated instance. Customers may want to migrate to a separate instance to take greater advantage of the Now Platform capabilities.

You must request a cloned instance and request activation of the Domain Migration Tool plugin before you can use it.

The Domain Migration Tool runs only if both data and process separation are enabled in the domain-separated instance:
• The glide.sys.domain.partitioning data property must be set to true.
• The glide.sys.comain.delegated_administration process property must be set to true.

**What the migration tool does**

• Automates much of the migration process, especially cleaning up data
• Migrates the domain-separated instance to a new non-domain-separated instance
• Deletes data from the non-domain-separated instance
**Note:** The tool doesn't delete data that is global, in the target domain, or in additional data domains (if specified).

- Collapses process data, or if unable to collapse deletes process data
- Keeps process records that are visible to the target domain
- Updates the sys_choice, sys_ui_list, and sys_ui_related_list special tables
- Cleans up records added by domain separation plugins:
  - Business rules
  - UI actions
  - Scheduled jobs
  - Installation exits
  - Navigation modules
- Disables domain separation and removes domains from the cloned instance:
  - Sets these properties to `false` in the cloned instance:
    - `glide.sys.domain.partitioning`
    - `glide.sys.domain.delegated_administration`
    - `glide.sys.domain.enabled`
  - Deletes all domains except the target domain and any additional specified data domains
- Updates the `Status` field in the domain_migration_tool_status table
  
The `Status` is `Finished` when the tool completes the process.
- Logs progress and status to syslog_domain
  
The source is `MigrationTool` for all log entries associated with migration.
  - Logs each data table and how many data tables remain
  - Logs each process table and which domain’s records are currently being inactivated or deleted

### What the migration tool doesn't do

- Clone the instance
  
  You must request Support to clone the instance for you before you can use the tool.
- Create another domain-separated instance
- Manage data in the source domain-separated instance
- Migrate records (data or process) if either data or process separation properties are disabled before you run the tool
- Alter any data on the source instance
- Delete data that is global, in the target domain, or in additional data domains (if specified)

### What you must do after running the tool

The Domain Migration Tool automates the removal of data outside the desired domains (the target domain, any additional data domains, and the global domain). You must evaluate all the remaining configurations to ensure that they are appropriate and work for your non-domain-separated instance. For example, if you had a business rule that set the domain field on records, you might want to disable this business rule, since it no longer serves a purpose.
Migrate a domain-separated instance to a dedicated instance
Move a customer from a domain-separated environment into their own dedicated instance environment.

Role required: admin

1. Navigate to **domain_migration_tool_status.list**.
2. Click **New**.
3. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target domain</td>
<td>Specify the domain you want to migrate. This is the domain used for both process and data. Only the target domain is retained, not any of its children, unless specified in the <strong>Additional data domains</strong> field.</td>
</tr>
<tr>
<td>Additional data domains</td>
<td>Optionally, specify any additional data domains you want to migrate. If you want to migrate the target domain and all of its children, you must specify all children.</td>
</tr>
</tbody>
</table>

4. Click **Submit**.
5. Open the form you just submitted.
6. Click **Start Migration**.
7. The **Status** is updated as the tool performs its functions.
   The **Status** is **Finished** when the migration is complete.

**Process administration**

Process administration allows administrators to set domain-specific policies.

The policies set lower in the domain hierarchy override policies set higher in the domain hierarchy. While in a domain, administrators can set domain-specific versions of these global policies and settings:

- Client scripts
- System policies
- Application and module names
- Application roles
- Module filters

**Warning:** All users with the admin role have special access to all system features, functions, and data because administrators can override ACL rules and pass all role checks. Grant this privilege carefully.

When users have the **admin** role, then all policies in the instance are available to them regardless of the assigned domain. They can enter a specific domain, and then only policies in that domain or higher are visible and processed during a relevant transaction. When an administrator modifies a policy that is in a higher domain or the global domain, the system automatically creates a new record for that administrator's current domain. It does not modify the original policy, application, or module record. This new record overrides the original.

To make changes to a policy in a lower-level domain, go into that domain and modify the policy. This approach creates the new policy record in your domain that overrides the original, higher-level policy record.

Do not make changes on the higher-level policy and then change the **Domain** field on that policy. This approach does not create a policy record in your lower-level domain, nor does it keep the policy record for the higher-level domain.
The `sys_overrides` field indicates that a policy, application, or module at a lower level in the hierarchy overrides a record at a higher level. The system automatically sets this field when an administrator attempts to modify a policy, application, or module that belongs to another domain higher in the hierarchy. Again, rather than actually changing the higher level record, the attempted update is changed into an insert, and the `sys_overrides` field is set to indicate the higher level policy, application, or module that is being overridden. Later when the records for a relevant transaction are loaded, the overriding domain-specific policy, application, or module is used instead of the original.

**Domains for process administration**

By default, process administration always uses the record's domain to determine what policies to apply.

The record's domain takes precedence over the user's domain. If there are no policies in the record's domain, delegated administration checks for policies in the next highest level of the domain hierarchy. The search for domain policies continues up the domain hierarchy until reaching the global domain. If there are no domain policies lower in the domain hierarchy, processes administration uses the policies for the global domain.

For example, Fred Luddy is a user in the Acme domain who can see records in the child domains of Acme: Atlanta, Acme: San Diego, and Acme: NY child domains. When he opens a record in the Acme: San Diego domain, process administration first checks for policies in the Acme: San Diego domain. If there are no policies at this level of the domain hierarchy, process administration checks for policies from the Acme domain. If there are no policies in the Acme domain, process administration uses the global domain policies as there are no other domains higher in the domain hierarchy.

**Sample process administration with domain specific applications**

The following example illustrates process administration with domain-specific applications and modules.

As the administrator of the Oceanic domain, David Loo decides to customize the Configuration application. To start with, David reviews the modules available in the Configuration application module.
Starting view of the Configuration application

David decides to rename the Configuration application to CMDB and to allow the inventory_admin role to see the application.
### Sample domain-specific changes to the Configuration application

Next, David decides to change the Incident application by activating the **Open - in "New" State** module and adding a new filter item to show open incidents in the Oceanic category.

**Sample domain-specific changes to the Open - "New" State module**

This creates a new module entry in the application rather than overwriting the existing module in the global domain.

If another administrator from another domain, such as Fred Luddy, logs in and looks at the Configuration application, the settings from the global domain appear.

David Loo’s view of applications
Enable verbose domain logging and debug messages

Domain log and debug messages allow you to troubleshoot domain configuration errors.

Role required: admin

1. In the Domain Separation Center, navigate to Domain Admin.
2. Click Configure Domain Center.
3. For Enable verbose domain logging, select the Yes check box.
4. Click Update.

View a real-time domain message

You can view real-time domain messages from the system logs.

Role required: admin

1. Enable verbose domain logging: Navigate to Domain Admin > Domain Separation Center > Configure Domain Center > Enables detail domain logging > Yes (or set property glide.sys.domain.verbose to True).
2. Navigate to System Diagnostics > Session Debug > Enable All. Because this is a real time review, there is no need to let the debug session run for a time before checking the log files.
4. Search for the text Query against table.

This query finds log messages in this format:

```
08:36:43.974: [Domain Paths] Query against table incident restricted by domain values [Database Atlanta[db53580b0a0a0a6501aa37c294a2ba6b], Database[287ee6fea9fe198100ada7950d0b1b73],
```
In this example, the user viewing the Incident table only saw records that matched the Database Atlanta, Database, Database San Diego, global, and NY DB domains.

**View a historical domain message**

You can view historical domain messages in the log file to troubleshoot domain separation issues.

Role required: admin

1. Enable verbose domain logging: Navigate to **Domain Admin > Domain Separation Center > Configure Domain Center > Enables detail domain logging > Yes** (or set property `glide.sys.domain.verbose` to `True`).
2. Navigate to **System Diagnostics > Session Debug > Enable All**.
3. Let the debug session run for a time period, such as a day, before checking the log files.
4. Navigate to **System Logs > Utilities > Node Log File Download**.
5. Open the record for the day you want to view. Log files use the naming format `localhost_log.<yyyy-mm-dd>.txt`.
6. Click the **Download** log related link.
7. Open the downloaded log file in a text editor and search for log messages with the following format:

   ```json
   Query against table incident restricted by domain values [global, Software[8a4dde73c6112278017a6a4baf547aa7]]
   ```

   In this example, a user only saw records from the Incident table that matched the global and Software domains.

**Troubleshoot domain separation errors**

If you encounter domain separation issues, review this list of solutions.

<table>
<thead>
<tr>
<th>Error or symptom</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>A domain sys_id points to a non-existent domain</td>
<td>This error occurs when a data record, such as a user or task record, has a <code>sys_domain</code> column value whose <code>sys_id</code> does not exist in the current domain table. The domain <code>sys_id</code> could have been accidentally deleted or it could refer to a previous domain table if you changed the domain table. To fix the error, open a list for the table containing the error, filter on the invalid <code>sys_domain</code> value. Then, either manually enter the correct <code>sys_domain</code> value or remove it.</td>
</tr>
</tbody>
</table>

**Note:** You can have invalid domain `sys_ids` in any table that references the domain table. For example, invalid domain IDs can occur in the User Visibility Domain `[sys_user_visibility]`, Group Visibility Domain `[sys_user_group_visibility]`, and Contained Domain `[domain_contains]` tables.

<table>
<thead>
<tr>
<th>Error or symptom</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>A domain path or domain number sys_id points to the wrong domain</td>
<td>This error occurs when a domain number or domain path query is out of sync with the actual domain name. This error can occur with domain numbers when adding domains requires renumbering or during the conversion from domain numbers to domain paths. To fix the error, check the results in the Domain Separation Center. If the error persists, you can manually edit the value for the <code>sys_domain_path</code> or <code>sys_domain_number</code> columns to point to the proper domain.</td>
</tr>
<tr>
<td>The domain tree structure is corrupt</td>
<td>This error occurs if there is a series of domain contains relationships that create an infinite loop among domains. To fix the error, open a list for the domain table and manually edit the domain contains values to not form a loop.</td>
</tr>
</tbody>
</table>

**Domain Separation Center**

Audit your domains regularly to reveal problems.

**What is the Domain Separation Center?**

The Domain Separation Center is a dashboard where you can schedule and configure audits for all of the domains stored in your domain_audit_definition table. The dashboard enables you to review audit results and dig deeper into domain errors and warnings. You can find the Domain Separation Center dashboard at `<ServiceNow-instance-name>/domaincenter`.

The Domain Separation Center provides many audits. You cannot create your own. You can, however, configure how often they run. Audits run on all of the domains stored in the domain_audit_definition table.
Configure audits

You can configure whether an audit is active and how frequently it runs.

1. In the Domain Separation Center, click **Configure Audits**.

   The **Configure Audits** page displays.
2. Configure each audit you want to be active. Audits are inactive by default.
   a. Click an audit.
   b. Click the Active box to activate the audit.
   c. Specify how often the audit runs in the Frequency field.
      The Domain Separation Center runs all audits marked with the same frequency at the same time. Do not select Daily for audits run on large tables.
   d. Repeat these steps for each audit you want to activate.

3. Click Save.

Schedule audits

You configured one or more audits to run daily, weekly, or monthly. The scheduler specifies what days and times to run those audits. All audits with the same scheduling frequency run sequentially staring at the time you configure.

1. In the Domain Separation Center, click Audit Schedules.
   The Audit Schedule page displays.
2. Configure the audit schedules.
   a. Click a schedule name.
   b. Specify the time of day to run the audit.
      Time units are 24 hour clocks, that is, 14 equals 2 PM.
   c. For weekly schedules, select the day of the week to run the audit, where 1 is Sunday.
   d. For monthly schedules, select the day of the month to run the audit.
   e. Repeat the procedure for the other schedules.
3. Click Save to save the configuration changes.
4. Click Execute Now to run all of the audits scheduled to run at the frequency shown at the top of the right pane, for example, if the pane title is, Domain Audit Schedule - Daily, all of the audits that run daily are run.

To see the status of a running audit, in the Domain Separation Center, click the number in the Running Audits box.

Execute audits immediately

Audits typically run as scheduled. You can, however run all audits on command.

1. In the Domain Separation Center, click Audit Schedules.
   The Audit Schedule page displays.
2. Click the name of the audit schedule you want to run, for example, daily, weekly, or monthly.
3. Click Execute Now.

To see the status of a running audit, in the Domain Separation Center, click the number in the Running Audits box.
Configure the Domain Separation Center

1. In the Domain Separation Center, click **Configure Domain Center**.

2. On the **Configure Domain Center** page, for **Enables detail domain logging**, select **Yes** to store detailed logs that help diagnose domain-related issues. Detailed logging might cause performance issues. These logs refer to server-side logs in the syslog_domain table. For information about viewing the logs, see View audits with warnings and failures.

3. In the slushbucket, move into the **Selected** column all of your large tables.

   Daily audits should not run on large tables. Grayed-out table names in the **Selected** column are large and cannot be moved to the **Available** column.

4. Click **Update**.

View audits with warnings and failures

On the dashboard, **Errors** and **Warnings** provide detailed information about audits that encountered problems. Logs related to domain separation reside on your server in the syslog_domain table.

1. In the Domain Separation Center, click the number in the **Errors** or **Warnings** box.

   The **Errors** or **Warnings** page displays, respectively.

2. Click one of the audits in the list.

   The page displays detailed information about problems with the audit you selected. The messages in **Audit Result Details** refer to values in the syslog_domain table for table audits that revealed errors or warnings.

3. To see the logs on the server that provide information about warning or error audits:

   a. Copy the **Detail ID** value in the left panel of a warning or error.
   
   b. In the Filter Navigator of HI, enter **syslog_domain.do**.

      The Domain Log page displays.

   c. In the **Source** search field, enter `=<Detail-ID>` (no space after the equals sign), for example, `=f6a00fd29a85b30a9503a81b9169678`.

      The Domain Log page displays only the logs related to the audit with the Detail ID you specified. Each row in the table specifies a different record the audit found problems in. Notice that the **Message** field on this page matches the values displayed in the Domain Service Center's **Message** column. The format of the message matches the audit type.

4. Click:

   - **Rerun Audit**—Rerun an audit to see if it still encounters a warning or error.
   - **Deactivate Audit**—Inactivate an audit.
   - **Copy Details**—Copy audit details to the clipboard.

View running and pending audits

Active audits periodically run or are queued to run, as scheduled. You can view their status as they run.
1. Click the number in the **Running Audits** box to view audits that are currently running or pending running.
   
   The **Running Audits** page displays.

2. Click an audit for more information about it.

### View inactive audits

1. Click the number in the **Inactive Audits** box.
   
   The **Inactive Audits** page displays all of the audits that are currently deactivated.

2. Click one of the audits to display more information about it.

3. To activate an audit, click the **Active** box and use the **Frequency** field to specify how often the audit runs.

4. Click **Update**.

### Configure the Domain Separation Center

Specify which tables in domains are large and whether you want detailed logging.

Role required: admin

You can schedule audits to run on a daily, weekly, or monthly basis. Audits run on very large tables can take a significant amount of time. For that reason, we advise you not to run audits daily on large tables. Starting a new audit on one that is taking more than a day to run can have negative consequences.

Detailed logging can provide greater insights into problems found during audits. Detailed logging, however, may hurt performance.

1. In the Domain Separation Center, click **Configure Domain Center**.
   
   The Configure Domain Center page appears.

2. For **Enables detail domain logging**, select **Yes** to store detailed logs that help diagnose domain-related issues. Detailed logging might cause performance issues.
   
   These logs refer to server-side logs in the syslog_domain table. For information about viewing the logs, see the **View audits with warnings and failures** section below.

3. In the slushbucket, move all of your large tables into the **Selected** column.
   
   Daily audits should not run on large tables. Grayed-out table names in the **Selected** column are large and cannot be moved to the **Available** column.

4. Click **Update**.

5. If you have very large tables that should never be audited, set the **com.glide.domain.audit.big_tables.additional** system property to a comma-separated list of those table names.

### Configure audits

You can configure whether an audit is active and how frequently it runs.

Role required: admin

1. In the Domain Separation Center, click **Configure Audits**.
   
   The Configure Audits page appears.

2. Configure each audit you want to be active. Audits are inactive by default.
   
   a) Click an audit.

   b) Click the **Active** check box to activate the audit.
c) Specify how often the audit runs in the **Frequency** field.

The Domain Separation Center runs all audits marked with the same frequency at the same time. Do not select **Daily** for audits run on large tables.

d) Repeat steps a-c for each audit you want to activate.

3. Click **Save**.

**Schedule audits**

Specify the time and day that audits are run.

Role required: admin

You configured one or more audits to run daily, weekly, or monthly. The scheduler specifies what days and times to run those audits. All audits with the same scheduling frequency run sequentially starting at the time you configure.

1. In the Domain Separation Center, click **Audit Schedules**.

   The Audit Schedule page appears.

2. Configure the audit schedules.

   a) Click a schedule name.

   b) Specify the time of day to run the audit.

   Time units use the 24-hour clock (that is, 14 equals 2 PM).

   c) For weekly schedules, select the day of the week to run the audit, where 1 is Sunday.

   d) For monthly schedules, select the day of the month to run the audit.

   e) Repeat the procedure for the other schedules.

3. Click **Save** to save the configuration changes.

4. Optional: Click **Execute Now** to run all the audits scheduled to run at the frequency shown at the top of the right pane.

   For example, if the pane title is **Domain Audit Schedule - Daily**, **Execute Now** immediately runs all the audits that are scheduled to run daily.

To see the status of a running audit, in the Domain Separation Center, click the number in the **Running Audits** box.

**Execute audits immediately**

Audits typically run as scheduled. You can, however, run all audits on command.

Role required: admin

You cannot run individual audits manually. You can, however, run all audits that are configured with the same scheduling frequency. For example, you can run all audits that are configured to run daily.

1. In the Domain Separation Center, click **Audit Schedules**.

2. Click the name of the audit schedule you want to run (for example, daily, weekly, or monthly).

3. Click **Execute Now**.

To see the status of a running audit, in the Domain Separation Center, click the number in the **Running Audits** box.

**View audits with warnings and errors**

The Domain Separation Center provides details about audit errors and warnings.

Role required: admin
On the Service Domain Center dashboard, **Errors** and **Warnings** provide detailed information about audits that encountered problems. Logs related to domain separation reside on your server in the syslog_domain table. Errors are issues that require immediate attention. Warnings do not lead to failures but present best practices, for example, not making the domain name too long.

1. In the Domain Separation Center, click the number in the **Errors** or **Warnings** box. The **Errors** or **Warnings** page appears.
2. Click one of the audits in the list. The page displays detailed information about problems with the audit you selected. The messages in **Audit Result Details** refer to values in the syslog_domain table on the server for table audits that revealed errors or warnings.
3. To see the logs on the server that provide information about warning or error audits:
   a) Copy the **Detail ID** value in the left panel of a warning or error.
   b) On the instance running the Domain Separation Center, in the **Filter navigator**, enter `syslog_domain.list`. The Domain Log page appears.
   c) In the search field of the **Source** column, enter `=<Detail-ID>` (no space after the equals sign), for example, `=f6a00fd29a85b300a9503a81b9169678`. The Domain Log page displays only the logs related to the audit with the Detail ID you specified. Each row in the table specifies a different record the audit found problems in. Notice that the **Message** field on this page matches the values displayed in the **Message** column of the Domain Service Center. The information included in the message matches the audit type.

4. Optionally, click:
   - **Rerun Audit** — Rerun an audit to see if it still encounters a warning or error.
   - **Deactivate Audit** — Inactivate an audit.
   - **Copy Details** — Copy audit details to the clipboard.

### View running and pending results

You can view running and pending audits to see their status.

Role required: admin

Active audits periodically run or are queued to run, as scheduled. You can view their status as they run.

1. Click the number in the **Running Audits** box to view audits that are currently running or pending running. The Running Audits page appears.
2. Click a running or pending audit to see information about it.

### View inactive audits

You can view all inactive audits in one place and optionally activate them.

Role required: admin

1. Click the number in the **Inactive Audits** box. The Inactive Audits page displays all the audits that are currently deactivated.
2. Click one of the audits to display more information about it.
3. Optional: Activate an audit by clicking the **Active** box and specifying how often the audit runs in the **Frequency** field.
4. Click **Update**.
Upgrades and conversions

The ServiceNow platform includes tools to help you during and after an upgrade, and also allows you to convert a ServiceNow Express instance to a ServiceNow Service Management enterprise platform.

See also

Upgrade to .

The upgrade process moves your instance to a new ServiceNow release version. Understand the difference between upgrading and patching, release definitions, rollback and backup options, and how to test your non-production and production instance upgrades.

Upgrade History module: Track every upgrade

The Upgrade History module tracks every upgrade made to an instance. Administrators can use the module to resolve upgrade conflicts and optionally to revert customizations to base system versions to take advantage of new features.

An upgrade history record is created for each upgrade that is run. To view an upgrade history record, navigate to System Diagnostics > Upgrade History and click the upgrade.

Note: Debug Upgrade provides detailed debugging output for transactions containing artifacts affected by the most recent upgrade, and is designed to assist in upgrade error resolution. See Debug upgrade.

Note: The Payload and Payload Hash fields have been removed from the Upgrade History record in a previous release.

Upgrade History record

<table>
<thead>

<td>Number of Upgrade Detail records for which the value of the disposition is updated, and the value of changed is equal to false. This does not appear on the form by default.</td>
</tr>
<tr>
<td>Skipped and different</td>
<td>Number of Upgrade Detail records for which the value of the disposition is skipped, and the value of changed is equal to true. This does not appear on the form by default.</td>
</tr>
<tr>
<td>Skipped and not different</td>
<td>Number of Upgrade Detail records for which the value of the disposition is skipped, and the value of changed is equal to false. This does not appear on the form by default.</td>
</tr>
</tbody>
</table>
**Review Skipped Records form section**

The Skipped Changes to Review related list displays each record that was skipped during the upgrade process. Use the list to review the reason for each skipped record in the list and then either merge your customization or revert your customization to the base system.

**Skipped Changes to Review related list**

To prevent your customizations from being overwritten during system upgrades, the upgrade process skips (does not apply the update to) objects that have been customized. To assist you in tracking and resolving skipped update records that need review, Skipped Changes to Review lists all updates skipped during the upgrade process.

By default, the list is filtered by Disposition Skipped Error, Disposition Skipped Manual Merge, Disposition Skipped, or Disposition Skipped (second pass), and the resolution status is either empty or not reviewed.

Navigate to **System Diagnostics > Upgrade History** to view the Skipped Changes to Review related list.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
### Field | Input Value
--- | ---
**Claim Status** | Outcomes:
- **N/A**: There are no claims on the record (no need to review)
- **Won conflict**: The loading application loaded the file but is in conflict with the previously loaded file. Recommendation: Review the two versions of the file to confirm your intended outcome.
- **No conflict**: There may be one or more applications loading but there is no conflict. However, it is still good to review the outcome to see if it's what you intended.
- **Lost conflict**: The file was not loaded because another application has a better claim on the file. Recommendation: Review the two versions of the file to see which should be loaded (or if they should be merged).

**Priority** | Relative importance of the conflict that caused the skip based on the following criteria:
- **1**: UI pages, UI macros, and more
- **2**: Business rules, security ACLs, and more
- **3**: Reports and more
- **4**: Form sections, choice sets, and more
- **5**: Everything else

**Resolution** | • Not reviewed: Records which have not been reviewed
- **Reviewed**: Records which have been reviewed
- **Reviewed and Merged**: Records which have been reviewed and have both the old and new changes
- **Reviewed and Retained**: Records which have been reviewed and have retained the updates from the latest upgrade
- **Reviewed and Reverted**: Records which have been reviewed and have reverted changes to the base system

**Comment** | During the process of resolving a skipped update, you have the option to add a **Comment** to any record. For example, the comment might explain the action that you took to future reviewers.

**Target name** | Name of the record corresponding to the current file.

**Plugin** | Plugin that contains the record.

**Type** | Current file type (such as Business Rule or UI Policy).

**Table** | Table that contains the record.

---

**Resolve a skipped update and set a resolution status**

To prevent your customizations from being overwritten during system upgrades, the upgrade process skips (does not apply the update to) objects that have been customized. One of your responsibilities as the administrator is to resolve each skipped update after an upgrade.

Role required: admin

You resolve an update by either retaining the customization or (when the software upgrade contains a feature that you would like to implement) by merging or overwriting the customization with the base system update.
When an object is customized, the system adds a corresponding record to the Customer Updates [sys_update_xml] table and then maintains current version information for all customized objects. The upgrade process skips changes to objects that have a current version in the Customer Updates table. When you follow the procedure, you perform one of the following actions:

- Retain (keep) a customization with no changes
- Retain a customization by merging changes from the updated object
- Revert a customized object to the updated version (that is, overwrite the customization)
- Review the skip and perform no action on the object

1. Navigate to **System Diagnostics > Upgrade History**.
2. Select the desired software version.
3. In the **Skipped Changes to Review related list**, select the update record to resolve.

4. Review the list of changes. For text fields, you can click in the field to open the Diff/Merge tool. Review the differences. Click a text box to view and edit the detailed differences.
5. Perform one of the following actions. You have the option to add a **Comment** to any record, for example, to explain the action to future reviewers.

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Retain the customized record as is and do not update it.</td>
<td>After reviewing the changes, set Resolution Status to Reviewed and Retained.</td>
</tr>
<tr>
<td></td>
<td>The record moves from the Skipped Changes to Review to Skipped Changes Reviewed related list.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Retain the customization by merging changes from the updated object.</th>
<th>a. Click Resolve Conflicts to navigate to the Resolve Conflicts form.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>b. Review the differences.</td>
</tr>
<tr>
<td></td>
<td>c. To merge a field:</td>
</tr>
<tr>
<td></td>
<td>• Click the right-arrow button for the field.</td>
</tr>
<tr>
<td></td>
<td>• Click a text box to view and edit the detailed differences.</td>
</tr>
<tr>
<td></td>
<td>• When you have merged all appropriate fields, click Merge.</td>
</tr>
</tbody>
</table>

After merging the customization changes:

- The Resolution Status changes to Reviewed and Merged.
- The record moves from the Skipped Changes to Review to the Skipped Changes Reviewed related list.
<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
</table>
| Discard the customization and update the record to match the base system for this upgrade. | After reviewing the changes, click **Revert to Base System**.  
  - The **Disposition** changes from **Skipped** to **Reverted**.  
  - The **Resolution Status** changes to **Reviewed and Reverted**.  
  - The system creates a Customer Update record.  
  - The record moves from the Skipped Changes to Review to the Skipped Changes Reviewed related list. |

**Note**: At any time after you revert a customization, you can click **Reapply Changes** to reapply the customization (undo the revert).

| Review the skip and perform no action on the object. | After reviewing the changes, set **Resolution Status** to **Reviewed**. The record moves from the Skipped Changes to Review to the Skipped Changes Reviewed related list. |
| Leave on the skipped list for a later decision, and note that you have not reviewed the record. | From the **Resolution** list, choose **Not Reviewed** to defer the decision on how to handle this conflict. The record stays on the Skipped Changes to Review related list. |

6. Click **Update**. Repeat the process to resolve each update record in the list.

Only skipped updates with a **Resolution Status** of **Not Reviewed** or a resolution set appear in the Skipped Changes to Review related list. Any action you take that changes the **Resolution Status** to a value other than **Not Reviewed** or **--None--** removes the skipped update from the list and moves it to the Skipped Changes Reviewed related list.

**Skipped Changes Reviewed related list**

Skipped Changes Reviewed lists update records that previously appeared on the Skipped Changes to Review related list and have been reviewed. When you select a skipped record to review and set a **Resolution Status** to a value other than **Not Reviewed**, the update record moves to the Skipped Changes Reviewed related list.

Navigate to **System Diagnostics > Upgrade History** to view the Skipped Changes Reviewed related list.

<td>• Not Latest: The system applied a change, but this change was overwritten later during the same upgrade.</td>
</tr>
</tbody>
</table>
### Revert a customization

To prevent customizations from being overwritten by system upgrades, the upgrade process automatically skips changes to objects that have been customized. You may want to overwrite your customizations when a software upgrade contains a feature that you would like to implement.

**Role required:** admin

To identify customized objects, the system adds a corresponding record in the Customer Updates [sys_update_xml] table. The table maintains the current version information for all objects that have been customized. The upgrade process skips changes to objects that have entries in the table. The upgrade process does not skip objects if only excluded fields have changed.

1. Navigate to **System Diagnostics > Upgrade History**.
2. Select the desired software version.
3. Filter the Upgrade Details related list by **Disposition is Skipped**.
4. Optional: Add another filter condition for **Changed is True** to return only the objects that have changed since the last upgrade.
5. Select the update record to implement.
   - The **File differences** field displays a side-by-side comparison of the customization and the default version. Deletions are highlighted in red, additions in green, and modifications in yellow.
6. Click **Revert to base system** to overwrite your customized object with the system default version.
   - The **Disposition** changes from **Skipped** to **Reverted**.
   - After you revert a customization, you have the option to click **Reapply Changes** to reapply your customizations (undo the revert).

## Changes Applied related list

Changes Applied lists all changes that were applied in this upgrade.

This list is ordered by priority and displays Upgrade Detail records for this upgrade that have a disposition of Updated, Updated (second pass), Inserted, Inserted (second pass), Deleted, Deleted (second pass), and for which the changed flag is true for all of the dispositions.

Navigate to **System Diagnostics > Upgrade History** to view the Changes Applied related list.

### Upgrade Monitor module: Upgrade an individual instance

The Upgrade Monitor helps you upgrade an individual instance. You can monitor the progress of an upgrade and resolve conflicts between the upgrade and customizations.

#### Set up

- Upgrade Monitor overview

#### Use

- Monitor an upgrade to an instance
- Process the skipped records list
- Resolve conflicts for an individual record

#### Troubleshoot and get help

- Debug upgrade for last upgrade session.
- Ask or answer questions in the Developer Community
- Search the Known Error Portal for known error articles
- Contact Customer Service and Support

---

### Upgrade Monitor overview

The Upgrade Monitor helps you upgrade an individual instance. You can monitor the progress of an upgrade and resolve conflicts between the upgrade and customizations.

### Set up for the Upgrade Monitor

In Quebec, the Upgrade Monitor is installed by default.

If you log in with the admin role while an upgrade is underway, the system automatically displays the Upgrade Progress screen. If no upgrade is in progress, you can navigate to **System Diagnostics > Upgrade Monitor**.

### How the Upgrade Monitor fits into the upgrade process

**Note:** For detailed information about the upgrade process, see Upgrade your instance.

The Upgrade Monitor concerns only part of the larger upgrade process:

1. Clone the production instance to a test instance and a non-production instance.
2. Apply the upgrade to the non-production instance.

3. On the upgraded non-production instance, process the skipped list.

4. Test the non-production instance to confirm that the instance still works and performs adequately. Compare to benchmark data from pre-upgrade production instance.

5. Apply the upgrade to the test instance. Import the update sets created on the non-production instance when you processed the skipped list. Repeat the testing to make sure that the process is working.

6. Apply the upgrade to the production instance. Import the update sets created on the non-production instance when you processed the skipped list. Test to confirm that the instance works and performs adequately.

Within this larger process, the Upgrade Monitor helps you upgrade individual instances:

- during the upgrade, it shows where in the process the system is
- after the upgrade, it reports what the upgrade did and for how long
- as you upgrade the first non-production instance, it helps you resolve conflicts between customizations and changes that are part of the upgrade
- on non-production instances, it provides information that can help you estimate how long the upgrade takes on the production instance.

**Note:** Debug Upgrade provides detailed debugging output for transactions containing artifacts affected by the most recent upgrade, and is designed to assist in upgrade error resolution. See Debug upgrade.

**Monitoring an individual instance as it upgrades**

While the upgrade is in progress the Upgrade Progress shows what the upgrade process has done, what it is doing, and what remains to be done.

When the upgrade completes, the system displays the Upgrade Summary Report. The Upgrade Summary Report provides information about conflicts between customizations versus the upgrade and provides a link to reconcile these conflicts. For information about understanding and resolving these conflicts, see Process the skipped records list.

When you upgrade a non-production instance, the Upgrade Summary Report can help you estimate how long the same upgrade takes on a production instance. For details about the elements on this report and how to use this information, see Upgrade Details form.

**Resolving conflicts**

To prevent losing customizations, the system skips upgrading records you have customized and provides you with a list of these skipped records.

As you upgrade your first non-production instance, go through the Skipped Changes to Review related list and resolve these conflicts. The system records the changes you make during this process in update sets.

You do not need to reconcile the skipped list on any instances you later upgrade. Instead, you can apply the upgrade then import the update sets containing your changes.

For details on reconciling conflicts, see Process the skipped records list.

**Factors affecting upgrade duration**

Various factors affect how long the system takes to perform an upgrade. The Upgrade Monitor can help you understand those factors and estimate how long the upgrade to your production instance takes.

Many factors can affect the duration of the upgrade process:
• The number of records in the database
• The number of customizations in the database
• The number of nodes in the instance
• The size of tables in the instance that require a schema-change in the instance.
• The number of fix scripts required and the size of the tables those fix scripts manipulate.

Upgrading a non-production instance can help you estimate how long the upgrade takes on production, but differences between the instances can significantly affect the duration:

• When you cloned the production instance to the non-production instance, you may have clone-excluded some tables. This reduces the size of the database and makes the non-production instance upgrade faster than the production instance.
• The production instance may have more memory and processing power.
• The production instance may have more nodes than the non-production instance.

After upgrading the first non-production instance, examine the Upgrade Summary Report for data to help estimate the impact of these factors.

Note: The performance of the upgrade engine is significantly enhanced and optimized for all types of upgrades (in-family, and family-to-family) in Madrid and later releases.

Upgrade Monitor

When an upgrade is not running, the Upgrade Monitor displays information about the next check for an available upgrade.

The Upgrade Monitor displays the next date and time when the system will check for an available upgrade.
To check immediately for an available upgrade, click **Check Now**.

If one or both of the triggers for upgrading the system ('Check distribution for possible upgrade' and 'Check database for possible upgrade') have been customized or are missing, the Upgrade Monitor displays a warning and provides a button for resolving the issues.

**Note:** If your instance is self-hosted (not hosted by ServiceNow) this message may not necessarily indicate a problem. If you have customized or disabled the upgrade job and want to keep that customization or disabled state, do not click the button to fix the upgrade issue.

**Upgrade Monitor with Issue Detected**

To resolve the issues with the upgrade jobs, click **Fix Upgrade Jobs**. This action reverts both upgrade triggers ('Check distribution for possible upgrade' and 'Check database for possible upgrade') to their base versions.

**Note:** 'Upgrade' job has been renamed to 'Check distribution for possible upgrade' starting Paris. 'Check Upgrade Script' job has been renamed to 'Check database for possible upgrade' starting Paris.
Monitor an upgrade to an instance

While the system is upgrading an instance, you can monitor its progress with the Upgrade Monitor. When the upgrade is done, you can view a summary of the results on the Upgrade Summary Report.

1. If necessary, navigate to System Diagnostics > Upgrade Monitor.
   - When an upgrade is in progress, the Upgrade Progress page shows its status.
2. Monitor the progress of the upgrade.
   - When the system finishes the upgrade, it displays the Upgrade Summary Report.

From the Upgrade Summary Report, resolve any conflicts that prevented the system from upgrading records.

Upgrade Progress

When an upgrade is underway, Upgrade Progress displays progress bars and other information to help monitor the process.
### Screen elements

<table>
<thead>
<tr>
<th>Screen element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Upgrade Progress</td>
<td>A progress bar depicting where the upgrade is in the overall process. The length of a section in the bar does not indicate the relative duration of that process.</td>
</tr>
<tr>
<td>Upgrade Progress: Upgrading Platform</td>
<td>The system is applying upgrades to elements that form the foundation of the platform.</td>
</tr>
<tr>
<td>Upgrade Progress: Updating Schema</td>
<td>The system is scanning the plugins to create a list of tables that require upgrading. This prevents the system from upgrading the same table multiple times.</td>
</tr>
<tr>
<td>Upgrade Progress: Loading Plugins</td>
<td>The system is loading both core and optional plugins. Some features require more than one plugin, so the number of plugins listed may not match the number of optional features installed.</td>
</tr>
<tr>
<td>Upgrade Progress: Completing</td>
<td>The system is upgrading components that need to be completed after the previous three stages are done.</td>
</tr>
</tbody>
</table>

**Note:** After the system finishes the Completing phase, it displays a separate screen showing Finalizing. The system tracks in update sets the changes made during the Upgrading Platform, Updating Schema, Loading Plugins, and Completing phases. It does not track changes made during Finalizing.

<table>
<thead>
<tr>
<th>Details</th>
<th>Shows the current activity, a progress bar for the current activity, and the file currently being updated.</th>
</tr>

**Node Upgrades**

![Node Upgrades](image)

The Node Upgrades section shows the status of the upgrade for each node in the instance. The color of the icon denotes the status, as illustrated by the legend (key) and to the right of the node icons. To see details about a node, position the cursor above the icon for that node. An arrow points to the node selected, and the information below the icons pertains to that node.

**Upgrade Summary Report: Node Upgrades**

The Node Upgrades section shows the status of the upgrade for each node in the instance. The color of the icon denotes the status, as illustrated by the legend (key) and to the right of the node icons. To see details about a node, position the cursor above the icon for that node. An arrow points to the node selected, and the information below the icons pertains to that node.
Schema Changes to Clone-excluded Tables

Upgrade Summary Report: Schema Changes to Clone-excluded tables

The Schema Changes to Clone-excluded Tables section shows a list of tables affected by the upgrade that were clone-excluded when you cloned the production instance to this instance. Because clone-excluded tables are empty, upgrading them takes less time than upgrading those same tables on the production instance. To estimate how much longer the production upgrade takes, note the size of the clone-excluded tables on the production instance.

Upgrade Summary Report: Top 10 Schema Changes by Duration

The Top 10 Schema Changes by Duration helps you understand which schema changes required the most time.

Process the skipped records list

If you customized or altered a record affected by this upgrade, such as a business rule or script, the upgrade generates a skip log record. You must resolve the differences between the upgraded and customized versions of the record by processing the skipped record list, or, in other terms, just processing the skipped list.

Role required: admin

Review the changes you made to baseline records, such as business rules and scripts, that appear on the skipped records list and revert to the baseline version if appropriate. Post-upgrade, thoroughly test all changes you made to these records.

1. If necessary, navigate to System Diagnostics > Upgrade Monitor.
   If the upgrade is still in progress, the system displays the Upgrade Progress screen. When the upgrade finishes, the system displays the Upgrade Summary Report.

2. After the system displays the Upgrade Summary Report, click the Click here link in the Skipped box.
   The system displays the System Upgrades form.

4. Click the row for the first record you want to reconcile.
   The system displays the Upgrade Details form for that record.
5. Evaluate how you want to resolve the conflict for this record and take the appropriate action:

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Retain the customized record as is and do not update it.</strong></td>
<td>After reviewing the changes, set Resolution Status to <strong>Reviewed and Retained</strong>. The record moves from the Skipped Changes to Review to Skipped Changes Reviewed related list.</td>
</tr>
</tbody>
</table>
| **Retain the customization by merging changes from the updated object.** | **a.** Click **Resolve Conflicts** to navigate to the Resolve Conflicts form.  
**b.** Review the differences.  
**c.** To merge a field:  
• Click the right-arrow button for the field.  
• Click a text box to view and edit the detailed differences.  
• When you have merged all appropriate fields, click **Merge**.  

After merging the customization changes:  
• The Disposition changes from **Skipped** to **Merged**.  
• The Resolution Status changes to **Reviewed and Merged**.  
• The record moves from the Skipped Changes to Review to the Skipped Changes Reviewed related list. |
| **Discard the customization and update the record to match the base system for this upgrade.** | After reviewing the changes, click **Revert to Base System**.  
• The Disposition changes from **Skipped** to **Reverted**.  
• The Resolution Status changes to **Reviewed and Reverted**.  
• The system creates a Customer Update record.  
• The record moves from the Skipped Changes to Review to the Skipped Changes Reviewed related list. |
| **Review the skip and perform no action on the object.** | After reviewing the changes, set Resolution Status to **Reviewed**. The record moves from the Skipped Changes to Review to the Skipped Changes Reviewed related list. |
| **Leave on the skipped list for a later decision, and note that you have not reviewed the record.** | From the Resolution list, choose **Not Reviewed** to defer the decision on how to handle this conflict. The record stays on the Skipped Changes to Review related list. |

- **Note:** At any time after you revert a customization, you can click **Reapply Changes** to reapply the customization (undo the revert).

- **Note:** The system tracks changes to records in an update set so you can apply these changes to another instance later. However, the system does not migrate the upgrade details records from one instance to the next. These records apply to a specific upgrade of a specific instance. If you want to preserve the Comments, Resolutions, or other information from the skipped list, export it from this instance.
6. In the **Comment** field, write the reasons for making your decision and other information you want to document.

7. Click **Update**.

   Post-upgrade, thoroughly test all changes you made to the records on the skipped record list.

**System Upgrades form**

When an upgrade is complete, the System Upgrades form displays key statistics about the upgrade and a related list of skipped records (the *skipped list*).

![](image)

<td>The total number of records the system inspected and/or processed for this upgrade.</td>
</tr>
</tbody>
</table>

### Resolve conflicts for an individual record

Reconcile differences between your customized record and the changes associated with the upgrade.

Role required: admin

1. From the Upgrade Details form for the record you are reconciling, click Resolve Conflicts.
   The system displays the Resolve Conflicts form, which highlights differences between the two versions of the record. The form displays information about the base system record on the left and the customized record on the right.

2. Compare the base system with the customized record for each field on this form. For non-script fields, edit the customized record on the right-hand side to include what you want from the base system and the customization.

3. If this record contains a script, check it for conflicts and resolve.
   a) Click inside the Script field.
      The system displays the Resolve Conflicts - Script form highlighting areas where the two versions of the script differ.
   b) Edit the right-hand side so that the script contains whichever content you want. To move a block of code from the left to right side, click the small arrows corresponding to that block in the middle column.
   c) Click OK.
      The system returns to the Resolve Conflicts form.

4. To save your changes to the record, click Save Merge.
   The system sets the Resolution for this record to Reviewed and Merged.
Upgrade Details form

From the Upgrade Details form, you can review an individual record affected by the upgrade and reconcile conflicts between the upgrade and customizations.

Upgrade Details form

Fields

<table>
<thead>
<tr>
<th>Screen element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>File name</td>
<td>The record the system has flagged as needing to be reconciled.</td>
</tr>
<tr>
<td>Screen element</td>

<td>-------------</td>
</tr>
<tr>
<td>Priority</td>
<td>The priority the system has assigned to resolving this conflict. Values range from one to five, with one representing the highest priority.</td>
</tr>
<tr>
<td>Comment</td>
<td>Comments to document your decisions about reconciling this record.</td>
</tr>
</tbody>
</table>
| Resolution     | How you elected to resolve this conflict:  
|                | • **Not Reviewed**  
|                | • **Reviewed** - reviewed but no action yet taken  
|                | • **Reviewed and Merged** - made changes to the record to reconcile the customized and upgraded versions  
|                | • **Reviewed and Retained** - left customizations in place without update from upgrade  
|                | • **Reviewed and Reverted** - customizations discarded, record updated according to upgrade  
|                | For more information, see [Process the skipped records list](#). |
| Disposition    | Action performed on this file during the selected upgrade:  
|                | • Inserted: The system inserted a new record.  
|                | • Updated: The system updated this record.  
|                | • Deleted: The system deleted this record.  
|                | • Skipped: The system did not change this record in order to preserve customizations.  
|                | • Reverted: This record was reverted to the base version.  
|                | • Table not found: The system could not find the table that contains this record.  
|                | • Unchanged: The system did not change this record because the baseline component has not changed since the last release.  
|                | • Skipped Manual Merge: The system did not change this record because updating it requires manual intervention.  
|                | • Skipped Apply Once: The system skipped this record because it had already applied an update from an xml file in the apply once folder.  
|                | • Not Latest: The system applied a change, but this change was overwritten later during the same upgrade. |
| Type           | The record type, for example *Script include*. |
| Target name    | Name of the skipped record, if applicable. |
| Update set     | Unused. |
| Plugin         | The plugin containing this record. |
| Table          | The table containing this record. |

### Fields

The fields this form displays depend on the type of record you are reconciling.

The left column shows the records fields in the base system, including the proposed changes that are part of the upgrade. The right column shows the fields for your customized record.
Debug upgrade

Diagnose and resolve issues you suspect may have resulted from the most recent upgrade by enabling upgrade debugging during a user session. Each transaction lists whether an artifact was skipped, customized by the customer, or modified by ServiceNow during the last family-to-family or patch version upgrade.

Administrators and technical personnel can use this output as an adjunct to the Upgrade History and Upgrade Monitor modules. Debug Upgrade is a component of standard ServiceNow session debugging. You enable Debug Upgrade, process a transaction (for example, load a form), then analyze the reported upgrade information. See Session debug.

Reported debug information

Debug Upgrade includes several expandable sections:

- Skipped During Last Upgrade
- Customer Customized
- ServiceNow Modified During Last Upgrade

These sections serve as a starting point for diagnosing when a function or artifact does not operate as expected after an upgrade. Each listing sorts by the dates the artifacts were processed, with the most recent appearing first. Expand the appropriate section, and click the name of a listed artifact to view the underlying artifact record. These records include update version history, which represents the state of a customizable object at specific times. See Version records.

The listed artifacts may require some kind of possible user intervention or action. Using underlying artifact detail, you can determine:

- what artifacts have changed?
- what artifacts have not been changed that would or should have?
- what changed artifacts were missed?
- what artifacts operate differently than expected (if referencing something that has changed during last upgrade)?

Depending on the answers to these questions, you may have to modify the selected artifact so it works in the way you expect. Conversely, you might simply accept the new updates made to the artifact, and its changed functionality.

Skipped during last upgrade

Lists artifact records that were skipped during the last upgrade that also ran during the last transaction. These records are standard objects that missed changes from ServiceNow because they were modified at some point by a user. See Resolve conflicts for an individual record.

Customer customized

Lists all artifact records that were customized at some point by users that also ran during the last transaction. This listing is not strictly related to the actual activities performed during the last upgrade session. The listing does include the records that appear under Skipped During Last Upgrade. However, not all records that appear in the Customer Customized list are included in Skipped During Last Upgrade.

Note: Customizations that you designate for replacement during upgrades, by setting the Replace on Upgrade field in the customization record to true, do not appear on the Customer Customized section list.

While this listing is not directly related to the activities performed during the last upgrade, it may be worthwhile to look at individual customization records listed on it. Some of the listed customization records may be referencing...
other records changed or skipped during upgrade. The activities performed during the last upgrade may have an impact on, or affect these relationships.

**ServiceNow modified during last upgrade**

Lists all standard (non-customized) artifact records modified by ServiceNow during the last upgrade that also ran during the last transaction.

**Enable and use debug upgrade**

Enable Debug Upgrade to analyze post-upgrade issues that may require follow up, then disable it when finished with the upgrade debugging session.

Role required: admin

1. Navigate to [System Diagnostics > Session Debug](#).
2. Select [Debug Upgrade](#) to enable the upgrade debugger.
3. Process a transaction (for example, load a form).
4. Click the [Skipped During Last Upgrade](#), [Customer Customized](#), or [ServiceNow Modified During Last Upgrade](#) header to view the appropriate list.

<table>

5. The ten most recent artifacts appear in the selected list. Click **Show more** to view all remaining artifacts.
6. Click the name of a listed artifact to view the underlying artifact record.
   For example, if you click a Script Include artifact, the underlying Script Include record appears.
7. To turn off Debug Upgrade and all session debugging after completing your session:
   a) Navigate to **System Diagnostics > Session Debug**.
   b) Select **Disable All** to disable the upgrade debugger.

**Upgrade Center**

Use to plan and manage your upgrades. Use the Upgrade Preview module to explore different release versions available to you and gain insights about the experience of an upgrade without actually upgrading your instance.
You can also monitor the status of any ongoing upgrade and view the summary of your latest upgrade with the new Upgrade Monitor module. The also features an Upgrade visual task board (VTB) to manage post-upgrade skips. A separate Upgrade History module can be used to view all your past upgrades.

**Key features**

**One-stop experience**

You can see all the details that are related to an upgrade.

**Preview your upgrade**

Use the Upgrade Preview module to have an unprecedented insight to an instance prior to an actual or a scheduled upgrade.

You can see the estimated time required to complete an upgrade. The estimated time is calculated from previous upgrades.

**Note:** If this is your first upgrade, **Estimated upgrade duration** doesn't show up.
Reduce post-upgrade review time by previewing the records that have been customized and are different from the upgrade version being previewed and might get skipped due to your customizations in the instance. You can then prioritize your work depending on the records listed in the skip list.

**Monitor an upgrade**

Use the Upgrade Monitor module to schedule and view the status of an ongoing upgrade. You can also reschedule the upgrade by clicking **Reschedule upgrade**. To check for an immediately available upgrade, click **Check for upgrade**.

If an upgrade is in progress, the user is automatically directed to the upgrade in progress page.

**Review previous upgrade detail**

Use the Upgrade History module to view the complete report of any upgrade made to an instance.
You can also view the resolution status of any previous upgrade with skipped records using the visual task board (VTB) view.
Get started

Select the tile to get started.

---

Exploring Upgrade Center

Get an overview of Upgrade Center so you can plan your upgrade ahead.

Upgrade Center helps you plan and manage your upgrades.

- **Previewing an upgrade**: Use the Upgrade Preview module to have an insight about the experience of an upgrade prior to the actual upgrade.
- **Scheduling and monitoring an upgrade**: Use the Upgrade Monitor module to schedule and monitor an upgrade in your instance.
- **Reviewing upgrade history**: Use the Upgrade History module to view reports of completed upgrades in your instance.

Upgrade Preview module

The Upgrade Preview module enables you to have an unprecedented insight to an instance prior to an actual upgrade. You can explore and preview upgrades to different ServiceNow release versions and see how your instance might be impacted with your current configurations. The Upgrade Preview utility helps you to plan, schedule, and prepare for an upgrade.
Find out what's new and changed in Paris Patch 2

Based on your release version, we've provided a list of fixed problems that may be relevant to you. You can also visit the ServiceNow product documentation site to generate personalized release notes, or you can review a list of open known errors on the Known Issue Portal.

Skipped list predictions for an upgrade to Paris Patch 2

When you upgrade to a newer release version, the upgrade can include new features and bug fixes. If customizations are detected during the upgrade, those files are skipped to ensure the upgrade doesn't overwrite any customizations. Here are some predictions of skipped records for an upgrade to the selected release version. Review these predicted skipped records to decide which version of the files you'll like to keep. Before you upgrade, you can also choose to revert some of your customizations to the base version which will send them through the upgrade without getting skipped.

Prepare for your upgrade

Before you upgrade, use the tools below to set a baseline for testing. If you've executed some Automated Test Framework (ATF) tests recently, the most recent results are shown here.

Automated Test Framework (ATF) results

83% Tests passed
**Note:** Depending on the eligibility of your instance, the list of available target versions for preview varies. Only the versions which are allowed for a particular instance to be upgraded to, show up on the list. If your instance is not eligible to be upgraded to any version, the drop down menu will be empty.

The following cards show up with more information.

<table>
<thead>
<tr>
<th>Card names</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Current version</td>
<td>Name of the current version.</td>
</tr>
<tr>
<td></td>
<td>• Upgraded on: Date on which the instance got upgraded to the current version</td>
</tr>
<tr>
<td></td>
<td>• End of life: Link to KB0610454 for more information about end of life</td>
</tr>
<tr>
<td>Previewing version</td>
<td>Information about the previewing version show up. If you haven't previewed any version, you are expected to select a version for preview and click Go. If you have already previewed a version, the following information shows up.</td>
</tr>
<tr>
<td></td>
<td>• Preview created: Date on which the preview was created</td>
</tr>
<tr>
<td></td>
<td>• View preview details: Link to the Upgrade Preview form</td>
</tr>
</tbody>
</table>

**Note:** Click **Refresh preview** if you want to regenerate a new preview of the same target version. Although clicking **Refresh preview** regenerates the skipped list, the reverted records won't get skipped. If you have reviewed and retained some records, they get replaced as soon as you click **Refresh preview**.

<table>
<thead>
<tr>
<th>Scheduled upgrade</th>
<th>Name of the next upgrade that has been scheduled to start. If there is no currently scheduled upgrade, the card shows No upgrade scheduled.</th>
</tr>
</thead>
</table>

**Note:** This card can have different messages depending on the schedule of the upgrade.

If there is an upgrade scheduled, the following information shows up.

- Estimated upgrade duration: Estimated duration needed to complete the scheduled upgrade

**Note:** If this is your first upgrade, there will be no information about estimated upgrade duration.

- Next scheduled upgrade: Date and time on which the next upgrade has been scheduled to start.

</table>

**Note:** Only the tests which are finished and have passed are considered for the ATF results. If one test runs more than once, only the recent execution is considered in the results.

---

**Upgrade Monitor module**

Schedule an upgrade and monitor the status of an ongoing upgrade using the Upgrade Monitor module. You can also view the upgrade summary and the list of records causing conflicts in your instance once the upgrade is complete.

**Access Upgrade Monitor**

If you log in with the admin role while an upgrade is underway, the system automatically displays the Upgrade Progress screen. If no upgrade is in progress, you can navigate to **Upgrade Center > Upgrade Monitor**.

**How the Upgrade Monitor fits into the upgrade process**

**Note:** For detailed information about the upgrade process, see **Upgrade your instance**.

The Upgrade Monitor concerns only part of the larger upgrade process:

1. Clone the production instance to a test instance and a non-production instance.
2. Apply the upgrade to the non-production instance.
3. On the upgraded non-production instance, **process the skipped list**.
4. Test the non-production instance to confirm that the instance still works and performs adequately. Compare to benchmark data from pre-upgrade production instance.
5. Apply the upgrade to the test instance. Import the update sets created on the non-production instance when you processed the skipped list. Repeat the testing to make sure that the process is working.
6. Apply the upgrade to the production instance. Import the update sets created on the non-production instance when you processed the skipped list. Test to confirm that the instance works and performs adequately.

Within this larger process, the Upgrade Monitor helps you upgrade individual instances:

- During the upgrade, it shows where in the process the system is
- After the upgrade, it reports what the upgrade did and for how long
- As you upgrade the first non-production instance, it helps you resolve conflicts between customizations and changes that are part of the upgrade
• On non-production instances, it provides information that can help you estimate how long the upgrade might take on the production instance

**Note:** Debug Upgrade provides detailed debugging output for transactions containing artifacts affected by the most recent upgrade, and is designed to assist in upgrade error resolution.

**Monitoring an individual instance as it upgrades**

While the upgrade is in progress the Upgrade Progress shows what the upgrade process has done, what it is doing, and what remains to be done.

When the upgrade completes, the system displays the Upgrade Summary Report. The Upgrade Summary Report provides information about conflicts between customizations versus changes in the upgrade and provides a link to reconcile these conflicts. For information about understanding and resolving these conflicts, see Process the skipped records list.

When you upgrade a non-production instance, the Upgrade Summary Report can help you estimate how long the same upgrade might take on a production instance. For details about the elements on this report and how to use this information, see Upgrade Details form.

**Resolving conflicts**

To prevent losing customizations, the system skips upgrading records you have customized and provides you with a list of these skipped records.

As you upgrade your first non-production instance, go through the Skipped Changes to Review related list and resolve these conflicts. The system records the changes you make during this process in update sets. See Review skipped records using related lists, for more information.

You do not need to reconcile the skipped list on any instances you later upgrade. Instead, you can apply the upgrade then import the update sets containing your changes.

For details on reconciling conflicts, see Process the skipped records list.

**Factors affecting upgrade duration**

Various factors affect how long the system takes to perform an upgrade. The Upgrade Monitor on non-production instance can help you understand those factors and estimate how long the upgrade to your production instance takes.

Many factors can affect the duration of the upgrade process:

• The number of records in the database
• The number of customizations in the database
• The number of nodes in the instance
• The size of tables in the instance that require a schema-change in the instance
• The number of fix scripts required and the size of the tables those fix scripts manipulate

Upgrading a non-production instance can help you estimate how long the upgrade takes on production, but differences between the instances can significantly affect the duration:

• When you cloned the production instance to the non-production instance, you may have clone-excluded some tables. This reduces the size of the database and makes the non-production instance upgrade faster than the production instance.
• The production instance may have more memory and processing power.
• The production instance may have more nodes than the non-production instance.
After upgrading the first non-production instance, examine the Upgrade Summary Report for data to help estimate the impact of these factors.

**Upgrade Monitor schedule states**

When an upgrade is scheduled, the Upgrade Monitor displays information about the next scheduled upgrade. It displays the date and time when the next scheduled upgrade will start. If there is no upgrade scheduled, the Upgrade Monitor displays **Status: No upgrade detected.**

**No upgrade scheduled**

There is no upgrade that has been scheduled currently.

You can also schedule an upgrade by clicking **Schedule upgrade.** To check for an immediately available upgrade, click **Check for upgrade.** It also shows the current version of your upgrade and the date it was upgraded on.
Upgrade scheduled

There is an upgrade that has been scheduled to start at a given time.

You can also reschedule the upgrade by clicking **Reschedule upgrade**. To check for an immediately available upgrade, click **Check for upgrade**. By clicking either **Reschedule upgrade** or **Schedule upgrade**, you will be directed to HI Upgrade Wizard.

Upgrade monitor with issue detected

If one or both of the triggers for upgrading the system ('Check distribution for possible upgrade' and 'Check database for possible upgrade') have been customized or are missing, the Upgrade Monitor displays a warning and provides a button for resolving the issues.

**Note:** If your instance is self-hosted (not hosted by ServiceNow) this message may not necessarily indicate a problem. If you have customized or disabled the upgrade job and want to keep that customization or disabled state, do not click the button to fix the upgrade issue.

To resolve the issues with the upgrade jobs, click the link in the message. This action reverts both upgrade triggers ('Check distribution for possible upgrade' and 'Check database for possible upgrade') to their base versions.
Note: 'Upgrade' job has been renamed to 'Check distribution for possible upgrade' starting Paris. 'Check Upgrade Script' job has been renamed to 'Check database for possible upgrade' starting Paris.

Upgrade History module

The Upgrade History module tracks every upgrade made to an instance. You can also view the complete report of an old upgrade or a recently completed upgrade version using this module.

To view an upgrade history record, navigate to Upgrade Center > Upgrade History and select an upgrade from the list. On selecting an upgrade from the list, the System Upgrades form appears.

System Upgrades form details

<table>

<td>Total number of copied records to review whose base records have been upgraded.</td>
</tr>
</tbody>
</table>

Click Skipped Record VTB related link to view and manage skipped records over VTB. See Skipped Records visual task board (VTB) for more information.

Click View Upgrade Summary Report related link to view the summary of an older upgrade over Upgrade Monitor module.

See Review skipped records using related lists for more information about related lists.
Previewing an upgrade

Use the Upgrade Preview module to have an insight about the experience of an upgrade prior to the actual upgrade. You can explore and preview upgrades to different ServiceNow release versions and see how your instance might be impacted with your current configurations.

- Preview predicted changes: Preview the changes that have been predicted to occur after an upgrade.
- Upgrade Preview form: Alternate view of a previewed upgrade.

View previewed upgrade

Use the Upgrade Preview form to have an alternate view of a previewed upgrade.

Role required: admin

1. Navigate to Upgrade Center > Preview module.
2. Select the target version to be previewed.
3. Click Go or Refresh Preview to run the selected preview.
4. Click View preview details on the Previewing version card to view the following related lists.
   - Predicted Skips to Review related list: The Upgrade Preview process informs you about the customizations that are predicted to be skipped during an upgrade. The upgrade preview process the skip files that have been customized. Predicted Skips to Review lists all the skipped files that haven't been reviewed yet.
   - Predicted Skips Reviewed related list: Predicted Skips Reviewed related list displays the records which have previously appeared on the Predicted Skips to Review related list and have been reviewed. When you select a skipped record to review and the Resolution Status has been set to a value other than Not Reviewed, the updated record moves to the Predicted Skips Reviewed related list.
• **Previewed Changes related list**: Previewed Changes related list gives the total number of records that are predicted to change when the upgrade occurs. Total record changes also includes possible predicted skip files known as Predicted skipped records.

See [Previewed changes](#) for more details about the related lists.

</table>

**Preview predicted changes**

Use the previewed changes table to view the list of total records that are predicted to change when the upgrade occurs.

**Preview skipped list prediction**

The **Total record changes** also includes records that are predicted to be skipped due to various reasons. The most common reason is due to customization. The reason an upgrade skips customizations is to avoid overwriting your customizations. Upgrade Preview attempts to predict which records will be skipped when the actual upgrade occurs. It predicts skips due to customizations, and some of the other more complex scenarios as well. It is possible to use Upgrade Preview to address these predicted customization skips before the upgrade occurs, which can prevent that skip from happening.

Click **View preview details** link on the **Previewing version** card. The Upgrade Preview form appears along with the following related lists details.

| Predicted Disposition | Action predicted to be performed on this file during the selected upgrade:  
  • Predicted Insert: The system is predicted to insert a new record.  
  • Predicted Update: The system is predicted to update this record.  
  • Reverted: This record was reverted to the base version, and won’t be skipped on the next upgrade.  
  • Predicted Skip: The system won’t change this record in order to preserve customizations.  
  • Predicted Skip (Manual Merge): The system won’t change this record because updating it requires manual intervention.  
  • Predicted Skip (Apply Once): The system is predicted to skip this record because it had already applied an update from an xml file in the apply once folder. |
| Priority           | Priority that has been assigned to resolve the conflict. Values range from one to five, with one representing the highest priority.  
  **Note:** ServiceNow prioritizes the skipped records based on the importance of the file types. The prioritization is done as follows:  
  • Priority 1 (highest priority): UI pages, UI macros, and more  
  • Priority 2: Business Rules, Security ACLs, and more  
  • Priority 3: Reports and more  
  • Priority 4: Form Sections, Choice Sets, and more  
  • Priority 5 (lowest priority): other |
| Resolution         | Ways to resolve a conflict.  
  • **Not reviewed:** Conflicted files that have not been reviewed yet  
  • **Reviewed:** Reviewed but no action has been taken yet  
  • **Review not needed:** Review of the skipped files are not required  
  • **Reviewed and Retained:** Left customizations in place without update from upgrade  
  • **Reviewed and Reverted:** Customizations discarded, record updated according to the upgrade version |
| Plugin             | Plugin containing the record |
| Related record     | Record that the changelist entry applies to |
Scheduling and monitoring an upgrade

Use the Upgrade Monitor module to schedule and monitor the status of an ongoing upgrade in your instance. You can also view the upgrade summary and the list of records causing conflicts in your instance once the upgrade is complete.

- Monitoring an upgrade: Monitor the progress of an ongoing upgrade in your instance
- Process the skipped records list: Resolve the differences between the upgraded and customized versions of a record by processing the skipped records list
- Resolve conflicts of a record: Resolve conflicts between your customized record and the changes associated with the upgrade

Monitor an upgrade to an instance

Monitor the progress of an ongoing upgrade in an instance with the Upgrade Monitor. When the upgrade is done, you can view a summary of the results on the Upgrade Summary Report.

Role required: admin

1. Navigate to Upgrade Center > Upgrade Monitor.

   ![Note](image)
   
   **Note:** If an upgrade is in progress, the user is automatically directed to Upgrade Center > Upgrade Monitor page.

2. Monitor the progress of the upgrade.

   When the system finishes the upgrade, it displays the Complete upgrade summary report.

   From the Upgrade Summary Report, resolve any conflicts that prevented the system from upgrading records.
Upgrade Progress

When an upgrade is underway, Upgrade Progress displays progress bars and other information to help monitor the process.

Skipped Records

Skipped Records from upgrade to Paris Patch 1

When you upgrade to a newer release version, the upgrade can include new features and bug fixes. If customizations are detected during the upgrade, those files are skipped to avoid conflicts. After your upgrade is complete, review these skipped records to decide which version of the files you’d like to keep.

## Skipped Records details

<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
</table>
| Total record changes         | Total number of records that have changed since the previous upgrade version  
|                               | • **Review changes**: List of records that have changed can be reviewed. See *System Upgrade form* for more details.                       |
| Skipped records              | Skipped records to prevent your customizations from being overwritten. If customizations are found in some records during the upgrade, those records are skipped.  
|                               | As an admin, you can resolve each update that was skipped due to a customization. To resolve a skipped update, you can review the reason for each skipped record and then either retain the customization or revert the customization to the base system. If you choose to revert some of the customizations to the base version, those records are sent through the upgrade without getting skipped.  
|                               | • **Total**: Total skipped records  
|                               | • **To review**: Total skipped records that are yet to be reviewed  
|                               | • **Reviewed**: Total skipped records that have been reviewed                                                                                      |
| Skipped records by priority  | ServiceNow prioritizes the skipped records based on the importance of the file types. The prioritization is done as follows:  
|                               | • Priority 1 (highest priority): UI pages, UI macros, and more  
|                               | • Priority 2: Business Rules, Security ACLs, and more  
|                               | • Priority 3: Reports and more  
|                               | • Priority 4: Form Sections, Choice Sets, and more  
|                               | • Priority 5 (lowest priority): other                                                                                                         |
| Skipped records by product   | Skipped records are sorted by product names                                                                                                                                 |
| Skipped records code changed/code unchanged | Skipped records are sorted depending on if there are changes in the code or not. |

**Note:** You can click **Skipped Record VTB** to view the resolution status of the current upgrade with skipped records using the visual task board (VTB) view. See *Skipped Records visual task board (VTB)* for more information.
Node Upgrades

The Node Upgrades section shows the status of the upgrade for each node in the instance. The color of the icon denotes the status, as illustrated by the legend (key) and to the right of the node icons. To see details about a node, position the cursor above the icon for that node. An arrow points to the node selected, and the information below the icons pertains to that node.

Schema Changes to Clone-excluded Tables

The Schema Changes to Clone-excluded Tables section shows a list of tables affected by the upgrade that were clone-excluded when you cloned the production instance to this instance. Because clone-excluded tables are empty, upgrading them takes less time than upgrading those same tables on the production instance. To estimate how much longer the production upgrade takes, note the size of the clone-excluded tables on the production instance.

View all schema change durations

The Top 10 Schema Changes by Duration helps you understand which schema changes required the most time.

## Top 10 Plugins by Duration

The Top 10 Plugins by Duration helps you see the plugins that required the most time. Click **View all plugin duration** to see the System Upgrade Metrics list filtered by current sys upgrade history log and sorted by duration. See View loaded files for a plugin for more information.

**View loaded files for a plugin**

Get a related list view of all the files loaded for a plugin by clicking **View all plugin duration**.

Role required: admin

1. Navigate to **Upgrade Center > Upgrade Monitor**.
   When the system finishes the upgrade, it displays the Upgrade Summary Report.
2. Scroll down to **Top 10 Plugins by Duration**.
3. Click **View all plugin duration**.
   The System Upgrade Metrics list of all the plugins and their durations shows up.
4. Click one of the plugins from the list to open the **System Upgrade Metrics** form view of that plugin. The Plugin Files related list of all the loaded files for that plugin is displayed.

Process the skipped records list

Process the skipped records list to resolve the differences between the upgraded and customized versions of a record. If you have customized or altered a record affected by this upgrade, such as a business rule or script, the upgrade generates a skip log record.

Role required: admin

Review the changes you made to baseline records, such as business rules and scripts, that appear on the skipped records list and revert to the baseline version if appropriate. Post-upgrade, thoroughly test all changes you made to these records.

1. Navigate to Upgrade Center > Upgrade Monitor.
   
   If the upgrade is still in progress, the system displays the Upgrade Progress screen. When the upgrade finishes, the system displays the Upgrade Summary Report.

2. After the system displays the Upgrade Summary Report, click the Review changes link in the Skipped box.
   
   The system displays the System Upgrades form.

4. Click the row for the first record you want to reconcile.
   
   The system displays the Upgrade details form for that record.

5. Evaluate how you want to resolve the conflict for this record and take the appropriate action:

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Retain the customized record as is and do not update it</td>
<td>After reviewing the changes, set Resolution Status to Reviewed and Retained. The record moves from the Skipped Changes to Review to Skipped Changes Reviewed related list. See Review skipped records using related lists.</td>
</tr>
</tbody>
</table>
   | Retain the customization by merging changes from the updated object | a. Click Resolve Conflicts to navigate to the Resolve Conflicts form.  
   b. Review the differences.  
   c. To merge a field:  
   • Click the right-arrow button for the field.  
   • Click a text box to view and edit the detailed differences.  
   • When you have merged all appropriate fields, click Merge.  
   After merging the customization changes:  
   • The Disposition changes from Skipped to Merged.  
   • The Resolution Status changes to Reviewed and Merged.  
   • The record moves from the Skipped Changes to Review to the Skipped Changes Reviewed related list. |
<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Discard the customization and update the record to match the base system for this upgrade</td>
<td>After reviewing the changes, click <strong>Revert to Base System</strong>. &lt;br&gt;• The <strong>Disposition</strong> changes from <strong>Skipped</strong> to <strong>Reverted</strong>. &lt;br&gt;• The <strong>Resolution Status</strong> changes to <strong>Reviewed and Reverted</strong>. &lt;br&gt;• The system creates a Customer Update record. &lt;br&gt;• The record moves from the Skipped Changes to Review to the Skipped Changes Reviewed related list.</td>
</tr>
<tr>
<td>Review the skip and perform no action on the object</td>
<td>After reviewing the changes, set <strong>Resolution Status</strong> to <strong>Reviewed</strong>. The record moves from the Skipped Changes to Review to the Skipped Changes Reviewed related list.</td>
</tr>
<tr>
<td>Leave on the skipped list for a later decision, and note that you have not reviewed the record</td>
<td>From the <strong>Resolution</strong> list, choose <strong>Not Reviewed</strong> to defer the decision on how to handle this conflict. The record stays on the Skipped Changes to Review related list.</td>
</tr>
</tbody>
</table>

**Note:** The system tracks changes to records in an update set so you can apply these changes to another instance later. However, the system does not migrate the upgrade details records from one instance to the next. These records apply to a specific upgrade of a specific instance. If you want to preserve the Comments, Resolutions, or other information from the skipped list, export it from this instance.

6. In the **Comment** field, write the reasons for making your decision and other information you want to document.

7. Click **Update**.  
   Post-upgrade, thoroughly test all changes you made to the records on the skipped record list.
System Upgrade form

When an upgrade is complete, the System Upgrades form displays key statistics about the upgrade and a related list of skipped records (the skipped list).
## System Upgrade details

<table>
<thead>

<td>Copies to review</td>
<td>Total number of copied records to review whose base records have been upgraded</td>
</tr>
</tbody>
</table>

## Resolve conflicts for an individual record

Reconcile differences between your customized record and the changes associated with the upgrade.

Role required: admin

1. From the Upgrade Details form for the record you are reconciling, click **Resolve Conflicts**.

   The system displays the Resolve Conflicts form, which highlights differences between the two versions of the record. The form displays information about the base system record on the left and the customized record on the right.

   **Note:** The system creates a new customer update record when you click **Resolve Conflicts**.

2. Compare the base system with the customized record for each field on this form. For non-script fields, edit the customized record on the right-hand side to include what you want from the base system and the customization.

3. If this record contains a script, check it for conflicts and resolve.
   a. Click inside the Script field.

      The system displays the Resolve Conflicts - Script form highlighting areas where the two versions of the script differ.

   b. Edit the right-hand side so that the script contains whichever content you want. To move a block of code from the left to right side, click the small arrows corresponding to that block in the middle column.

   c. Click **OK**.

   The system returns to the Resolve Conflicts form.
4. To save your changes to the record, click **Save Merge**.

   The system sets the **Resolution** for this record to **Reviewed and Merged**.
Upgrade details form

From the Upgrade Details form, you can review an individual record affected by the upgrade and reconcile conflicts between the upgrade and customizations.
Use the following fields to track your progress in reviewing skipped records:
- Priority is based on the elements contained within the record. For example, a Business Rule has a higher priority than a UI Page because it contains script, SQL, and HTML fields.
- Use Resolution Status to keep track of whether the skipped record was reviewed and ignored, retained in its customized form, or reverted to the base system version.
- You can add Comments to a record to keep a log of your thoughts and actions.

Fields

The fields this form displays depend on the type of record you are reconciling. The left column shows the records fields in the base system, including the proposed changes that are part of the upgrade. The right column shows the fields for your customized record.

Reviewing upgrade history

The Upgrade History module tracks every upgrade made to an instance. You can also view the complete report of an old upgrade or a recently completed upgrade version using this module.

- **Upgrade history related lists:** Use the related lists to resolve, track and review the skipped records in an upgrade
- **Visual task board (VTB) view of skipped records:** Use the VTB view to see the resolution status of any previous upgrade with skipped records

Review skipped records using related lists

Use different related lists to resolve, track and review the skipped records in an upgrade.

Role required: admin

1. Navigate to Upgrade Center > Upgrade History.
   A list of upgrades is displayed.
2. Select an upgrade from the list.
   System Upgrades form is displayed.
3. Select any of the following related lists to review the skipped records.
   - **Skipped Changes to Review related list**
     Resolve the skipped update records by tracking and reviewing them in the Skipped Changes to Review related list. To prevent your customizations from being overwritten during system upgrades, the upgrade process skips (does not apply the update to) objects that have been customized. See Resolve a skipped update and set a resolution status for more information.
   - **Skipped Changes Reviewed related list**
     View the list of the reviewed skipped records in the Skipped Changes Reviewed related list. When you select a skipped record to review and set a Resolution Status to a value other than Not Reviewed, the update record moves from Skipped Changes to Review related list to the Skipped Changes Reviewed related list.
   - **Copies to Review related list**
     Copies to Review lists all the records that need to be reviewed.
   - **Copies Reviewed related list**
     Copies Reviewed lists all the records that have been reviewed.
   - **Customization Unchanged related list**
     Customizations Unchanged lists all records that were skipped (due to a customization), but there have been no changes from the last upgrade. See Revert a customization for more information.
   - **Changes Applied related list**
     Changes Applied lists all changes that were applied in this upgrade.
   - **Claim Outcomes to Review related list**
     During system upgrades, the Claim Status tab displays outcomes to review and resolve.
   - **Upgrade Details related list**
Upgrade Details lists all Upgrade Details records for this upgrade.

**Note:** The Copies to Review and Copies Reviewed related lists are Platform specific related lists.

## Upgrade history related lists details

The following table gives the description of each field in all the related lists within the upgrade history module.

### Related lists details

<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
</table>
| File name                  | File name has different description for different related lists  
  • Skipped Changes to Review related list: Name of skipped Upgrade Detail record  
  • Skipped Changes Reviewed related list: Name of the reviewed Upgrade Detail record  
  • Copies to Review related list: Name of the record that needs to be reviewed  
  • Copies Reviewed related list: Name of the record that has been reviewed  
  • Customization Unchanged related list: Name of unchanged sys_upgrade_history_log record. Select it if you want to access Upgrade Details and add comment text, or set a resolution status for it  
  • Changes Applied related list: Current upgrade file name  
  • Claim Outcomes to Review related list: Name of skipped Upgrade Detail record  
  • Upgrade Details related list: Current upgrade file name |

| Disposition                | Action performed on this file during the selected upgrade:  
  • Inserted: The system inserted a new record.  
  • Updated: The system updated this record.  
  • Deleted: The system deleted this record.  
  • Skipped: The system did not change this record in order to preserve customizations.  
  • Reverted: This record was reverted to the base version.  
  • Table not found: The system could not find the table that contains this record.  
  • Unchanged: The system did not change this record because the baseline component has not changed since the last release.  
  • Skipped Manual Merge: The system did not change this record because updating it requires manual intervention.  
  • Skipped Apply Once: The system skipped this record because it had already applied an update from an xml file in the apply once folder.  
  • Not Latest: The system applied a change, but this change was overwritten later during the same upgrade. |
### Revert a customization

To prevent customizations from being overwritten by system upgrades, the upgrade process automatically skips changes to objects that have been customized. You may want to overwrite your customizations when a software upgrade contains a feature that you would like to implement.

**Role required:** admin

To identify customized objects, the system adds a corresponding record in the Customer Updates [sys_update_xml] table. The table maintains the current version information for all objects that have been customized. The upgrade process skips changes to objects that have entries in the table. The upgrade process does not skip objects if only excluded fields have changed.

1. Navigate to **Upgrade Center > Upgrade History**.
2. Select the desired software version.
3. Filter the Upgrade Details related list by **Disposition is Skipped**.
4. Optional: Add another filter condition for **Changed is True** to return only the objects that have changed since the last upgrade.
5. Select the update record to implement.

The **File differences** field displays a side-by-side comparison of the customization and the default version. Deletions are highlighted in red, additions in green, and modifications in yellow.
6. Click **Revert to base system** to overwrite your customized object with the system default version.

   - The Disposition changes from **Skipped** to **Reverted**.
   - After you revert a customization, you have the option to click **Reapply Changes** to reapply your customizations (undo the revert).

**Resolve a skipped update and set a resolution status**

Review the reason for each skipped record to resolve each skipped update after an upgrade.

Role required: admin

You resolve an update by either retaining the customization or by merging or overwriting the customization with the base system update.

**Note:** Objects that are customized and that did not change in the base system since the last upgrade require no action on your part.

When an object is customized, the system adds a corresponding record to the Customer Updates [sys_update_xml] table and then maintains current version information for all customized objects. The upgrade process skips changes to objects that have a current version in the Customer Updates table. When you follow the procedure, you perform one of the following actions:

- Retain a customization with no changes
- Retain a customization by merging changes from the updated object
- Revert a customized object to the updated version (that is, overwrite the customization)
- Review the skip and perform no action on the object

1. Navigate to **Upgrade Center > Upgrade History**.
2. Select the desired software version.
3. In the Skipped Changes to Review related list, select the update record to resolve. See **Review skipped records using related lists**.
4. Review the list of changes. For text fields, you can click in the field to open the Diff/Merge tool. Review the differences. Click a text box to view and edit the detailed differences.
5. Perform one of the following actions. You have the option to add a **Comment** to any record, for example, to explain the action to future reviewers.

  **Skipped Changes to Review related list**

<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Retain the customized record as is and do not update it.</td>
<td>After reviewing the changes, set <strong>Resolution Status</strong> to <strong>Reviewed and Retained</strong>. The record moves from the Skipped Changes to Review to Skipped Changes Reviewed related list.</td>
</tr>
</tbody>
</table>
### Field
Retain the customization by merging changes from the updated object.

### Input Value
- **a.** Click Resolve Conflicts to navigate to the Resolve Conflicts form.
- **b.** Review the differences.
- **c.** To merge a field:
  - Click the right-arrow button for the field.
  - Click a text box to view and edit the detailed differences.
  - When you have merged all appropriate fields, click **Merge**.

After merging the customization changes:
- The Resolution Status changes to Reviewed and Merged.
- The record moves from the Skipped Changes to Review to the Skipped Changes Reviewed related list.

### Field
Discard the customization and update the record to match the base system for this upgrade.

### Input Value
After reviewing the changes, click **Revert to Base System**.
- **Disposition** changes from **Skipped** to **Reverted**.
- **Resolution Status** changes to **Reviewed and Reverted**.
- The system creates a Customer Update record.
- The record moves from the Skipped Changes to Review to the Skipped Changes Reviewed related list.

#### Note:
At any time after you revert a customization, you can click **Reapply Changes** to reapply the customization.

### Field
Review the skip and perform no action on the object.

### Input Value
After reviewing the changes, set **Resolution Status** to **Reviewed**. The record moves from the Skipped Changes to Review to the Skipped Changes Reviewed related list.

### Field
Leave on the skipped list for a later decision, and note that you have not reviewed the record.

### Input Value
From the **Resolution** list, choose **Not Reviewed** to defer the decision on how to handle this conflict. The record stays on the Skipped Changes to Review related list.

6. Click **Update**. Repeat the process to resolve each update record in the list.

Only skipped updates with a **Resolution Status** of **Not Reviewed** or without a resolution set appear in the Skipped Changes to Review related list. Any action you take that changes the **Resolution Status** to a value other than **Not Reviewed** or **--None--** removes the skipped update from list and moves it to the Skipped Changes Reviewed related list.
Skipped Records visual task board (VTB)

View the resolution status of any previous upgrade with skipped records using the visual task board (VTB) view. An upgrade history record is created for each upgrade that is run.

To view the history report navigate to Upgrade Center > Upgrade History. You can then select an upgrade from the list to view the upgrade history details. Click the Skipped Record VTB related link to view and manage the skipped records over VTB.

**Note:** The Skipped Record VTB related link shows up only when there are skipped records for the version upgrade.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not Reviewed</td>
<td>Tasks which have not been reviewed</td>
</tr>
<tr>
<td>Reviewed</td>
<td>Tasks which have been reviewed</td>

### Update default labels in VTB view

Filter skipped records in the task board of the VTB with the implementation of color-coded labels. You can filter the skipped records by assigning a color to each of the products.

Role required: admin

1. Navigate to **Upgrade Center > Upgrade History**.
2. Select an upgrade from the list.
   The System Upgrades form appears.
3. Click the **Skipped Record VTB** related link to view the resolution status of the skipped records over VTB.

   **Note:** The **Skipped Record VTB** related link shows up only when there are skipped records for the version upgrade.

   The VTB view of the resolution status of the skipped records shows up.

4. Click **Labels** to show the default labels.
   The default labels consist of Include codes, Does not include code and Others categories.

   **Note:** The Include and Does not include codes categories indicate if there is any change in the code of the skipped records. All products fall under Other category of labels. The product labels are assigned with different colors. The tasks get assigned based on the label colors of the products.
5. Optional: If you want to add a label, click **Add Label**.

Enter the name of the label you want to create. You can also change the color of a label by clicking the color circle.

![Labels](image)

**Note:** The new labels and colors are saved only for the current visual task board and don't get rolled over to the next updated board. If you want the new label updates to show up in the next updated board, navigate to **Upgrade Center > Administration > Properties > Upgrade Center VTB Labels**. Set the colors as required and the updated colors start showing up from the next generated board.

Click on a skipped record in the VTB to update the task. See **Upgrade History Task form** for more information.
View import history

View your import history by accessing the **My Application Import History** module.

Role required: admin

1. Navigate to **System Applications** > **My Application Import History**. The list of import history records in your instance shows up.
2. Select one of the imports from the list for more information about that import. The form view of sys_upgrade_history record shows up.

**Note:** To learn more about importing from Source Control, see ServiceNow Studio. Once the importing is done, use the **My Application Import History** module to view the import history.

Quick access to plugins and history records

Reduce the navigating time by directly accessing plugins, application installation history records, and update set commits history records. The filters for the plugins and history records are automatically implemented in the plugins and history records views.

Role required: admin

**Plugins and application installation history records**

1. Navigate to **System Definition** > **Plugin Installation History**.
2. Select any of the plugins or history records to access them directly.

**Update set commit history records**

1. Navigate to **System Update Sets** > **Update Sets to Commit**.
2. Select any of the update sets to directly view the commit history of that update set.

Explore upgrade history log

Reduce processing time by extracting all upgrade related logs into a separate file named database-upgrade_<timestamp>.log. You can also zip the file and attach it to upgrade history.

Role required: admin

When the upgrade starts, the upgrade log messages are written to both the localhost_log file and the database-upgrade_<timestamp>.log file. When the upgrade is done, the database-upgrade_<timestamp>.log file is uploaded to the upgrade history table.

1. Navigate to **System Logs** > **Utilities**.

**Note:** You can implement this step to view the extracted database-upgrade_<timestamp>.log file only after the upgrade is done.
2. Click **Node Log File Download**.
   The database-upgrade_<timestamp>.log file appears in the list of log files.

   **Note:** The localhost_log file consists of all the logs. The database-upgrade_<timestamp>.log file consists of logs only related to the upgrade.

3. Go to **Upgrade Center > Upgrade History**.
   A list of upgrades shows up.

4. Click the required upgrade from the list. You can see database-upgrade_<timestamp>.log file is automatically attached to the upgrade.

   **Note:** The database-upgrade_<timestamp>.log file gets attached only if the glide.db.upgrade.log.save_to_db.enabled property is set to True. By default, the glide.db.upgrade.log.save_to_db.enabled is set to True.

5. Download the zipped database-upgrade_<timestamp>.log file.

   **Note:** The database-upgrade_<timestamp>.log file has been zipped to reduce the download time.

### Administration

The Administration module contains properties for managing .

### Properties

On the properties form, you can set parameters that control how the system executes.

**Upgrade Duration Estimation Properties**

<table>
<thead>
<tr>
<th>Field / Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Queries upgrade duration estimate</td>
<td>A non-production instance queries the upgrade duration estimate. If this property is absent, the system uses all remote instance records to query the upgrade duration estimate. You can also copy the sys_id of the remote instance record you wish to query for upgrade duration estimate. The system uses the highest duration from the results.</td>
</tr>
<tr>
<td>glide.upgrade.preview.duration.instance.id</td>
<td></td>
</tr>
</tbody>
</table>

**Upgrade Visual Task Board Properties**

<table>
<thead>
<tr>
<th>Field / Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable an admin or user with admin role to own Upgrade VTB</td>
<td>Upgrade VTB owner must be an admin. If this property is absent, the system uses the first admin user from active admin users list. The active admin users list is sorted by username.</td>
</tr>
<tr>
<td>glide.upgrade.center.task_board.owner</td>
<td></td>
</tr>
<tr>
<td>Field / Element</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Enable admins or users with admin role to be members of Upgrade VTB glide.upgrade_center.task_board.members</td>
<td>Upgrade VTB members must be an admin. If this property is absent, the system adds all active admin users as members.</td>
</tr>
</tbody>
</table>

**Upgrade Center VTB Labels list**

The Upgrade Center VTB Labels list under Administration module shows all the labels in the Upgrade Visual Task Board (VTB). You can also change the color of the existing labels.

If you want to change the color of an existing label, navigate to **Upgrade Center > Administration > Properties > Upgrade Center VTB Labels**

---

**Note:** If you update the color of an existing label, the change will not be reflected in the current version upgrade related board. The change will be seen only from the next version upgrade.
