**Example: cURL Request**

This example shows a request for obtaining all change model records.

```
curl "https://instance.servicenow.com/api/sn_chg_rest/v1/change/model \
--request GET \
--header "Accept:application/json" \
--user "username":"password"
```

For brevity, this response only shows a single change model object.

```
{
  "result": {
    "record_preset": {
      "display_value": "type=normal^assignment_group=a715cd759f2002002920bde8132e7018^short_description=Automated Change^EQ",
      "value": "type=normal^assignment_group=a715cd759f2002002920bde8132e7018^short_description=Automated Change^EQ"
    },
    "color": {
      "display_value": "#488df4",
      "value": "#488df4"
    },
    "default_change_model": {
      "display_value": "false",
      "value": false
    }
  }
```
This model is intended to capture a record of an automated change. There are no approvals associated with this change model.

There are no approvals associated with this change model.

This model is intended to capture a record of an automated change. There are no approvals associated with this change model.
Change Management - GET /sn_chg_rest/change/model/{sys_id}
Retrieves the change model identified by the specified sys_id.

You can then use this change model to create the desired change request. For additional information on change models, see Change Models.

**URL format**

Versioned URL: /api/sn_chg_rest/{api_version}/change/model/{sys_id}
Default URL: /api/sn_chg_rest/change/model/{sys_id}
Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the change model record to retrieve from the Change Model [chg_model] table.</td>
</tr>
</tbody>
</table>

Data type: String

      "value": "2020-09-28 15:53:12",
      "display_value_internal": "2020-09-28 08:53:12"
    }
  }
}
```
Change Management - GET /sn_chg_rest/change/normal

Retrieves one or more normal change requests based on the specified criteria.

**URL format**

Versioned URL: /api/sn_chg_rest/{api_version}/change/normal

Default URL: /api/sn_chg_rest/change/normal

**Supported request parameters**

<table>
<thead>
<tr>
<th>Path parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>api_version</strong></td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Query parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>name-value pairs</strong></td>
<td>Name-value pairs to use to filter the result set. The name is the field on which the specified value is filtered. This parameter is mutually exclusive with <em>sysparm_query</em>. For example, instead of using &amp;sysparm_query=active=true, you can simplify the calling statement by using &amp;active=true. You can also use the display value when the field is a choice or reference type field, such as &amp;state=closed instead of &amp;state=7. To specify multiple key-value pairs, separate each with an ampersand, such as &amp;active=true&amp;assigned_to=john.smith. Data type: String</td>
</tr>
<tr>
<td><strong>order</strong></td>
<td>Field by which to sort the returned change requests. Default: number Data type: String</td>
</tr>
<tr>
<td><strong>sysparm_limit</strong></td>
<td>Maximum number of records to return. For requests that exceed this number of records, use the <em>sysparm_offset</em> parameter to paginate record retrieval. Data type: Number</td>
</tr>
</tbody>
</table>
### Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_offset</td>
<td>Starting record index for which to begin retrieving records. Use this value to paginate record retrieval. This functionality enables the retrieval of all records regardless of the number of records, in small manageable chunks. For example, the first time you call this endpoint, <code>sysparm_offset</code> is set to &quot;0&quot;. To simply page through all available records, use <code>sysparm_offset=sysparm_offset+sysparm_limit</code>, until you reach the end of all records. Do not pass a negative number in the <code>sysparm_offset</code> parameter. Data type: Number Default: 0</td>
</tr>
</tbody>
</table>
| sysparm_query    | Encoded query used to filter the result set. Syntax: `sysparm_query=<col_name><operator><value>`.  
  • `<col_name>`: Name of the table column to filter against.  
  • `<operator>`: Supports the following values:  
    ◦ `=`: Exactly matches `<value>`.  
    ◦ `!=`: Does not match `<value>`.  
    ◦ `^`: Logically AND multiple query statements.  
    ◦ `^OR`: Logically OR multiple query statements.  
    ◦ `LIKE`: `<col_name>` contains the specified string. Only works for `<col_name>` fields whose data type is string.  
    ◦ `STARTSWITH`: `<col_name>` starts with the specified string. Only works for `<col_name>` fields whose data type is string.  
    ◦ `ENDSWITH`: `<col_name>` ends with the specified string. Only works for `<col_name>` fields whose data type is string.  
  `<value>`: Value to match against.  
  All parameters are case-sensitive. Queries can contain more than one entry as `sysparm_query=<col_name><operator><value>[<operator><col_name><operator><value>]`. For example:  
  ```javascript
  (sysparm_query=caller_id=javascript:gs.getUserID()^active=true)
  ```
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Encoded queries also supports order by functionality. To sort responses based</td>
</tr>
<tr>
<td></td>
<td>on certain fields, use the ORDERBY and ORDERBYDESC clauses in <strong>sysparm_query</strong>.</td>
</tr>
<tr>
<td></td>
<td>Syntax:</td>
</tr>
<tr>
<td></td>
<td>• ORDERBY&lt;col_name&gt;</td>
</tr>
<tr>
<td></td>
<td>• ORDERBYDESC&lt;col_name&gt;</td>
</tr>
<tr>
<td></td>
<td>For example: sysparm_query=active=true^ORDERBYnumber^ORDERBYDESCcategory</td>
</tr>
<tr>
<td></td>
<td>This query filters all active records and orders the results in ascending order</td>
</tr>
<tr>
<td></td>
<td>by number, and then in descending order by category.</td>
</tr>
<tr>
<td></td>
<td>If part of the query is invalid, such as by specifying an invalid field name,</td>
</tr>
<tr>
<td></td>
<td>the instance ignores the invalid part. It then returns rows using only the</td>
</tr>
<tr>
<td></td>
<td>valid portion of the query. You can control this behavior using the property</td>
</tr>
<tr>
<td></td>
<td><strong>glide.invalid_query.returns_no_rows</strong>. Set this property to true to return</td>
</tr>
<tr>
<td></td>
<td>no rows on an invalid query.</td>
</tr>
</tbody>
</table>

**Note:** The **glide.invalid_query.returns_no_rows** property controls the behavior of all queries across the instance, such as in lists, scripts, [GlideRecord.query()](https://docs.servicenow.com/c Platform/cxwikis/), and web service APIs.

Example: cURL request

curl
  "https://instance.servicenow.com/api/sn_chg_rest/v1/change/normal?sysparm_query-active=true^ORDERBYnumber" \  
--request GET \  
--header "Accept:application/json" \  
--user "username":"password"

[
  result: [
  
    sys_id: {
      value: "1c87925347c12200e0ef563dbb9a7177",
      display_value: "1c87925347c12200e0ef563dbb9a7177"
    },
    state: {
      value: "-5",
      display_value: "New"
    },
    type: {
      value: "normal",
      display_value: "Normal"
    },
    ... // all valid fields in record, example below
    short_description: {
      value: "Add network switch to cabinet",
      display_value: "Add network switch to cabinet"
    },
  },
  ... // next record found , ... // and so on
  ]
]

Example: Python request

```python
# Install requests package for python
import requests

# Set the request parameters
url =  
  'https://instance.servicenow.com/api/sn_chg_rest/v1/change/normal?sysparm_query-active=true^ORDERBYnumber'

# Set the user credentials
```
user = 'username'
pwd = 'password'

# Set the proper headers
headers = {"Accept":"application/xml"}

# Make the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)

<?xml version="1.0" encoding="UTF-8"?>
<response>
  <result>
    <sys_id>
      <value>1c87925347c12200e0ef563dbb9a7177</value>
      <display_value>1c87925347c12200e0ef563dbb9a7177</display_value>
    </sys_id>
    <state>
      <value>-5</value>
      <display_value>New</display_value>
    </state>
    <type>
      <value>normal</value>
      <display_value>Normal</display_value>
    </type>

    // all valid fields in record, single parameter example below
    <short_description>
      <value>Add network switch to cabinet</value>
      <display_value>Add network switch to cabinet</display_value>
    </short_description>

    // next record found }, ... // and so on
  </result>
</response>
Change Management - GET /sn_chg_rest/change/normal/{sys_id}
Retrieves the normal change request identified by the specified sys_id.

URL format
Versioned URL: /api/sn_chg_rest/{api_version}/change/normal/{sys_id}
Default URL: /api/sn_chg_rest/change/normal/{sys_id}

Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the normal change request to retrieve from Change Request [change_request] table. Data type: String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
**Request headers**

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: <strong>application/json</strong> or <strong>application/xml</strong>. Default: <strong>application/json</strong></td>
</tr>
</tbody>
</table>

**Response headers**

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Status codes**

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

**Status codes**

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Request completed successfully.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not Found. The specified record could not be found.</td>
</tr>
<tr>
<td>500</td>
<td>Internal Server Error. A logic error on the server-side code occurred.</td>
</tr>
</tbody>
</table>

**Response body parameters (JSON or XML)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name-value pairs</td>
<td>Values for all fields in the associated change request. Data type: Object</td>
</tr>
<tr>
<td>state</td>
<td>State of the change request prior to the delete. Data type: Object</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>state: {</td>
<td>Display state to display in a UI. Data type: String</td>
</tr>
<tr>
<td>display_value:</td>
<td>State to display in a UI. Data type: String</td>
</tr>
<tr>
<td>value: &quot;String&quot;</td>
<td></td>
</tr>
<tr>
<td>state.value</td>
<td>Internal state value. Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the change request. Data type: String</td>
</tr>
<tr>
<td>type: {</td>
<td>Type of change request. Data type: Object</td>
</tr>
<tr>
<td>display_value:</td>
<td>Change type to display in a UI. Value is always &quot;Normal&quot;. Data type: String</td>
</tr>
<tr>
<td>value: &quot;String&quot;</td>
<td></td>
</tr>
<tr>
<td>type.value</td>
<td>Internal type value. Value is always &quot;normal&quot;. Data type: String</td>
</tr>
</tbody>
</table>

**Example: cURL request**

```bash
curl
   "https://instance.servicenow.com/api/sn_chg_rest/v1/change/normal/b0dbda5347c12200e0ef563dbbb9a718f"
   --request GET
   --header "Accept:application/json"
   --user "username":"password"
{
   result: [
   ]
```
Example: Python request

```python
# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/sn_chg_rest/v1/change/normal/b0dbda5347c12200e0ef563dbbb9a718f'

# Set the user credentials
user = 'username'
pwd = 'password'

# Set the proper headers
headers = {'Accept': 'application/xml'}

# Make the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.content)
    exit()
```
# Decode the XML response into a dictionary and use the data
print(response.content)

```xml
<?xml version="1.0" encoding="UTF-8"?>
<response>
  <result>
    <sys_id>b0dbda5347c12200e0ef563dbb9a718f</sys_id>
    <state>
      <value>-5</value>
      <display_value>New</display_value>
    </state>
    <type>
      <value>normal</value>
      <display_value>Normal</display_value>
    </type>
    // all valid fields in record, single parameter example below
    <short_description>
      <value>Add network switch to cabinet</value>
      <display_value>Add network switch to cabinet</display_value>
    </short_description>
  </result>
</response>
```

Change Management - GET /sn_chg_rest/change/standard
Retrieves one or more standard change requests based on the specified criteria.

**URL format**

Versioned URL: /api/sn_chg_rest/{api_version}/change/standard

Default URL: /api/sn_chg_rest/change/standard

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>
## Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name-value pairs</td>
<td>Name-value pairs to use to filter the result set. The name is the field on which the specified value is filtered. This parameter is mutually exclusive with <code>sysparm_query</code>. For example, instead of using <code>&amp;sysparm_query=active=true</code>, you can simplify the calling statement by using <code>&amp;active=true</code>. You can also use the display value when the field is a choice or reference type field, such as <code>&amp;state=closed</code> instead of <code>&amp;state=7</code>. To specify multiple key-value pairs, separate each with an ampersand, such as <code>&amp;active=true&amp;assigned_to=john.smith</code>. Data type: String</td>
</tr>
<tr>
<td>order</td>
<td>Field by which to sort the returned change requests. Default: <code>number</code></td>
</tr>
<tr>
<td>sysparm_limit</td>
<td>Maximum number of records to return. For requests that exceed this number of records, use the <code>sysparm_offset</code> parameter to paginate record retrieval. Data type: String</td>
</tr>
<tr>
<td>sysparm_offset</td>
<td>Starting record index for which to begin retrieving records. Use this value to paginate record retrieval. This functionality enables the retrieval of all records regardless of the number of records, in small manageable chunks. For example, the first time you call this endpoint, <code>sysparm_offset</code> is set to &quot;0&quot;. Simply page through all available records, use <code>sysparm_offset=sysparm_offset+sysparm_limit</code>, until you reach the end of all records. Do not pass a negative number in the <code>sysparm_offset</code> parameter. Data type: Number</td>
</tr>
</tbody>
</table>
| sysparm_query   | Encoded query used to filter the result set. Syntax: `sysparm_query=<col_name><operator><value>`.  
- `<col_name>`: Name of the table column to filter against.  
- `<operator>`: Supports the following values:  
  - `=`: Exactly matches `<value>`.  
  - `!`: Does not match `<value>`.  
  - `^`: Logically AND multiple query statements.  
  - `^OR`: Logically OR multiple query statements. |
### Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LIKE: &lt;col_name&gt;</td>
<td>&lt;col_name&gt; contains the specified string. Only works for &lt;col_name&gt; fields whose data type is string.</td>
</tr>
<tr>
<td>STARTSswith: &lt;col_name&gt;</td>
<td>&lt;col_name&gt; starts with the specified string. Only works for &lt;col_name&gt; fields whose data type is string.</td>
</tr>
<tr>
<td>ENDSswith: &lt;col_name&gt;</td>
<td>&lt;col_name&gt; ends with the specified string. Only works for &lt;col_name&gt; fields whose data type is string.</td>
</tr>
<tr>
<td>&lt;value&gt;: Value to match against.</td>
<td></td>
</tr>
</tbody>
</table>

All parameters are case-sensitive. Queries can contain more than one entry, such as:

```
sysparm_query=<col_name><operator><value>[<operator><col_name><operator><value>]
```

For example:

```
{sysparm_query=caller_id=javascript:gs.getUserID()^active=true}
```

Encoded queries also support order by functionality. To sort responses based on certain fields, use the **ORDERBY** and **ORDERBYDESC** clauses in `sysparm_query`.

**Syntax:**

- **ORDERBY**<col_name>
- **ORDERBYDESC**<col_name>

For example: `sysparm_query=active=true^ORDERBYnumber^ORDERBYDESCcategory`

This query filters all active records and orders the results in ascending order by number, and then in descending order by category.

If part of the query is invalid, such as by specifying an invalid field name, the instance ignores the invalid part. It then returns rows using only the valid portion of the query. You can control this behavior using the property **glide.invalid_query.returns_no_rows**. Set this property to true to return no rows for an invalid query.

**Note:** The **glide.invalid_query.returns_no_rows** property controls the behavior of all queries across the instance, such as in lists, scripts (`GlideRecord.query()`), and web service APIs.

**Data type:** String

**textSearch**

String to use to search all standard change request record fields. This search uses ServiceNow full text search platform functionality and defaults to **IR_AND_OR_QUERY**.

            value: "-5",
            display_value: "New"
        },
        ..., // all valid fields in record, example below
        short_description: {
            value: "Add network switch to cabinet",
            display_value: "Add network switch to cabinet"
        }
    },
    ]
}
```

**Change Management - GET /sn_chg_rest/change/standard/template**

Retrieves one or more standard change templates based on the specified criteria.

**URL format**

*Versioned URL:* /api/sn_chg_rest/{api_version}/change/standard/template

*Default URL:* /api/sn_chg_rest/change/standard/template
**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name-value pairs</td>
<td>Name-value pairs to use to filter the result set. The name is the field on which the specified value is filtered. This parameter is mutually exclusive with sysparm_query. For example, instead of using &amp;sysparm_query=active=true, you can simplify the calling statement by using &amp;active=true. You can also use the display value when the field is a choice or reference type field, such as &amp;state=closed instead of &amp;state=7. To specify multiple key-value pairs, separate each with an ampersand, such as &amp;active=true&amp;assigned_to=john.smith. Data type: String</td>
</tr>
<tr>
<td>order</td>
<td>Field by which to sort the returned standard change templates. Data type: String Default: number</td>
</tr>
<tr>
<td>sysparm_limit</td>
<td>Maximum number of records to return. For requests that exceed this number of records, use the sysparm_offset parameter to paginate record retrieval. Data type: Number Default: 500</td>
</tr>
<tr>
<td>sysparm_offset</td>
<td>Starting record index for which to begin retrieving records. Use this value to paginate record retrieval. This functionality enables the retrieval of all records regardless of the number of records, in small manageable chunks. For example, the first time you call this endpoint, sysparm_offset is set to &quot;0&quot;. To simply page through all available records, use sysparm_offset=sysparm_offset+sysparm_limit, until you reach the end of all records. Do not pass a negative number in the sysparm_offset parameter. Data type: Number</td>
</tr>
</tbody>
</table>
### Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default: 0</td>
<td>Encoded query used to filter the result set.</td>
</tr>
<tr>
<td>sysparm_query</td>
<td>Syntax: <code>sysparm_query=&lt;col_name&gt;&lt;operator&gt;&lt;value&gt;</code>.</td>
</tr>
<tr>
<td></td>
<td>• <code>&lt;col_name&gt;</code>: Name of the table column to filter against.</td>
</tr>
<tr>
<td></td>
<td>• <code>&lt;operator&gt;</code>: Supports the following values:</td>
</tr>
<tr>
<td></td>
<td>◦ <code>=</code>: Exactly matches <code>&lt;value&gt;</code>.</td>
</tr>
<tr>
<td></td>
<td>◦ <code>!=</code>: Does not match <code>&lt;value&gt;</code>.</td>
</tr>
<tr>
<td></td>
<td>◦ <code>^</code>: Logically AND multiple query statements.</td>
</tr>
<tr>
<td></td>
<td>◦ <code>^OR</code>: Logically OR multiple query statements.</td>
</tr>
<tr>
<td></td>
<td>◦ <code>LIKE</code>: <code>&lt;col_name&gt;</code> contains the specified string. Only works for <code>&lt;col_name&gt;</code> fields whose data type is string.</td>
</tr>
<tr>
<td></td>
<td>◦ <code>STARTSWITH</code>: <code>&lt;col_name&gt;</code> starts with the specified string. Only works for <code>&lt;col_name&gt;</code> fields whose data type is string.</td>
</tr>
<tr>
<td></td>
<td>◦ <code>ENDSWITH</code>: <code>&lt;col_name&gt;</code> ends with the specified string. Only works for <code>&lt;col_name&gt;</code> fields whose data type is string.</td>
</tr>
<tr>
<td></td>
<td>◦ <code>&lt;value&gt;</code>: Value to match against.</td>
</tr>
</tbody>
</table>

All parameters are case-sensitive. Queries can contain more than one entry as
```
sysparm_query=<col_name><operator><value>[<operator><col_name><operator><value>]
```

For example:
```
(sysparm_query=caller_id=javascript:gs.getUserID()^active=true)
```

Encoded queries also supports order by functionality. To sort responses based on certain fields, use the `ORDERBY` and `ORDERBYDESC` clauses in `sysparm_query`.

Syntax:
- `ORDERBY<col_name>`
- `ORDERBYDESC<col_name>`

For example: `sysparm_query=active=true^ORDERBYnumber^ORDERBYDESCcategory`

This query filters all active records and orders the results in ascending order by number, and then in descending order by category.

If part of the query is invalid, such as by specifying an invalid field name, the instance ignores the invalid part. It then returns rows using only the
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>valid portion of the query.</td>
<td>You can control this behavior using the property <code>glide.invalid_query.returns_no_rows</code>. Set this property to true to return no rows on an invalid query.</td>
</tr>
</tbody>
</table>

Note: The `glide.invalid_query.returns_no_rows` property controls the behavior of all queries across the instance, such as in lists, scripts (GlideRecord.query()), and web service APIs.

Data type: String

<table>
<thead>
<tr>
<th>textSearch</th>
<th>String to use to search all standard change request record fields. This search uses ServiceNow full text search platform functionality and defaults to <code>IR_AND_OR_QUERY</code>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>String</td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: <code>application/json</code> or <code>application/xml</code>. Default: <code>application/json</code></td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Request completed successfully.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal Server Error. A logic error on the server-side code occurred.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name-value pairs</td>
<td>All fields with their associated values for the identified standard change template. Data type: Object</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id information for the change request. Data type: Object</td>
</tr>
<tr>
<td></td>
<td>sys_id: { display_value: &quot;String&quot;, value: &quot;String&quot; }</td>
</tr>
<tr>
<td>sys_id.display_value</td>
<td>Sys_id of the change request to display in a UI. Data type: String</td>
</tr>
<tr>
<td>sys_id.value</td>
<td>Sys_id of the change request. Data type: String</td>
</tr>
<tr>
<td>template</td>
<td>Information about the standard change template. Data type: Object</td>
</tr>
<tr>
<td></td>
<td>template: { display_value: &quot;String&quot;,</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------</td>
</tr>
<tr>
<td>value: &quot;String&quot;</td>
<td></td>
</tr>
<tr>
<td>template.display_value</td>
<td>Template information to display in the UI.</td>
</tr>
<tr>
<td>template.value</td>
<td>Template sys_id.</td>
</tr>
</tbody>
</table>

**Example: cURL request**

```bash
curl
  "https://instance.servicenow.com/api/sn_chg_rest/v1/change/standard/template?sysparm_query=
  active=true"ORDERBYnumber"
--request GET \
--header "Accept:application/json" \n--user "username":"password"
```

```json
{
  result: [
    {
      sys_id: {
        value: "92b8544047810200e90d87e8dee490b0",
        display_value: "92b8544047810200e90d87e8dee490b0"
      },
      template : {
        value: "1c8e02ec47410200e90d87e8dee49057",
        display_value: "Add network switch to datacenter cabinet"
      },
      // all valid fields in record, example below
      short_description: {
        value: "Standard change template to add network switch to cabinet",
        display_value: "Standard change template to add network switch to cabinet"
      }
    },
    // next record found }, ... // and so on
  ]
}
```

**Example: Python request**

```python
# Install requests package for python
import requests
```

data = response.json()
print(data)
```
Change Management - PATCH /sn_chg_rest/change/{sys_id}

Updates the change request identified by the specified sys_id with the key-value pairs in the request body or URL.

**URL format**

Versioned URL: /api/sn_chg_rest/{api_version}/change/{sys_id}

Default URL: /api/sn_chg_rest/change/{sys_id}

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the change request to modify. Located in the Change Request [change_request] table. Data type: String</td>
</tr>
</tbody>
</table>
Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name-value pairs</td>
<td>Name-value pairs for the fields to update. Request body parameters override URL parameters. However, required parameters must be specified in the URL. Data type: String</td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| data | Name-value pairs for the field(s) to update in the associated change request. For example, to update the short description file, enter a name-value pair similar to the following:  
```bash
--data "{"short_description": "my short desc" }"
```
Data type: String |

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

**Request headers**

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json OR application/xml. Default: application/json</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Supported types: application/json OR application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

**Response headers**

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
</table>
Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Request completed successfully.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not Found. The specified record could not be found.</td>
</tr>
<tr>
<td>500</td>
<td>Internal Server Error. A logic error on the server-side code occurred.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>Updated change request record. Each element in this object corresponds to a field in the record in the Change Request [change_request] table. All elements contain value and display_value name-value pairs. Some contain display_value_internal name-value pairs. Data type: Object</td>
</tr>
</tbody>
</table>

Example: cURL request

```bash
curl "https://instance.servicenow.com/api/sn_chg_rest/v1/change/b0dbda5347c12200e0ef563dbb9a718f" \ --request PATCH \ --header "Accept: application/json" \ --header "Content-Type: application/json" \ --data "{"short_description": "Reboot the server at 6 am\" }" \ --user "username":"password"
```

Change Management - PATCH /sn_chg_rest/change/{sys_id}/approvals
Allows the current user to approve or reject a change request approval record for the specified change request.

URL format
Versioned URL: /api/sn_chg_rest/{api_version}/change/{sys_id}/approvals
Default URL: /api/sn_chg_rest/change/{sys_id}/approvals

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the change request for which the approval/rejection applies. Located in the Change Request [change_request] table. Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>comments</td>
<td>Required if state is rejected. Reason that the change was rejected. Data type: String</td>
</tr>
</tbody>
</table>
| state | Required. Approval state. For example: --data "{"state": "approved"}"

Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• approved</td>
</tr>
<tr>
<td></td>
<td>• rejected</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.
### Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad request. Indicates a bad request type such as the user not having the authority to approve or reject the change request.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name-value pairs</td>
<td>Values for all fields in the associated change request. Data type: Object</td>
</tr>
<tr>
<td>state</td>
<td>Current state of the change request. Data type: Object</td>
</tr>
<tr>
<td></td>
<td><code>state: {</code>&lt;br&gt;</td>
</tr>
<tr>
<td>state.display_value</td>
<td>State to display in a UI. Data type: String</td>
</tr>
<tr>
<td>state.value</td>
<td>Internal state value. Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the change request being approved/rejected. Data type: String</td>
</tr>
<tr>
<td>type</td>
<td>Type of change request. Data type: Object</td>
</tr>
<tr>
<td></td>
<td><code>type: {</code>&lt;br&gt;</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>type.display_value</td>
<td>Change type to display in a UI. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• Emergency</td>
</tr>
<tr>
<td></td>
<td>• Normal</td>
</tr>
<tr>
<td></td>
<td>• Standard</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>type.value</td>
<td>Internal type value. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• emergency</td>
</tr>
<tr>
<td></td>
<td>• normal</td>
</tr>
<tr>
<td></td>
<td>• standard</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

**Example: cURL request**

```bash
curl
  "https://instance.servicenow.com/api/sn_chg_rest/v1/change/0f4ac6c4b750230096c3e4f6ee11a9fe/approvals"
  --request POST 
  --header "Accept: application/json" 
  --header "Content-Type: application/json"
  --data "{"state": "approved"}"
  --user "username":"password"
```

```json
{
  result: [
    {
      sys_id: "0f4ac6c4b750230096c3e4f6ee11a9fe",
      state: {
        value: "-2",
        display_value: "Scheduled"
      },
      type: {
        value: "normal",
        display_value: "Normal"
      }
    }
  ]
}
```
Example: Python request

```python
# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.service-now.com/api/sn_chg_rest/v1/change/0f4ac6c4b750230096c3e4f6ee11a9fe/approvals'

# Set the user credentials
user = 'username'
pwd = 'password'

# Set the proper headers
headers = {'Content-Type': 'application/json', 'Accept': 'application/xml'}

# Make the HTTP request
response = requests.patch(url, auth=(user, pwd), headers=headers, data='{"state": "approved"}')

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)
```

```xml
<?xml version="1.0" encoding="UTF-8"?>
<response>
  <result>
    <sys_id>0f4ac6c4b750230096c3e4f6ee11a9fe</sys_id>
  </result>
</response>
```
Change Management - PATCH /sn_chg_rest/change/{change_sys_id}/schedule/first_available

Updates the planned start and end times of a change request using the first available time slot found.

Role required: sn_change_writer

ℹ️ Note: Use the link provided in the response body `worker.link` property to view the schedule status.

See also:
- GET /sn_chg_rest/change/ci/{cmdb_ci_sys_id}/schedule
- GET /sn_chg_rest/change/{change_sys_id}/schedule

URL format

Versioned URL: /api/sn_chg_rest/{api_version}/change/{change_sys_id}/schedule/first_available

Default URL: /api/sn_chg_rest/change/{change_sys_id}/schedule/first_available
Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>change_sys_id</td>
<td>Sys_id of the change request on which to update with the next available time slot. Located in the Change Requests [change_request] table. The selected change request must have a configuration item (cmdb_ci).</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>duration_in_seconds</td>
<td>Duration of change in seconds, that is, how much time is required to complete the change request task. Data type: Integer</td>
</tr>
<tr>
<td>planned_start_time</td>
<td>Optional. Date and time that the change request is planned to start implementation in UTC. Retrieve the available time slot start at or later than this time. If not provided, the system uses the current time as the start time. Time format: yyyy-mm-dd hh:mm:ss Data type: String</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>

</tbody>
</table>

### Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>202</td>
<td>System accepted the request.</td>
</tr>
</tbody>
</table>
| 400         | Bad Request. A bad request type or malformed request was detected. Possible issues:  
• The duration_in_seconds body parameter value is invalid or was not provided.  
• Invalid planned_start_time body parameter value provided.  
• The specified change request does not have an associated configuration item (cmdb_ci).  
• User does not have read access to the fields of the change request. |
| 403         | Forbidden. User does not have write access to the planned start and end date values of the change request. |
| 404         | Not Found. The specified record could not be found. Possible issues:  
• System cannot find the change request based on information provided.  
• User does not have read access to the record. |
## Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

<tr>
<td>worker.sysId</td>
<td>Sys_id of the worker associated with the change request.</td>
<td>String</td>
</tr>
<tr>
<td>status</td>
<td>Only appears if an error is encountered. Status of the endpoint processing. Possible values: • failure</td>
<td>String</td>
</tr>
</tbody>
</table>

**Get change request schedule status**

Use the value provided in the **worker.link** to determine if the change record has been successfully scheduled for the first available time slot. The value is in the following format:

https://instance.service-now.com/api/sn_chg_rest/change/worker/<worker_sys_id>

Use the worker.link details to run the provided sys_id in GET /sn_chg_rest/change/worker/{sys_id} to view results.

The response body contains the status and provides results when processing is complete.

If an available time slot is found, the system updates the change request with the first available slot. When the state is complete, the **messages.infoMessages** reveals that the first available time slot has been set.

One of the following scheduling response values for **messages.infoMessages** are provided in the response body:
• Change has been updated – Change requested has been updated for time slot.
• No slots found for <number> days from now – No time slots available for change request duration provided within the number of days defined in the schedule window.

**Note:** The change request scheduling time slot default value is 90 days. To change this value, modify the `change.conflict.next_available.schedule_window` property. For more information, see Configure conflict analysis properties.

The following GET `/sn_chg_rest/change/worker/{sys_id}` example shows output provided using the ID provided in the worker.link detail. The results indicate that processing is complete and the change request has been updated with the first available time slot.

```json
{
  "result": {
    "worker": {
      "sysId": "355c62e0a4c87010f87712198fe9cacf",
      "link": "https://instance.service-now.com/api/sn_chg_rest/change/worker/355c62e0a4c87010f87712198fe9cacf"
    },
    "request": {
      "change_sys_id": "87ae5e900a0a2c3e263e8304e727c646",
      "duration_in_seconds": 10800,
      "timezone": "America/Los_Angeles"
    },
    "state": {
      "value": 3,
      "display_value": "Complete"
    },
    "type": "schedule",
    "messages": {
      "errorMessages": [],
      "warningMessages": [],
      "infoMessages": [
        "Change has been updated"
      ]
    }
  }
}
```
Example: cURL request

curl
  "https://instance.service-now.com/api/sn_chg_rest/change/87ae5e900a0a2c3e263e8304e727c646/schedule/first_available" \
  --request PATCH \
  --header "Accept:application/json" \
  --header "Content-Type:application/json" \
  --data "{"duration_in_seconds":"10800"}" \
  --user "username":"password"

Results include worker.link details you can use to run the provided sys_id in the GET /sn_chg_rest/change/worker/ endpoint.

```json
{
  "result": {
    "worker": {
      "sysId": "355c62e0a4c87010f87712198fe9cacf",
      "link": "https://instance.service-now.com/api/sn_chg_rest/change/worker/355c62e0a4c87010f87712198fe9cacf"
    },
    "request": {
      "change_sys_id": "87ae5e900a0a2c3e263e8304e727c646",
      "duration_in_seconds": 10800,
      "timezone": "America/Los_Angeles"
    },
    "state": {
      "value": 1,
      "display_value": "Waiting"
    },
    "type": "schedule",
    "messages": {
      "errorMessages": [],
      "warningMessages": [],
      "infoMessages": []
    }
  }
}
```

Change Management - PATCH /sn_chg_rest/change/{change_sys_id}/task/{task_sys_id}

Updates the change request task identified by the specified sys_ids with the key-value pairs in the request body or the URL.
**URL format**

Versioned URL: `/api/sn_chg_rest/{api_version}/change/{change_sys_id}/task/{task_sys_id}`

Default URL: `/api/sn_chg_rest/change/{change_sys_id}/task/{task_sys_id}`

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>change_sys_id</td>
<td>Sys_id of the change request to which the task is associated. Verifies whether the specified task is associated with the specified change request. Located in the Change Request [change_request] table. Data type: String</td>
</tr>
<tr>
<td>task_sys_id</td>
<td>Sys_id of the task to modify. Located in the Change Task [change_task] table. Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key-value pairs</td>
<td>Name-value pairs for the fields to update. Request body parameters override URL parameters. However, required parameters must be specified in the URL. Data type: String</td>
</tr>
</tbody>
</table>

**Request body parameters (XML or JSON)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data</td>
<td>Name-value pairs for the field(s) to update in the associated change request. For example, to update the short description file, enter a name-value pair similar to the following: <code>--data &quot;{&quot;short_description&quot;: &quot;my short desc&quot;}&quot;</code></td>
</tr>
</tbody>
</table>
Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
</tbody>
</table>
Status codes (continued)

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not Found. The specified record could not be found.</td>
</tr>
<tr>
<td>500</td>
<td>Internal Server Error. A logic error on the server-side code occurred.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name-value pairs</td>
<td>All fields (key) with their associated values for the identified change request task prior to the delete. Data type: Object</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id information for the change request task. Data type: Object</td>
</tr>
<tr>
<td></td>
<td>sys_id: { display_value: &quot;String&quot;, value: &quot;String&quot; }</td>
</tr>
<tr>
<td>sys_id.display_value</td>

</tr>
</tbody>
</table>

**Example: cURL request**

```bash
curl
  "https://instance.servicenow.com/api/sn_chg_rest/v1/change/emergency/b0dbda5347c12200e0ef563dbb9a718f"
  --request PATCH
  --header "Accept: application/json"
  --header "Content-Type: application/json"
  --data "{"no_such_field": "this will be ignored", }"
  --user "username":"password"
```

```json
{
  result: [  
    {
      sys_id: "b0dbda5347c12200e0ef563dbb9a718f",
    },
    state: {
      value: "-4",
      display_value: "Assess"
    },
    type: {
      value: "emergency",
      display_value: "Emergency"
    },
    ..., // all valid fields in record, example below
    short_description: {
      value: "Reboot server",
    }
  ]
}
```
Example: Python request

```python
# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/sn_chg_rest/v1/change/emergency/b0dbda5347c12200e0ef563dbb9a718f?state=assess'

# Set the user credentials
user = 'username'
pwd = 'password'

# Set the proper headers
headers = {'Content-Type': 'application/json', 'Accept': 'application/xml'}

# Do the HTTP request
response = requests.patch(url, auth=(user, pwd), headers=headers, data='{"state": "assess", "no_such_field": "this will be ignored" }')

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)
```

```xml
<?xml version="1.0" encoding="UTF-8"?>
<response>
  <result>
    <sys_id>b0dbda5347c12200e0ef563dbb9a718f</sys_id>
    <state>
```

<td></td>
<td><strong>Data type: String</strong></td>
</tr>
<tr>
<td>__meta.ignoredFields</td>
<td>Name-value pairs that were passed in the call, but were not applied to the change request as they either do not exist in the base record or the fields are read-only.</td>
</tr>
</tbody>
</table>

**Example: cURL request**

```
curl
  "https://instance.servicenow.com/api/sn_chg_rest/v1/change/normal/b0dbda5347c12200e0ef563dbb9a718f?state=assess" \
  --request PATCH \
  --header "Accept: application/json" \
  --header "Content-Type: application/json" \
  --data "{"state": "assess" \n      "no_such_field": "this will be ignored" }" \
  --user "username":"password"
```
Example: Python request

```python
# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/sn_chg_rest/v1/change/normal/b0dbda5347c12200e0ef563dbb9a718f7/state=assess'

# Set the user credentials
user = 'username'
pwd = 'password'

# Set the proper headers
headers = {'Content-Type': 'application/json', 'Accept': 'application/xml'}

# Make the HTTP request
response = requests.patch(url, auth=(user, pwd), headers=headers, data='{"state": "assess", "no_such_field": "this will be ignored" }')

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)
```
Change Management - PATCH /sn_chg_rest/change/standard/{sys_id}
Updates the standard change request identified by the specified sys_id with the parameters in the request body or in the URL.

**URL format**
- **Versioned URL**: /api/sn_chg_rest/{api_version}/change/standard/{sys_id}
- **Default URL**: /api/sn_chg_rest/change/standard/{sys_id}

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
</tbody>
</table>
Path parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sys_id</td>
<td>Sys_id of the change request to modify. Located in the [change_request] table.</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>

if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)
```

```xml
<response>
  <result>
    <error>
      <message>Complete Risk Assessment to calculate risk</message>
      <detail></detail>
    </error>
    <status>failure</state>
  </result>
</response>
```
Change Management - POST /sn_chg_rest/change

Creates a change request record based on the default change request record. Multiple change request creations within a single call is not supported.

To create a change request for a desired model or type, other than the default of Normal, you must pass in either the model or type parameter. You can obtain the list of available change models using the Change Management - GET /sn_chg_rest/change/model or Change Management - GET /sn_chg_rest/change/model/{sys_id} endpoints.

**URL format**

**Versioned URL:** /api/sn_chg_rest/{api_version}/change

**Default URL:** /api/sn_chg_rest/change

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name-value</td>
<td>Name-value pairs for the fields to update. Request body parameters override URL parameters. However, required parameters must be specified in the URL.</td>
</tr>
<tr>
<td>value pairs</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** To create a change request for a desired model or type, rather than the default of "Normal", you must pass in either the model or type parameter. For example, chg_model=Normal or type=Normal.

Data type: String
Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data</td>
<td>Name-value pairs for the field(s) to update in the associated change request. For example, to update the short description file, enter a name-value pair similar to the following: <code>--data &quot;{&quot;short_description&quot;:&quot;my short desc&quot; }&quot;</code> . Data type: String</td>

Change Management - POST /sn_chg_rest/change/{sys_id}/ci

Creates the association between a change request and Configuration Management Database (CMDB) configuration items (CI).

The creation of the association is done asynchronously, which means that a response is provided immediately and contains details for the worker. The worker does the actual work after the response.

**URL format**

Versioned URL: /api/sn_chg_rest/{api_version}/change/{sys_id}/ci
Default URL: /api/sn_chg_rest/change/{sys_id}/ci

    </state>
  </result>
</response>
```
Change Management - POST /sn_chg_rest/change/{sys_id}/refresh_impacted_services

Populates the impacted services/configuration items (CIs) related list based on the primary CI.

The primary CI appears on the change request form and affected CI related list.

Note: All work items for this endpoint are performed asynchronously.

URL format

Versioned URL: /api/sn_chg_rest/{api_version}/change/{sys_id}/refresh_impacted_services

Default URL: /api/sn_chg_rest/change/{sys_id}/refresh_impacted_services

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>
Path parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sys_id</td>
<td>Sys_id of the change request to use to refresh the impacted services.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml.</td>
</tr>
<tr>
<td></td>
<td>Default: application/json</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Supported types: application/json or application/xml.</td>
</tr>
<tr>
<td></td>
<td>Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
**Status codes**

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>200</strong></td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td><strong>401</strong></td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td><strong>404</strong></td>
<td>Not Found. The specified record could not be found.</td>
</tr>
<tr>
<td><strong>500</strong></td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

**Response body parameters (JSON or XML)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>messages</td>
<td>Message information. Data type: Object</td>
</tr>
<tr>
<td></td>
<td>&quot;messages&quot;: {</td>
</tr>
<tr>
<td></td>
<td>&quot;errorMessages&quot;: [Array],</td>
</tr>
<tr>
<td></td>
<td>&quot;infoMessages&quot;: [Array],</td>
</tr>
<tr>
<td></td>
<td>&quot;warningMessages&quot;: [Array]</td>
</tr>
<tr>
<td>messages.errorMessages</td>
<td>Error messages encountered while processing the request. For example:</td>
</tr>
<tr>
<td></td>
<td>Invalid CMDB_CI sys_id provided</td>
</tr>
<tr>
<td>messages.infoMessages</td>
<td>Information messages encountered while processing the request. For example:</td>
</tr>
<tr>
<td></td>
<td>CMDB_CI sys_id already associated to provided.</td>
</tr>
</tbody>
</table>

**Example: cURL request**

```bash
curl
  "https://instance.servicenow.com/api/sn_chg_rest/v1/change/c286d61347c12200e0ef563dbb9a71df/refresh_impacted_services" \
  --request POST \
  --header "Accept:application/json" \
  --header "Content-Type:application/json" \
  --user "username":"password"
```

```
{
  result: {
    worker: {
      sysId: "aa31c308b75033000999e4f6ee1a9c2",
      link: "http://instance.service-now.com/api/sn_chg_rest/change/worker/aa31c308b75033000999e4f6ee1a9c2"
    },
    request: "",
    state: {
      value: 1,
      display_value: "Waiting"
    }
  }
```
Example: Python request

```python
# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/sn_chg_rest/v1/change/c286d61347c12200e0ef563dbb9a71df/refresh_impacted_services'

# Set the user credentials
user = 'username'
pwd = 'password'

# Set the proper headers
headers = {'Content-Type': 'application/json', 'Accept': 'application/xml'}

# Make the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)
```

```xml
<?xml version="1.0" encoding="UTF-8"?>
<response>
    <result>
        <request>{"task":"c286d61347c12200e0ef563dbb9a71df"}</request>
        <messages></messages>
        <state>
```

Change Management - POST /sn_chg_rest/change/standard/{standard_change_template_id}

Creates one standard change request based on an existing standard change template as specified by the passed-in template sys_id. Multiple standard change request creations within a single call is not supported.

URL format

Versioned URL: /api/sn_chg_rest/{api_version}/change/standard/{standard_change_template_id}

Default URL: /api/sn_chg_rest/change/standard/{standard_change_template_id}

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td>standard_change_template_id</td>
<td>Sys_id of the standard change template on which to base the new standard change request. Located in the Standard Change Template [std_change_record_producer] table.</td>
</tr>
</tbody>
</table>
Query parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name-value pairs</td>
<td>Fields within the specified standard change template to modify when creating the request. The key is the field name within the template and the value is the information to populate in the field. Fields that cannot be modified and are ignored if passed in:</td>
</tr>
<tr>
<td></td>
<td>• Description</td>
</tr>
<tr>
<td></td>
<td>• Backout plan</td>
</tr>
<tr>
<td></td>
<td>• Test plan</td>
</tr>
<tr>
<td></td>
<td>• Implementation plan</td>
</tr>
<tr>
<td></td>
<td>• Read-only fields as defined in ACLs</td>
</tr>
<tr>
<td></td>
<td>• Fields that do not exist in the specified standard change template</td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>

<tr>
<td>404</td>
<td>Not Found. The specified record could not be found.</td>
</tr>
<tr>
<td>500</td>
<td>Internal Server Error. A logic error on the server-side code occurred.</td>
</tr>
</tbody>
</table>

Response body
The API returns these JSON or XML elements in the response body.

Elements returned in the response body

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name-value pairs</td>
<td>Name-value pairs of the fields that were created in the standard change request. Data type: Object</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id information of the newly created standard change request. Data type: Object</td>
</tr>
<tr>
<td>sys_id.display_value</td>
<td>Sys_id of the standard change request to display in a UI. Data type: String</td>
</tr>
<tr>
<td>sys_id.value</td>
<td>Sys_id of the standard change request.</td>
</tr>
</tbody>
</table>
Elements returned in the response body (continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
</tbody>
</table>

| __meta.ignoredFields | Key-value pairs that were passed in the call, but were not applied to the change request as they either do not exist in the base record or the fields are read-only. |
| Data type: Array |

Example: Sample cURL request

```bash
curl "https://instance.servicenow.com" \
--request POST \
--header "Accept:application/json" \
--user "username":"password"

{
    result: [{
        sys_id: {
            value: "1c87925347c12200e0ef563dbb9a7177",
            display_value: "1c87925347c12200e0ef563dbb9a7177"
        },
        ..., // all valid fields in record, example below
        short_description: {
            value: "Add network switch to cabinet",
            display_value: "Add network switch to cabinet"
        }
        __meta: {
            ignoredFields: ["no_such_field"]
        }
    }
}
```

Example: Sample Python request

```python
# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com'
```
# Set the user credentials
user = 'username'
pwd = 'password'

# Set the proper headers
headers = {'Accept':'application/xml'}

# Make the HTTP request
response = requests.post(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:',
          response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)

<?xml version="1.0" encoding="UTF-8"?>
<response>
  <result>
    <sys_id>
      <value>1c87925347c12200e0ef563dbb9a7177</value>
      <display_value>1c87925347c12200e0ef563dbb9a7177</display_value>
    </sys_id>

    // all valid fields in record, single parameter example below
    <short_description>
      <value>Add network switch to cabinet</value>
      <display_value>Add network switch to cabinet</display_value>
    </short_description>

  </result>
</response>

Change Management - POST /sn_chg_rest/change/{change_sys_id}/task

Creates one change request task based on the default change request task record and associates it with the specified change request. Multiple change request task creations within a single call is not supported.
URL format
Versioned URL: /api/sn_chg_rest/{api_version}/change/{change_sys_id}/task
Default URL: /api/sn_chg_rest/change/{change_sys_id}/task

Supported request parameters

Path parameters

<table>
<thead>
<tr>

**CI Lifecycle Management API**

The CI Lifecycle Management API provides the ability to manipulate configuration item (CI) operational states and apply CI actions.

The API interfaces adhere to restrictions and allowances specified by not allowed CI actions, compatible CI actions, and not allowed operational transitions. If an interface attempts a restricted operation, the operation is blocked, an error is logged, and a task is created if appropriate.
CI Lifecycle Management - DELETE /now/cilifecyclemgmt/actions
Removes a configuration item (CI) action for a list of CIs.

URL format
Versioned URL: /api/now/{api_version}/cilifecyclemgmt/actions
Default URL: /api/now/cilifecyclemgmt/actions

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>actionName</td>
<td>Required. Configuration item action name. Data type: String</td>
</tr>
<tr>
<td>requestorId</td>
<td>Required. Sys_id of a workflow context, or an operator user ID returned from the CI Lifecycle Management - POST /now/cilifecyclemgmt/operators endpoint. Operator user IDs are located in the CI State Registered Users [statemgmt_register_users] table. Data type: String</td>
</tr>
<tr>
<td>sysIds</td>
<td>Required. Comma-separated list of CI sys_ids. Data type: String</td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json, application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed by the endpoint. Review the response body <code>result.result</code> parameter to verify the outcome of the operation. If the endpoint encounters errors while processing the request, error codes and messages appear in the response body <code>result.errors</code> parameter.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>
## Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>Object encapsulating the result of the request. Data type: Object</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>result.errors</td>
<td>List of objects in which each object represents an error encountered while processing the request. Data type: Array</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>result.errors.error</td>
<td>Identifier for a state management error encountered while processing the request. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• CI_ACTION_ALREADY_SET</td>
</tr>
<tr>
<td></td>
<td>• CI_ACTION_NOT_SET</td>
</tr>

</tbody>
</table>

Data type: String

result.errors.message | Message providing details on the associated error. Data type: String

result.result | Flag indicating whether the CI action was successfully removed. Possible values: Data type: String
• true: CI action was removed.
• false: CI action was not removed.

Example: cURL request
Remove a CI action from two CIs.

```
curl --request DELETE \\
'https://instance.service-now.com/api/now/cilifecyclemgmt/actions?actionName=Patching&requestorId=621b5a09309e5010f877773aa7167c0a&sysIds=00a9a80d3790200044e0bfc8bcbe5d1c,d0fdbc8437201000deabfc8bcbe5d33' \\
--header 'Accept: application/json' \\
--user "username":"password"
```

The response body confirms that the CI action was removed from the CIs.

```
{
  "result": {
    "result": true
  }
}
```
Example: Python request
Remove a CI action from two CIs.

```python
# Need to install requests package for python
import requests

import json

# Set the API endpoint URL for the request
url = "https://instance.service-now.com/api/now/cilifecyclemgmt/actions/"

# Set credentials
user = "username"
pwd = "password"

# Set query parameters
params = {
    "actionName": "Provisioning",
    "requestorId": "621b5a09309e5010f877773aa7167c0a",
    "sysIds": "00a9a80d3790200044e0bfc8bcbe5d1c,d0fdbc8437201000deeabfc8bcbe5d33"
}

# Set HTTP headers
headers = {
    "Accept": "application/json"
}

# Issue the HTTP request
response = requests.delete(url, auth=(user, pwd), params=params, headers=headers)

# Check for HTTP status codes other than 200
if response.status_code != 200:
    print("Status:", response.status_code, "Headers:", response.headers, "Error Response:", response.content)
    exit()

# Display the JSON response
print(json.dumps(response.json()))
```

The response body shows that the specified CI action is not set for the CIs.

```json
{
    "result": {
        "result": false,
        "errors": {
            
```
CI Lifecycle Management - DELETE /now/cilifecyclemgmt/operators/{req_id}
Unregisters an operator for non-workflow users.

**URL format**

Versioned URL: /api/now/{api_version}/cilifecyclemgmt/operators/{req_id}
Default URL: /api/now/cilifecyclemgmt/operators/{req_id}

**Supported request parameters**

### Path parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td>req_id</td>
<td>Sys_id of a workflow context, or an operator user ID returned from the CI Lifecycle Management - POST /now/cilifecyclemgmt/operators endpoint.</td>
</tr>
</tbody>
</table>

Operator user IDs are located in the CI State Registered Users [statemgmt_register_users] table.
Data type: String
Query parameters

<table>

<td>UNSUPPORTED_SYS_ID</td>
<td></td>
</tr>
</tbody>
</table>

Data type: String

result.errors.message | Message providing details on the associated error. Data type: String

result.result | Flag indicating whether the operator was successfully unregistered. Possible values:  
\* true: Operator was successfully unregistered.  
\* false: Operator was not successfully unregistered. Data type: String

**Example: cURL request**

Unregister an operator by user ID.
curl --request DELETE \
"https://instance.service-now.com/api/now/cilifecyclemgmt/operators/3cf1b3cc30121010f877773aa7167c6e" \
--header "Accept: application/json" \
--user "username":"password"

The response body verifies that the operator was unregistered.

```
{
    "result": {
        "result": true
    }
}
```

Example: Python request

Unregister an operator by user ID.

```python
# Need to install requests package for python
import requests
import json

# Set the API endpoint URL for the request
url = "https://instance.service-now.com/api/now/cilifecyclemgmt/operators/0c7f674830521010f877773aa7167cdf"

# Set credentials
user = "username"
pwd = "password"

# Set HTTP headers
headers = {
    "Accept": "application/json"
}

# Issue the HTTP request
response = requests.delete(url, auth=(user, pwd), headers=headers)

# Check for HTTP status codes other than 200
if response.status_code != 200:
    print("Status:"+ response.status_code, "Headers:"+ response.headers, "Error Response:"+ response.content)
    exit()
```
The response body shows that the operator could not be unregistered. Verify that the `req_id` path parameter contains a valid operator user ID field value.

```json
{
    "result": {
        "result": false,
        "errors": [
            {
                "message": "Requestor [0c7f674830521010f877773aa7167cdf] is not registered",
                "error": "INVALID_REQUESTOR"
            }
        ]
    }
}
```

**CI Lifecycle Management - GET /now/cilifecyclemgmt/actions/{sys_id}**

Returns a list of active configuration item (CI) actions for the specified CI.

**URL format**

**Versioned URL:** `/api/now/{api_version}/cilifecyclemgmt/actions/{sys_id}`

**Default URL:** `/api/now/cilifecyclemgmt/actions/{sys_id}`

Data type: String

result.errors.message | Message providing details on the associated error. |
Data type: String

result.result        | Flag indicating whether the list of active CI actions was returned for all specified CIs. Possible values: |
|                    | • true: List of active CI actions was returned. |
|                    | • false: List of active CI actions was not returned. |
Data type: String
Example: cURL request

curl --request GET \
'https://instance.service-now.com/api/now/cilifecyclemgmt/actions/00a9a80d3790200044e0bfc8bcbe5d1c' \
--header 'Accept: application/json' \
--user "username":"password"

The response body shows that no CI actions are active for the specified CI.

{
  "result": {
    "ciActions": [
      "no_active_action"
    ],
    "result": true
  }
}

Example: Python request

#Need to install requests package for python
import requests
import json

# Set the API endpoint URL for the request
url = 
  "https://instance.service-now.com/api/now/cilifecyclemgmt/actions/d0fdbc8437201000deeabfc8bcbe5d33"

# Set credentials
user = "username"
pwd = "password"

# Set HTTP headers
headers = { 
  "Accept": "application/json"
}

# Issue the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP status codes other than 200
if response.status_code != 200:
The response body shows that a CI action with name "Patching" is active for the specified CI.

```
{
  "result": {
    "ciActions": ["Patching"],
    "result": true
  }
}
```

**CI Lifecycle Management - GET /now/cilifecyclemgmt/compatActions**

</table>
| result | Flag indicating whether the two specified CI actions are compatible. Possible values:  
• `true`: CI actions are compatible.  
• `false`: CI actions are not compatible.  
Data type: String |

Example: cURL request

Check compatibility of Patching and Provisioning CI actions.

```
curl --request GET  
'https://instance.service-now.com/api/now/cilifecyclemgmt/compatActions?actionName=Patching 
&otherActionName=Provisioning' 
--header 'Accept: application/json' 
--user "username":"password"
```

The response body confirms that the two CI actions are compatible.

```
{
    "result": true
}
```
Example: Python request

Check compatibility of Patching and Disposing CI actions.

```python
# Need to install requests package for python
import requests

# Set the API endpoint URL for the request
url =
  "https://instance.service-now.com/api/now/cilifecyclemgmt/compatActions?actionName=Patchin
g&otherActionName=Disposing"

# Set credentials
user = "username"
pwd = "password"

# Set HTTP headers
headers = {
  "Accept": "application/json"
}

# Issue the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP status codes other than 200
if response.status_code != 200:
    print("Status:", response.status_code, "Headers:", response.headers, "Error Response:", response.content)
    exit()

# Display the JSON response
print(json.dumps(response.json()))
```

The response body shows that the two CI actions are incompatible.

```json
{
  "result": false
}
```

CI Lifecycle Management - GET /now/cilifecyclemgmt/leases/{sys_id}/expired

Determines whether the lease has expired for the requestor of a configuration item (CI) action applied to the specified CI.
## URL format

- **Versioned URL:** `/api/now/{api_version}/cilifecyclemgmt/leases/{sys_id}/expired`
- **Default URL:** `/api/now/cilifecyclemgmt/leases/{sys_id}/expired`

## Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, <code>v1</code> or <code>v2</code>. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the CI that is the target of the applied CI action.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>actionName</td>
<td>Required. Name of the CI action applied to the specified CI.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>requestorId</td>
<td>Required. Sys_id of a workflow context, or an operator user ID returned from the CI Lifecycle Management - POST /now/cilifecyclemgmt/operators endpoint. Operator user IDs are located in the CI State Registered Users [statemgmt_register_users] table.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

### Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see [Supported REST API headers](#).
Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed by the endpoint. Review the response body result.result parameter to verify the outcome of the operation. If the endpoint encounters errors while processing the request, error codes and messages appear in the response body result.errors parameter.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>Object encapsulating the result of the request. Data type: Object</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>result</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td>&quot;result&quot;: {</td>
</tr>
<tr>
<td></td>
<td>&quot;errors&quot;: [Array],</td>
</tr>
<tr>
<td></td>
<td>&quot;result&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>result.errors</td>
<td>List of objects in which each object represents an error encountered while processing the request. Data type: Array</td>
</tr>
<tr>
<td></td>
<td>&quot;errors&quot;: [</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&quot;error&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;message&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>result.errors.error</td>
<td>Identifier for a state management error encountered while processing the request. Possible values: CI_ACTION_ALREADY_SET, CI_ACTION_NOT_SET, DUPLICATE_CI_ACTION_RECORD, DUPLICATE_OPS_STATE_RECORD, DUPLICATE_SYS_ID, INCOMPATIBLE_CI_ACTION, INVALID_CI_ACTION, INVALID_DELETE, INVALID_INPUT_PARAMETERS, INVALID_LEASETIME, INVALID_OPS_STATE, INVALID_OPS_STATE_TRANSITION, INVALID_REQUESTOR, INVALID_REQUESTOR_FOR_CI, INVALID_SYS_ID, MUTEX_UNAVAILABLE, NOT_ALLOWED_CI_ACTION</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>result.errors.message</td>
<td>Message providing details on the associated error.</td>
</tr>
<tr>
<td>result.result</td>
<td>Flag indicating whether the lease for the requestor of the applied CI action has expired. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: Requestor's lease has expired.</td>
</tr>
<tr>
<td></td>
<td>• false: Requestor's lease has not expired.</td>
</tr>
</tbody>
</table>

**Example: cURL request**

```
curl --request GET \\ 'https://instance.service-now.com/api/now/cilifecyclemgmt/leases/00a9a80d3790200044e0bfc8bbe5dc/expired?actionName=Patching&requestorId=621b5a09309e5010f877773aa7167c0a' \\
--header 'Accept: application/json' \\
--user "username":"password"
```

The response body shows that the lease for the requestor of the applied CI action has not expired.

```
{
    "result": {
        "result": false
    }
}
```

**Example: Python request**

```
# Need to install requests package for python
import requests
import json

# Set the API endpoint URL for the request
```
url =
  "https://instance.service-now.com/api/now/cilifecyclemgmt/leases/affd3c8437201000deabfc8bcbe5dc3/expired?actionName=Patching&requestorId=4cab9b5301a9010f877773aa7167ca9"

# Set credentials
user = "username"
pwd = "password"

# Set HTTP headers
headers = {
    "Accept": "application/json"
}

# Issue the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP status codes other than 200
if response.status_code != 200:
    print("Status:", response.status_code, "Headers:", response.headers, "Error Response:", response.content)
    exit()

# Display the JSON response
print(json.dumps(response.json()))

The response body shows that the lease for the requestor of the applied CI action has expired.

{
    "result": {
        "result": true
    }
}

**CI Lifecycle Management - GET /now/cilifecyclemgmt/notAllowedAction**

Determines whether a specified configuration item (CI) action is not allowed for a CI of a specified class when in a specified operational state.

**URL format**

Versioned URL: /api/now/{api_version}/cilifecyclemgmt/notAllowedAction

Default URL: /api/now/cilifecyclemgmt/notAllowedAction
**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>actionName</td>
<td>Required. Name of the CI action to check.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>ciClass</td>
<td>Required. CI class.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>opsLabel</td>
<td>Required. Operational state to check.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

**Request body parameters (XML or JSON)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Headers**

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

**Request headers**

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>
Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Status codes**

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed by the endpoint. Review the response body result.result parameter to verify the outcome of the operation. If the endpoint encounters errors while processing the request, error codes and messages appear in the response body result.errors parameter.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

**Response body parameters (JSON or XML)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>Flag indicating whether the CI action is restricted (not allowed) for CIs of the specified type when in the specified operational state. Possible values: • true: CI action is restricted (not allowed). • false: CI action is unrestricted (allowed). Data type: String</td>
</tr>
</tbody>
</table>
Example: cURL request

Check whether the Patching CI action is restricted (not allowed) for computers in the DR Standby operational state.

curl --request GET \
"https://instance.service-now.com/api/now/cilifecyclemgmt/notAllowedAction?actionName=Patch\ning&ciClass=cmdb_ci_computer&opsLabel=DR+Standby" \
--header "Accept: application/json" \
--user "username":"password"

The response body confirms that this action is restricted (not allowed) for the specified CI class when in the specified operational state.

```
{
  "result": true
}
```

Example: Python request

Check whether the Provisioning action is restricted (not allowed) for network firewall hardware CIs when in the Retired operational state.

```python
# Need to install requests package for python
import requests
import json

# Set the API endpoint URL for the request

# Set credentials
user = "username"
pwd = "password"

# Set HTTP headers
headers = {
    "Accept": "application/json"
}

# Issue the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP status codes other than 200
if response.status_code != 200:
```
print("Status": response.status_code, "Headers": response.headers, "Error Response":, response.content)
exit()

# Display the JSON response
print(json.dumps(response.json()))

The response body confirms that this action is unrestricted (allowed) for the specified CI class when in the specified operational state.

{
  "result": false
}

CI Lifecycle Management - GET /now/cilifecyclemgmt/notAllowedOpsTransition

Determines whether a configuration item (CI) from a specified class can transition from a specified operational state to a second specified operational state.

**URL format**

Versioned URL: /api/now/{api_version}/cilifecyclemgmt/notAllowedOpsTransition

Default URL: /api/now/cilifecyclemgmt/notAllowedOpsTransition

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ciClass</td>
<td>Required. CI class to check transition restrictions for. Data type: String</td>
</tr>
<tr>
<td>opsLabel</td>
<td>Required. Label of current CI operational state.</td>
</tr>
</tbody>
</table>
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>transitionOpsLabel</td>
<td>Required. Label of operational state that is the target of the transition. Data type: String</td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.
### Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed by the endpoint. Review the response body <code>result.result</code> parameter to verify the outcome of the operation. If the endpoint encounters errors while processing the request, error codes and messages appear in the response body <code>result.errors</code> parameter.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| result | Flag indicating whether the specified operational state transition is restricted (not allowed) for the specified CI class. Possible values:  
• true: Operational state transition is restricted (not allowed).  
• false: Operational state transition is unrestricted (allowed).  
Data type: String |

### Example: cURL request

Check whether transition from Retired operational state to DR Standby operational state is restricted (not allowed) for Linux server CIs.

```
curl --request GET "https://instance.service-now.com/api/now/cilifecyclemgmt/notAllowedOpsTransition?ciClass=cmdb_ci_computer&opsLabel=Retired&transitionOpsLabel=DR+Standby" 
--header "Accept: application/json" 
--user "username":"password"
```

The response body shows that the specified operational state transition is unrestricted (allowed) for this CI class.
Example: Python request

Check whether transition from Repair in Progress operational state to DR Standby operational state is restricted (not allowed) for Linux server CIs.

```python
# Need to install requests package for python
import requests
import json

# Set the API endpoint URL for the request
url =
    "https://instance.service-now.com/api/now/cilifecyclemgmt/notAllowedOpsTransition?ciClass=cmdb_ci_linux_server&opsLabel=Repair+in+Progress&transitionOpsLabel=DR+Standby"

# Set credentials
user = "username"
pwd = "password"

# Set HTTP headers
headers = {
    "Accept": "application/json"
}

# Issue the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP status codes other than 200
if response.status_code != 200:
    print("Status:", response.status_code, "Headers:", response.headers, "Error Response:", response.content)
    exit()

# Display the JSON response
print(json.dumps(response.json()))
```

The response body shows that the specified operational state transition is restricted (not allowed) for this CI class.

```json
{
    "result": true
}
```
**CI Lifecycle Management - GET /now/cilifecyclemgmt/requestors/{req_id}/valid**

Determines whether the specified active workflow user or registered user is a valid requestor.

**URL format**

Versioned URL: `/api/now/{api_version}/cilifecyclemgmt/requestors/{req_id}/valid`

Default URL: `/api/now/cilifecyclemgmt/requestors/{req_id}/valid`

**Supported request parameters**

<table>
<thead>
<tr>
<th>Path parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>api_version</strong></td>
<td>Optional. Version of the endpoint to access. For example, <code>v1</code> or <code>v2</code>. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td><strong>req_id</strong></td>
<td>Sys_id of a workflow context, or an operator user ID returned from the CI Lifecycle Management - POST /now/cilifecyclemgmt/operators endpoint. Operator user IDs are located in the CI State Registered Users [statemgmt_register_users] table. Data type: String</td>
</tr>
</tbody>
</table>

<table>

</tr>
</tbody>
</table>
## Name | Description
--- | ---
• INVALID_REQUESTOR_FOR_CI | 
• INVALID_SYS_ID | 
• MUTEX_UNAVAILABLE | 
• NOT_ALLOWED_CI_ACTION | 
• OPS_STATE_NOT_SET | 
• UNPRIORITIZED_OPS_STATE | 
• UNSUPPORTED_SYS_ID | 

Data type: String

result.errors.message | Message providing details on the associated error.
Data type: String

result.result | Flag indicating whether the specified active workflow user or registered user is a valid requestor.
Possible values:
• true: Valid requestor.
• false: Invalid requestor.
Data type: String

### Example: cURL request
```bash
curl --request GET \\
'https://instance.service-now.com/api/now/cilifecyclemgmt/requestors/4cab9b95301a9010f87773aa7167ca9/valid' \\
--header 'Accept: application/json' \\
--user "username":"password"

```

```
{
    "result": {
        "result": true
    }
}
```

### Example: Python request
```python
# Need to install requests package for python
import requests
import json
```
# Set the API endpoint URL for the request
url = "https://instance.service-now.com/api/now/cilifecyclemgmt/requestors/621b5a09309e5010f877773aa7167c0a/valid"

# Set credentials
user = "username"
pwd = "password"

# Set HTTP headers
headers = {
    "Accept": "application/json"
}

# Issue the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP status codes other than 200
if response.status_code != 200:
    print("Status: ", response.status_code, "Headers:", response.headers, "Error Response:", response.content)
    exit()

# Display the JSON response
print(json.dumps(response.json()))

{
    "result": {
        "result": false
    }
}

**CI Lifecycle Management - GET /now/cilifecyclemgmt/statuses/{sys_id}**

Returns the current operational state for the specified configuration item (CI).

**URL format**

Versioned URL: /api/now/{api_version}/cilifecyclemgmt/statuses/{sys_id}
Default URL: /api/now/cilifecyclemgmt/statuses/{sys_id}
Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the CI.</td>
</tr>
<tr>

**Example: cURL request**

```
curl --request GET
'https://instance.service-now.com/api/now/cilifecyclemgmt/statuses/aac0b1213784200044e0bfc8bcbe5de3' \
--header 'Accept: application/json'
--user "username":"password"
```

```
{
    "result": {
        "operationalState": "Repair in Progress",
        "result": true
    }
}
```

**Example: Python request**

```
# Need to install requests package for python
import requests
import json

# Set the API endpoint URL for the request
url =
    "https://instance.service-now.com/api/now/cilifecyclemgmt/statuses/aac0b1213784200044e0bfc8bcbe5de3"

# Set credentials
user = "username"
pwd = "password"

# Set HTTP headers
headers = {
    "Accept": "application/json"
}

# Issue the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)
```
# Check for HTTP status codes other than 200
if response.status_code != 200:
    print("Status:", response.status_code, "Headers:", response.headers, "Error Response:",
          response.content)
    exit()

# Display the JSON response
print(json.dumps(response.json()))

{
    "result": {
        "operationalState": "Ready",
        "result": true
    }
}

**CI Lifecycle Management - PATCH /now/cilifecyclemgmt/leases/{sys_id}**

Extends the specified configuration item (CI) action's lease expiration time for the specified user.

If the previous lease has expired, the new lease time starts immediately.

**URL format**

*Versioned URL:* /api/now/{api_version}/cilifecyclemgmt/leases/{sys_id}

*Default URL:* /api/now/cilifecyclemgmt/leases/{sys_id}

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the CI for which to extend the lease. Data type: String</td>
</tr>
</tbody>
</table>
Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>actionName</td>
<td>Required. Name of the associated CI action.</td>
</tr>
<tr>

### Example: cURL request

Extend the duration of a Patching CI action requestor lease by 24 hours.

```bash
curl --request PATCH
  'https://instance.service-now.com/api/now/cilifecyclemgmt/leases/affd3c8437201000deeabfc8bcbe5dc3?actionName=Patching&leaseTime=24:00:00&requestorId=e7c3402d305a9010f877773aa7167c2a'
    --header 'Accept: application/json'
    --header 'Content-Type: application/json'
    --user "username":"password"

{
  "result": {
    "result": true
  }
}
```

### Example: Python request

Extend the duration of a Provisioning CI action requestor lease by 90 minutes.

```python
# Need to install requests package for python
import requests
import json

# Set the API endpoint URL for the request
url =
  "https://instance.service-now.com/api/now/cilifecyclemgmt/leases/affd3c8437201000deeabfc8bcbe5dc3?actionName=Provisioning&leaseTime=01:30:00&requestorId=e7c3402d305a9010f877773aa7167c2a"

# Set credentials
user = "username"
pwd = "password"
```
# Set HTTP headers
headers = {
    "Accept": "application/json"
}

# Issue the HTTP request
response = requests.patch(url, auth=(user, pwd), headers=headers)

# Check for HTTP status codes other than 200
if response.status_code != 200:
    print("Status:", response.status_code, "Headers:", response.headers, "Error Response:", response.content)
    exit()

# Display the JSON response
print(json.dumps(response.json()))

{
    "result": {
        "result": true
    }
}
Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>actionName</td>
<td>Required. Name of the CI action to add to the list.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>leaseTime</td>
<td>Time duration for which the lease is valid for specified CI action.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td></td>
<td>Format: HH:MM:SS</td>
</tr>
<tr>
<td>oldActionNames</td>
<td>Comma-separated list of old CI actions that all CIs should be in.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>requestorId</td>
<td>Required. Sys_id of a workflow context, or an operator user ID returned from</td>
</tr>
<tr>
<td></td>
<td>the CI Lifecycle Management - POST /now/cilifecyclemgmt/operators endpoint.</td>
</tr>
<tr>
<td></td>
<td>Operator user IDs are located in the CI State Registered Users [statemgmt_register_users] table.</td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td>UNSUPPORTED_SYS_ID</td>
<td></td>
</tr>
</tbody>
</table>

Data type: String

result.errors.message Message providing details on the associated error.
Data type: String

result.result Flag indicating whether the CI action was set for all CIs in the list.
Possible values:
- true: CI actions were set.
- false: CI actions were not set.
Data type: String

**Example: cURL request**

Add a Patching CI action to two CIs.

curl --request POST \
"https://instance.service-now.com/api/now/cilifecyclemgmt/actions?actionName=Patching&reques\storId=621b5a09309e5010f877773aa7167c0a&sysIds=00a9a80d3790200044e0bf\c8bcbe5d1c,d0fdbc8437201000deebfc8bcbe5d33" \
   --header "Accept: application/json" \
   --header "Content-Type: application/json" \
   --user "username":"password"

```json
{
  "result": {
    "result": true
  }
}
```
## Example: Python request

Add a Provisioning CI action to the two CIs from the cURL example above.

```python
# Need to install requests package for python
import requests
import json

# Set the API endpoint URL for the request
url = "https://instance.service-now.com/api/now/cilifecyclemgmt/actions/"

# Set credentials
user = "username"
pwd = "password"

# Set query parameters
params = {
    "actionName": "Provisioning",
    "requestorId": "621b5a09309e5010f877773aa7167c0a",
    "sysIds": "00a9a80d3790200044e0bfc8bcbe5d1c,d0fdbc8437201000deeabfc8bcbe5d33"
}

# Set HTTP headers
headers = {
    "Accept": "application/json",
    "Content-Type": "application/json"
}

# Issue the HTTP request
response = requests.post(url, auth=(user, pwd), params=params, headers=headers)

# Check for HTTP status codes other than 200
if response.status_code != 200:
    print("Status:" , response.status_code, "Headers:" , response.headers, "Error Response:" , response.content)
    exit()

# Display the JSON response
print(json.dumps(response.json()))
```

The request is processed successfully, but the Provisioning CI action is not added to the two CIs because it is incompatible with the Patching CI action.

```json
{
  "result": {
    "result": false,
  }
}
```
"errors": [
  {
    "message": "Incompatible CI Actions [Provisioning] and [Patching] for sys_id 00a9a80d3790200044e0bfc8bcbe5d1c",
    "error": "INCOMPATIBLE_CI_ACTION"
  },
  {
    "message": "Incompatible CI Actions [Provisioning] and [Patching] for sys_id d0fdbc8437201000deeabfc8bcbe5d33",
    "error": "INCOMPATIBLE_CI_ACTION"
  }
]

CI Lifecycle Management - POST /now/cilifecyclemgmt/operators
Registers an operator for a non-workflow user.

URL format
Versioned URL: /api/now/{api_version}/cilifecyclemgmt/operators
Default URL: /api/now/cilifecyclemgmt/operators

Example: cURL request

curl --request POST "https://instance.service-now.com/api/now/cilifecyclemgmt/operators" --header "Accept: application/json" --header "Content-Type: application/json" --user "username":"password"

{
  "result": {
    "result": true,
    "requestorId": "6f992b8430121010f877773aa7167c42"
  }
}

Example: Python request

# Need to install requests package for python
import requests
import json

# Set the API endpoint URL for the request
url = "https://instance.service-now.com/api/now/cilifecyclemgmt/operators"

# Set credentials
user = "username"
pwd = "password"

# Set HTTP headers
headers = {
    "Accept": "application/json",
    "Content-Type": "application/json"
}

# Issue the HTTP request
response = requests.post(url, auth=(user, pwd), headers=headers)

# Check for HTTP status codes other than 200
if response.status_code != 200:
    print("Status:", response.status_code, "Headers:", response.headers, "Error Response:", response.content)
    exit()

# Display the JSON response
print(json.dumps(response.json()))
**CI Lifecycle Management - POST /now/cilifecyclemgmt/statuses**

Sets the operational state for a specified list of configuration items (CIs).

**URL format**

Versioned URL: `/api/now/{api_version}/cilifecyclemgmt/statuses`

Default URL: `/api/now/cilifecyclemgmt/statuses`

**Supported request parameters**

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oldOpsLabels</td>
<td>Comma-separated list of old CI operational states in which all CIs should be included.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>opsLabel</td>
<td>Required. Label of the operational state to set for the specified CIs.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>requestorId</td>
<td>Required. Sys_id of a workflow context, or an operator user ID returned from the CI Lifecycle Management - POST /now/cilifecyclemgmt/operators endpoint. Operator user IDs are located in the CI State Registered Users [statemgmt_register_users] table.</td>
</tr>
</tbody>
</table>

<td></td>
</tr>
<tr>
<td>• UNPRIORITIZED_OPS_STATE</td>
<td></td>
</tr>
<tr>
<td>• UNSUPPORTED_SYS_ID</td>
<td></td>
</tr>
</tbody>
</table>

Data type: String

<table>
<thead>
<tr>
<th>result.errors.message</th>
<th>Message providing details on the associated error.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>result.result</th>
<th>Flag indicating whether the desired state was set for all CIs included in the request. Possible values:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• true: Operational state set.</td>
</tr>
<tr>
<td></td>
<td>• false: Operational state not set.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>
Example: cURL request

Set the Repair in Progress operational state for two CIs.

curl --request POST "https://instance.service-now.com/api/now/cilifecyclemgmt/statuses?opsLabel=Repair%20in%20Progress&requestorId=23d58bc030121010f877773aa7167c83&sysIds=affd3c8437201000deabfc8bce5dc3,aac0b1213784200044e0bfc8bce5de3" --header "Accept: application/json" --header "Content-Type: application/json" --user "username":"password"

The response body shows that the desired operational state was set for both CIs specified in the request.

```
{
  "result": {
    "result": true
  }
}
```

Example: Python request

Set the Retired operational state for a CI.

```python
# Need to install requests package for python
import requests
import json

# Set the API endpoint URL for the request
url = "https://instance.service-now.com/api/now/cilifecyclemgmt/statuses"

# Set credentials
user = "username"
pwd = "password"

# Set query parameters
params = {
    "opsLabel": "Retired",
    "requestorId": "06168bc030121010f87773aa7167c86",
    "sysIds": "780b8ce8735423002728660c4cf6a7e7"
}

# Set HTTP headers
headers = {
    "Accept": "application/json",

```
The response indicates that the specified `requestorId` is not a valid workflow context `sys_id` or operator user ID.

```json
{
  "result": {  
    "result": false,
    "errors": [  
      {  
        "message": "Requestor [06168bc030121010f877773aa7167c86] is not registered",
        "error": "INVALID_REQUESTOR"
      }  
    ]
  }
}
```

**CMDB Data Ingestion API**

The CMDB Data Ingestion API enables the batch ingestion of an array of objects into an Import Set table.

**Note:** With the release of Quebec, the Import Set API has added the `insertMultiple` endpoint. This new endpoint is strongly preferred over the CMDB Data Ingestion API as it has benefits for both scale and performance. From Quebec onward, any usage of the CMDB Data Ingestion API should be migrated to use the `insertMultiple` endpoint.

This API is activated through the Configuration Management Database (CMDB) (com.snc.cmdb) plugin.
CMDB Data Ingestion - POST /cmdb/ingest/{data_source_sys_id}

Inserts records into the Import Set table associated with the data source record identified by the passed-in sys_id.

The request body must contain the JSON array of objects (payload) to insert in the Import Set table. Each object equates to a row in the table, each name-value pair equates to a column. The JSON payload must leverage the field names from the import set without the "u_" prefix. For example, the field name "u_matching_record" should be "matching_record" in the request body payload. If the Import Set table exists, the endpoint appends the rows (objects) to the existing Import Set table. No checking for duplicates or updating of existing records is performed.

If you are initially building an application, you must first create the associated data source record in your instance before calling this endpoint. If you are just using this endpoint to add records to an existing Import Set table, you do not need to create the data source record, but you must know its sys_id. The data source record describes the Import Set table in which to insert the specified payload. This table must extend the Import Set Rows [sys_import_set_row] table. Also, the data source must be set to Attachment and the format set to JSON. For more information on data sources, see Data sources.

If the Import Set table defined in the data source record does not exist, the endpoint attaches the passed-in payload to the data source record. To create the initial Import Set table, you must manually import the data into the Import Set table. To import the data, on the associated Data Source form, click the Test Load 20 Records or Load All Records link in the Related Links section. Once the Import Set table is created, you cannot add columns to the table using this endpoint. If name-value pairs are later passed in that do not exist in the Import Set table, they are ignored without warning. If you need to modify the columns within the Import Set table, you can manually add them to the table. You can also delete or rename the Import Set table, and call the endpoint again using the new payload.

You must have the cmdb_import_api_admin role to access this endpoint.

**URL format**

Versioned URL: /api/now/{api_version}/cmdb/ingest/{data_source_sys_id}

Default URL: /api/now/cmdb/ingest/{data_source_sys_id}
## Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>data_source_sys_id</td>
<td>Sys_id of the data source record.</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>Free-form array of objects that describe the data to append to the associated Import Set table. Each object in the array defines a row in the Import Sets table; each name-value pair a column.</td>
</tr>
</tbody>
</table>

**Note:** This array must be named, such as "{"records":{"hostname": "Hostname1", "serialnumber": "2acd3873-7fc5-454c-8844-e7769e4d6cfc", "model": "Model Id"},{"vendor": "ABC Co"}}".

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see [Supported REST API headers](#).

#### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json OR application/xml. Default: application/json</td>
</tr>
</tbody>
</table>
Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>201</td>
<td>Created. An attachment was added to the data source.</td>
</tr>
<tr>
<td>202</td>
<td>Accepted. Rows were added to the Import Set table.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>404</td>
<td>Not found. The requested item was not found.</td>
</tr>
<tr>
<td>409</td>
<td>Conflict. Attachment already exists on the data source.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
<tr>
<td>501</td>
<td>Not Implemented. Request format is not supported.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>error</td>
<td>Describes an encountered error. Data type: Object</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>error</td>
<td>Additional information about the error.</td>
</tr>
<tr>
<td>error.message</td>
<td>Message describing the error.</td>
</tr>
<tr>
<td>import_set</td>
<td>Name of the Import Set table to which the payload was appended.</td>
</tr>
<tr>
<td>staged_row_count</td>
<td>Number of rows appended to the Import Set table.</td>
</tr>
<tr>
<td>staging_table</td>
<td>Name of the data source record used to stage the payload.</td>
</tr>
<tr>
<td>status</td>
<td>Error status.</td>
</tr>
</tbody>
</table>

**Example: Sample cURL request**

```bash
curl "instance.service-now.com/api/now/cmdb/ingest/4dd9686d1b9800103d374087bc4bcb3d" \
--request POST \
--header "Accept: application/json" \
--header "Content-Type:application/json" \
--data "{"records": [{"hostname": "Hostname1", "serialnumber": "2acd3873-7fc5-454c-8844-e7769e4d6cfc", "model": "Model 5100"},{"vendor": "ABC Co"}],
{"hostname": "Hostname2", "serialnumber": "3adb3873-7fc5-564d-8844-e7769e4d6ded", "model": "Model 5200"},{"vendor": "ACME Co"}]"
--user "username":"password"
```

**Successful**

```json
{
    "result": {
        "staged_row_count": 2,
        ...
    }
}
```
Example: Sample Python request

```python
# Need to install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/now/cmdb/ingest/4dd9686d1b9800103d374087bc4bcb3d'

# Set the user credentials
user = 'username'
pwd = 'password'

# Set the proper headers
headers = {'Content-Type': 'application/json', 'Accept': 'application/xml'}

# Do the HTTP request
response = requests.post(url, auth=(user, pwd), headers=headers, data='{"records": [{"hostname": "Hostname1", "serialnumber": "2acd3873-7fc5-454c-8844-e7769e4d6cfc", "model": "Model 5100"}, {"vendor": "ABC Co"}], [{"hostname": "Hostname2", "serialnumber": "3adb3873-7fc5-564d-8844-e7769e4d6ded", "model": "Model 5200"}, {"vendor": "ACME Co"}]}')

# Check for HTTP codes other than 202
if response.status_code != 202:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.json())
    exit()

# Decode the JSON response into a dictionary and use the data
data = response.json()
print(data)

Error response

{
    "error": {
        "message": "No request body provided",
        "detail": "Confirm your request body is correct"
    }
}
```
CMDB Instance API

Performs create, read, update, and delete operations on existing CMDB tables. Only one record can be inserted, updated, or deleted at a time.

This API requires the user have the ITIL role.

CMDB Instance - GET /now/cmdb/instance/{classname}

Returns the available configuration items (CI) for a specified Configuration Management Database (CMDB) class (table).

URL format

Versioned URL: /api/now/v1/cmdb/instance/{className}
Default URL: /api/now/cmdb/instance/{className}

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>className</td>
<td>CMDB class name. This is the name of the table that contains the desired CI records, such as cmdb_ci_linux_server or cmdb_ci_apache_web_server. Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_limit</td>
<td>Maximum number of records to return. For requests that exceed this number of records, use the sysparm_offset parameter to paginate record retrieval. This limit is applied before ACL evaluation. If no records return, including records you have access to, rearrange the record order so records you have access to return first. Note: Unusually large sysparm_limit values can impact system performance.</td>
</tr>
<tr>
<td>Data type: Number</td>
<td></td>
</tr>
</tbody>
</table>

### Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Default: 1000</strong></td>
<td></td>
</tr>
<tr>
<td><strong>sysparm_offset</strong></td>
<td>Starting record index for which to begin retrieving records. Use this value to paginate record retrieval. This functionality enables the retrieval of all records regardless of the number of records, in small manageable chunks. For example, the first time you call this endpoint, <code>sysparm_offset</code> is set to &quot;0&quot;. To simply page through all available records, use <code>sysparm_offset=sysparm_offset + sysparm_limit</code>, until you reach the end of all records. Do not pass a negative number in the <code>sysparm_offset</code> parameter. Data type: Number Default: 0</td>
</tr>
<tr>
<td><strong>sysparm_query</strong></td>
<td>Encoded query used to filter the result set. Syntax: <code>sysparm_query=&lt;col_name&gt;&lt;operator&gt;&lt;value&gt;</code>.</td>
</tr>
<tr>
<td></td>
<td>• <code>&lt;col_name&gt;</code>: Name of the table column to filter against.</td>
</tr>
<tr>
<td></td>
<td>• <code>&lt;operator&gt;</code>: Supports the following values:</td>
</tr>
<tr>
<td></td>
<td>◦ <code>=</code>: Exactly matches <code>&lt;value&gt;</code>.</td>
</tr>
<tr>
<td></td>
<td>◦ <code>!</code>: Does not match <code>&lt;value&gt;</code>.</td>
</tr>
<tr>
<td></td>
<td>◦ <code>^</code>: Logically AND multiple query statements.</td>
</tr>
<tr>
<td></td>
<td>◦ <code>^OR</code>: Logically OR multiple query statements.</td>
</tr>
<tr>
<td></td>
<td>◦ LIKE: <code>&lt;col_name&gt;</code> contains the specified string. Only works for <code>&lt;col_name&gt;</code> fields whose data type is string.</td>
</tr>
<tr>
<td></td>
<td>◦ <code>STARTSWITH</code>: <code>&lt;col_name&gt;</code> starts with the specified string. Only works for <code>&lt;col_name&gt;</code> fields whose data type is string.</td>
</tr>
<tr>
<td></td>
<td>◦ <code>ENDSWITH</code>: <code>&lt;col_name&gt;</code> ends with the specified string. Only works for <code>&lt;col_name&gt;</code> fields whose data type is string.</td>
</tr>
<tr>
<td></td>
<td><code>&lt;value&gt;</code>: Value to match against.</td>
</tr>
<tr>
<td></td>
<td>All parameters are case-sensitive. Queries can contain more than one entry, as <code>sysparm_query=&lt;col_name&gt;&lt;operator&gt;&lt;value&gt;&lt;operator&gt;&lt;col_name&gt;&lt;operator&gt;&lt;value&gt;</code>.</td>
</tr>
<tr>
<td></td>
<td>For example:</td>
</tr>
<tr>
<td></td>
<td><code>{sysparm_query=caller_id=javascript:gs.getUserID()^active=true}</code></td>
</tr>
</tbody>
</table>
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Encoded queries also supports order by functionality. To sort responses based on certain fields, use the ORDERBY and ORDERBYDESC clauses in sysparm_query.</td>
</tr>
<tr>
<td></td>
<td>Syntax:</td>
</tr>
<tr>
<td></td>
<td>• ORDERBY&lt;col_name&gt;</td>
</tr>
<tr>
<td></td>
<td>• ORDERBYDESC&lt;col_name&gt;</td>
</tr>
<tr>
<td></td>
<td>For example: sysparm_query=active=true^ORDERBYnumber^ORDERBYDESCcategory</td>
</tr>
<tr>
<td></td>
<td>This query filters all active records and orders the results in ascending order by number, and then in descending order by category.</td>
</tr>
<tr>
<td></td>
<td>If part of the query is invalid, such as by specifying an invalid field name, the instance ignores the invalid part. It then returns rows using only the valid portion of the query. You can control this behavior using the property glide.invalid_query.returns_no_rows. Set this property to true to return no rows on an invalid query.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> The glide.invalid_query.returns_no_rows property controls the behavior of all queries across the instance, such as in lists, scripts (GlideRecord.query()), and web service APIs.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>

</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Name of a CI within the specified class.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the CI.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>
Example: Sample cURL request

```
curl "https://instance.servicenow.com/api/now/cmdb/instance/cmdb_ci_linux_server" \
--request GET \
--header "Accept:application/json" \
--user 'username':'password'
```

"result": [
  {
    "sys_id": "3a290cc60a0a0bb400000bdb386af1cf",
    "name": "PS LinuxApp01"
  },
  {
    "sys_id": "3a5dd3dbc0a8ce0100655f1ec66ed42c",
    "name": "PS LinuxApp02"
  }
]

CMDB Instance - DELETE /now/cmdb/instance/{classname}/{sys_id}/relation/{rel_sys_id}

Deletes the relation for the specified configuration item (CI).

**URL format**

Versioned URL: /api/now/v1/cmdb/instance/{className}/{sys_id}/relation/{rel_sys_id}

Default URL: /api/now/cmdb/instance/{className}/{sys_id}/relation/{rel_sys_id}

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>className</td>
<td>CMDB class name. This is the name of the table that contains the desired CI records, such as cmdb_ci_linux_server or cmdb_ci_apache_web_server. Data type: String</td>
</tr>
<tr>
<td>rel_sys_id</td>
<td>Sys_id of the relation to remove. Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the CI.</td>
</tr>
</tbody>
</table>
### Path parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

#### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

#### Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.
### Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not found. The requested item was not found.</td>
</tr>
<tr>
<td>405</td>
<td>Invalid method. The functionality is disabled.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Example: Sample cURL request

```bash
curl "https://instance.servicenow.com/api/now/cmdb/instance/cmdb_ci_linux_server/0f4ac6c4b750230096c3e4f6ee11a9fe/relation/b0dbda5347c12200e0ef56d9a718f" \
--request DELETE \
--user 'username':'password'
```

### CMDB Instance - GET /now/cmdb/instance/{classname}/{sys_id}

Returns attributes and relationship information for a specified configuration item (CI) record.

### URL format

- **Versioned URL**: `/api/now/{api_version}/cmdb/instance/{className}/{sys_id}`
- **Default URL**: `/api/now/cmdb/instance/{className}/{sys_id}`
Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>className</td>
<td>CMDB class name. This is the name of the table that contains the desired CI records, such as cmdb_ci_linux_server or cmdb_ci_apache_web_server. Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the CI record to retrieve. Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

Response parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attributes</td>
<td>Data attributes currently in the CI record. The available attributes depend on the specified CMDB class. You can locate the available attributes in the associated CMDB table which typically begins with &quot;cmdb_ci&quot;, such as cmdb_ci_linux_server or cmdb_ci_mfp_printer.</td>
</tr>
<tr>
<td></td>
<td>Data type: Object</td>
</tr>
</tbody>
</table>
## Response parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>error</td>
<td>Information on any errors encountered while processing the endpoint request.</td>
</tr>
<tr>
<td></td>
<td>Data type: Object</td>
</tr>
<tr>
<td></td>
<td>&quot;error&quot;: {</td>
</tr>
<tr>
<td></td>
<td>&quot;detail&quot;: &quot;String&quot;,</td>
</tr>
</tbody>
</table>
|                         |   "message": "String"
<p>| error.detail             | Additional information about the error.                                    |
|                          | Data type: String                                                           |
| error.message            | Message that identifies the error.                                         |
|                          | Data type: String                                                           |
| inbound_relations        | List of objects that define the inbound relations associated with the CI.   |
|                          | Data type: Array                                                            |
|                         | &quot;inbound_relations&quot;: [                                                     |
|                         |   {                                                                        |
|                         |     &quot;sys_id&quot;: &quot;String&quot;,                                                   |

CMDB Instance - POST /now/cmdb/instance/{classname}
Creates a single configuration item (CI) with the specified outbound and inbound relations within the specified Configuration Management Database (CMDB) table.

⚠️ Note: If the CMDB class has a dependent identification rule defined, then the input payload must contain the sys_id of the parent CI.

URL format
Versioned URL: /api/now/v1/cmdb/instance/{className}
Default URL: /api/now/cmdb/instance/{className}

**Status codes**

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.
### Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not found. The requested item was not found.</td>
</tr>
<tr>
<td>405</td>
<td>Invalid method. The functionality is disabled.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON or XML)

#### Response parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attributes</td>
<td>Data attributes currently in the CI record. The available attributes depend on the specified CMDB class. You can locate the available attributes in the associated CMDB table which typically begins with &quot;cmdb_ci&quot;, such as cmdb_ci_linux_server or cmdb_ci_mfp_printer. Data type: Object</td>
</tr>
<tr>
<td>error</td>
<td>Information on any errors encountered while processing the endpoint request. Data type: Object</td>
</tr>
</tbody>
</table>

```
"error": {
    "detail": "String",
    "message": "String"
}
```
### Response parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>error.detail</td>
<td>Additional information about the error. Data type: String</td>
</tr>
<tr>

CMDB Instance - PUT /now/cmdb/instance/{classname}/{sys_id}

Updates the specified configuration item (CI) record with the specified attribute name-value pairs. This endpoint does not create, update, or delete the associated relations.

⚠️ Note: This endpoint does not conform to the HTML specifications. Standard PUT endpoints are destructive in that they remove any elements that are not included in the request. This endpoint does not remove non-specified elements.

**URL format**

Versioned URL: /api/now/v1/cmdb/instance/{className}/{sys_id}

Default URL: /api/now/cmdb/instance/{className}/{sys_id}
## Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>className</td>
<td>CMDB class name. This is the name of the table that contains the desired CI records, such as cmdb_ci_linux_server or cmdb_ci_apache_web_server.</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the CI record to update.</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attributes</td>
<td>Data attributes to replace in the CI record. The available attributes depend on the specified CMDB class. You can locate the available attributes in the associated CMDB table which typically begins with &quot;cmdb_ci&quot;, such as cmdb_ci_linux_server or cmdb_ci_mfp_printer.</td>
</tr>
<tr>
<td>source</td>
<td>Required. Entity that updated the information. This must be one of the choice values specified in the discovery_source field in the Configuration Item [cmdb_ci] table.</td>
</tr>
</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see [Supported REST API headers](#).
Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not found. The requested item was not found.</td>
</tr>
<tr>
<td>405</td>
<td>Invalid method. The functionality is disabled.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>
# Response body parameters (JSON or XML)

## Response parameters

CMDB Instance - POST /now/cmdb/instance/{classname}/{sys_id}/relation

Adds an inbound and/or outbound relation to the specified configuration item (CI). The specified CI is the parent.

URL format

Versioned URL: /api/now/v1/cmdb/instance/{className}/{sys_id}/relation

Default URL: /api/now/cmdb/instance/{className}/{sys_id}/relation

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>className</td>
<td>CMDB class name. This is the name of the table that contains the desired CI records, such as cmdb_ci_linux_server or cmdb_ci_apache_web_server.</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the CI record to update.</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>

CMDB Meta API

Use the CMDB Meta API to obtain meta data on a CMDB class.

This API requires that the user have the ITIL role.

**CMDB Meta - GET /now/cmdb/meta/{classname}**

Returns the meta data for the specified CMDB class.

**URL format**

Versioned URL: /api/now/{api_version}/cmdb/meta/{className}

Default URL: /api/now/cmdb/meta/{className}

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| api_version | Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.  
Data type: String |
| className | CMDB class name. This is the name of the table that contains the desired CI records, such as cmdb_ci_linux_server or cmdb_ci_apache_web_server.  
Data type: String |

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Headers**

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see [Supported REST API headers](#).

**Request headers**

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml.</td>
</tr>
<tr>
<td></td>
<td>Default: application/json</td>
</tr>
</tbody>
</table>

**Response headers**

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Status codes**

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).

**Status codes**

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not found. The requested item was not found.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>
## Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>

Consumer API

The Consumer REST API enables you to retrieve and update Customer Service Management (CSM) consumer records.

In addition, you can generate new social media profile records when creating a consumer.

The Consumer API requires the Customer Service plugin (com.sn_customerservice) and is provided within the now namespace.

Users require the csm_ws_integration role for full API access.

Consumer - GET /now/consumer

Retrieves a specified set of Customer Service Management (CSM) consumer records.

URL format

Versioned URL: /api/now/{api_version}/consumer
Default URL: /api/now/consumer

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
</tbody>
</table>

Data type: String
## Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| sysparm_limit      | Maximum number of records to return. For requests that exceed this number of records, use the `sysparm_offset` parameter to paginate record retrieval.  
Data type: Number  
Default: 10                                                                                     |
| sysparm_offset     | Starting record index for which to begin retrieving records. Use this value to paginate record retrieval. This functionality enables the retrieval of all records, regardless of the number of records, in small manageable chunks.  
For example, the first time you call this endpoint, `sysparm_offset` is set to "0". To simply page through all available records, use `sysparm_offset=sysparm_offset+sysparm_limit`, until you reach the end of all records.  
Do not pass a negative number in the `sysparm_offset` parameter.  
Data type: Number  
Default: 0                                                                                     |
| sysparm_query      | Encoded query used to filter the result set.  
For example:  
```plaintext
sysparm_query=caller_id=javascript:gs.getUserID()^active=true
```

The encoded query supports `order by`. To sort responses based on certain fields, use the `ORDERBY` and `ORDERBYDESC` clauses in `sysparm_query`. For example,  
```plaintext
sysparm_query=active=true^ORDERBYnumber^ORDERBYDESCcategory
```
filters all active records and orders the results in ascending order by number first, and then in descending order by category.  

If part of the query is invalid, such as by specifying an invalid field name, the instance ignores the invalid part. It then returns rows using only the valid portion of the query. You can control this behavior using the property `glide.invalid_query.returns_no_rows`. Set this property to true to return no rows on an invalid query. |
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The glide.invalid_query returns_no_rows property controls the behavior of all queries across the instance, such as in lists, scripts (GlideRecord.query()), and web service APIs. Data type: String</td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Element</th>

</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

The endpoint may return the following JSON or XML elements in the response body. In addition to the list of elements defined below (which define the elements in a base system), the endpoint also returns any custom fields added to the Consumer [csm_consumer] table. For additional information on these elements, refer to your specific table definition [System Definition > Tables].

Example: Python request

#Need to install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/now/consumer?sysparm_limit=1'

# Eg. User name="username", Password="password" for this code sample.
user = 'username'
pwd = 'password'

# Set proper headers
headers = {'Accept':"application/xml"}

# Do the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)
<xml version="1.0" encoding="UTF-8">
<response>
  <result>
    <country>USA</country>
    <gender>Female</gender>
    <city>Atlanta</city>
    <number>CSMR0000003</number>
    <street>1201 Peachtree St NE</street>
    <first_name>Dee</first_name>
    <last_name>Sam</last_name>
    <email>dee.sam@mailinator.com</email>
    <active>true</active>
    <primary>false</primary>
  </result>
</response>
Consumer - GET /now/consumer/{id}
Retrieves the specified Customer Service Management (CSM) consumer record.

**URL format**
Versioned URL: /api/now/{api_version}/consumer/{id}
Default URL: /api/now/consumer/{id}

**Supported request parameters**

| Path parameters |
|-----------------|-------------------------------------------------------------|
| **Name**       | **Description**                                            |
| api_version    | Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String |
| id             | Sys_id of the consumer record to return. Located in the Consumer [csm_consumer] table. Data type: String |

| Query parameters |
|------------------|---------------------------------------------------------------|
| **Name**         | **Description**                                              |
| None             |                                                               |

<table>
<thead>
<tr>
<th>Request body parameters (XML or JSON)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

**Headers**
The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
</tbody>
</table>
| 404         | Indicates that the request is invalid. Could be due to one of the following reasons:  
|             | • Requested case does not exist.                                           |
|             | • User does not have access to the consumer record.                        |
| 500         | Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error. |

Response body parameters (JSON or XML)

The endpoint may return the following JSON or XML elements in the response body. In addition to the list of elements defined below (which define the elements in a base system), the endpoint also returns any custom fields added to the Consumer [csm_consumer] table. For additional information on these elements, refer to your specific table definition [System Definition > Tables].
<table>

Consumer - POST /now/consumer

Creates a new Customer Service Management (CSM) consumer.

In addition, you can create a social media profile for the consumer using this endpoint. To create the profile, you must specify the following parameters in the request body:

- social_channel
- social_handle
- social_handle_url

⚠️ Warning: This endpoint does not perform parameter validation as doing so can create excessive overhead. If a request parameter is misspelled, is not valid, or is not supported by the endpoint, it is ignored without warning.

URL format

Versioned URL: /api/now/{api_version}/consumer
Default URL: /api/now/consumer

</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
**Request headers**

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports application/json.</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Only supports application/json.</td>
</tr>
</tbody>
</table>

**Response headers**

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Status codes**

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>201</td>
<td>New consumer record was successfully created.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal Server Error. A logic error on the server-side code occurred.</td>
</tr>
</tbody>
</table>

**Response body parameters (JSON or XML)**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>Sys_id of the newly created consumer record.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>
Example: cURL request

curl -X POST "https://instance.servicenow.com/api/now/consumer" \
-H "Accept: application/json" \
-H "Content-Type: application/json" \
-d "{" \n"country": "USA", \n"notes": "Never comes in before 10am", \n"gender": "Female", \n"city": "San Marcos", \n"prefix": "Ms", \n"title": "Director", \n"notification": "1", \n"business_phone": "(555)555-1234", \n"mobile_phone": "(555)555-1235", \n"street": "123 Sesame St", \n"state": "CA", \n"fax": "(555)555-1236", \n"first_name": "Jane", \n"zip": "92001", \n"home_phone": "(555)555-1234", \n"last_name": "Brown", \n"active": "true", \n"middle_name": "Dell", \n"time_zone": "PST", \n"name": "Jane Brown", \n"household": "4", \n"user": "c3d35d82c37122005871d44d81d3ae91", \n"primary": "false" \n}" \
--user "username":"password"

{ 
"result": "0f5c13addb93230057c3fd441d9619b8"
}

Example: Python request

# Need to install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/now/consumer'

# Eg. User name="username", Password="password" for this code sample.
user = 'username'
pwd = 'password'

# Set proper headers
headers = {"Content-Type":"application/json","Accept":"application/json"}

# Do the HTTP request
response = requests.post(url, auth=(user, pwd), headers=headers, data="{"country":"Norway","notes":"Do not call after 5pm","gender":"Female","city":"San Marcos","prefix":"Ms","suffix":"Jr.","title":"Director","notification":"1","business_phone":"(555)555-1234" }")

# Check for HTTP codes other than 201
if response.status_code != 201:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.json())
    exit()

# Decode the JSON response into a dictionary and use the data
data = response.json()
print(data)

"result":"00d033eddbd32300a2a451735e961972"
## Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, <code>v1</code> or <code>v2</code>. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_limit</td>
<td>Maximum number of records to return. For requests that exceed this number of records, use the <code>sysparm_offset</code> parameter to paginate record retrieval. Data type: Number Default: 10</td>
</tr>
<tr>
<td>sysparm_offset</td>
<td>Starting record index for which to begin retrieving records. Use this value to paginate record retrieval. This functionality enables the retrieval of all records, regardless of the number of records, in small manageable chunks. For example, the first time you call this endpoint, <code>sysparm_offset</code> is set to &quot;0&quot;. To simply page through all available records, use <code>sysparm_offset=sysparm_offset+sysparm_limit</code>, until you reach the end of all records. Do not pass a negative number in the <code>sysparm_offset</code> parameter. Data type: Number Default: 0</td>
</tr>
<tr>
<td>sysparm_query</td>
<td>Encoded query used to filter the result set. For example: <code>sysparm_query=caller_id=javascript:gs.getUserID()^active=true</code> The encoded query supports <code>order by</code>. To sort responses based on certain fields, use the ORDERBY and ORDERBYDESC clauses in <code>sysparm_query</code>. For example, <code>sysparm_query=active=true^ORDERBYnumber^ORDERBYDESCcategory</code></td>
</tr>
</tbody>
</table>
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>filters all active records and orders the results in ascending order by number first, and then in descending order by category.</td>
</tr>
<tr>
<td></td>
<td>If part of the query is invalid, such as by specifying an invalid field name, the instance ignores the invalid part. It then returns rows using only the valid portion of the query. You can control this behavior using the property <code>glide.invalid_query.returns_no_rows</code>. Set this property to true to return no rows on an invalid query.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> The <code>glide.invalid_query.returns_no_rows</code> property controls the behavior of all queries across the instance, such as in lists, scripts (<code>GlideRecord.query()</code>), and web service APIs.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: <code>application/json</code> or <code>application/xml</code>. Default: <code>application/json</code></td>
</tr>
</tbody>
</table>
Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

The endpoint may return the following JSON or XML elements in the response body. In addition to the list of elements defined below (which define the elements in a base system), the endpoint also returns any custom fields added to the Contact [customer_contact] table. For additional information on these elements, refer to your specific table definition [System Definition > Tables].

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>account</td>
<td>Sys_id of the account record to which the contact is associated; Account [customer_account] table. Data type: String</td>
</tr>
</tbody>
</table>
| active  | Flag that indicates whether the contact is active within the system. Possible values:  
  • true: Contact is active  
  • false: Contact is inactive |
<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| agent_status  | Status of the agent. Possible values:  
  • Off work  
  • On break  
  • On route  
  • On site  
  Data type: String  
  Maximum length: 40 |
| building      | Sys_id of the record that describes the building in which the contact resides; Building [cmn_building] table.  
  Data type: String |
| calendar_integration | Calendar application that the contact uses.  
  • 1: Outlook  
  Data type: Number (Integer)  
  Default: 1 |
| city          | City in which the contact resides.  
  Data type: String  
  Maximum length: 40 |
| company       | Sys_id of the company record to which the contact is associated; Company [core_company] table.  
  Data type: String |
| cost_center   | Sys_id of the cost center associated with the contact; Cost Center [cmn_cost_center] table.  
  Data type: String |
| country       | Country code of the country in which the contact resides.  
  Data type: String |
<table>

Contact - GET /now/contact/{id}
Retrieves the specified Customer Service Management (CSM) contact.

**URL format**

Versioned URL: /api/now/{api_version}/contact/{id}
Default URL: /api/now/contact/{id}

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>id</td>
<td>Sys_id of the contact to retrieve. Located in the Contact [customer_contact] table.</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Request body parameters (XML or JSON)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

### Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
</tbody>
</table>
| 404         | Indicates that the request is invalid. Could be due to one of the following reasons:  
  - Requested case does not exist.  
  - User does not have access to the case. |
| 500         | Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error. |
Response body parameters (JSON or XML)

The endpoint may return the following JSON or XML elements in the response body. In addition to the list of elements defined below (which define the elements in a base system), the endpoint also returns any custom fields added to the Contact [customer_contact] table. For additional information on these elements, refer to your specific table definition [System Definition > Tables].

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>account</td>
<td>Sys_id of the account record to which the contact is associated; Account [customer_account] table.</td>
</tr>
<tr>
<td>active</td>
<td>Flag that indicates whether the contact is active within the system.</td>
</tr>
<tr>
<td>calendar_integration</td>
<td>Calendar application that the contact uses.</td>
</tr>
<tr>
<td>agent_status</td>
<td>Status of the agent.</td>
</tr>
<tr>
<td>building</td>
<td>Sys_id of the record that describes the building in which the contact resides; Building [cmn_building] table.</td>
</tr>
<tr>
<td>building</td>
<td></td>
</tr>
</tbody>
</table>

**Example:**

```
{  
  "account": "87654321",  
  "active": true,           
  "agent_status": "On site",  
  "building": "123 Main St",  
  "calendar_integration": "Outlook"  
}
```

Example: Python request

#Need to install requests package for python
import requests
# Set the request parameters
url = 'https://instance.servicenow.com/api/now/contact/268e22b0d7300200e5982cf65e6103d3'

# Eg. User name="username", Password="password" for this code sample.
user = 'username'
pwd = 'password'

# Set proper headers
headers = {'Accept':"application/xml"}

# Do the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)

<?xml version="1.0" encoding="UTF-8"?>
<response>
  <result>
    <calendar_integration>1</calendar_integration>
    <last_position_update/>
    <last_login_time/>
    <last_login_device/>
    <source/>2018-05-14 21:11:33</source>
    <building/>
    <web_service_access_only>false</web_service_access_only>
    <notification>2</notification>
    <sys_updated_on>2018-05-14 20:55:30</sys_updated_on>
    <sys_domain>global</sys_domain>
    <agent_status/>
    <state/>
    <vip>false</vip>
    <sys_created_by>admin</sys_created_by>
    <longitude/>
    <zip/>
  </result>
</response>
Contact - POST /now/contact

Creates a new Customer Service Management (CSM) contact.

In addition, you can create a social media profile for the contact using this endpoint. To create the profile, you must specify the following parameters in the request body:

- `social_channel`
- `social_handle`
- `social_handle_url`

⚠️ **Warning:** This endpoint does not perform parameter validation as doing so can create excessive overhead. If a request parameter is misspelled, is not valid, or is not supported by the endpoint, it is ignored without warning.

**URL format**

Versioned URL: `/api/now/{api_version}/contact`
Default URL: `/api/now/contact`

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
### Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>account</td>
<td>Sys_id of the account record to which the contact is associated; Account [customer_account] table. Data type: String</td>
</tr>
<tr>
<td>active</td>
<td>Flag that indicates whether the contact is active within the system. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: Contact is active</td>
</tr>
<tr>
<td></td>
<td>• false: Contact is inactive</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
<tr>

Headers
The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports application/json.</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Only supports application/json.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>201</td>
<td>New contact record was successfully created.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal Server Error. A logic error on the server-side code occurred.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>

Continuous Integration/Continuous Delivery (CI/CD) API

The CI/CD API provides endpoints that enable integration with common DevOps tools for building pipelines. These tools include Jenkins, Azure Pipelines, GitLab, GitHub Actions, Atlassian Bamboo/Pipelines, and more.

It provides integrators with the ability to build CI/CD pipelines for Now Platform applications driven by pull/merge request workflows typical in source-driven development. It leverages the Source Control, Application Repository, and Automated Test Framework features.

The CI/CD API provides the following product and feature areas:

- Source control
  - Apply remote changes for an application linked to a remote Git repository through the Source Control feature in Studio, on a specific instance.
• Application repository: Available for scoped applications, global application, application customizations for scoped applications on the ServiceNow Store, and through plugins.
  ◦ Publish an application from an instance to the connected application repository.
  ◦ Install an application onto an instance from the connected application repository.
  ◦ Rollback an application that was installed through rollback context.
• Batch
  ◦ Define a JSON manifest file to batch install multiple applications together.
  ◦ Rollback the entire batch install through rollback context.
• Plugins
  ◦ Activate a plugin.
  ◦ Rollback a plugin through rollback context.
• Automated Test Framework (ATF)
  ◦ Start an ATF test suite.
  ◦ Obtain the pass/fail result of an ATF test suite.
• Instance scan
  ◦ Start an instance scan (full, point scan on table, point scan on record, scoped application, update set, combination of these items.)
  ◦ Obtain the pass/fail result of an instance scan run.
• Progress
  ◦ Obtain the percentage completion on an instance for processes initiated by other endpoint calls. You can use this feature to poll until progress completion before proceeding with the next step.

This API uses an asynchronous response model. When you call an endpoint, such as to run a test suite /sn_cicd/testsuite/run, the endpoint kicks off the associated function, such as starting the execution of the test suite. The endpoint then returns a response message that contains the execution status of the requested function, typically Pending, along with a unique identifier and link. Use this information to obtain additional information about the progress, source, results, and/or findings of the request. Depending on the function request, you can use one of the following means to obtain additional information about the request:
• Call the /sn_cicd/progress/{progress_id} endpoint using the links.progress.id parameter returned by the initiating endpoint.

• Call the /sn_cicd/testsuite/results/{result_id} endpoint using the links.result.id parameter returned by the initiating endpoint.

• Call the /sn_cicd/instance_scan/result/{progress_id} endpoint using the links.progress.id parameter returned by the initiating endpoint.

• Link out to the links.<progress/result/source/findings>.url parameter returned by the initiating endpoint.

**Note:** To install an application from a repository, the application must first be published to the repository using the /sn_cicd/app_repo/publish endpoint. Once published, any instance connected to that repository can then install and rollback the application. If the application is not first published, the installation request fails.

The sn_cicd.sys_ci_automation or admin role is required to use this API.

For additional information on CI/CD, see:

**CI/CD - GET /sn_cicd/app/batch/results/{result_id}**

Returns the results of a batch install based on a specified result identifier.

Call this method after calling the /sn_cicd/app/batch/install endpoint to obtain the results of the batch install. Use the value returned in the links.results.id parameter of the return results of /sn_cicd/app/batch/install endpoint as the result_id for this endpoint. You can also call the /api/sn_cicd/progress/{progress_id} endpoint to obtain information on the progress of the installation if it has not yet completed.

**URL format**

Versioned URL: /api/sn_cicd/{api_version}/app/batch/results/{result_id}

Default URL: /api/sn_cicd/app/batch/results/{result_id}
Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>result_id</td>
<td>Sys_id of the batch installation for which to return results information. This value is returned in the <code>links.results.id</code> parameter of the <code>/sn_cicd/app/batch/install</code> endpoint. Data type: String</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| error         | Error message.  
Data type: String |
| batch_items   | JSON array, where each object provides details of a package installation.  
Data type: Array  
```
"batch_items": [{
   "customization_version": "String",
   "id": "String",
   "install_date": "String",
   "name": "String",
   "notes": "String",
```
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>batch_items.customization_version</td>
<td>Only applicable when the <code>batch_items.type</code> parameter is set to <code>application</code> or <code>plugin</code> and the <code>requested_customization_version</code> parameter is passed in the batch install request. Version of the store application or scoped ServiceNow plugin customization package to install, such as 1.0.2 or 2.3. Data type: String</td>
</tr>
<tr>
<td>batch_items.id</td>
<td>Sys_id of the application or identifier of the plugin to install. Same as the <code>packages.id</code> parameter in the initiating <code>/sn_cicd/app/batch/install</code> endpoint call. Data type: String</td>
</tr>
<tr>
<td>batch_items.install_date</td>
<td>Date and time that the package was installed. Empty if the request is still in progress. Data type: String</td>
</tr>
<tr>
<td>batch_items.name</td>
<td>Name of the package. Data type: String</td>
</tr>
<tr>
<td>batch_items.notes</td>
<td>User specified notes about the package. Same as the <code>packages.notes</code> parameter in the initiating <code>/sn_cicd/app/batch/install</code> endpoint call. Data type: String</td>
</tr>
</tbody>
</table>
| batch_items.state | Current state of the associated package installation. Possible values:  
• Failed  
• In progress |
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>batch_items.status_message</td>

}
CI/CD - GET /sn_cicd/instance_scan/result/{progress_id}

Returns the current progress and status of the CI/CD instance scan function associated with a passed-in progress ID. Call this method after calling one of the other instance scan CI/CD endpoints such as /sn_cicd/instance_scan/full_scan or /sn_cicd/instance_scan/point_scan.

⚠  Note: This endpoint is part of the CICD Instance Scan Execution Service API and is used under the sn_cicd namespace.

**URL format**

Versioned URL: /api/sn_cicd/{api_version}/instance_scan/result/{progress_id}
Default URL: /api/sn_cicd/instance_scan/result/{progress_id}

**Supported request parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>progress_id</td>
<td>Unique identifier of the function for which to return progress information. This value is returned in the <code>links.progress.id</code> parameter of the endpoint that initiated the action, such as /sn_cicd/instance_scan/full_scan or /sn_cicd/instance_scan/point_scan. Data type: String</td>
</tr>
</tbody>
</table>
## Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

### Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>

</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Status codes

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

#### Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>The user credentials are incorrect.</td>
</tr>
<tr>
<td>403</td>
<td>Forbidden. The user is not an admin or does not have the sn_cicd.sys_ci_automation role.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request.</td>
</tr>
</tbody>
</table>

### Request body

The API accepts these JSON or XML elements in the request body.
Elements accepted in the request body

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Response body

The API returns these JSON or XML elements in the response body.

Elements returned in the response body

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>error</td>
<td>Error message. Data type: String</td>
</tr>
<tr>
<td>links</td>
<td>All links and sys_ids associated with the response. Data type: Object</td>
</tr>
<tr>
<td>links.findings</td>
<td>Object that contains information about the instance scan findings.</td>
</tr>
<tr>
<td>links.findings.label</td>
<td>Additional information about the instance scan findings.</td>
</tr>
<tr>
<td>links.findings.url</td>
<td>URL to use to retrieve a list of records that violated the checks.</td>
</tr>
<tr>
<td>links.progress</td>
<td>Describes the progress link information. Data type: Object</td>
</tr>
<tr>
<td>links.progress.id</td>
<td>Unique identifier of the progress detail.</td>
</tr>
<tr>
<td>links.progress.url</td>
<td>URL to use to retrieve the progress details. Data type: String</td>
</tr>
<tr>
<td>links.results</td>
<td>Results information. Data type: Object</td>
</tr>
</tbody>
</table>
Elements returned in the response body (continued)

Example: Sample cURL request

curl 'instance.service-now.com/api/sn_cicd/instance_scan/result/a74c70a11b7800103d374087bc4bcb28' \
--request GET \
--header 'Accept: application/json' \
--user 'username':'password'

{
    "result": {
        "links": {
            "findings": {
                "url": "https://instance.service-now.com/api/now/table/scan_finding?sysparm_query%3Dresult%3D6f4cf8651b7800103d374087bc4bcb41%5EORDERBYsys_id",
                "label": "First 10,000 findings"
            },
            "progress": {
                "id": "a74c70a11b7800103d374087bc4bcb28",
                "url": "https://instance.service-now.com/api/sn_cicd/progress/a74c70a11b7800103d374087bc4bcb28"
            },
            "results": {
                "id": "a74c70a11b7800103d374087bc4bcb28",
                "url": "https://instance.service-now.com/api/sn_cicd/instance_scan/result/a74c70a11b7800103d374087bc4bcb28"
            }
        }
    },
    "status": "2",
    "status_label": "Successful",
    "status_message": "",
    "status_detail": "",
    "error": ""
}

Example: Sample Python request

# Need to install requests package for python
import requests

# Set the request parameters
url = 'https://instance.service-now.com/api/sn_cicd/result/a74c70a11b7800103d374087bc4bcb28'

# Eg. User name="username", Password="password" for this code sample.
user = 'username'
pwd = 'password'

# Set proper headers
headers = {'Accept': 'application/json'}

# Do the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.json())
    exit()

# Decode the JSON response into a dictionary and use the data
data = response.json()
print(data)

{
    "result": {
        "links": {
            "findings": {
                "url":
                  "https://instance.service-now.com/api/now/table/scan_finding?sysparm_query%3Dresult%3D6f4cf8651b7800103d374087bc4bcb41%5EORDERBYSysId",
                "label": "First 10,000 findings"
            },
            "progress": {
                "id": "a74c70a11b7800103d374087bc4bcb28",
                "url":
                  "https://instance.service-now.com/api/sn_cicd/progress/a74c70a11b7800103d374087bc4bcb28"
            }
        }
    }
}
CI/CD - GET /sn_cicd/progress/{progress_id}

Returns the current progress and status of the CI/CD function associated with a passed-in progress ID.

Call this method after calling one of the other CI/CD endpoints such as /sn_cicd/app_repo/publish, /sn_cicd/app_repo/install, or /sn_cicd/testsuite/run.

URL format

Versioned URL: /api/sn_cicd/{api_version}/progress/{progress_id}
Default URL: /api/sn_cicd/progress/{progress_id}

Supported request parameters

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

    }
}
CI/CD - GET /sn_cicd/testsuite/results/{result_id}

Returns the results of a test suite run based on a specified results identifier.

Call this endpoint after calling /sn_cicd/progress/{progress_id} to obtain the result of the executed test suite.

**URL format**

Versioned URL: /api/sn_cicd/{api_version}/testsuite/results/{result_id}

Default URL: /api/sn_cicd/testsuite/results/{result_id}

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>result_id</td>
<td>Unique identifier of the test suite results to retrieve. The corresponding /sn_cicd/progress/{progress_id} endpoint call returns this information. Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Request body parameters (XML or JSON)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>The user credentials are incorrect.</td>
</tr>
<tr>
<td>403</td>
<td>Forbidden. The user is not an admin or does not have the sn_cicd.sys_ci_automation role.</td>
</tr>
<tr>
<td>404</td>
<td>Not found. The requested item was not found.</td>
</tr>
<tr>
<td>405</td>
<td>Invalid method. The functionality is disabled.</td>
</tr>
<tr>
<td>409</td>
<td>Conflict. The requested item is not unique.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request.</td>
</tr>
</tbody>
</table>
### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>child_suite_results</td>
<td>Results of nested test suites. The format of this content is the same as the parent test.</td>
</tr>
<tr>
<td>error</td>
<td>Error message.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>links</td>
<td>Object that contains all links and sys_ids associated with the response.</td>
</tr>
<tr>
<td></td>
<td>Data type: Object</td>
</tr>
<tr>
<td>links.results</td>
<td>Object that contains the results information.</td>
</tr>
<tr>
<td></td>
<td>Data type: Object</td>
</tr>
<tr>
<td>links.results.id</td>
<td>Unique identifier of the results information. Use this value when calling the endpoint <code>/sn_cicd/testsuite/results/{result_id}</code>.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>links.results.url</td>
<td>URL to use to obtain the results of the endpoint execution, such as results.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>percent_complete</td>
<td>Percentage of the request that is complete.</td>
</tr>
<tr>
<td>rolledup_test_error_count</td>
<td>Number of tests with errors.</td>
</tr>
<tr>
<td></td>
<td>Data type: Number</td>
</tr>
<tr>
<td>rolledup_test_failure_count</td>
<td>Number of tests that failed.</td>
</tr>
<tr>
<td></td>
<td>Data type: Number</td>
</tr>
<tr>
<td>rolledup_test_skip_count</td>
<td>Number of tests that were skipped.</td>
</tr>
<tr>
<td></td>
<td>Data type: Number</td>
</tr>
<tr>
<td>rolledup_test_success_count</td>
<td>Number of tests that ran successfully.</td>
</tr>
<tr>
<td></td>
<td>Data type: Number</td>
</tr>
<tr>
<td>status</td>
<td>Numeric execution state. Used with <code>status_label</code>, such as 0: Pending.</td>
</tr>
<tr>
<td></td>
<td>Values:</td>
</tr>
</tbody>
</table>

    "test_suite_name": "Quick Test",
    "child_suite_results": []
  }
}
CI/CD - POST /sn_cicd/app/batch/install
Installs two or more packages in a single specified batch.

A batch can contain any combination of the following types:

• Application:
  ◦ Scoped applications in the ServiceNow Store that are not owned by your company
  ◦ Scoped or global applications in the application repository that are owned by your company
  ◦ Your application customizations for Store applications in the application repository

• ServiceNow plugin:
  ◦ Application customizations for scoped applications that were packaged in a plugin and were published to the application repository.

⚠️ Note: This endpoint uses an asynchronous response model. When you call an endpoint, it kicks off the associated function, such as starting the execution of the batch install plan. The endpoint then returns a response message that contains the execution status of the requested function, typically Pending, along with a unique identifier and link. Use this information to obtain additional information about the progress or results of the request.

URL format

Versioned URL: /api/sn_cicd/{api_version}/app/batch/install
Default URL: /api/sn_cicd/app/batch/install

Supported request parameters

<table>
<thead>
<tr>
<th>Path parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>
### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

### Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| name     | Required. User specified descriptive name for this batch request.  
Data type: String |
| notes    | User specified additional notes about the batch install plan.  
Data type: String  
Default: Null |
| packages | Required. JSON array, where each object specifies details of a package to install.  
Data type: Array |

```json
"packages": [{
  "id": "String",
  "load_demo_data": Boolean,
  "notes": "String",
  "requested_customization_version": "String",
  "requested_version": "String",
  "type": "String"
}]
```

| packages.id | Required. Sys_id of the application or identifier of the plugin to install.  
Data type: String |
|-------------|----------------------------------------------------------------------------------------------------------------------------------|
| packages.load_demo_data | Flag that indicates whether demo data is loaded when installing the package.  
Valid values: |
### Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
|                                           | • true: Demo data should be loaded.  
   • false: Demo data should not be loaded.  
   Data type: Boolean  
   Default: false |
| packages.notes                            | User specified notes about the package.  
   Data type: String  
   Default: Null |
| packages.requested_customization_version  | Version of the application customization to the store application or to the scoped ServiceNow plugin to install, such as 1.0.2 or 2.3.  
   Data type: String  
   Default: None. If this parameter is not set, then the system does not look for customizations for the application. |
| packages.requested_version                | Required if packages.type is set to application; ignored if set to plugin. Version of the package to install, such as 1.0.2 or 2.3.  
   Data type: String |
| packages.type                            | Required. Type of package.  
   Valid values:  
   • application  
   • plugin  
   Data type: String |

**Example: cURL request**

This example initiates a batch installation called Release 2.2 Deployment that contains three packages (one of each type) to install.

```bash
curl 'instance.servicenow.com/api/sn_cicd/app/batch/install \
  --request POST \
  --header 'Accept: application/json' \
  --user 'username': 'password' \
  --data { "name": "Release 2.2 Deployment",  
"packages": [ 
  {  
    "id": "syd_id_abcefghi",  
    "type": "application",  
    "load_demo_data": false,  
    "requested_version": "1.0.2",  
    "notes": "User specific text to describe this application install"  
  },  
  {  
    "id": "syd_id_defabcde",  
    "type": "application",  
    "requested_version": "1.0.0",  
    "requested_customization_version": "2.0.7",  
    "notes": "Customization for CSM App1"  
  },  
  {  
    "id": "com.glide.some.plugin",  
    "type": "plugin",  
    "load_demo_data": true,  
    "notes": "Plugin related notes"  
  }] 
} 

{  
"result": {  
  "links": {  
    "progress": {  
      "id": "c159b1e9db1c0010b5e3f6c5ae961903",  
      "url":  
      "https://instance.servicenow.com/api/sn_cicd/progress/c159b1e9db1c0010b5e3f6c5ae961903"  
    }  
  }  
}  
```
CI/CD - POST /sn_cicd/app/batch/rollback/{rollback_id}

Rolls back all of the packages associated with a specific batch installation to their previous versions.

This endpoint works in conjunction with the /sn_cicd/app/batch/install endpoint. The rollback_id is provided in the return results of this endpoint. When this endpoint is called, it rolls back all packages specified in the associated install; you cannot rollback individual packages. If there is no previous version, the endpoint uninstalls the associated package.

⚠️ Note: This endpoint uses an asynchronous response model. When you call an endpoint, it kicks off the associated function, such as starting the execution of the batch install plan. The endpoint then returns a response message that contains the execution status of the requested function, typically Pending, along with a unique identifier and link. Use this information to obtain additional information about the progress or results of the request.

**URL format**

Versioned URL: /api/sn_cicd/{api_version}/app/batch/rollback/{rollback_id}

Default URL: /api/sn_cicd/app/batch/rollback/{rollback_id}
Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>rollback_id</td>
<td>Sys_id of the batch installation plan for which to rollback the installed packages to their previous versions. This value is returned in the links.rollback.id parameter of the /sn_cicd/app/batch/install endpoint. Data type: String</td>
</tr>
</tbody>
</table>

    "status_detail": "",
    "error": "",
    "percent_complete": 0
  }
}
```

**CI/CD - POST /sn_cicd/app_repo/install**

Installs the specified application from the application repository onto the instance making the endpoint call.

Using this endpoint you are able to install both unaltered and customized ServiceNow base system and ServiceNow Store applications, customized ServiceNow plugins, and your own ServiceNow applications.

The following outlines the parameters that you need to pass to implement specific use cases. All parameters that are not specified are not passed in and use the associated defaults.
• To only install the base application and not the corresponding application customizations.
  ◦ sys_id: Sys_id of the base application that has been customized.
  ◦ base_app_version: Version of the base application to install.

• To install a specified version of application customizations and automatically install the recommended base application version. The recommended base application version is the version of the base application that was installed on the instance at the time that the customizations were last published. Every version of application customizations has a corresponding recommended base application version.
  ◦ sys_id: Sys_id of the application that has been customized.
  ◦ auto_upgrade_base_app: true
  ◦ version: Version of the application customizations to install.

• To install the latest version of the application customizations and its corresponding recommended base application version.
  ◦ sys_id: Sys_id of the application that has been customized.
  ◦ auto_upgrade_base_app: true

• To install the latest version of the application customizations, but not upgrade the base application to the application customizations recommended base application version.
  ◦ sys_id: Sys_id of the application that has been customized.
  ◦ auto_upgrade_base_app: false

• To install application customizations along with the scoped ServiceNow plugin of the current release.
  ◦ scope: Scope of the plugin that has been customized OR
  ◦ sys_id: Sys_id of the application that has been customized. This is not the ID of the plugin.
  ◦ version: Version of the application customizations to install.

• To install application customizations for an already installed and activated scoped plugin.
  ◦ sys_id: Sys_id of the application that has been customized. This is not the ID of the plugin.
  ◦ auto_upgrade_base_app: false
  ◦ version: Version of the application customizations to install.
Since base plugins can have only one version per family release, the `auto_upgrade_base_app` and `base_app_version` parameters do not apply to application customization installs for plugins. To activate a plugin for the first time on an instance, use the `/sn_cicd/plugin/{plugin_id}/activate` endpoint instead.

ℹ️ **Note:** This endpoint uses an asynchronous response model. When you call an endpoint, it kicks off the associated function, such as starting the execution of the batch install plan. The endpoint then returns a response message that contains the execution status of the requested function, typically Pending, along with a unique identifier and link. Use this information to obtain additional information about the progress or results of the request.

**URL format**

**Versioned URL:** `/api/sn_cicd/{api_version}/app_repo/install`

**Default URL:** `/api/sn_cicd/app_repo/install`

</tr>
</thead>
</table>
| auto_upgrade_base_app | • true: Automatically upgrade the associated base application.  
• false: Leave the base application as the version currently installed on the instance.  
Data type: Boolean  
Default: false |
| base_app_version     | Version of the base application to install. A base application is any third-party application that is available in the ServiceNow Store.  
If the application has no application customizations, or if the application has application customizations and you are only updating the base application, then enter the updated version of the application in this parameter. If you are updating application customizations, don’t pass this parameter, but rather pass the version parameter.  
Data type: String  
Default: Null |
| scope               | Required if sys_id is not specified. Scope name of the application, such as x_aah_custom_app. You can locate this value in the scope field in the Custom Application [sys_app] table or Store Application [sys_store_app] table.  
Data type: String |
| sys_id              | Required if scope is not specified. Sys_id of the application to install. You can locate this value in the Sys ID field in the Custom Application [sys_app] table or Store Application [sys_store_app] table.  
Data type: String |
| version             | Version of the application to install.  
Data type: String  
Default: If the base_app_version parameter is empty and the auto_upgrade_base_app parameter is set to... |

}
}
```

**CI/CD - POST /sn_cicd/app_repo/rollback**

Initiates a rollback of a specified application to a specified version.
Note: The rollback functionality is only available after the installation is complete.

URL format

Versioned URL: /api/sn_cicd/{api_version}/app_repo/rollback

Default URL: /api/sn_cicd/app_repo/rollback

Supported request parameters

<table>
<thead>
<tr>
<th>Path parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>---</td>
</tr>
<tr>
<td>api_version</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Query parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>---</td>
</tr>
<tr>
<td>scope</td>
</tr>
<tr>
<td>sys_id</td>
</tr>
<tr>
<td>version</td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: <code>application/json</code> or <code>application/xml</code>. Default: <code>application/json</code></td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>The user credentials are incorrect.</td>
</tr>
<tr>
<td>403</td>
<td>Forbidden. The user is not an admin or does not have the <code>sn_cicd.sys_ci_automation</code> role.</td>
</tr>
<tr>
<td>405</td>
<td>Invalid method. The functionality is disabled.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request.</td>
</tr>
</tbody>
</table>
# Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>error</td>
<td>Error message. Data type: String</td>
</tr>
<tr>
<td>links</td>
<td>All links and sys_ids associated with the response. Data type: Object</td>
</tr>
<tr>
<td>links.progress</td>
<td>Describes the progress link information. Data type: Object</td>
</tr>
<tr>
<td>links.progress.id</td>
<td>Unique identifier to use to obtain the progress details for the operation. Use this value when calling the endpoint /sn_cicd/progress/{progress_id}. Data type: String</td>
</tr>
<tr>
<td>links.progress.url</td>
<td>URL to use to retrieve the progress details. Data type: String</td>
</tr>
<tr>
<td>percent_complete</td>
<td>Percentage of the request that is complete. Data type: Number</td>
</tr>
<tr>
<td>status</td>
<td>Numeric execution state. Used with status_label. Values:</td>
</tr>
<tr>
<td></td>
<td>• 0 (Pending)</td>
</tr>
<tr>
<td></td>
<td>• 1 (Running)</td>
</tr>
<tr>
<td></td>
<td>• 2 (Successful)</td>
</tr>
<tr>
<td></td>
<td>• 3 (Failed)</td>
</tr>
<tr>
<td></td>
<td>• 4 (Canceled)</td>

CI/CD - POST /sn_cicd/instance_scan/full_scan

Runs all active checks present in your instance.

You can run checks that are provided with Instance Scan or you can create your own checks. For more information, see Instance Scan.

ℹ️ Note: This endpoint is part of the CICD Instance Scan Execution Service API and is used under the sn_cicd namespace.

### URL format

**Versioned URL:** /api/sn_cicd/{api_version}/instance_scan/full_scan

**Default URL:** /api/sn_cicd/instance_scan/full_scan

### Supported request parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

#### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml.</td>
</tr>
</tbody>
</table>
Request headers (continued)

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default:</td>
<td>application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>

    }
}
```
CI/CD - POST /sn_cicd/instance_scan/point_scan

Executes all applicable checks against a specified record.

For example, if you execute a point scan against a Catalog Item, only the checks applicable to the Catalog Item table run, and only the specified record is scanned.

You can run checks that are provided with Instance Scan or you can create your own checks. For more information, see Instance Scan.

⚠️ **Note:** This endpoint is part of the CICD Instance Scan Execution Service API and is used under the sn_cicd namespace.

**URL format**

Versioned URL: /api/sn_cicd/{api_version}/instance_scan/point_scan

Default URL: /api/sn_cicd/instance_scan/point_scan

**Supported request parameters**

CI/CD - POST /sn_cicd/instance_scan/suite_scan/combo/{combo_sys_id}

Runs a scan using a suite and target (scoped apps or update sets) that have already run previously.

Before calling this endpoint, you must call the /sn_cicd/instance_scan/suite_scan/{suite_sys_id}/scoped_apps or /sn_cicd/instance_scan/suite_scan/{suite_sys_id}/update_sets endpoints, or execute a suite scan in the UI.

ℹ️ Note: This endpoint is part of the CICD Instance Scan Execution Service API and is used under the sn_cicd namespace.

### URL format

Versioned URL: /api/sn_cicd/{api_version}/instance_scan/suite_scan/combo/{combo_sys_id}

Default URL: /api/sn_cicd/instance_scan/suite_scan/combo/{combo_sys_id}

### Supported request parameters

#### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td>combo_sys_id</td>
<td>The sys_id of the scan to run. The scan must be an existing scan that you want to re-run. Located in the Combo [scan_combo] table.</td>
</tr>
</tbody>
</table>

#### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>

```
CI/CD - POST /sn_cicd/instance_scan/suite_scan/{suite_sys_id}/scoped_apps

Runs all active checks inside a suite against a list of scoped apps.

⚠️ Note: This endpoint is part of the CICD Instance Scan Execution Service API and is used under the sn_cicd namespace.

**URL format**

Versioned URL: /api/sn_cicd/{api_version}/instance_scan/suite_scan/{suite_sys_id}/scoped_apps

Default URL: /api/sn_cicd/instance_scan/suite_scan/{suite_sys_id}/scoped_apps

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>suite_sys_id</td>
<td>The sys_id of the suite to run. Located in the Suite [scan_check_suite] table.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Request body parameters (XML or JSON)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>app_scope_sys_ids</td>
<td>Required. A list of sys_ids of the scoped applications to scan. Located in the Application [sys_scope] table. The array can't be an empty array. Data type: Array</td>
</tr>
</tbody>
</table>

app_scope_sys_ids: ["String", "String", "String"]

**Example: cURL request**

This example runs all active checks inside a suite against one scoped application.

```
curl
  "https://instance.servicenow.com/api/sn_cicd/instance_scan/suite_scan/833655cc1b94101046e87733cd4bcb4e/scoped_apps" \
  --request POST \
  --header "Accept:application/json" \
  --header "Content-Type:application/json" \
  --data '{app_scope_sys_ids: ["078e8020950f12a215a92e8ad9b346e0"]}' \
  --user 'username':'password'
```

**Response body - success.**

```json
{
  "result": {
    "links": {
      "progress": {
        "id": "147fc14b1b572010178aed72604bcbca",
        "url": "https://instance.servicenow.com/api/sn_cicd/progress/147fc14b1b572010178aed72604bcbca"
      }
    },
    "status": "O",
    "status_label": "Pending",
    "status_message": "",
    "status_detail": "",
  }
}
```
CI/CD - POST /sn_cicd/instance_scan/suite_scan/{suite_sys_id}/update_sets

Runs all active checks inside a suite against a list of update sets.

⚠️ **Note:** This endpoint is part of the CICD Instance Scan Execution Service API and is used under the sn_cicd namespace.

**URL format**

Versioned URL: /api/sn_cicd/{api_version}/instance_scan/suite_scan/
(suite_sys_id)/update_sets

Default URL: /api/sn_cicd/instance_scan/suite_scan/{suite_sys_id}/update_sets

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>suite_sys_id</td>
<td>The sys_id of the suite to run. Located in the Suite [scan_check_suite] table. Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

Example: cURL request

curl 'instance.servicenow.com/api/sn_cicd/plugin/com.glide.web_service_aggregate/activate'
   --request POST \
   --header 'Accept: application/json' \
   --user 'username':'password'

{
   "result": {
      "links": {
         "progress": {
            "id": "5b3f052db580010caf55268dc961963",
            "url": "https://instance.service-now.com/api/sn_cicd/progress/5b3f052db580010caf55268dc961963"
         },
         "status": "0",
         "status_label": "Pending",
         "status_message": "",
         "status_detail": "",
         "error": "",
         "percent_complete": 0
      }
   }
}

Example: Python request

# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/sn_cicd/plugin/com.glide.web_service_aggregate/activate'

# Set the user credentials
user = 'username'
pwd = 'password'

# Set the proper headers
headers = {'Accept':'application/json'}

# Make the HTTP request
response = requests.post(url, auth=(user, pwd), headers=headers)
# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.json())
    exit()

# Decode the JSON response into a dictionary and use the data
data = response.json()
print(data)

{
    "result": {
        "links": {
            "progress": {
                "id": "5b3f052ddb580010caf55268dc961963",
                "url": "https://instance.service-now.com/api/sn_cicd/progress/5b3f052ddb580010caf55268dc961963"
            }
        },
        "status": "0",
        "status_label": "Pending",
        "status_message": "",
        "status_detail": "",
        "error": "",
        "percent_complete": 0
    }
}

CI/CD - POST /sn_cicd/plugin/{plugin_id}/rollback

Rolls back the specified plugin to the previous installed version. If no prior version has been installed, returns an error.

URL format

Versioned URL: /api/sn_cicd/{api_version}plugin/{plugin_id}/rollback
Default URL: /api/sn_cicd/plugin/{plugin_id}/rollback
## Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>

    "links": {
      "progress": {
        "id": "6185dd61db980010caf55268dc961916",
        "url": "https://instance.service-now.com/api/sn_cicd/progress/6185dd61db980010caf55268dc961916"
      }
    },
    "status": "0",
    "status_label": "Pending",
    "status_message": "",
    "status_detail": "",
    "error": "",
    "percent_complete": 0
  }
}

**CI/CD - POST /sn_cicd/sc/apply_changes**

Starts applying changes from a remote source control to a specified local application or application-customization.

**URL format**

Versioned URL: /api/sn_cicd/{api_version}/sc/apply_changes
**Default URL:** /api/sn_cicd/sc/apply_changes

**Supported request parameters**

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto_upgrade_base_app</td>
<td>Only applicable when changes are applied for app-customization and the latest commit on the Git repository is built on a version that is later than that of the base application that is currently installed on the local instance. Flag that indicates whether the system should auto upgrade the base application to a later version. Data type: Boolean Default: true</td>
</tr>
<tr>
<td>branch_name</td>
<td>Name of the branch in the source control system from which to acquire the application. Data type: String Default: Default branch specified on the source control system.</td>
</tr>
<tr>
<td>sys_id</td>
<td>Required if scope is not specified. The sys_id of the application for which to apply the changes. Data type: String</td>
</tr>
<tr>
<td>scope</td>
<td>Required if sys_id is not specified. The scope name of the application for which to apply the changes, such as x_aah_custom_app. You can locate this value in the scope field in the Custom Application [sys_app] table or Store Application [sys_store_app] table for the app-customization. Data type: String</td>
</tr>

        "status_detail": "",
        "error": "",
        "percent_complete": 0
    }
}

CI/CD - POST /sn_cicd/testsuite/run

Starts a specified automated test suite. The test suite runs on the instance from which the endpoint was called.

⚠️ Note: If the suite you are running contains UI tests, you must have either a scheduled Client Test Runner open, or be able to configure headless Test Runner execution. To learn more see Headless browser for Automated Test Framework.

URL format

Versioned URL: /api/sn_cicd/{api_version}/testsuite/run
Default URL: /api/sn_cicd/testsuite/run
### Supported request parameters

#### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>

#### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| browser_name | Name of the browser to use to run the client test. This value must match what is specified in the scheduled client test runner. For additional information on scheduled client test runners, see [Scheduled Client Test Runners](#). Data type: String Valid values: (must be all lower-case)  
  - any  
  - chrome  
  - firefox  
  - edge  
  - ie  
  - safari  
  Default: any |
| browser_version | Starting value of the version of the browser specified in browser_name to use to run the test. For example, if you enter "9", that would enable all 9.x.x.x versions. This value must match what is specified in the scheduled client test runner. Data type: String |
| os_name       | Name of the operating system under which to run the test suite. This value must match what is specified in the scheduled client test runner. Data type: String |
Query parameters (continued)

    },
    "status": "0",
    "status_label": "Pending",
    "status_message": "",
    "status_detail": "",
    "error": "",
    "percent_complete": 0
  }
}

CSM Attachment API

The CSM Attachment API provides endpoints that allow both internal and external users to upload, download, and remove attachments associated with a table and to retrieve attachment metadata.

Only attachments associated with tables specified in the glide.rest.attachment_csm_api.allowed_tables system property are valid in any of the associated endpoint calls. Any logged in user, both snc_internal and snc_external, can access this API. Guests and public users do not have access rights.

This API respects any system limitations on uploaded files, such as maximum file size and allowed attachment types. You can control these settings using the com.glide.attachment.max_size and glide.attachment.extensions properties.

By default, this API has a rate limit of 500 per hour for unauthenticated and snc_external users. For more information about rate limiting, see Inbound REST API rate limiting.

**CSM Attachment - DELETE /now/attachment_csm/{sys_id}**

Deletes the specified attachment.
URL format

Versioned URL: /api/now/{api_version}/attachment_csm/{sys_id}
Default URL: /api/now/v1/attachment_csm/{sys_id}

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>204</td>
<td>Successful. Indicates the request completed successfully.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. Indicates that the attachment from this table might not be accessible. Verify that the associated table is included in the glide.rest.attachment_csm_api.allowed_tables system property.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not found. The requested item was not found.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Example: Sample cURL request

```bash
curl
  "https://instance.servicenow.com/api/now/v1/attachment_csm/615ea769c0a80166001cf5f2367302f5b"
  --request DELETE
  --user 'username':'password'
```

None
Example: Sample Python request

```python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/now/v1/attachment_csm/615ea769c0a80166001cf5f23673025f5'

# Eg. User name="username", Password="password" for this code sample.
user = 'username'
pwd = 'password'

# Do the HTTP request
response = requests.delete(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 204
if response.status_code != 204:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.json())
    exit()

print('Successfully Deleted')
```

CSM Attachment - GET /now/attachment_csm

Returns the metadata for multiple attachments.

ℹ️ **Note:** You can reference all sysparm query parameters using either their full name or their shortened name (without the `sysparm_` prefix). For example, for `sysparm_limit` you can also use `limit`.

**URL format**

Versioned URL: /api/now/{api_version}/attachment_csm

Default URL: /api/now/v1/attachment_csm
## Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_limit</td>
<td>Maximum number of records to return. For requests that exceed this number of records, use the sysparm_offset parameter to paginate record retrieval. This limit is applied before ACL evaluation. If no records return, including records you have access to, rearrange the record order so records you have access to return first. Note: Unusually large sysparm_limit values can impact system performance. Data type: Number Default: 1000</td>
</tr>
<tr>
<td>sysparm_offset</td>
<td>Starting record index for which to begin retrieving records. Use this value to paginate record retrieval. This functionality enables the retrieval of all records regardless of the number of records, in small manageable chunks. For example, the first time you call this endpoint, sysparm_offset is set to &quot;0&quot;. simply page through all available records, use sysparm_offset=sysparm_offset+sysparm_limit, until you reach the end of all records. Do not pass a negative number in the sysparm_offset parameter. Data type: Number Default: 0</td>
</tr>
<tr>
<td>sysparm_query</td>
<td>Required. Encoded query to use to search for attachments. This parameter must at least contain sysparm_query=table_name=&lt;table&gt; where &lt;table&gt; can only be those tables specified in the glide.rest.attachment_csm_api.allowed_tables property located in the System Properties [sys_properties] table. For example: sysparm_query=file_name=kb_knowledge.</td>
</tr>
</tbody>
</table>
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax: <code>sysparm_query=&lt;col_name&gt;&lt;operator&gt;&lt;value&gt;</code></td>
<td></td>
</tr>
</tbody>
</table>
- `<col_name>`: Name of the table column to filter against.  
- `<operator>`: Supports the following values:  
  - `=`: Exactly matches `<value>`.  
  - `!`: Does not match `<value>`.  
  - `^`: Logically AND multiple query statements.  
  - `^OR`: Logically OR multiple query statements.  
  - LIKE: `<col_name>` contains the specified string. Only works for `<col_name>` fields whose data type is string.  
  - STARTSWITH: `<col_name>` starts with the specified string. Only works for `<col_name>` fields whose data type is string.  
  - ENDSWITH: `<col_name>` ends with the specified string. Only works for `<col_name>` fields whose data type is string.  
- `<value>`: Value to match against.  
All parameters are case-sensitive. Queries can contain more than one entry, such as `sysparm_query=<col_name><operator><value>[<operator><col_name><operator><value>`.  
For example:  
```
sysparm_query=caller_id=javascript:gs.getUserID()^active=true
```
Encoded queries also supports order by functionality. To sort responses based on certain fields, use the `ORDERBY` and `ORDERBYDESC` clauses in `sysparm_query`.  
Syntax:  
- `ORDERBY<col_name>`  
- `ORDERBYDESC<col_name>`  
For example: `sysparm_query=active=true^ORDERBYnumber^ORDERBYDESCcategory`  
This query filters all active records and orders the results in ascending order by number, and then in descending order by category.  
Data type: String
Request body parameters (XML or JSON)

<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. For example, use image/jpeg or image/png to accept JPEG or PNG image files exclusively. To allow all image types, specify image/*; to allow any file type, specify <em>/</em>. Default: <em>/</em></td>
</tr>
</tbody>
</table>
## Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X-Attachment-Metadata</td>
<td>Metadata about the returned file, such as size, name, and file type.</td>
</tr>
</tbody>
</table>

## Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. Indicates that the attachment from this table might not be accessible. Verify that the associated table is included in the <code>glide_rest_attachment_csm_api_allowed_tables</code> system property.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

## Response body parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binary file</td>
<td></td>
</tr>
</tbody>
</table>

## Example: Sample cURL request

```
curl *https://instance.servicenow.com/api/now/v1/attachment_csm/615ea769c0a80166001cf5f2367302f5/file" \
  --request GET \
  --header "Accept:*/**" \
  --user 'username':'password'
```

<Binary file>
Example: Sample Python request

```python
# Install requests package for python
import requests

# Set the request parameters
url =
'https://instance.servicenow.com/api/now/v1/attachment_csm/615ea769c0a80166001cf5f2367302f5/file'

# Eg. User name="username", Password="password" for this code sample.
user = 'username'
pwd = 'password'

# Set proper headers
headers = {'Accept': '*/*'}

# Do the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:',
          response.json())
    exit()

# Binary file
```

CSM Attachment - GET /now/attachment_csm/{sys_id}

Returns the metadata for the attachment file with the specific attachment sys_id.

URL format

Versioned URL: /api/now/{api_version}/attachment_csm/{sys_id}
Default URL: /api/now/v1/attachment_csm/{sys_id}
Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the attachment record for which to return metadata. This attachment must belong to one of the tables listed within the glide.rest.attachment_csm_api.allowed_tables property in the System Properties [sys_properties] table. Data type: String</td>
</tr>
</tbody>
</table>
Response headers

### Element Description

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result.table_name</td>
<td>Name of the table to which the attachment is associated.</td>
</tr>
<tr>
<td>result.table_sys_id</td>
<td>Sys_id of the table associated with the attachment.</td>
</tr>
<tr>
<td>result.updated_by_name</td>
<td>Full name of entity that last updated the attachment file.</td>
</tr>
</tbody>
</table>

### Example: Sample cURL request

```bash
curl
  "https://instance.servicenow.com/api/now/v1/attachment_csm/615ea769c0a80166001cf5f2367302f5" \ 
  --request GET \ 
  --header "Accept:application/json" \ 
  --user "username":"password"
```

```json
|
| "result": |
| "table_sys_id": "5054b6f8c0a80006056addcf551ecf8",
| "size_bytes": "462",
| "download_link": |
| "https://instance.service-now.com/api/now/v1/attachment_csm/615ea769c0a80166001cf5f2367302f5/file",
| "sys_updated_on": "2019-05-21 04:12:21",
| "sys_id": "615ea769c0a80166001cf5f2367302f5",
| "image_height": "",
| "sys_created_on": "2019-05-21 04:12:21",
| "file_name": "blocks.swf",
| "sys_created_by": "glide.maint",
| "compressed": "true",
| "average_image_color": "",
| "sys_updated_by": "glide.maint",
| "sys_tags": "",
| "table_name": "content_block_programmatic",
| "image_width": "",
| "sys_mod_count": "0",
```
Example: Sample Python request

```python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/now/v1/attachment_csm/615ea769c0a80166001cf5f2367302f5'

# Eg. User name="username", Password="password" for this code sample.
user = 'username'
pwd = 'password'

# Set proper headers
headers = {'Accept': 'application/xml'}

# Do the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)
```

```xml
<?xml version="1.0" encoding="UTF-8"?>
<response>
  <result>
    <table_sys_id>5054b6f8c0a800060056adDCF551ecf8</table_sys_id>
    <size_bytes>462</size_bytes>
    <download_link>https://instance.service-now.com/api/now/v1/attachment_csm/615ea769c0a80166001cf5f2367302f5/file</download_link>
    <sys_updated_on>2019-05-21 04:12:21</sys_updated_on>
  </result>
</response>
```
CSM Attachment - POST /now/attachment_csm/file

Uploads a specified binary file as an attachment to a specified record.

The endpoint also returns the metadata for the saved attachment.

**URL format**

Versioned URL: /api/now/{api_version}/attachment_csm/file

Default URL: /api/now/v1/attachment_csm/file

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
</tbody>
</table>
Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>encryption_context</td>
<td>Sys_id of an encryption context record. Specify this parameter to allow only users with the specified encryption context to access the attachment. For additional information on encryption context records, see Encryption Support. Data type: String Default: Attached file is not encrypted with any encryption context.</td>
</tr>
<tr>
<td>file_name</td>
<td>Required. Name to give the attachment. Note: The file to attach must be specified after the last parameter in the passed-in query parameter list. Data type: String</td>
</tr>
<tr>
<td>table_name</td>
<td>Required. Name of the table to which you want to attach the file. This table must be listed within the glide.rest.attachment_csm_api.allowed_tables system property in the System Properties [sys_properties] table. Data type: String</td>
</tr>
<tr>
<td>table_sys_id</td>
<td>Required. Sys_id of the record on the specified table to which you want to attach the file. Data type: String</td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;String&gt;</td>
<td>Path to the binary file to attach to the specified record. Data type: String</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Required. Data format of the file to post. For example, use image/jpeg or image/png to post JPEG or PNG image files exclusively. To allow all image types, specify image/*; to allow any file type, specify <em>/</em>.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. Indicates that the attachment from this table might not be accessible. Verify that the associated table is included in the glide.rest.attachment_csm_api.allowed_tables system property.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not Found. Indicates the record specified by the table_name and table_sys_id parameters does not exist or is not accessible by the current user.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>
# Response body parameters (JSON or XML)

}
CSM Attachment - POST /now/attachment_csm/upload

Uploads a multipart file attachment.

The multipart POST method does not accept any parameters. You must specify the table name and record sys_id values within the form body. See the cURL example below for a sample of a multipart/form-data request.

⚠️ **Note:** When using multipart POST, ensure the file content is contained in the final part of the message only. Earlier parts should contain only metadata such as table name and record sys_id.

When sending a multipart/form-data POST request to upload a file attachment, include attachment data in the form body, not in the URL parameters or request body.

**Mandatory values**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Content-Type</td>
<td>Content-Type of the file, included in the message body for multipart uploads.</td>
</tr>
<tr>
<td></td>
<td>⚠️ <strong>Note:</strong> You must define the Content-Type within the file portion of the POST message, not within the form data.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>table_name</td>
<td>Name of the table to which you want to attach the file. This table must be specified in the glide.rest.attachment_csm_api.allowed_tables property in the System Properties [sys_properties] table.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>table_sys_id</td>
<td>Sys_id of the record on the specified table to which you want to attach the file.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

**URL format**

Versioned URL: /api/now/{api_version}/attachment_csm/upload

Default URL: /api/now/v1/attachment_csm/upload
## Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>

</tr>
</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see [Supported REST API headers](#).

#### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Set this value to <code>multipart/form-data</code> when using the multipart POST method.</td>
</tr>
</tbody>
</table>

#### Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Location</td>
<td>URL of the new attachment in the ServiceNow platform instance.</td>
</tr>
</tbody>
</table>
### Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>201</td>
<td>Successful. Indicates the request completed successfully.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. Indicates that the attachment from this table might not be accessible. Verify that the associated table is included in the <code>glide.rest.attachment_csm_api.allowed_tables</code> system property.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not found. The requested item was not found.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>Metadata of the requested attachment. Data type: Object</td>
</tr>
</tbody>
</table>

```
Example: Sample Python request

```python
# This example uses the Python Requests Library and you will need to install requests package for python
# Documentation can be found at http://docs.python-requests.org/en/master/user/quickstart/
import requests
import print
import json

# Specify the Endpoint URL replacing instance with your ServiceNow Instance Name
url = 'https://instance.service-now.com/api/now/v1/attachment_csm/upload'

# Specify Parameters for File Being Uploaded, the table_name and table_sys_id should be replaced with values that make sense for your use case
payload = {'table_name': 'incident', 'table_sys_id': '81f8915bdb6ba20028927416bf961971'}

# Specify Files To Send and Content Type. When specifying files to send make sure you specify the path to the file, in this example the file was located in the same directory as the python script being executed. It is important to specify the correct file type
files = {'file': ('issue_screenshot.JPG', open('issue_screenshot.JPG', 'rb'), 'image/jpg', {'Expires': '0'})}

# Eg. User name="username", Password="password" for this code sample. This will be sent across as basic authentication
user = 'username'
pwd = 'password'

# Set proper headers
headers = {'Accept': '*/*'}

# Send the HTTP request
response = requests.post(url, auth=(user, pwd), headers=headers, files=files, data=payload)

# Check for HTTP codes other than 201
if response.status_code != 201:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.json())
```
exit()

# Print Response Details

print 'Response Status Code:', response.status_code

print ''

print('Response Payload:)

print json.dumps(response.json(), indent=4)

Response Status Code: 201

Response Payload:

{

CTI API

The CTI API provides REST resources that enable Computer Telephony Integration (CTI) providers to interact with the Cloud Call Center framework.

Using this API, integrators are able to:
• Invoke CTI operations using custom operation handlers within the Cloud Call Center framework.
• Pass events from a CCP provider to a ServiceNow instance.
• Render transcripts and recordings for a specified agent call.

This API runs in the `sn_cti_core` namespace. Before you are able to access this API, you must install the Cloud Call Center Core (sn_cti_core) application. For information on this installation, see Install Cloud Call Center applications.

For additional information on the Cloud Call Center, see Cloud Call Center.

**CTI_API - GET /sn_cti_core/cti_api/call_analysis/{interaction_sys_id}**

Renders transcripts and recordings for a specified agent call.

Now components use this endpoint in Agent and Manager workspaces to render associated agent call transcripts and recordings. To access this endpoint, the user credentials that you pass in the call must have the workspace_user, interaction_agent, or admin role.

This endpoint has a corresponding extension point, `sn_cti_core.CTICallAnalysisExtractor`, that is responsible for rendering the call data. The base system provides an implementation for Amazon Connect. If your implementation is different, you should customize this extension point before utilizing this endpoint. Also, the response parameters returned by this endpoint correspond to the implementation of this extension point. For additional information on implementing extension points, see Using extension points to extend application functionality and Extension points in Cloud Call Center.

**URL format**

Default URL: `/api/sn_cti_core/cti_api/call_analysis/{interaction_sys_id}`

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>interaction_sys_id</td>
<td>Sys_id of the agent call for which to render transcript and recording. Located in the Interaction [interaction] table. Data type: String</td>
</tr>
</tbody>
</table>
Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
</tbody>
</table>
**Response body parameters (JSON or XML)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Depends on the implementation in the sn_cti_core.CTICallAnalysisExtractor extension point.</td>
</tr>
</tbody>
</table>

**Example: cURL request**

The following example requests the rendering of a specific agent call.

```bash
curl -X POST \\nhttps://instance.servicenow.com/api/sn_cti_core/cti_api/call_analysis/88f2d9b7dbd7101058f05214dc96192a \
-H 'Accept: application/json' \
-H 'Content-Type: application/json' \
-u 'username':'password'
```

Rendered call data based on the processing specified in the sn_cti_core.CTICallAnalysisExtractor extension point.

```json
{
    "result":{
        "status":"success",
        "recordingData":{
            "recordingUrls":[
                "https://instance.awsapps.com/connect/get-recording?format=wav&callLegId=7626da7f-e083-4085-b77a-85bfea18fe24",
            ],
            "status":"success"
        },
        "transcriptData":{
```

bye.

CTI_API - POST /sn_cti_core/cti_api/providers/{provider}/components/{component}/versions/{version}

Invokes Computer Telephony Integration (CTI) operations using a specified operation handlers within the Cloud Call Center framework.

Before calling this endpoint, you must create a provider configuration record and associated message transformers. This is typically done when the Cloud Call Center framework is initially implemented in your instance. For additional information, see Provider configuration in Cloud Call Center.

A message transformer is responsible for parsing the payload specified in the request body of this endpoint and setting the payload data on an associated CTIOperationRequest object. An operation handler is then responsible for getting the information from the CTIOperationRequest object and using the data to process the requested operation.
After the message transformer finishes parsing the passed in payload, the Cloud Call Center framework instantiates the specified operation handler. The operating handler uses the `CTIOperationResponse - Scoped, Global API` GET methods to obtain the information that it needs from the associated `CTIOperationRequest` object to process the requested operation.

You define the operation handler to invoke, and its associated parameters, in the request body of this endpoint call. The specified operation handler must be defined in your instance within the Operation Handler `[sn_cti_operation_handler]` table. For additional information on creating operation handlers, see Configure a contact flow for an automated caller interaction.

The ServiceNow base system provides working operation handlers and message transformers that enable connection to Amazon Connect. When building contact flows within Amazon Connect, there are two integration points between Amazon services and a ServiceNow instance:

- Amazon Web Services (AWS) Lambda Proxy (Invoke AWS Lambda function)
- AWS Lex Bot (Get Customer Input)

You can find the available operation handlers and message transformers for these integration points in the Operation Handlers `[sn_cti_operation_handler]` and Provider Message Transformer `[sn_cti_provider_msg_transformer]` tables.

In addition, the user credentials that you pass in the call must have the `sn_cti_core.service` or `admin` role to access this endpoint.

For additional information on the Cloud Call Center, see Cloud Call Center.

**URL format**

Default URL: `/api/sn_cti_core/cti_api/providers/{provider}/components/{component}/versions/{version}`

**Supported request parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>component</td>
<td>Label of your provider component, such as <code>sn_aws_connect_lambda_proxy_component</code> or <code>sn_aws_connect_lex_intent_processor_component</code>. Located in the Component field of the Provider Component <code>[sn_cti_provider_component]</code> table. Data type: String</td>
</tr>
</tbody>
</table>
Path parameters (continued)

<table>

    "interactionId": "973b07c8dfe710100231dbdb5e961908",
    "statusCode": 200,
    "message": "success"
  }
}
```  

CTI_API - POST /sn_cti_core/cti_api/softphone/sources/{source}/actor/{actor}/

Passes events from a Contact Control Panel (CCP) provider to a ServiceNow instance.

Typically you call this endpoint from your CCP UI page to perform various tasks (events), such as changing the presence state of an agent or changing the state of a record on call completion. To access this endpoint, the user credentials that you pass in the call must have the sn_openframe_user or admin role.

This endpoint has a corresponding extension point, sn_cti_core.SoftPhoneEventSink, that is responsible for determining the action that is actually performed by this endpoint call for each event. The base system provides an implementation for Amazon Connect events. If your implementation is different, you should customize this extension point before utilizing this endpoint. The request body and response formats of this endpoint correspond to the implementation of this extension point. For additional information on
implementing extension points, see Using extension points to extend application functionality and Extension points in Cloud Call Center.

**URL format**

Default URL: `/api/sn_cti_core/cti_api/softphone/sources/{source}/actor/{actor}/events/{event}`

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| actor | Emitter of the event, such as agent or external_system. The specific values are determined by the implementer.  
Data type: String |
| event | Name of the event in the Computer Telephony Integration (CTI) vendor’s system, such as Available or Offline. The specific values are determined by the implementer but must be a single word/phrase without spaces or special characters.  
Data type: String |
| sources | Identifier of the vendor’s Softphone UI page, such as aws_ccp.  
Data type: String |

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

**Request body parameters (XML or JSON)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Implementation specific. Determined by the implementation of the sn_cti_core.SoftPhoneEventSink extension point.</td>
<td></td>
</tr>
</tbody>
</table>

**Headers**

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: <code>application/json</code> or <code>application/xml</code>. Default: <code>application/json</code></td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Example: cURL request

The following example passes AgentStatusOne event information to the ServiceNow instance. The request body parameters are determined by the implementation of the `sn_cti_core.SoftPhoneEventSink` extension point.

```bash
curl -X POST https://instance.servicenow.com/api/sn_cti_core/cti_api/softphone/sources/aws_ccp/actor/agent/events/AgentStatusOne
   -H 'Accept: application/json'
   -H 'Content-Type: application/json'
   -u 'username':'password'
   -d '{
```
No response parameters are returned.

```
{
  "result": {}
}
```

**Customer Central API**

The Customer Central API provides access to customer information and configuration details.
Use this API to obtain information records (cards) that were previously generated through the Customer Central interface.

You must have the admin or sn_esm_agent role to access this API. In addition, before this API is available in your instance you must activate the com.sn_csm_customer_central plugin.

For additional information, see Customer Central.

**Customer Central - GET /cust_central/custinfo/{context}/{context_instance}/{target}**

Returns customer information and configuration details for a specific customer context.

Customer context is determined by the customer content table that you specify, either the Consumer [csm_consumer] or Contact [customer_contact] table, and its associated target table. This information is located in the Customer Information Context [sn_customercentral_cust_info_config] table.

This endpoint returns all active records (cards) within the following Customer Central configuration tables for the specified customer context:

- List Configuration [sn_customercentral_list_config]
- Record Configuration [sn_customercentral_record_config]
- Report Configuration [sn_customercentral_report_config]
- Report Group Configuration [sn_customercentral_report_group_config]

You must define any additional configuration records that you need through the Customer Central interface. For details, see Configure customer central.

**URL format**

**Versioned URL:** /api/sn_customercentral/{api_version}/cust_central/custinfo/{context}/{context_instance}/{target}

**Default URL:** /api/sn_customercentral/cust_central/custinfo/{context}/{context_instance}/{target}
## Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>context</td>
<td>Name of the customer context table to use. Valid values: • customer_contact • csm_consumer Data type: String</td>
</tr>
<tr>
<td>context_instance</td>
<td>Sys_id of the record in the table specified in the context parameter to return. Data type: String</td>
</tr>
<tr>
<td>target</td>
<td>Target table associated with the customer context table specified in the context parameter. The combination of the context parameter and target parameter define a unique customer information context. This information is located in the Customer Information Context [sn_customercentral_cust_info_config] table. Data type: String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>before</td>
<td>Return all configuration records created before the specified date and time. Date type: String Format: YYYY-MM-DD or the format defined in the glide.sys.date_format system property Default: Return all configuration records created before current session time.</td>
</tr>
</tbody>
</table>
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>end</td>
<td>Last record to return. Use this value to paginate record retrieval or use with the <strong>start</strong> parameter to select a specific set of records to return. Data type: Number Default: Last record in file</td>
</tr>
<tr>
<td>start</td>
<td>Starting record index for which to begin retrieving records. Use this value to paginate record retrieval. This functionality enables the retrieval of all records, regardless of the number of records, in small manageable chunks. Do not pass a negative number. Data type: Number Default: 0</td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>

Data Classification API

The Data Classification API enables you to group data by type.

With the Data Classification API, you can:

- Assign data classifications to existing dictionary entries.
- Look up the data classifications for specific dictionary entries.
- Remove all data classifications associated with specific dictionary entries.
- Retrieve a list of all data classifications available in the current domain.

This API requires the Data Classification [com.glide.data_classification] plugin.
For more information, see Data Classification.

Data Classification - GET /data_classification/getAllDataClasses

Returns a list of all data classifications available in the current domain.

Requires the admin, data_classification_admin, or data_classification_auditor role.

URL format

Default URL: /api/now/data_classification/getAllDataClasses

<tr>
<td>result.parent.sys_id</td>
<td>Sys_id of the parent data classification from the Data Classification [data_classification] table. Data type: String</td>
</tr>
<tr>
<td>result.parent.name</td>
<td>Name of the parent data classification.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>result.sys_id</td>
<td>Sys_id of the data classification from the Data Classification [data_classification] table. Data type: String</td>
</tr>
<tr>
<td>result.name</td>
<td>Name of the data classification.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

**Example: cURL request**

Retrieves a list of all the available data classifications.

```bash
curl "https://instance.servicenow.com/api/now/data_classification/getAllDataClasses" \
  --request GET \
  --header "Accept:application/json" \
  --user 'username': 'password'
```
Data Classification - POST /data_classification/classify

Assigns pre-defined or user-defined data classifications to existing dictionary entries.

Requires the admin or data_classification_admin role.

**URL format**

Default URL: /api/now/data_classification/classify
# Supported request parameters

## Path parameters

<table>
<thead>
<tr>

<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

## Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dictionary_entries</td>
<td>Required. The sys_ids of the records you want to classify. The sys_ids are from the Dictionary [sys_dictionary] table. Entered as a comma-separated list enclosed in a string. Data type: String</td>
</tr>
<tr>
<td>data_classes</td>
<td>Required. The sys_ids of the data classifications you want to assign. The sys_ids are from the Data Classification [data_classification] table. Entered as a comma-separated list enclosed in a string. Data type: String</td>
</tr>
</tbody>
</table>

## Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Supported types: application/json or application/xml.</td>
</tr>
</tbody>
</table>
Request headers (continued)

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>Message describing the result of the operation.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

Example: cURL request

Assigns a data classification to a dictionary entry.

```bash
curl "https://instance.servicenow.com/api/now/data_classification/classify" \
  --request POST \
  --header "Accept:application/json" \
  --header "Content-Type:application/json" \
  --data "{"dictionary_entries": "445de0a6dba30300efc57416bf9619b0"","data_classes": "40edb1f51bbce50b92a10a61a4bc8a"}"```
Data Classification - POST /data_classification/clear
Removes all data classifications for the specified dictionary entries.
Requires the admin or data_classification_admin role.

**URL format**
Default URL: /api/now/data_classification/clear

**Supported request parameters**

<table>
<thead>
<tr>
<th>Path parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Query parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

**Request body parameters (XML or JSON)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dictionary_entries</td>
<td>Required. The sys_ids of the records you want to remove classifications from. The sys_ids are from the Dictionary [sys_dictionary] table. Entered as a comma-separated list enclosed in a string. Data type: String</td>
</tr>
</tbody>
</table>

**Headers**
The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>Message describing the result of the operation. Data type: String</td>
</tr>
</tbody>
</table>

Example: cURL request

Clears the data classifications for a dictionary entry.
curl "https://instance.servicenow.com/api/now/data_classification/clear" \  
--request POST  
--header "Accept:application/json" \  
--header "Content-Type:application/json" \  
--data "{  
"dictionary_entries": "445de0a6dba30300efc57416bf9619b0"  
}"  
--user 'username': 'password'  

```json  
{  
  "result": "Classifications removed for the specified dictionary entries"  
}  
```

**Data Classification - POST /data_classification/getClassification**

Retrieves all data classifications for the specified dictionary entries.

Requires the admin, data_classification_admin, or data_classification_auditor role.

**URL format**

Default URL: /api/now/data_classification/getClassification

**Supported request parameters**

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Query parameters

<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>
### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>Result of the request. Returns a JSON object containing each dictionary entry's sys_id with an array of its associated data classifications. If there are no associated data classifications, it returns a message describing the result of the operation. Data classifications can be organized into parent-child relationships. If there are parent data classifications, they are identified in the result. Data type: Object</td>
</tr>
<tr>
<td>result.name</td>
<td>Name of the data classification. Data type: String</td>
</tr>
<tr>
<td>result.parent</td>
<td>Entry for a parent data classification. Data type: Object</td>
</tr>
<tr>
<td>result.parent.name</td>
<td>Name of the parent data classification. Data type: String</td>
</tr>
<tr>
<td>result.parent.sys_id</td>
<td>Sys_id of the parent data classification from the Data Classification [data_classification] table. Data type: String</td>
</tr>
<tr>
<td>result.sys_id</td>
<td>Sys_id of the data classification from the Data Classification [data_classification] table.</td>
</tr>
</tbody>
</table>
### Example: cURL request

Get the data classifications associated with a specific dictionary entry.

```bash
curl "https://instance.servicenow.com/api/now/data_classification/getClassification" \
  --request POST \
  --header "Accept:application/json" \
  --header "Content-Type:application/json" \
  --data "{" \
    "dictionary_entries": "445de0a6dba30300efc57416bf9619b0" \
  }" \
  --user 'username':'password'
```

```json
{
  "result": {
    "445de0a6dba30300efc57416bf9619b0": [
      {
        "parent": {
          "sys_id": "a9670fc773fc1010ae8dd21efaf6a735",
          "name": "Confidential"
        },
        "sys_id": "348107b951d71010f877f3f178e7dd0d",
        "name": "Personally identifiable information"
      }
    ]
  }
}
```

### DevOps API

The DevOps API provides endpoints that enable the interaction with external DevOps tools.

This REST API enables integrators to:

- Retrieve the available DevOps tools associated with an instance.
- Retrieve the schema object for a code resource, plan, or orchestration resource.
- Check if an orchestration task is under change control and check its change control status.
• Create callbacks to associate with task executions under change control.
• Send various event payloads, which are transformed into normalized objects and stored as code, orchestration, and plan objects.
• Search a commit, branch, or repository using encoded queries and specific search/sort criteria.
• Register artifact versions and packages along with their associated pipeline execution and commits.
• Create and manage onboarding application and tool events.

For additional information, see DevOps.

**DevOps - GET /devops/code/schema**

Returns the schema object for a specified code resource: commit, repository, or branch.

Once you have the required schema object, use it to create the request body for your corresponding POST call: POST /code/commit, POST /code/repository, or POST /code/branch.

⚠️ **Note:** This endpoint only returns the request body elements that are required.

**URL format**

Versioned URL: /api/sn_devops/{api_version}/devops/code/schema

Default URL: /api/sn_devops/devops/code/schema

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>
Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>resource</td>
<td>Required. Type of resource schema to return. Valid values (not case-sensitive): • commit • repository • branch</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports application/json.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.
## Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Request completed successfully.</td>
</tr>
<tr>
<td>401</td>
<td>Invalid or missing authentication.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

## Response body parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>branch</td>
<td>Description of the branch in which the code commit was made.</td>
</tr>
<tr>
<td></td>
<td>Data type: Object</td>
</tr>
<tr>
<td></td>
<td>&quot;branch&quot;: {</td>
</tr>
<tr>
<td></td>
<td>&quot;name&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;path&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>branch.name</td>
<td>Name of the branch in which the code commit was made.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>branch.path</td>
<td>Relative path of the branch.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>committedDate</td>
<td>Date/time on which the code was committed in source DevOps tool.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td></td>
<td>Format: ISO 8601 with time zone offset</td>
</tr>
<tr>
<td></td>
<td>For example: 1970-01-01T08:15:30-05:00</td>
</tr>
<tr>
<td>committer</td>
<td>Description of the person/entity that requested the commit.</td>
</tr>
<tr>
<td></td>
<td>Data type: Object</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>&quot;committer&quot;</td>
<td></td>
</tr>
<tr>
<td>&quot;email&quot;: &quot;String&quot;</td>
<td></td>
</tr>
<tr>
<td>committer.email</td>
<td>Email address of the person that requested the commit. Data type: String</td>
</tr>
<tr>
<td>details</td>
<td>Details of the commit. Data type: Object</td>
</tr>
<tr>
<td>&quot;details&quot;:</td>
<td></td>
</tr>
<tr>
<td>&quot;action&quot;: &quot;String&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;additions&quot;: Number,</td>
<td></td>
</tr>
<tr>
<td>&quot;changes&quot;: Number,</td>
<td></td>
</tr>
<tr>
<td>&quot;deletions&quot;: Number,</td>
<td></td>
</tr>
<tr>
<td>&quot;file&quot;: &quot;String&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;totalChanges&quot;: Number</td>
<td></td>
</tr>
<tr>
<td>details.action</td>
<td>Action that was performed on the file. Data type: String</td>
</tr>
<tr>
<td>details.additions</td>
<td>Total number of additions in the file. Data type: Number</td>
</tr>
<tr>
<td>details.changes</td>
<td>Total number of changes that were made. Data type: Number</td>
</tr>
<tr>
<td>details.deletions</td>
<td>Total number of deletions in the file. Data type: Number</td>
</tr>
<tr>
<td>details.file</td>
<td>Path of the file that was modified relative to the branch. Data type: String</td>
</tr>
<tr>
<td>details.totalChanges</td>
<td>Total number of additions and deletions. Data type: Number</td>
</tr>
<tr>
<td>id</td>
<td>Source platform identifier or the commit SHA. Data type: String</td>
</tr>
<tr>
<td>name</td>
<td>Name of the branch, such as &quot;Master&quot;. Data type: String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>path</td>
<td>Relative path of the branch.</td>
</tr>
<tr>
<td>repository</td>
<td>Description of the repository in which the commit was made.</td>
</tr>
<tr>
<td>repository.name</td>
<td>Name of the repository.</td>
</tr>
<tr>
<td>repository.url</td>
<td>URL of the repository in the source DevOps tool.</td>
</tr>
<tr>
<td>url</td>
<td>URL of the specified resource.</td>
</tr>
</tbody>
</table>

For example for resource=commit: "https://github.com/mycompany/mobileplatform/commit/3fa85f6457174562b3fc2c963f66afa6"
For resource=repository: "https://github.com/mycompany/mobileplatform"

**Example: Sample cURL request for resource=branch**

```bash
curl "https://instance.servicenow.com/api/sn_devops/v1/devops/code/schema?resource=branch" \
  --request GET \
  --header "Accept:application/json" \
  --user "username":"password"
```

```json
{
  "result": {
    "name": "Master",
    "path": "refs/heads/master",
    "repository": {
      "name": "Platform-Mobile",
      "url": "https://github.com/mycompany/mobileplatform"
    }
  }
}
```
Example: Sample cURL request for resource=commit

```
  --request GET
  --header "Accept: application/json"
  --user "username":"password"
```

```json
{
  "result": {
    "id": "3fa85f64-5717-4562-b3fc-2c963f66afa6",
    "url": "https://github.com/mycompany/mobileplatform/commit/3fa85f6457174562b3fc2c963f66afa6",
    "committedDate": "1970-01-01T08:15:30-05:00",
    "repository": {
      "name": "Platform-Mobile",
      "url": "https://github.com/mycompany/mobileplatform"
    },
    "branch": {
      "name": "master",
      "path": "refs/heads/master"
    },
    "committer": {
      "email": "lenn@smithworksinc.com"
    },
    "details": [
      {
        "additions": 0,
        "deletions": 0,
        "totalChanges": 0,
        "file": "src/test/java/com/mycompany/app/App.java",
        "action": "modified",
        "changes": "A
         public void testAppConstructor()
         {
           App.main(null);
         }

         public void testDatabase()
         {
           app.main();
         }

         @Test
         public void testHelloWorld()
         {
           assertEquals("Hello World!", outContent.toString());
         }
      }
    ]
  }
}
```
Example: Sample cURL request for resource=repository

curl
"https://instance.servicenow.com/api/sn_devops/v1/devops/code/schema?resource=repository"

--request GET
--header "Accept:application/json"
--user "username":"password"

{
  "result": {
    "name": "Platform-Mobile",
    "url": "https://github.com/mycompany/mobileplatform"
  }
}

DevOps - GET /devops/onboarding/status

Returns the current status of the specified onboarding event which is processed or being processed asynchronously by the DevOps service.

URL format

Versioned URL: /api/sn_devops/{api_version}/devops/onboarding/status
Default URL: /api/sn_devops/devops/onboarding/status

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>
Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>Unique identifier of the onboarding event whose status to return. This value is provided in the return results of the endpoint that invoked the event request, such as /devops/onboarding/app or /devops/onboarding/tool. Data type: String</td>
</tr>
</tbody>
</table>

Request body parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

                }
            ]
        }
    }
}
DevOps - GET /devops/orchestration/changeControl
Checks if the orchestration task is under change control.

URL format
Versioned URL: /api/sn_devops/{api_version}/devops/orchestration/changeControl
Default URL: /api/sn_devops/devops/orchestration/changeControl

Supported request parameters

| Path parameters |
|-----------------|--------------------------------------------------|
| Name            | Description                                      |
| api_version     | Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. |

    }
}
```

DevOps - GET /devops/orchestration/schema

Returns the schema object for a specified orchestration resource.

Once you have the required schema object, use it to create the request body for your corresponding POST call: /orchestration/orchestrationTask or /orchestration/taskExecution.

⚠️ Note: This endpoint only returns the request body elements that are required.

**URL format**

Versioned URL: /api/sn_devops/{api_version}/devops/orchestration/schema

Default URL: /api/sn_devops/devops/orchestration/schema
## Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>resource</td>
<td>Type of resource schema to return. Valid values (not case-sensitive):</td>
</tr>
<tr>
<td></td>
<td>• build_details</td>
</tr>
<tr>
<td></td>
<td>• callback</td>
</tr>
<tr>
<td></td>
<td>• orchestration_task</td>
</tr>
<tr>
<td></td>
<td>• task_execution</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

### Request body parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

#### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports application/json.</td>
</tr>
</tbody>
</table>
Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Status codes**

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Request completed successfully.</td>
</tr>
<tr>
<td>401</td>
<td>Invalid or missing authentication.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

**Response body parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>callbackURL</td>
<td>URL of the callback. Data type: String</td>
</tr>
<tr>
<td>endDateTime</td>
<td>Date/time that the task execution ended. Data type: String</td>
</tr>
<tr>
<td>name</td>
<td>Name of the orchestration task. Data type: String</td>
</tr>
<tr>
<td>number</td>
<td>Task execution number. Same as an incident number. Data type: String</td>
</tr>
</tbody>
</table>
| orchestrationTaskDetails | Description of the orchestration task. Data type: Object 

```json
"orchestrationTaskDetails": {
    "message": "String",
```
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>orchestrationTaskDetails.message</td>
<td>Free-form text message. Data type: String</td>
</tr>
<tr>
<td>orchestrationTaskDetails.name</td>
<td>Name of the orchestration task. Data type: String</td>
</tr>
<tr>
<td>orchestrationTaskDetails.triggerType</td>
<td>The way the orchestration task was started. Data type: String</td>
</tr>
<tr>
<td>orchestrationTaskDetails.url</td>
<td>URL of the associated orchestration tool's orchestration task. Data type: String</td>
</tr>
<tr>
<td>orchestrationTaskURL</td>
<td>URL of the orchestration task. Data type: String</td>
</tr>
<tr>
<td>result</td>
<td>Execution result of the task execution. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• Success</td>
</tr>
<tr>
<td></td>
<td>• Failed</td>
</tr>
<tr>
<td>startDateTime</td>
<td>Date/time that the task execution started. Data type: String</td>
</tr>
<tr>
<td>taskExecutionURL</td>
<td>URL of the task to execute. Data type: String</td>
</tr>
<tr>
<td>triggerType</td>
<td>The way the orchestration task was started. Valid values:</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>• upstream</td>
<td>Upstream job triggered this job.</td>
</tr>
<tr>
<td>• user</td>
<td>User manually started the job.</td>
</tr>
<tr>
<td>• scm</td>
<td>Git/scm tool code commit triggered the job.</td>
</tr>
<tr>
<td>Data type</td>
<td>String</td>
</tr>
<tr>
<td>url</td>
<td>URL of the associated orchestration tool's orchestration task.</td>
</tr>
<tr>
<td>Data type</td>
<td>String</td>
</tr>
</tbody>
</table>

**Example: Sample cURL request with resource=task_execution**

```
curl -X GET 
'https://instance.servicenow.com/api/sn_devops/v1/devops/orchestration/schema?resource=task_execution' 
-H 'Accept: application/json'
-u 'username':'password'
```

```
{
"result": {
 "number": 40,
 "url": "https://jenkins.mycompany.com:8080/job/Mobile-Platform-CI/40/",
 "startDateTime": "1970-01-01T08:15:30-05:00",
 "endDateTime": "1970-01-01T08:25:30-05:00",
 "triggerType": "upstream",
 "result": "Success",
 "orchestrationTaskDetails": {
 "name": "Mobile-Platform-CI",
 "url": "https://jenkins.mycompany.com:8080/job/Mobile-Platform-CI/"
 }
}
```

**Example: Sample cURL request with resource=orchestration_task**

```
curl -X GET 
-H 'Accept: application/json'
-u 'username':'password'
```
Example: Sample cURL request with resource=callback

curl -X GET \\
'https://instance.servicenow.com/api/sn_devops/v1/devops/orchestration/schema?resource=task_execution' \\
-H 'Accept: application/json' \\
-u 'username': 'password'

{
 "result": {
  "callbackURL": "http://127.0.0.1:8090/jenkins/sn-devops/9b0feb79-f0b9-4661-83ef-2861b8924784",

  "orchestrationTaskDetails": {
   "message": "Started by upstream project \"felipe-upstream\" build number 27",
   "triggerType": "upstream"
  }
 }
}

DevOps - GET /devops/orchestration/stepMapping

Verifies that the information being passed is valid for the creation of an orchestration task and is valid for association to a previously created step.

URL format

Versioned URL: /api/sn_devops/{api_version}/devops/orchestration/stepMapping

Default URL: /api/sn_devops/devops/orchestration/stepMapping
## Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
<td>String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>branchName</td>
<td>Name of the branch associated with the orchestration task.</td>
<td>String</td>
</tr>
<tr>
<td>isMultiBranch</td>
<td>If the orchestration tool is Jenkins, flag that indicates whether the project is of type Multibranch. Valid values:</td>
<td>Boolean</td>
</tr>
<tr>
<td></td>
<td>• true: Project is of type Multibranch.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• false: Project is not of type Multibranch.</td>
<td></td>
</tr>
<tr>
<td>parentStageName</td>
<td>If the orchestration task is a child nested inside a parent orchestration task, the name of the parent orchestration task.</td>
<td>String</td>
</tr>
<tr>
<td>parentStageURL</td>
<td>If the orchestration task is a child nested inside a parent orchestration task, the URL of the parent orchestration task.</td>
<td>String</td>
</tr>
<tr>
<td>orchestrationTaskName</td>
<td>Required. Name of the orchestration task.</td>
<td>String</td>
</tr>
<tr>
<td>orchestrationTaskURL</td>
<td>Required. URL of the orchestration task.</td>
<td>String</td>
</tr>
</tbody>
</table>
### Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>

<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>status</td>
<td>Flag that indicates whether the verification was successful.</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
<tr>
<td>stepValid</td>
<td>Flag that indicates whether the information sent is valid.</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
</tbody>
</table>

Example: Sample cURL request

```bash
curl -X GET
"https://instance.servicenow.com/api/sn_devops/v1/devops/orchestration/stepMapping?toolId=f0ca45679323008b52f3b457415ae6&orchestrationTaskName=Platform-Analytics-UAT-Deployment&orch"```
Results if information is valid.

```
{
    "result": {
        "stepValid": true,
        "status": "Success"
    }
}
```

Example: Sample cURL request

```
curl -X GET
"https://instance.servicenow.com/api/sn_devops/v1/devops/orchestration/stepMapping?toolId=f0ca45679323008b52f3b457415ae6&orchestrationTaskName=Platform-Analytics-UAT-Deployment&orchestrationTaskURL=https%253A%252F%252Fjenkins.mycompany.com%253A8080%252Fjob%252FMobile-Platform-deploy%252F&toolType=jenkins "
-H "Accept: application/json" \ 
-u "username":"password"
```

Results if information is invalid.

```
{
    "result": {
        "stepValid": false,
        "status": "Success"
    }
}
```

DevOps - GET /devops/plan/schema

Returns the schema object for a specific plan: app, version, or work item.

Once you have the required schema object, use it to create the request body for your corresponding POST call; POST /plan/app, POST /plan/version, or POST /plan/workitem.

⚠️ Note: This endpoint only returns the request body elements that are required.

URL format

Versioned URL: /api/sn_devops/{api_version}/devops/plan/schema
Default URL: /api/sn_devops/devops/plan/schema
Supported request parameters

Path parameters

}
DevOps - POST /devops/artifact/registration

Enables orchestration tools to register artifacts into a ServiceNow instance.

This endpoint creates new artifacts and artifact versions, and associates them to commits. The following describes the endpoint process flow:

- If the toolId is passed in the request, the endpoint validates that the tool exists within the instance. It also checks if the artifact repository specified in artifacts.repositoryName exists, and if not, creates it under the associated artifact tool.

- If the toolId is not passed in the request, a repository is created but it is not linked to any artifact tool.

- It then checks if the artifact specified in artifacts.name already exists, and if not, creates it under the associated repository.

- If the artifact.version is passed in the request:
  - If it does not exist, a new artifact version record is created in the associated Artifact Version [sn_devops_artifact_version] table.
  - The endpoint then looks for associated task executions based on the provided build details (pipelineName or projectName, taskExecutionNumber, branchName, and stageName) and the orchestrationToolId parameter.
  - If a task execution is found, and its post-processing is complete, the artifact version is linked to the task execution and stored in the Artifact to TaskExecution [sn_devops_m2m_artifact_execution] table. Commits linked to these task executions are also associated to the artifact version and stored in the Artifact Version to Commit [sn_devops_m2m_artifact_version_commit] table. Any commits that are
linked to previous task executions that did not create an artifact, are also associated with the artifact version.

- If a task execution is found, and its post-processing is not complete, then the request is persisted in the Artifact Staged Request [sn_devops_artifact_staging] table. The staged request contains a reference to the task execution.
- If a task execution is not found, the request is persisted in the staging table. The staged request contains the build details.

- If the `artifact.version` is not passed in, then depending on the tool configuration, the artifact version is either retrieved by calling the `/devops/tool/artifact` endpoint if your artifact tool supports webhooks or through a custom subflow that retrieves the artifact version from the artifact tool.

For additional information on artifacts, see Using DevOps change acceleration for releases.

**URL format**

Versioned URL: /api/sn_devops/{api_version}/devops/artifact/registration

Default URL: /api/sn_devops/devops/artifact/registration

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>orchestrationToolId</td>
<td>Required. Sys_id of the orchestration tool associated with the artifact. Located in the Orchestration Tool [sn_devops_orchestration_tool] table. The endpoint uses this information to locate task execution information.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>
### Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>toolId</td>
<td>Sys_id of the artifact tool associated with the artifact. Located in the Artifact Tool [sn_devops_artifact_tool] table.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

### Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>artifacts</td>
<td>At least one entry required. Array of objects in which each object uniquely identifies an artifact version to register.</td>
</tr>
<tr>
<td></td>
<td>Data type: Array</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>artifacts.name</td>
<td>Required. Artifact file name.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td></td>
<td>Maximum length: 160 characters</td>
</tr>
<tr>
<td>artifacts.repositoryName</td>
<td>Required. Artifact repository name. If the specified repository record does not exist, it is created.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td></td>
<td>Maximum length: 160 characters</td>
</tr>
<tr>
<td>artifacts.semanticVersion</td>
<td>Semantic version of the artifact.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td></td>
<td>Format: MAJOR.MINOR.PATCH</td>
</tr>
<tr>
<td></td>
<td>Examples of possible values:</td>
</tr>
</tbody>
</table>
Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>artifacts.version</td>
<td>Required if <strong>toolId</strong> is not passed. Artifact version.</td>

</table>
Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Default: Null</td>
</tr>
</tbody>
</table>

**Headers**

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see [Supported REST API headers](#).

**Request headers**

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports <code>application/json</code>.</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Only supports <code>application/json</code>.</td>
</tr>
</tbody>
</table>

**Response headers**

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Status codes**

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Success. Success with response body.</td>
</tr>
<tr>
<td>201</td>
<td>Created. Success with response body.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. The request URI does not match the APIs in the system, or the operation failed for unknown reasons. Invalid headers can also cause this error.</td>
</tr>
</tbody>
</table>
### Status codes (continued)

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

### Response body parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>response</td>
<td>Results of the artifact registration request.</td>
</tr>
<tr>
<td></td>
<td>Data type: Object</td>
</tr>
<tr>
<td></td>

    }
  }
}
DevOps - POST /devops/onboarding/app

Creates an onboarding app event that is asynchronously processed by the DevOps service.

This endpoint can perform the following actions:
- Create applications.
- Associate DevOps objects such as, plan, repository, and pipeline, to an application.
- Create a change step record and associate a change approval process to a pipeline.

All of these actions are tool and capability specific. The following table outlines the actions available for each supported tool.

<table>
<thead>
<tr>
<th>Tool</th>

  }
}

DevOps - POST /devops/onboarding/tool

Creates an onboarding tool event that is asynchronously processed by the DevOps service.

Depending on the type of tool for which the request is posted, the endpoint performs the following actions:

- Creates the tool within the associated ServiceNow instance
- Connects to the tool
- Tries to configure the tool (only if the connection is successful)
- Discovers the tool (only if the connection is successful)
All of these actions are tool specific and are executed based on the integration capabilities for the specified tool.

The return results for this endpoint only indicate whether the request was posted, it does not indicate whether the associated tools were created. The actual tool creation is processed asynchronously. To obtain the status of the tool creation and all other actions, you must call the `/devops/onboarding/status` endpoint and pass in the `onboardingRequestID` parameter that is returned by this endpoint.

Before you are able to access this endpoint, your admin must have configured the DevOps connection and credential alias (CreateDevOpsTool) to setup tools in the instance. For details, see Setting up DevOps tools. In addition, the calling entity must have the devops.integration.user role.

**URL format**

Versioned URL: `/api/sn_devops/{api_version}/devops/onboarding/tool`

Default URL: `/api/sn_devops/devops/onboarding/tool`

|          | Data type: String                                                                                                                                                                                                                                                                                                                         |
| tools.password | Required except for Agile tool. Password to use to access the tool. Supported authentications are basic and token; OAuth is not supported.                                                                                                                                                                                            |
|          | Data type: String                                                                                                                                                                                                                                                                                                                         |
| tools.type | Required. Type of tool to create, such as GitHub or BitBucket. The specified value must be one of the Tool labels in the Tool Integrations [sn_devops_tool_integration] table.                                                                                                                                                                       |
|          | Data type: String                                                                                                                                                                                                                                                                                                                         |
| tools.useMidServer | Flag that indicates whether the tool connects through a MID Server.                                                                                                                                                                                                             |
|          | Valid values:
|          | • true: Connects through a MID Server.
|          | • false: Does not connect through a MID Server.                                                                                                                                                                                                                                                                                           |
|          | Data type: Boolean                                                                                                                                                                                                                                                                                                                         |
| tools.username | Required except for Agile tool. User name to use to access the tool through this endpoint.                                                                                                                                                                                        |
|          | Data type: String                                                                                                                                                                                                                                                                                                                         |
| tools.url | Required except for Agile tool. URL of the tool to create. The DevOps service uses this URL to integrate with the tool.                                                                                                                                                               |
|          | Data type: String                                                                                                                                                                                                                                                                                                                         |
Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports application/json.</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Only supports application/json.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>202</td>
<td>Onboarding request was successfully created.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>Results of the onboarding request. Data type: Object</td>
</tr>
</tbody>
</table>

"result": {
  "code": "String",
}
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result.code</td>
<td>HTTP status code. Data type: String</td>
</tr>
<tr>
<td>result.details</td>
<td>Detailed message about the onboarding request. Data type: String</td>
</tr>
<tr>
<td>result.errors</td>
<td>Description of any error that occurred. Data type: Object</td>
</tr>
<tr>
<td>result.error.message</td>
<td>Error message. Data type: String</td>
</tr>
<tr>
<td>result.onboardingRequestID</td>
<td>Unique identifier of the onboarding request. Use this value when calling the /devops/onboarding/status endpoint to obtain the status of the associated tool onboarding process. Data type: String</td>
</tr>
<tr>
<td>result.status</td>
<td>Status of the onboarding request, either Success or Failed. Data type: String</td>
</tr>
</tbody>
</table>

**Example: cURL request**

The following example shows how to onboard GitHub.

curl -X POST "https://servicenow-instance/api/sn_devops/v1/devops/onboarding/tool" \
-H "Accept: application/json" \
-H "Content-Type: application/json" \
-u "username":"password" \
-d "tool":{ "name": "Primary GitHub", "type": "GitHub", "url": "https://api.github.com", "username": "username", "password": "password", }
DevOps - POST /devops/orchestration/changeControl

Registers a callback with a ServiceNow instance for an orchestration task under change control, which can be called once a decision has been made on the change request.

Before you call this endpoint, you must have an orchestration task created in your ServiceNow instance. You can create this task either through Discovery or by calling the DevOps - POST /devops/orchestration/stepMapping endpoint. You must also ensure that the orchestration task is associated to a previously defined pipeline step and that change control is enabled (by selecting the Change control option on the App Stage form.) For details, see Accelerating DevOps change.

URL format

Versioned URL: /api/sn_devops/{api_version}/devops/orchestration/changeControl
Default URL: /api/sn_devops/devops/orchestration/changeControl
# Supported request parameters

## Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| api_version | Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.  
Data type: String |

## Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| toolId | Required. Sys_id of the DevOps tool for which to place the specified task under change control. Located in the Orchestration Tool [sn_devops_orchestration_tool] table.  
Data type: String |
| toolType | Type of tool. Valid value: Any value that identifies the tool, such as "jenkins".  
Data type: String |

## Request body parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| callbackURL        | Required. URL that the ServiceNow instance can call back once the associated change request approval process is complete. This callback should let the pipeline execution continue or not, based on the approval result.  
Data type: String |
<p>| changeRequestDetails | Name-value pairs of the fields to set when closing a change request. This object can contain any fields in |</p>
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>the Change Request record</td>
<td>except the following:</td>
</tr>
<tr>
<td>• assignment_group</td>
<td></td>
</tr>
<tr>
<td>• business_service</td>
<td></td>
</tr>
<tr>
<td>• cmdb_ci</td>
<td></td>
</tr>
<tr>
<td>• impact</td>
<td></td>
</tr>
<tr>
<td>• number</td>
<td></td>
</tr>
<tr>
<td>• risk</td>
<td></td>
</tr>
<tr>
<td>• risk_impact_analysis</td>
<td></td>
</tr>
<tr>
<td>• standard_change_template</td>
<td></td>
</tr>
<tr>
<td>• sys_id</td>
<td></td>
</tr>
<tr>
<td>• template</td>
<td></td>
</tr>
<tr>
<td>• type</td>
<td></td>
</tr>
</tbody>
</table>

If these fields are included in the request, the endpoint returns a 400 error and the change request is not updated. Also, if you include fields that require other mandatory fields to be set, and those fields are not sent, the request will fail during later processing of the pipeline. This failure is noted in the work notes of the change request, along with an error message for that particular change request, such as:

Change request update failed with reason: <Error Message from platform>. Canceling change request and the related step execution.
Request body parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>You can also pass the boolean parameter <strong>setCloseCode</strong> in this object to specify whether to set closure information on the associated Change Request record.</td>
</tr>
<tr>
<td></td>
<td>• If set to true, the close_code field is set to the status of the job and the close_notes field is set to a link to the step execution in the associated Change Request record. The default value is true.</td>
</tr>
<tr>
<td></td>
<td>• If set to false, the close_code and close_notes fields are not set and a link to the step execution is set in the work_notes field.</td>
</tr>
<tr>
<td></td>
<td>Data type: Object</td>
</tr>
<tr>
<td>isMultiBranch</td>
<td>If the orchestration tool is Jenkins, flag that indicates whether the project is of type Multibranch.</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Project is of type Multibranch.</td>
</tr>
<tr>
<td></td>
<td>• false: Project is not of type Multibranch.</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
<tr>
<td></td>
<td>Default: false</td>
</tr>
<tr>
<td>orchestrationTaskDetails</td>
<td>Required. Description of the orchestration task.</td>
</tr>
<tr>
<td></td>
<td>Data type: Object</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>orchestrationTaskDetails.message</td>
<td>Free-form text message. Data type: String</td>
</tr>
<tr>
<td>orchestrationTaskDetails.triggerType</td>
<td>Required. The way the orchestration task was started. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• upstream: Upstream job triggered this job.</td>
</tr>
<tr>
<td></td>
<td>• user: User manually started the job.</td>
</tr>
<tr>
<td></td>
<td>• scm: Git/scm tool code commit triggered the job. Data type: String</td>
</tr>
<tr>
<td>orchestrationTaskDetails.upstreamTaskExecutionURL</td>
<td>Required if triggerType is set to upstream. Upstream task execution URL. For example: <a href="https://jenkins.mycompany.com:8080/job/Mobile-Platform-test/40/">https://jenkins.mycompany.com:8080/job/Mobile-Platform-test/40/</a> Data type: String</td>
</tr>
<tr>
<td>orchestrationTaskURL</td>
<td>Required. URL of the orchestration task for which to create the call back. For example: <a href="https://jenkins.mycompany.com:8080/orchestration_task/Mobile-Platform-deploy/">https://jenkins.mycompany.com:8080/orchestration_task/Mobile-Platform-deploy/</a></td>
</tr>
</tbody>
</table>
## Request body parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>parentNode</td>
<td>If the orchestration task is a child nested inside a parent orchestration task, this value contains the parent node details.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>&quot;parentNode&quot;: {</td>

<td>&quot;upstreamStageName&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;upstreamTaskExecutionURL&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>parentNode.id</td>
<td>Unique ID for the parent node.</td>
</tr>
<tr>
<td></td>
<td>In Jenkins, this value corresponds to a pipeline stage ID.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>parentNode.name</td>
<td>Name of the parent node.</td>
</tr>
<tr>
<td></td>
<td>In Jenkins, this value corresponds to a pipeline stage name.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>parentNode.upstreamStageName</td>
<td>Name of the parent node’s upstream orchestration task.</td>
</tr>
<tr>
<td></td>
<td>In Jenkins, this value corresponds to a pipeline stage name.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>parentNode.upstreamTaskExecutionURL</td>
<td>URL of the parent node’s upstream task execution.</td>
</tr>
</tbody>
</table>
Request body parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>In Jenkins, this value corresponds to a pipeline stage execution URL. Data type: String</td>
</tr>
<tr>
<td>parentStageName</td>
<td>If the orchestration task is a child nested inside a parent orchestration task, the name of the parent orchestration task. Data type: String</td>
</tr>
<tr>
<td>parentStageURL</td>
<td>If the orchestration task is a child nested inside a parent orchestration task, the URL of the parent orchestration task. Data type: String</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Only supports application/json.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
</table>
Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>201</td>
<td>Request completed successfully.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Invalid or missing authentication.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>changeControl</td>
<td>Flag that indicates whether the orchestration task is under change control. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: Under change control.</td>
</tr>
<tr>
<td></td>
<td>• false: Not under change control</td>
</tr>
<tr>
<td></td>
<td>Possible values:</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
</tbody>
</table>

Example: Sample cURL request

```
curl -X POST "https://instance.servicenow.com/api/sn_devops/v1/devops/orchestration/changeControl?toolId=f0ca45679323008b52f3b457415ae6&toolType=jenkins" -H "accept: application/json" -H "Content-Type: application/json" -u "username":"password"
-d "{"orchestrationTaskURL":"https://jenkins.mycompany.com:8080/orchestration task/Mobile-Platform-deploy/", 
"callbackURL":"https://jenkins.mycompany.com:8080/sn-devops/964aca59-0cae-4d9b-a36d-5929f426cf31"}
```
"orchestrationTaskDetails":{
    "message":"Started by upstream project \"Mobile-Platform-test\" build number 40",
    "triggerType":"upstream",
    "upstreamTaskExecutionURL":"https://jenkins.mycompany.com:8080/job/Mobile-Platform-test/40/*"}
}*

Response:

```
{
  "result": {
    "changeControl": true,
    "status": "Success"
  }
}
```

Example: The following example shows how to pass fields in the changeRequestDetails object when closing a change request.

```
curl -X POST
  "https://instance.servicenow.com/api/sn_devops/v1/devops/orchestration/changeControl?toolId=f0ca4567932308b52f3b457415ae6&toolType=jenkins"
  -H "accept: application/json"
  -H "Content-Type: application/json"
  -u "username":"password" 
  -d "{
    "callbackURL":"http://192.168.0.4:3000/jenkins/sn-devops/pipeline_839b7605-b98d-4831-bc87-96829de7da37",
    "orchestrationTaskURL":"http://192.168.0.4:3000/jenkins/job/java_sample_tests#deploy",
    "isMultiBranch":"false",
    "orchestrationTaskName":"java_sample_tests#deploy",
    "orchestrationTaskDetails":{
      "triggerType":"upstream",
      "upstreamTaskExecutionURL":"http://192.168.0.4:3000/jenkins/job/java_sample_tests/129/execution/node/35/wfapi/describe",
      "taskExecutionURL":"http://192.168.0.4:3000/jenkins/job/java_sample_tests/129/execution/node/50/wfapi/describe"
    },
    "changeRequestDetails":{
      "setCloseCode":false,
```
DevOps - POST /devops/orchestration/stepMapping

Verifies that the information being passed is valid for the creation of an orchestration task and is valid for association to a previously created step. If both are valid, it creates the orchestration task and makes the association.
URL format

Versioned URL: /api/sn_devops/{api_version}/devops/orchestration/stepMapping
Default URL: /api/sn_devops/devops/orchestration/stepMapping

Supported request parameters

Path parameters

<td>If the orchestration task is a child nested inside a parent orchestration task, the name of the parent orchestration task. Data type: String</td>
</tr>
<tr>
<td>parentStageURL</td>
<td>If the orchestration task is a child nested inside a parent orchestration task, the URL of the parent orchestration task. Data type: String</td>
</tr>
<tr>
<td>orchestrationTaskName</td>
<td>Required. Name of the orchestration task. This is the same task referenced in the <code>orchestrationTaskURL</code>. Data type: String</td>
</tr>
<tr>
<td>orchestrationTaskURL</td>
<td>Required. URL of the orchestration task. For example: <a href="https://jenkins.mycompany.com:8080/orchestration_task/Mobile-Platform-deploy/">https://jenkins.mycompany.com:8080/orchestration_task/Mobile-Platform-deploy/</a> Data type: String</td>
</tr>
</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see [Supported REST API headers](#).
Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports <code>application/json</code>.</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Only supports <code>application/json</code>.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>201</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>status</td>
<td>Flag that indicates whether the verification was successful. Data type: Boolean</td>
</tr>
<tr>
<td>stepValid</td>
<td>Flag that indicates whether the information sent is valid. Data type: Boolean</td>
</tr>
</tbody>
</table>
Example: Sample cURL request

```
curl -X POST
  "https://instance.servicenow.com/api/sn_devops/v1/devops/orchestration/stepMapping?toolId=
f0ca45679323008b52f3b457415ae6&toolType=jenkins"
-H "Accept: application/json"
-H "Content-Type: application/json"
-u "username":"password"
-d "{
  \"orchestrationTaskURL\":\" http://127.0.0.1:8090/jenkins/job/CorpSite/job/master#deploy
  PROD/\",
  \"orchestrationTaskName\":\" master#deploy PROD\"
}"
```

Results if information is valid.

```
{
  "result": {
    "stepValid": true,
    "status": "Success"
  }
}
```

Results if information is invalid.

```
{
  "result": {
    "stepValid": false,
    "status": "Success"
  }
}
```

DevOps - POST /devops/package/registration

Enables orchestration tools to create new artifact packages that contain specified artifact versions.

Artifact packages are used to display commits to change approvers when they view a change request. For commits to show in change requests, the package must be created in the stage prior to the stage containing the change approval.

Any artifact versions included in the package registration request should already be registered with DevOps. For details on registering artifact versions, see DevOps - POST /devops/artifact/registration.

Typically, you will pass in the `artifacts.version` and `artifacts.name` parameters when identifying an artifact version to include in a package. You can also
use the advanced features of this endpoint which allows you to pass the build details for each artifact version instead of the version itself. Artifact-specific build details include the following parameters:

- `artifacts.pipelineName` or `artifacts.projectName`
- `artifacts.taskExecutionNumber`
- `artifacts.stageName`
- `artifacts.branchName`

The endpoint uses these artifact-specific build details to look up task execution information and then copies the associated versions to the package. It uses non-artifact specific build details (`pipelineName` or `projectName`, `taskExecutionNumber`, `branchName`, and `stageName`) to associate the created package to a pipeline execution.

ℹ️ **Note**: This endpoint does not support updates. It always creates a new package even if one with same name already exists.

For additional information on artifact packages, see [Using DevOps change acceleration for releases](#).

**URL format**

Versioned URL: `/api/sn_devops/{api_version}/devops/package/registration`

Default URL: `/api/sn_devops/devops/package/registration`

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>

        ],
        "update": [],
        "found": []
      }
    }
  },
  "responseCode": 201
}
```

**DevOps - POST /devops/tool/{capability}**

Posts the passed in payload to the Inbound Event [sn_devops_inbound] table for processing by a custom DevOps subflow.

Call this endpoint from the associated webhook in your tool, specified by the passed in `capability` parameter. A custom subflow, to process the passed in payload, must already be defined in your ServiceNow instance. Based on a predefined schedule, the DevOps Master Flow picks up the webhook event information from the Inbound Event table and passes it to the custom subflow, which then process the payload. For more information on creating a custom subflow, see Creating DevOps subflows.
**URL format**

Versioned URL: `/api/sn_devops/{api_version}/devops/tool/{capability}`

Default URL: `/api/sn_devops/devops/tool/{capability}`

**Supported request parameters**

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>

  }
}
```

DevOps - PUT /devops/orchestration/changeControl/{changeControlId}

Updates the change control information for the specified orchestration task.

**URL format**

**Versioned URL**: /api/sn_devops/{api_version}/devops/orchestration/changeControl/{changeControlId}

**Default URL**: /api/sn_devops/devops/orchestration/changeControl/{changeControlId}

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>changeControlId</td>
<td>Sys_id of the change control task. Located in the Callback [sn_devops_callback] table. Data type: String</td>
</tr>
</tbody>
</table>
Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>toolId</td>
<td>Required. Sys_id of the DevOps tool associated with the change control task. Located in the Orchestration Tool [sn_devops_orchestration_tool] table. Data type: String</td>
</tr>
</tbody>
</table>

Request body parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>callbackURL</td>
<td>Required. URL that the ServiceNow instance can call back once the associated change request approval process is complete. This callback should let the pipeline execution continue or not, based on the approval result. Data type: String</td>
</tr>
</tbody>
</table>
| orchestrationTaskDetails | Required. Description of the orchestration task. Data type: Object  

  "orchestrationTaskDetails": {  
    "message": "String",  
    "triggerType": "String",  
    "upstreamTaskExecutionURL": "String"  
  }

<table>
<thead>
<tr>
<th>orchestrationTaskDetails.message</th>
<th>Free-form text message. Data type: String</th>
</tr>
</thead>
<tbody>
<tr>
<td>orchestrationTaskDetails.triggerType</td>
<td>Required. The way the orchestration task was started. Valid values:</td>
</tr>
</tbody>
</table>
### Request body parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>orchestrationTaskDetails.upstreamTaskExecutionURL</td>
<td>Required if <code>triggerType</code> is set to <code>upstream</code>. Upstream task execution URL.</td>
</tr>
<tr>
<td></td>
<td>For example: <a href="https://jenkins.mycompany.com:8080/job/Mobile-Platform-test/40/">https://jenkins.mycompany.com:8080/job/Mobile-Platform-test/40/</a></td>
</tr>
<tr>
<td>orchestrationTaskURL</td>
<td>Required. URL of the orchestration task.</td>

     "orchestrationTaskURL":"https://jenkins.mycompany.com:8080/job/Mobile-Platform-deploy/
                      
     "toolType":"
```
Response:

```
{
   "result": {
      "change_control": true
   }
}
```

**Email API**

With the Email API you can receive and send email messages using REST.

**Security**

Users must have the email_api_send role to send email.

**Email - GET /now/email/{id}**

Returns the email details for the specified email record.

**URL format**

Versioned URL: /api/now/{api_version}/email/{id}

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>
Path parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>Sys_id of the email for which to return details. Located in the Email [sys_email] table.</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_fields</td>
<td>Comma-separated list of fields to return in the response.</td>
</tr>
<tr>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.
### Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>403</td>
<td>Indicates the record is not found or the requesting user does not have access to the record. Verify the user has the proper role and access permissions.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bcc</td>
<td>List of the email addresses of the blind copied recipients of the email message. Maps to the blind_copied field. Data type: Array</td>
</tr>
<tr>
<td>cc</td>
<td>List of the email addresses of the copied recipients for the email message. Maps to the copied field. Data type: Array</td>
</tr>
<tr>
<td>headers</td>
<td>Name-value pairs of the headers associated with the message and their values. Data type: Object</td>
</tr>
<tr>
<td>html</td>
<td>HTML-enabled body of the email message. Maps to the body field. Data type: String</td>
</tr>
<tr>
<td>id</td>
<td>Sys_id of the email record. Data type: String</td>
</tr>
<tr>
<td>importance</td>
<td>Importance of the email message. Maps to the importance field. Data type: String</td>
</tr>
<tr>
<td>state</td>
<td>Processing state of the email message. Indicates whether the system scheduled jobs have processed the email message.</td>
</tr>
<tr>
<td>Element</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| Values include: | • error  
• ignored  
• processed  
• ready  |
| Data type: String | |
| subject | Subject of the email message. Maps to the subject field.  
Data type: String |
| text | Text-only body of the email message. Maps to the body_text field.  
Data type: String |
| to | List of the email addresses of the direct recipients of the email message. Maps to the recipients field.  
Data type: Array |
| type | Current state of the email message as incoming or outgoing mail.  
Values include:  
• received  
• received-ignored  
• send-failed  
• send-ignored  
• send-ready  
• sent  |
| Data type: String | |

**Example: Sample cURL request**

}
```
# Example: Sample Python request

```python
# Need to install requests package for python
# easy_install requests

import requests

# Set the request parameters
url = 'http://instance.servicenow.com/api/now/v1/email'

# Eg. User name="username", Password="password" for this code sample.
user = 'username'
pwd = 'password'

# Set proper headers
headers = {"Content-Type": "application/json", "Accept": "application/json"}

# Do the HTTP request
response = requests.post(url, auth=(user, pwd), headers=headers, data="{
    "to": [
    "User1 <user1@example.com>",
    "User2 <user2@example.com>"
    ],
    "cc": [
    "User3 <user3@example.com>",
    "User4 <user4@example.com>"
    ],
    "bcc": [
    "User5 <user5@example.com>",
    "User6 <user6@example.com>"
    ],
    "subject": "Hello There",
    "text": "Test Message",
    "html": "<b>Test Message</b>",
    "table_name": "incident",
    "table_record_id": "136b2140bd0312004d7d1371f1abbdb6",
    "headers": {
    "X-Custom": "header"
    }
}
")

# Check for HTTP codes other than 200
```
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.json())
    exit()

# Decode the JSON response into a dictionary and use the data
data = response.json()
print(data)

{
    "result": {
        "id": "b963219a44b02200964f63773cd6adfc",
        "links": [
            {
                "rel": "self",
                "href": "/now/v1/email/b963219a44b02200964f63773cd6adfc"
            },
            {
                "rel": "status",
                "href": "/now/v1/email/b963219a44b02200964f63773cd6adfc?sysparm_fields=id,type,state,error"
            }
        ]
    }
}

External Content Ingestion API

The External Content Ingestion API provides endpoints that enable ingestion of content from sources outside of your ServiceNow® instance into the ServiceNow® AI Search application's index.

External Content Ingestion API – DELETE /ais/external_content/deleteByQuery/
{schema_table_name}

Deletes all external documents that match the specified query from the AI Search index.

URL format

Versioned URL: /api/now/{api_version}/ais/external_content/deleteByQuery/
{schema_table_name}?query={query}
## Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>schema_table_name</td>
<td>The name of the external content schema table that defines the schema for the indexed documents to delete. For example, u_ext_content.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>A valid URL-escaped query for the schema table specified by <code>schema_table_name</code>. For example, title=Introduction to query for documents whose title is Introduction.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

### Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see [Supported REST API headers](#).

#### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports <code>application/json</code>.</td>
</tr>
</tbody>
</table>
Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>error</td>
<td>Object describing the error encountered during processing of the request.</td>
</tr>
<tr>
<td>error.detail</td>
<td>Details of the error encountered during processing of the request.</td>
</tr>
<tr>
<td>error.message</td>
<td>Message for the error encountered during processing of the request.</td>
</tr>
<tr>
<td>result</td>
<td>Result from a successfully processed request.</td>
</tr>
</tbody>
</table>

Data type: Object

```json
"error": {
  "detail": "String",
  "message": "String"
}
```
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| status | Status of an unsuccessful request.  
Valid values:  
* failure  
Data type: String |

**Example: cURL request**
Delete documents with title field values *Introduction* and *Report for 31 October 2020* from the u_ext_content schema table.

curl  
"https://instance.service-now.com/api/now/v2/ais/external_content/deleteByQuery/u_ext_content?query=title%3DIntroduction%20OR%20title%3DReport%20for%2031%20October%202020"  
--request DELETE  
--user "username":"password"  
--header "Accept: application/json"

```json
{
  "result": "Delete By Query Successfully Executed"
}
```

**Example: Python request**
Delete documents with title field values *Introduction* and *Report for 31 October 2020* from the u_ext_content schema table.

```python
#Need to install requests package for python  
import requests  
import json

# Set the API endpoint URL for the request  
url =  
"https://instance.servicenow.com/api/now/v2/ais/external_content/deleteByQuery/u_ext_content"

# Set credentials  
user = "username"  
pwd = "password"

# Set query parameters  
parameters = {
```
"query": "title=Introduction OR title=Report for 31 October 2020"
}

# Set HTTP headers
headers = {
    "Accept": "application/json"
}

# Issue the HTTP request
response = requests.delete(url, auth=(user, pwd), params=parameters, headers=headers)

# Check for HTTP status codes other than 200
if response.status_code != 200:
    print("Status:", response.status_code, "Headers:", response.headers, "Error Response:",
    response.content)
    exit()

# Display the JSON response
print(json.dumps(response.json()))

{
    "result": "Delete By Query Successfully Executed"
}

External Content Ingestion API – DELETE /ais/external_content/deleteDocument/
{schema_table_name}/{document_id}

Deletes the external document with a specified unique identifier from the AI
Search index.

**URL format**

**Versioned URL:** /api/now/{api_version}/ais/external_content/deleteDocument/
{schema_table_name}/{document_id}

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>
Path parameters (continued)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>document_id</td>
<td>The unique identifier for the external document to delete. For example, ADMIN-2027858531-16. Data type: string</td>
</tr>
<tr>
<td>schema_table_name</td>
<td>The name of the external content schema table that defines the schema for the indexed document to delete. For example, u_ext_content. Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports application/json.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>error</td>
<td>Object describing the error encountered during processing of the request. Data type: Object</td>
</tr>
<tr>
<td>error.detail</td>
<td>Details of the error encountered during processing of the request. Data type: String</td>
</tr>
<tr>
<td>error.message</td>
<td>Message for the error encountered during processing of the request. Data type: String</td>
</tr>
<tr>
<td>result</td>
<td>Result from a successfully processed request. Data type: String</td>
</tr>
<tr>
<td>status</td>
<td>Status of an unsuccessful request. Valid values: failure</td>
</tr>
</tbody>
</table>
**Example: cURL request**

Delete the document with identifier `ADMIN-2587918521-27` from the `u_ext_content` schema table.

```
curl
  'https://instance.service-now.com/api/now/v2/ais/external_content/deleteDocument/u_ext_content/ADMIN-2587918521-27' 
  --request DELETE 
  --user 'username':'password' 
  --header 'Accept: application/json'

{
  "result":"Document removed"
}
```

**Example: Python request**

Delete the document with identifier `ADMIN-2587918521-27` from the `u_ext_content` schema table.

```
# Need to install requests package for python
import requests
import json

# Set the API endpoint URL for the request
url =

# Set credentials
user = "username"
pwd = "password"

# Set HTTP headers
headers = {
  "Accept": "application/json",
}

# Issue the HTTP request
response = requests.delete(url, auth=(user, pwd), headers=headers)
```
# Check for HTTP status codes other than 200
if response.status_code != 200:
    print("Status:", response.status_code, "Headers:", response.headers, "Error Response:", response.content)
exit()

# Display the JSON response
print(json.dumps(response.json()))

{
    "result":"Document removed"
}

External Content Ingestion API – POST /ais/external_content/ingestDocument/
{schema_table_name}

Sends a list of external documents to the AI Search ingestion batcher for indexing. After indexing completes, content from the ingested documents becomes searchable.

You can associate stored binary content with an external document by following these steps:

1. Store the binary content in AI Search using the POST /ais/external_content/
   storeContent endpoint. Record the value of the result response body parameter.

2. When sending the external document to AI Search using this endpoint, set its content_pointer request body parameter to match the recorded result response body parameter value.

During ingestion, AI Search parses the binary content and adds its searchable content to the indexed record that represents the external document. Parsing removes the stored content object.

URL format

Versioned URL: /api/now/{api_version}/ais/external_content/ingestDocument/
{schema_table_name}
Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>schema_table_name</td>
<td>The name of the external content schema table that defines the schema for external documents in the request. For example, u_ext_content. Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[array]</td>
<td>Required. Unnamed array of objects in which each object represents an external document to ingest for indexing. Data type: Array</td>
</tr>
<tr>
<td>array.content_pointer</td>
<td>Identifier for an instance of binary content stored using the POST /ais/external_content/storeContent endpoint. During ingestion, AI Search parses the binary content and adds</td>
</tr>
</tbody>
</table>
Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>its searchable content to the indexed record that represents the external document. Parsing removes the stored content object.</td>
</tr>
<tr>
<td>![Note:]</td>
<td>This identifier should match the result response body element returned by the storeContent endpoint.</td>
</tr>
<tr>
<td>![Data type:]</td>
<td>String</td>
</tr>
<tr>
<td>[array].document_id</td>
<td>Required. Unique identifier for the external document in the external content schema table specified by the schema_table_name path parameter.</td>
</tr>
<tr>
<td>![Note:]</td>
<td>When you ingest a document, it overwrites any existing document in the same external content schema table that has the same document_id. If two or more documents in the same ingestion request have the same document_id, the request fails.</td>
</tr>
<tr>
<td>![Data type:]</td>
<td>String</td>
</tr>
<tr>
<td>[array].principals</td>
<td>Object containing key-value pairs that describe the external document’s access permissions for externally defined security principals (users and groups).</td>
</tr>
</tbody>
</table>
### Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image.png" alt="Image" /></td>
<td><img src="description.png" alt="Description" /></td>
</tr>
</tbody>
</table>

**Note:**

If you omit this parameter for a document, the request succeeds, but AI Search rejects the document with the ingestion feedback message *The principal of the document is missing.*

If this parameter object does not include any key-value pairs that grant access to a document, the request succeeds, but AI Search rejects the document with the ingestion feedback message *The principal of the document is invalid.*

**Data type:** Object

```
"principals": {
  "everyone": Boolean,
  "groups.deny": [Array],
  "groups.read": [Array],
  "none": Boolean,
  "users.deny": [Array],
  "users.read": [Array]
}
```

**Versions supported:** Available starting in v2 of the API.

**[array].principals.everyone**

Flag that indicates whether access to the external document is allowed for all users. When this parameter is set to **true**, all Now Platform users can view the indexed record created from the document.

**Note:** If you set both this parameter and **[array].principals.none** to **true** for a document, the request succeeds, but AI Search rejects the document with ingestion feedback message *The principal of the document is invalid.* You can only set one of these two parameters to **true** in a request.
### Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>

<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Status codes**

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.
## Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>202</td>
<td>Partial Success. The request was processed. Some documents have ingestion feedback warning or error messages.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

## Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| error         | Object describing the error encountered during processing of the request.  

Data type: Object

```
"error": {
   "detail": "String",
   "message": "String"
}
```

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| error.detail  | Details of the error encountered during processing of the request.

</tr>
<tr>
<td></td>
<td>]</td>
</tr>
<tr>
<td>result.feedback.document_id</td>
<td>Unique identifier for the external document as specified in the request body.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>result.feedback.messages</td>
<td>Array of unnamed objects in which each object represents an ingestion feedback message logged during indexing of the external document.</td>
</tr>
<tr>
<td></td>
<td>Data type: Array</td>
</tr>
<tr>
<td></td>
<td>&quot;messages&quot;: [</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&quot;code&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;component&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;level&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;message&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>]</td>
</tr>
<tr>
<td>result.feedback.messages.code</td>
<td>Code for an exception thrown by the indexing workflow component that logged the ingestion feedback message.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>result.feedback.messages.component</td>
<td>Identifier for the indexing workflow component that logged the ingestion feedback message. Data type: String</td>
</tr>
<tr>
<td>result.feedback.messages.level</td>
<td>Logging level for the ingestion feedback message. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• ERROR</td>
</tr>
<tr>
<td></td>
<td>• INFO</td>
</tr>
<tr>
<td></td>
<td>• MINOR_ERROR</td>
</tr>
<tr>
<td></td>
<td>• WARN</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>result.feedback.messages.message</td>
<td>Text logged for the ingestion feedback message. Data type: String</td>
</tr>
<tr>
<td>status</td>
<td>Status of an unsuccessful request. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• failure</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

**Precedence order for principal permissions**

The precedence order for `array.principals` permissions depends on the value of the `user_read_takes_precedence_over_group_deny` attribute for the indexed source used to ingest an external document.

<table>
<thead>
<tr>
<th>Attribute value</th>
<th>Precedence order for principal permissions</th>
</tr>
</thead>
<tbody>
<tr>
<td>true</td>
<td>From highest precedence to lowest:</td>
</tr>
<tr>
<td></td>
<td>1. <code>array.principals.everyone,</code></td>
</tr>
<tr>
<td></td>
<td>2. <code>array.principals.none</code></td>
</tr>
<tr>
<td></td>
<td>3. <code>array.principals.users.deny</code></td>
</tr>
<tr>
<td></td>
<td>4. <code>array.principals.users.read</code></td>
</tr>
</tbody>
</table>
### Attribute value

<table>
<thead>
<tr>
<th>Precedence order for principal permissions</th>
</tr>
</thead>
<tbody>
<tr>
<td>4. <code>[array].principals.groups.deny</code></td>
</tr>
<tr>
<td>5. <code>[array].principals.groups.read</code></td>
</tr>
</tbody>
</table>

**Note:** This is the default attribute value for external content indexed sources.

<table>
<thead>
<tr>
<th>false</th>
</tr>
</thead>
</table>

From highest precedence to lowest:

1. `[array].principals.everyone`, `[array].principals.none`  
2. `[array].principals.users.deny`, `[array].principals.groups.deny`  
3. `[array].principals.users.read`, `[array].principals.groups.read`  

**Note:** For instructions on setting this attribute value, see Change the precedence of user read and group deny permissions for an external content indexed source.

### Example: cURL request

Feed two external documents (with content pointers to binary content objects previously stored using the `POST /ais/external_content/storeContent` endpoint) for indexing into the `u_ext_content` schema table.

```bash
curl  
'https://instance.servicenow.com/api/now/v2/ais/external_content/ingestDocument/u_ext_content'  
--request POST  
--user 'username':'password'  
--header 'Accept: application/json'  
--header 'Content-Type: application/json'  
--data '  
{  
  "document_id": "ADMIN-2027858531-16",  
  "content_pointer": "749b52a1-baa8-4556-a4f3-00404c95e6a8",  
  "properties": {  
    "title": "Introduction",  
  
```
Example: Python request

Feed two external documents (with content pointers to binary content objects previously stored using the POST /ais/external_content/storeContent endpoint) for indexing into the u_ext_content schema table.

```python
# Need to install requests package for python
import requests
import json

# Set the API endpoint URL for the request
url = "https://instance.servicenow.com/api/now/v2/ais/external_content/ingestDocument/u_ext_content"

# Set credentials
user = "username"
pwd = "password"

# Set HTTP headers
headers = {
    "Accept": "application/json",
    "Content-Type": "application/json"
}

data = json.dumps(
    [
        {
            "document_id": "ADMIN-2027858531-16",
            "content_pointer": "749b52a1-baa8-4556-a4f3-00404c95e6a8",
            "properties": {
                "title": "Introduction",
                "url": "file:///myhost/reports/Introduction.pdf",
                "file_name": "Introduction.pdf",
                "file_size": "10285",
```
# Issue the HTTP request
response = requests.post(url, auth=(user, pwd), headers=headers, data=data)

# Check for HTTP status codes other than 200
if response.status_code != 200:
    print("Status:", response.status_code, "Headers:", response.headers, "Error Response:", response.content)
### External Content Ingestion API – POST ais/external_content/storeContent

Stores binary content as a content object in AI Search.

You can associate stored binary content with an external document by following these steps:

1. Store the binary content using this endpoint. Record the value of the `result` response body parameter.

2. Send the external document to AI Search using the **POST /ais/external_content/ingestDocument/** endpoint. Set the document's `content_pointer` request body parameter to match the recorded `result` response body parameter value.

During ingestion, AI Search parses the binary content and adds its searchable content to the indexed record that represents the external document. Parsing removes the stored content object.

### URL format

**Versioned URL:** /api/now/{api_version}/ais/external_content/storeContent
### Supported request parameters

#### Path parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>

#### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

#### Request body parameters

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[binary data]</td>
<td>Required. Binary content to store as a content object in AI Search.</td>
</tr>
</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

#### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports application/json.</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• application/msword</td>
</tr>
<tr>
<td></td>
<td>• application/octet-stream</td>
</tr>
<tr>
<td></td>
<td>• application/pdf</td>
</tr>
<tr>
<td></td>
<td>• application/vnd.ms-excel</td>
</tr>
</tbody>
</table>
Request headers (continued)

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>

<tr>
<td>• application/vnd.openxmlformats-officedocument.wordprocessingml.document</td>
<td></td>
</tr>
<tr>
<td>• application/vnd.openxmlformats-officedocument.wordprocessingml.template</td>
<td></td>
</tr>
<tr>
<td>• text/html</td>
<td></td>
</tr>
<tr>
<td>• text/plain</td>
<td></td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>
## Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>error</td>
<td>Object describing the error encountered during processing of the request. Data type: Object.</td>
</tr>
</tbody>
</table>
|              | ```json
"error": {
"detail": "String",
"message": "String"
}
```                                                                                      |
| error.detail | Details of the error encountered during processing of the request. Data type: String.                                                      |
| error.message| Message for the error encountered during processing of the request. Data type: String.                                                       |
| result       | Identifier for the binary content object stored by successful request. Data type: String.                                                   |
|              | ```json
"result": "91841766-2a5f-4c64-a20a-27ca485eca21"
```                                                                                      |

**Note:** To attach the stored content to an ingested external document, specify this identifier as the `content_pointer` request body element for a request to the `ingestDocument` endpoint.

<table>
<thead>
<tr>
<th>status</th>
<th>Status of an unsuccessful request. Valid values:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>failure</strong></td>
</tr>
<tr>
<td></td>
<td>Data type: String.</td>
</tr>
</tbody>
</table>

**Example: cURL request**

Store binary content for a PDF file as a content object.

```bash
curl 'https://instance.servicenow.com/api/now/v2/ais/external_content/storeContent' \   
--request POST 
```
--user 'username':'password' \
--header 'Content-Type: application/pdf' \
--data-binary '@Report-2020-08-31.pdf'

The response body includes the unique identifier for the new content object.

```
{
    "result" : "fb439a4f-62ad-4dab-9654-5088d99a6ff9"
}
```

**Example: Python request**

Store binary content for a PDF file as a content object.

```python
# Need to install requests package for python
import requests
import json

# Set the API endpoint URL for the request
url = "https://instance.servicenow.com/api/now/v2/ais/external_content/storeContent"

# Set credentials
user = "username"
pwd = "password"

# Set HTTP headers
headers = {
    "Content-Type": "application/pdf",
}

# Read binary data from file on local filesystem
with open('./Introduction.pdf', 'rb') as file:
    data = file.read()

# Issue the HTTP request
response = requests.post(url, auth=(user, pwd), headers=headers, data=data)

# Check for HTTP status codes other than 200
if response.status_code != 200:
    print("Status:" , response.status_code, "Headers:" , response.headers, "Error Response:" , response.content)
    exit()

# Display the JSON response
print(json.dumps(response.json()))
```
The response body includes the unique identifier for the new content object.

```
{
    "result": "749b52a1-baa8-4556-a4f3-00404c95e6a8"
}
```

**HR REST API**

This API provides methods that return information about employees that work or live in the United States.

To access this API you must have the sn_hr_core.usa_employee_only role and the Human Resources Scoped App: Core (com_sn_hr_core) plugin activated.

**HR REST - GET /get_usa_employee_profile**

Returns employee profile information for employees based in the United States.

The returned information can be either:

- Employee profile information for a specified employee ID.
- Information for employees that have been added, or whose information has been updated, on or after a specified date.

ℹ️ **Note:** Employees must either have their work or home country specified as the United States for this endpoint to include them in the return results.

In addition, the endpoint sends the following parameters to the integrated CIC Plus application (see the Returns section for descriptions):

- EmployeeIdentifier
- FirstName
- MiddleName
- LastName
- Email
- WorkAddress
- WorkCity
- WorkState
- WorkPostalCode
- WorkCountry
- HomeAddress
- HomeCity
- HomeState
- HomePostalCode
- HomeCountry
- BirthDate
- HireDate

**URL format**

Default URL: `/api/sn_hr_core/hr_rest_api/get_usa_employee_profile`

**Supported request parameters**

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>employee_identifier</td>
<td>Unique identifier of an employee. The calling system generates this value and can be in whatever format is consistent with their system. To obtain this value, first call the endpoint using the <code>updated_after</code> parameter.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This parameter is mutually exclusive with the <code>updated_after</code> parameter. This parameter defines a unique employee, whereas <code>updated_after</code> returns a group of employees created/updated after a specified date.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>sysparm_limit</td>
<td>Maximum number of records to return. For requests that exceed this number of records, use the <code>sysparm_offset</code> parameter to paginate record retrieval.</td>
</tr>
<tr>
<td></td>
<td>Data type: Number</td>
</tr>
<tr>
<td></td>
<td>Default: 100,000</td>
</tr>
<tr>
<td>sysparm_offset</td>
<td>Starting record index for which to begin retrieving records. Use this value to paginate record retrieval.</td>
</tr>
</tbody>
</table>
Query parameters (continued)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_offset</td>
<td>This functionality enables the retrieval of all records, regardless of the number of records, in small manageable chunks.</td>
</tr>
<tr>
<td></td>
<td>For example, the first time you call this endpoint, <code>sysparm_offset</code> is set to &quot;0&quot;. To simply page through all available records, use <code>sysparm_offset=sysparm_offset +sysparm_limit</code>, until you reach the end of all records.</td>
</tr>
</tbody>
</table>

| updated_after   | Date to use to determine the employee data to return. All United States-based employees (work or home) that were added to your instance, or whose information was updated on or after this date, are included in the return results. |
|                 | **Note:** This parameter is mutually exclusive with the `employee_identifier` parameter.                                                                                                                        |
|                 | Data type: String                                                                                                                                                                                            |
|                 | Format: YYYY-MM-DD HH:MM:SS or YYYY-MM-DD (time defaults to 00:00:00)                                                                                                                                       |

</table>

**Example: Sample cURL request for a specific employee’s information**

```bash
curl -X GET 
"https://instance.servicenow.com/api/sn_hr_core/V1/hr_rest_api/get_usa_employee_profile?employee_identifier=231"
-H "accept: application/json"
-u "username":"password"

{"result": [
{"EmployeeIdentifier": "231",
"FirstName": "Harold",
"MiddleName": "William",
"LastName": "Lewis",
"Suffix": "Mr.",
"Email": "Howard.Lewis@example.com",
"BirthDate": ",
"HireDate": "2021-02-18",
"Company": "ServiceNow Inc",
"ResidenceAddress": ",
"ResidenceCity": "SD",
"ResidenceState": "CA",
"ResidencePostalCode": ",
"ResidenceCountry": ",
"WorkAddress": "2617 South Robinson Avenue, Oklahoma City",
"WorkCity": "Oklahoma",
"WorkState": "OK",
"WorkPostalCode": "73109",
"WorkCountry": "USA",
"ReHire": ",
}]
```
Example: Sample cURL request for a list of employees added/updated on or after 05/18/2019

```bash
curl -X GET
  "https://instance.servicenow.com/api/sn_hr_core/v1/hr_rest_api/get_usa_employee_profile?update_after=2019-05-18"
-H "accept: application/json"
-u "username":"password"
```

```json
{"result": [
  {
    "EmployeeIdentifier": "2345",
    "FirstName": "Cheryl",
    "MiddleName": "Lynn",
    "LastName": "Smith",
    "Suffix": "Mrs.",
    "Email": "Cheryl.Smith@example.com",
    "BirthDate": "",
    "HireDate": "2019-06-18",
    "Company": "ServiceNow Inc",
    "ResidenceAddress": "",
    "ResidenceCity": "SD",
    "ResidenceState": "CA",
    "ResidencePostalCode": "",
    "ResidenceCountry": "",
    "WorkAddress": "2617 South Robinson Avenue, Oklahoma City",
    "WorkCity": "Oklahoma",
    "WorkState": "OK",
    "WorkPostalCode": "73109",
    "WorkCountry": "USA",
    "ReHire": ""
  },
  {
    "EmployeeIdentifier": "1111",
    "FirstName": "Thomas",
    "MiddleName": "",
    "LastName": "Doe",
    "Suffix": "Mr.",
    "Email": "Thomas.Doe@example.com",
    "BirthDate": "1978-05-22",
    "HireDate": "2019-08-14",
    "Company": "",
    "ResidenceAddress": "",
    "ResidenceCity": "San Jose",
    "ResidenceState": "CA",
    "ResidencePostalCode": "",
    "ResidenceCountry": ""
  }
]}
```
Example: Sample Python request

```python
# Need to install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/sn_hr_core/V1/hr_rest_api/get_usa_employee_profile?employee_identifier=231'

# Eg. User name="username", Password="password" for this code sample.
user = 'username'
pwd = 'password'

# Set proper headers
headers = {"Accept": "application/json"}

# Do the HTTP request
response = requests.post(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.json())
    exit()

# Decode the JSON response into a dictionary and use the data
data = response.json()
print(data)

{"result": [
}]
```
Identification and Reconciliation API

The Identification and Reconciliation API uses the Identification and Reconciliation engine (IRE) to minimize creation of duplicate Configuration Items (CIs) and to reconcile CI attributes by only accepting information from authorized sources when updating the Configuration Management Database (CMDB).

Users must have the itil or asset role to use this API.

For more information on the IRE, see Identification and Reconciliation engine (IRE).

Identification and Reconciliation - POST /now/identifyreconcile

Inserts or updates configuration items (CIs) in the CMDB by applying identification and reconciliation rules to the specified payload (request body). Use this API instead of updating the CMDB directly.

Use the Identification and Reconciliation - POST /now/identifyreconcile/query endpoint to simulate submission of a payload to this endpoint without committing changes to the database.

Use the Identification and Reconciliation - POST /now/identifyreconcile/enhanced endpoint instead if you need to specify Enhanced IRE options. For more on Enhanced IRE options, see Identification and Reconciliation engine (IRE).

**URL format**

Versioned URL: /api/now/{api_version}/identifyreconcile

Default URL: /api/now/identifyreconcile

**Supported request parameters**

### Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>relationship. For non-dependency relationships, this information is in the Relationship Sources [sys_rel_source] table. Data type: Object</td>
</tr>
<tr>
<td>relations.sys_rel_source_info.source_name</td>
<td>Discovery source name. Default: Discovery source passed in the API method parameter.</td>
</tr>
<tr>
<td>relations.sys_rel_source_info.source_feed</td>
<td>Any string that is a sub-discovery/scan within the discovery source. Default: ‘UNKNOWN’ is stored in the source_feed column when creating a record in sys_rel_source table.</td>
</tr>
<tr>
<td>relations.type</td>
<td>The type of relationship existing between the parent and child items. This must be a name field value from the CI Relationship Type [cmdb_rel_type] table. Data type: String</td>
</tr>
</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports application/json.</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Only supports application/json.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>None</td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>

Data type: String

result.relations.warnings

Array of objects in which each object describes a warning encountered while processing this dependent relationship CI.

Data type:

```json
{  
  "warnings": [  
    {  
      "error": "String",  
      "message": "String"  
    }  
  ]
}
```

result.relations.warnings.error

The type of warning encountered while processing this dependent relationship CI.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>result.relations.warnings.message</code></td>
<td>The warning message encountered while processing this dependent relationship CI.</td>
</tr>
</tbody>
</table>

**Example: cURL request**

Submit a payload containing a Linux server (with serial number and network adapter related-item lookups) and an IP switch, with an IP Connection dependent relationship between them.

```bash
curl "https://instance.servicenow.com/api/now/identifyreconcile" \
--request POST \
--header "Accept: application/json" \
--header "Content-Type: application/json" \
--user "username:password" \
--data '{ "items": [{ "className": "cmdb_ci_linux_server", "values": { "sys_class_name": "cmdb_ci_linux_server", "name": "lnux101", "host_name": "lnux101.servicenow.com", "ip_address": "10.11.12.173", "os_name": "Linux Red Hat" }, }, "lookup": [{ "className": "cmdb_serial_number", "values": { "serial_number": "lnux101", "serial_number_type": "uuid", "valid": "true" } }, { "className": "cmdb_ci_network_adapter", "values": { "name": "eth0", "ip_address": "10.11.12.173", "mac_address": "00:55:51:21:26:2f" } } ] }
```
The Linux server CI is identified via a Hardware Rule search for its name on the Hardware [cmdb_ci_hardware] table and is processed as an update to an existing CI in the Linux Server [cmdb_ci_linux_server] table. The IP switch is similarly identified via a Hardware Rule search for its name on the Hardware table and updates an existing CI in the IP Switch [cmdb_ci_ip_switch] table. Finally, the IP Connection dependent relationship between the server and the switch is inserted as a new record in the CI Relationship [cmdb_rel_ci] table.

**Example: Python request**

Submit a payload containing entries for two load-balancer pool member CIs, two load-balancer pool CIs, a BigIP load balancer CI, and two load-balancer service instance CI. Each pool owns one pool member and is owned by the BigIP load balancer, and both service instances run on the load balancer.

```python
# Need to install requests package for python
import requests

# Set the API endpoint URL for the request
url = 'https://instance.servicenow.com/api/now/identifyreconcile'

# Set credentials
user = 'username'
pwd = 'password'

# Set HTTP headers
headers = {
```

Identification and Reconciliation - POST /now/identifyreconcile/enhanced

Inserts or updates configuration items (CIs) in the CMDB by applying identification and reconciliation rules to the specified payload (request body). Use this API instead of updating the CMDB directly.

Use the Identification and Reconciliation - POST /now/identifyreconcile/queryEnhanced endpoint to simulate submission of a payload to this endpoint without committing changes to the database.

This method is similar to the Identification and Reconciliation - POST /now/identifyreconcile method, but adds the following functionality:

- Partial payloads
  - In case of an item having a warning or error, indicates if an item operation is INSERT_AS_PARTIAL or INSERT_INCOMPLETE.
  - Returns the sys_ids of partial payloads that were merged with existing partial payloads.
- Supports payload deduplicate feature.
- Generates a summary.

URL format

Versioned URL: /api/now/{api_version}/identifyreconcile/enhanced

Default URL: /api/now/identifyreconcile/enhanced

Supported request parameters

<table>
<thead>
<tr>
<th>Path parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
</tbody>
</table>
### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>options</td>
<td>Comma-separated list of name-value pairs representing Enhanced IRE options. As an example, to override the default values for the partial payloads, deduplicate payloads, and generate summary Enhanced IRE options: partial_payloads: false, partial_commits: false, deduplicate_payloads: false.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> By default or if partial_payloads is set to true, both partial_commits and deduplicate_payloads are enabled, even if they are set to false, as those features are essential for partial payloads functionality. For more on Enhanced IRE options, see Identification and Reconciliation engine (IRE).</td>
</tr>
<tr>
<td>sysparm_data_source</td>
<td>Identifies the source of the CI information. This must be one of the choice values defined for the discovery_source field of the Configuration Item [cmdb_ci] table.</td>
</tr>
</tbody>
</table>

Valid values for each name-value pair:

- true: Enable this Enhanced IRE option.
- false: Disable this Enhanced IRE option.

Data type: String

### Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>items</td>
<td>Array of objects in which each object describes a CI to create or update.</td>
</tr>
</tbody>
</table>

Data type: Array

items.related

Array of objects in which each object describes an item record to create or update, based on a related table that has a reference to the top-level CI that is being identified. Rules in the Related Entries [cmdb_related_entry] table define what type of records can be in this array.

The related table may or may not extend the Configuration Item [cmdb_ci] table. These records are not used to identify the configuration item.

Data type: Array

"related": [
  {
    "className": "String",
    "internal_id": "String",
    "sys_object_source_info": {Object},
    "values": {Object}
  }
]

items.related.className

Required. The sys_class_name or class/table name of the related item to create or update.

Data type: String
### Request body parameters (XML or JSON) (continued)

<td></td>
<td>]</td>
</tr>
<tr>
<td>referenceItems.referenced</td>
<td>The <strong>internal_id</strong> defined for the item being referenced by another item. Data type: String</td>
</tr>
<tr>
<td>referenceItems.referencedBy</td>
<td>The <strong>internal_id</strong> defined for the item that references another item. Data type: String</td>
</tr>
<tr>
<td>referenceItems.referenceField</td>
<td>Name of the reference field in the class/table for the <strong>referencedBy</strong> item. Data type: String</td>
</tr>
</tbody>
</table>
### Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| relations | Array of objects in which each object describes a relationship between two items defined in the payload. An object in this array can use either of two formats:  
  - The object can define a relationship between two top-level items (or using `parent` and `child` name-value pairs, with values representing item indexes from the payload items array.  
  - The object can define a relationship between any two items, including top-level, related, or lookup items, using `parent_id` and `child_id` key/value pairs, with values representing `internal_id` values defined for those items.  
  
  **Data type:** Array  
  ```json
  "relations": [
    {
      "child": Number,
      "parent": Number,
      "sys_rel_source_info": (Object),
      "type": "String"
    }
  ]
  ```
|
### Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>relations.child</td>
<td>The integer index of the object in the items array that represents the child in the relationship.</td>
</tr>
<tr>
<td>relations.child_id</td>
<td>The internal_id of the child item in the relationship.</td>
</tr>
<tr>
<td>relations.parent</td>
<td>The integer index of the object in the items array that represents the parent in the relationship.</td>
</tr>
<tr>
<td>relations.parent_id</td>
<td>The internal_id of the parent item in the relationship.</td>
</tr>
<tr>
<td>relations.sys_rel_source_info</td>
<td>Discovery source information for the relationship. For non-dependency relationship this information is in the Relationship Sources [sys_rel_source] table.</td>
</tr>
</tbody>
</table>

```json
"child_id": "String",
"parent_id": "String",
"sys_rel_source_info": {
  (Object),
  "type": "String"
}
```

### Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>relations.sys_rel_source_info.source_name</td>
<td>Discovery source name. Default: Discovery source passed in the API method parameter.</td>
</tr>
<tr>
<td>relations.sys_rel_source_info.source_feed</td>
<td>Any string that is a sub-discovery/scan within the discovery source. Default: ‘UNKNOWN’ is stored in the source_feed column when creating a record in sys_rel_source table.</td>
</tr>
<tr>
<td>relations.type</td>
<td>The type of relationship existing between the parent and child items. This must be a name field value from the CI Relationship Type [cmdb_rel_type] table. Data type: String</td>
</tr>
</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

#### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports <code>application/json</code>.</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Only supports <code>application/json</code>.</td>
</tr>
</tbody>
</table>
Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request.</td>
</tr>
</tbody>
</table>

Error message detail "Chunk [...] is not a valid entry" indicates that the **options** query parameter is not in the correct name-value pair format.

For example, specifying an **options** parameter of **partial** produces a 500 status code with "Chunk [partial] is not a valid entry" in the message detail.

Response body parameters (JSON or XML)

<table>
<thead>
<tr>

<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>• DELETE:</td>
<td>An existing CI is removed from the target table.</td>
</tr>
<tr>
<td>• INSERT:</td>
<td>The additional CI is inserted into the target table as a new record.</td>
</tr>
<tr>
<td>• NO_CHANGE:</td>
<td>No operation is performed for the additional CI.</td>
</tr>
<tr>
<td>• UPDATE:</td>
<td>An existing CI in the target table is updated.</td>
</tr>
<tr>
<td>• UPDATE_WITH_DOWNGRADE:</td>
<td>An existing CI in the target table is updated and its class is changed to a more generic class.</td>
</tr>
<tr>
<td>• UPDATE_WITH_SWITCH:</td>
<td>An existing CI in the target table is updated and its class is changed to another class that is not an ancestor or descendant of the original class.</td>
</tr>
<tr>
<td>• UPDATE_WITH_UPGRADE:</td>
<td>An existing CI in the target table is updated and its class is changed to a more specialized class (descendent class).</td>
</tr>
</tbody>
</table>

Data type: String

result.additionalCommittedItems.sysId

The sys_id found for this additional CI through identification.

Notable values:

• Unknown: Identification of this additional CI failed. See errors for details.

Data type: String

result.additionalCommittedItems.warnings

Array of objects in which each object describes a warning encountered while processing this additional CI.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result.additionalCommittedItems.warnings.error</td>
<td>The type of warning encountered while processing this additional CI. Data type: String</td>
</tr>
<tr>
<td>result.additionalCommittedItems.warnings.message</td>
<td>The warning message encountered while processing this additional CI. Data type: String</td>
</tr>
<tr>
<td>result.additionalCommittedRelations</td>
<td>Array of objects in which each object describes a dependent relationship CI not included in the request body list to insert or update. Data type: Array</td>
</tr>
<tr>
<td>result.additionalCommittedRelations.className</td>
<td>The sys_class_name of this additional dependent relationship CI. Only supported value: • cmdb_rel_ci: The CI Relationship table. Data type: String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td><code>result.additionalCommittedRelations.errorCount</code></td>
<td>The number of errors encountered while processing this additional dependent relationship CI. Data type: Number</td>
</tr>
<tr>
<td><code>result.additionalCommittedRelations.errors</code></td>
<td>Array of objects in which each object describes an error encountered while processing this additional dependent relationship CI. Data type: Array</td>
</tr>
<tr>
<td><code>result.additionalCommittedRelations.errors.error</code></td>
<td>The type of error encountered while processing this additional dependent relationship CI. Data type: String</td>
</tr>
<tr>
<td><code>result.additionalCommittedRelations.errors.message</code></td>
<td>The error message encountered while processing this additional dependent relationship CI. Data type: String</td>
</tr>
<tr>
<td><code>result.additionalCommittedRelations.inputIndices</code></td>
<td>Array of index values for dependent relationship CI objects in the request body <code>relations</code> array that correspond to this additional dependent relationship CI. Data type: Array</td>
</tr>
<tr>
<td><code>result.additionalCommittedRelations.markers</code></td>
<td>Array of markers for internal use.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td><code>result.additionalCommittedRelations.mergedPayloadIds</code></td>
<td>Array of sys_id values for partial payloads from the CMDB IRE Partial Payloads [cmdb_ire_partial_payloads] table that were merged during processing of this additional dependent relationship CI.</td>
</tr>
</tbody>
</table>
| `result.additionalCommittedRelations.operation` | The operation performed for this additional dependent relationship CI. Possible values:  
  - **INSERT**: The dependent relationship CI is inserted into the target table as a new record.  
  - **INSERT_AS_INCOMPLETE**: The dependent relationship CI had errors and is inserted into the CMDB IRE Incomplete Payloads [cmdb_ire_incomplete_payloads] table.  
  - **INSERT_AS_PARTIAL**: The dependent relationship CI had errors and is inserted into the CMDB IRE Partial Payloads [cmdb_ire_partial_payloads] table. |
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• NO_CHANGE: No operation is performed for the dependent relationship CI.</td>
<td></td>
</tr>
<tr>
<td>• UPDATE: An existing dependent relationship CI in the target table is updated.</td>
<td></td>
</tr>
</tbody>
</table>

**result.items**

Array of objects in which each object describes a CI included in the request body `items` array.

Data type: Array

```json
"items": [
  {
    "additionalRelatedItems": [],
    "className": "String",
    "duplicateLookupIndices": {},
    "errorCount": Number,
    "errors": [],
    "identificationAttempts": [],
    "identifierEntrySysId": "String",
    "info": [],
    "inputIndices": [],
    "markers": [],
    "mergedPayloadIds": [],
    "operation": "String",
    "relatedItems": [],
    "relatedSysIds": [],
    "sysId": "String",
    "warnings": []
  }
]
```

**result.items.additionalRelatedItems**

Array of objects in which each object describes a related CI (table lookup CI) from the CMDB IRE Partial Payloads `[cmdb_ire_partial_payloads]` table.

Data type: Array

<td></td>
</tr>
<tr>
<td>• <strong>UPDATE</strong> WITH <strong>UPGRADE</strong>: An existing CI in the target table is updated and its class is changed to a more specialized class (descendent class).</td>
<td></td>
</tr>
</tbody>
</table>

Data type: String

```json
result.items.relatedItems
```

Array of objects in which each object describes a related CI (table lookup CI) from the request body items.lookup array.

Data type:

```json
"relatedItems": [
  {
    "className": "String",
    "inputIndices": [Array],
    "markers": [Array],
    "mergedPayloadIds": [Array],
    "sysId": "String"
  }
]
```

result.items.relatedItems.className

The sys_class_name of the related item.

Data type: String

result.items.relatedItems.inputIndices

Array of index values for CIs and lookup items from the request body items and items.lookup arrays that correspond to this related item.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result.items.relatedItems.inputIndices.mainIndex</td>
<td>Index value from the request body <code>items</code> array. CI parent to the related item.</td>
</tr>
<tr>
<td>result.items.relatedItems.inputIndices.subIndex</td>
<td>Index value from the request body <code>items.lookup</code> array.</td>
</tr>
<tr>
<td>result.items.relatedItems.markers</td>
<td>Array of marker values for internal use.</td>
</tr>
<tr>
<td>result.items.relatedItems.mergedPayloadIds</td>
<td>Array of <code>String</code> values for entries in the CMDB IRE Partial Payloads <code>[cmdb_ire_partial_payloads]</code> table that were merged into this CI during processing.</td>
</tr>
<tr>
<td>result.items.relatedSysIds</td>
<td>Array of <code>String</code> values for related items (table lookup items) from the request body <code>items.lookup</code> array.</td>
</tr>
</tbody>
</table>

**Notable values:**
- `null`: No sys_id was identified for this related item.
<table>
<thead>
<tr>
<th>Name</th>

</table>

**Data type:** Array

result.relations.warnings

Array of objects in which each object describes a warning encountered while processing this dependent relationship CI.

**Data type:** Array

```
"warnings": [
  {
    "error": "String",
    "message": "String"
  }
]
```

result.relations.warnings.error

The type of warning encountered while processing this dependent relationship CI.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result.relations.warnings.message</td>
<td>The warning message encountered while processing this dependent relationship CI.</td>
</tr>
</tbody>
</table>

**Example: cURL request**
Submit a partial payload for a computer CI.

```
curl "https://instance.servicenow.com/api/now/identifyreconcile/enhanced" \  
  --request POST \  
  --header "Accept: application/json" \  
  --header "Content-Type: application/json" \  
  --user "username":"password" \  
  --data '{ \  
    "items": [ \  
      { \  
        "className": "cmdb_ci_computer", \  
        "sys_object_source_info": { \  
          "source_name": "ServiceNow", \  
          "source_native_key": "ncomputer3367" \  
        }, \  
        "values": { \  
          "cpu_core_count": "6", \  
          "ram": "8192", \  
          "manufacturer": "DELL", \  
          "company": "My Company" \  
        } \  
      } \  
    ] \  
  }'  
```

The response shows that the payload has been inserted into the CMDB IRE Partial Payloads [cmdb_ire_partial_payloads] table.

```json
{
  "result": {
    "items": [{
      "className": "cmdb_ci_computer",
      "operation": "INSERT_AS_PARTIAL",
      "sysId": "Unknown",
      "partialSysIds": ["1aec79151bb45010593876a61a4bcb28"]
    }
  ]
}
```
"identifierEntrySysId": "Unknown",
"errors": [],
"warnings": [{
  "error": "MISSING_MATCHING_ATTRIBUTES",
  "message": "In payload missing minimum set of input values for criterion (matching) attributes from identify rule for table [cmdb_ci_hardware]. Add these input values in payload item '{"className":"cmdb_ci_computer","values":{"discovery_source":"ServiceNow","company":"My Company","cpu_core_count":"6","ram":"8192","manufacturer":"DELL","sys_object_source_info":{"source_name":"ServiceNow","source_native_key":"ncomputer3367"},"settings":{},"sys_ire_info":{"ire_received_time":"2020-05-14 20:14:51"}}'",
  "identificationAttempts": [{
    "info": "sys_object_source NO_MATCH",

    "attemptResult": "NO_MATCH",
    "attributes": [],
    "hybridEntryCiAttributes": []
  }, {
    "identifierName": "Hardware Rule",
    "attemptResult": "SKIPPED",
    "attributes": ["serial_number", "serial_number_type"],
    "searchOnTable": "cmdb_serial_number",
    "hybridEntryCiAttributes": []
  }, {
    "identifierName": "Hardware Rule",
    "attemptResult": "SKIPPED",
    "attributes": ["serial_number"],
    "searchOnTable": "cmdb_ci_hardware",
    "hybridEntryCiAttributes": []
  }, {
    "identifierName": "Hardware Rule",
    "attemptResult": "SKIPPED",
    "attributes": ["name"],
    "searchOnTable": "cmdb_ci_hardware",
    "hybridEntryCiAttributes": []
  }, {
    "identifierName": "Hardware Rule",
    "attemptResult": "SKIPPED",
    "attributes": ["mac_address", "name"],
    "searchOnTable": "cmdb_ci_network_adapter",
    "hybridEntryCiAttributes": []
  }],
}]}
Submit a second partial payload that completes the description of the computer CI, with the summary generation Enhanced IRE option enabled.

```
curl  
    "https://instance.servicenow.com/api/now/identifyreconcile/enhanced?options=generate_summary:true" 
    --request POST 
    --header "Accept: application/json" 
    --header "Content-Type: application/json" 
    --user "username":"password" 
    --data '{ 
    
    }'
```

The response shows that the computer CI is inserted, and displays a summary of operations performed.

Example: Python request
Submit a payload containing entries for three Linux server CIs and generate a summary of operations performed for this payload.

```python
# Need to install requests package for python
import requests

# Set the API endpoint URL for the request
url = 'https://instance.servicenow.com/api/now/identifyreconcile/enhanced'

# Set credentials
user = 'username'
pwd = 'password'

# Set query parameters
params = {
    "options": "generate_summary:true"
}

# Set HTTP headers
headers = {
    "Accept": "application/json",
    "Content-Type": "application/json"
}

# Define JSON payload
payload = {
    "items": [
```
{  
  "className": "cmdb_ci_linux_server",
  "sys_object_source_info": {
    "source_name": "ServiceNow",
    "native_source_key": "linserver273"
  },
  "values": {
    "name": "linuxserver9423",
    "serial_number": "m51ced54747j89ed561n2bn674sa",
    "ram": "16384",
    "ip_address": "92.251.144.62",
    "company": "b7e831bdc0a80169015ae10f3c4d6cd",
    "discovery_source": "ServiceNow"
  }
},
{  
  "className": "cmdb_ci_linux_server",
  "sys_object_source_info": {
    "source_name": "ServiceNow",
    "native_source_key": "linserver913"
  },
  "values": {
    "name": "linuxserver9331",
    "serial_number": "2b1g6ds5ae48k4n2m4n32xc4c6s",
    "ram": "16384",
    "ip_address": "135.172.23.7",
    "company": "b7e831bdc0a80169015ae10f3c4d6cd",
    "discovery_source": "ServiceNow"
  }
},
{  
  "className": "cmdb_ci_linux_server",
  "sys_object_source_info": {
    "source_name": "ServiceNow",
    "native_source_key": "linserver972"
  },

    "ip_address": "89.174.215.57",
    "company": "b7e831bdc0a80169015ae10f3c4d6cd",
    "discovery_source": "ServiceNow"
  }
}
# Issue the HTTP request
response = requests.post(url, auth=(user, pwd), params=params, headers=headers,
    json=payload)

# Check for HTTP status codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:',
          response.content)
    exit()

# Decode the JSON response into a dictionary and use the data
data = response.json()
print(data)

All three CIs are updated, and the operation summary is generated.

Identification and Reconciliation - POST /now/identifyreconcile/query

Determines the CMDB operation (insert/update) to perform with the specified payload (request body), without committing the operations in the database.

Use this endpoint to simulate submission of a payload (request body) to the Identification and Reconciliation - POST /now/identifyreconcile endpoint.
Use the Identification and Reconciliation - POST /now/identifyreconcile/enhanced endpoint instead if you need to specify Enhanced IRE options. For more on Enhanced IRE options, see Identification and Reconciliation engine (IRE).

### URL format

Versioned URL: `/api/now/{api_version}/identifyreconcile/query`

Default URL: `/api/now/identifyreconcile/query`

### Supported request parameters

#### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>

#### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_data_source</td>
<td>Identifies the source of the CI information. This must be one of the choice values defined for the discovery_source field of the Configuration Item [cmdb_ci] table. Data type: String Default: Insert the API payload into the incomplete payloads table.</td>
</tr>
</tbody>
</table>

#### Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>items</td>
<td>Array of objects in which each object describes a CI to create or update. Data type: Array</td>
</tr>
</tbody>
</table>
### Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>items.className</strong></td>
<td>Required. The <code>sys_class_name</code> (class/table name) of the CI to create or update. This value can be any CMDB table, such as <code>cmdb_ci_linux_server</code> or <code>cmdb_ci_win_server</code>. Data type: String</td>
</tr>
<tr>
<td><strong>items.internal_id</strong></td>
<td>Unique identifier for this item in this payload. Can be any value, but must be unique within the payload. Data type: String</td>
</tr>
<tr>
<td><strong>items.lookup</strong></td>
<td>Array of objects in which each object describes a lookup-based identification record. These records are used to identify the top-level configuration item based on a lookup table that has a reference back to the Configuration Item [cmdb_ci] table. Data type: Array</td>
</tr>
</tbody>
</table>
Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>items.lookup.className</td>
<td>Required. The sys_class_name or class/table name of the CI to create or update. This value can be any CMDB class/table, such as cmdb_serial_number or cmdb_ci_network_adapter or a non-CMDB hierarchy class. Data type: String</td>
</tr>
<tr>
<td>items.lookup.internal_id</td>
<td>Unique identifier for this lookup record in this payload. Can be any value, but must be unique within the payload. Data type: String</td>
</tr>
<tr>
<td>items.lookup.sys_object_source_info</td>
<td>Object describing a unique CI identifier for a specified data source. Different sources may have different name-value pairs for the same CI. Data type: Object</td>
</tr>
</tbody>
</table>

```json
"lookup": [
  {
    "className": "String",
    "internal_id": "String",
    "sys_object_source_info": {
      "source_feed": "String",
      "source_name": "String"
    }
  }
]
```
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>items.lookup.sys_object_source_info.source_feed</code></td>
<td>Name that uniquely identifies the feed sending this CI. Use if the source can have multiple feeds. Data type: String</td>
</tr>
<tr>
<td><code>items.lookup.sys_object_source_info.source_name</code></td>
<td>Data source for the CI information. This value must be one of the choice values defined for the discovery_source field of the Configuration Item [cmdb_ci] table. Data type: String</td>
</tr>
<tr>
<td><code>items.lookup.sys_object_source_info.source_native_key</code></td>
<td>Unique key/id from the source for the CI. Can be any string that is unique to the item. Data type: String</td>
</tr>
<tr>
<td><code>items.lookup.sys_object_source_info.source_recency_timestamp</code></td>
<td>UTC date and time that CI was scanned. Data type: String Format: YYYY-MM-DD hh:mm:ss</td>
</tr>
<tr>
<td><code>items.lookup.values</code></td>
<td>Object describing fields this lookup item as name/value pairs, where the name is the field name. Data type: Object</td>
</tr>
</tbody>
</table>
### Request body parameters (XML or JSON) (continued)

| relations                                 | Array of objects in which each object describes a relationship between two items defined in the payload. An object in this array can use either of two formats:
|                                           | • The object can define a relationship between two top-level items using **parent** and **child** name-value pairs, with values representing item indexes from the payload **items** array. |
|                                           | • The object can define a relationship between any two items, including top-level, related, or lookup items, using **parent_id** and **child_id** key/value pairs, with values representing **internal_id** values defined for those items. |
|                                           | Data type: Array                                                           |

```json
"relations": [
]
```
<table>
<thead>

</tr>
<tr>
<td>relations.sys_rel_source_info.source_name</td>
<td>Discovery source name. Default: Discovery source passed in the API method parameter.</td>
</tr>
<tr>
<td>relations.sys_rel_source_info.source_feed</td>
<td>Any string that is a sub-discovery/scan within the discovery source. Default: 'UNKNOWN' is stored in the source_feed column when creating a record in sys_rel_source table.</td>
</tr>
<tr>
<td>relations.type</td>
<td>The type of relationship existing between the parent and child items. This must be a name field value from the CI Relationship Type [cmdb_rel_type] table. Data type: String</td>
</tr>
</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
## Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports application/json.</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Only supports application/json.</td>
</tr>
</tbody>
</table>

## Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

## Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Data type: String

result.relations.warnings

Array of objects in which each object describes a warning encountered while processing this dependent relationship CI.

Data type:

```json
"warnings": [
    {
        "error": "String",
        "message": "String"
    }
]
```

result.relations.warnings.error

The type of warning encountered while processing this dependent relationship CI.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result.relations.warnings.message</td>
<td>The warning message encountered while processing this dependent relationship CI.</td>
</tr>
</tbody>
</table>

**Example: cURL request**

Simulate submission of a payload containing a Linux server (with serial number and network adapter related-item lookups) and an IP switch, with an IP Connection relationship between them.

```bash
curl "https://instance.servicenow.com/api/now/identifyreconcile/query" \
  --request POST  \
  --header "Accept: application/json"  \
  --header "Content-Type: application/json"  \
  --user "username":"password"  \
  --data '{ \
    "items": [{ \
      "className": "cmdb_ci_linux_server", \n      "values": { \
        "sys_class_name": "cmdb_ci_linux_server", \n        "name": "lnux101", \n        "host_name": "lnux101.servicenow.com", \n        "ip_address": "10.11.12.173", \n        "os_name": "Linux Red Hat" \n      }, \n      "lookup": [{ \
        "className": "cmdb_serial_number", \n        "values": { \n          "serial_number": "lnux101", \n          "serial_number_type": "uuid", \n          "valid": "true" \n        } \n      }, { \n        "className": "cmdb_ci_network_adapter", \n        "values": { \n          "name": "eth0", \n          "ip_address": "10.11.12.173", \n          "mac_address": "00:55:51:21:26:2f" \n        } \n      }] \n    } 
  }
```
The Linux server CI is identified via a Hardware Rule search for its name on the Hardware [cmdb_ci_hardware] table and is processed as an update to an existing CI in the Linux Server [cmdb_ci_linux_server] table. The IP switch is similarly identified via a Hardware Rule search for its name on the Hardware table and updates an existing CI in the IP Switch [cmdb_ci_ip_switch] table. Finally, the IP Connection relationship between the server and the switch is inserted as a new record in the CI Relationship [cmdb_rel_ci] table.

Example: Python request

Simulate submission of a payload containing entries for two load-balancer pool member CIs, two load-balancer pool CIs, a BigIP load balancer CI, and two load-balancer service instance CI. Each pool owns one pool member and is owned by the BigIP load balancer, and both service instances run on the load balancer.

```python
# Need to install requests package for python
import requests

# Set the API endpoint URL for the request
url = 'https://instance.servicenow.com/api/now/identifyreconcile/query'

# Set credentials
user = 'username'
pwd = 'password'

# Set HTTP headers
headers = {
    'Content-Type': 'application/json',
    'Authorization': 'Basic ' + base64.b64encode(user + ':' + pwd).decode(),
}
```
"Accept": "application/json",
"Content-Type": "application/json"
}

# Define JSON payload
payload = {
    "items": [
        {
            "className": "cmdb_ci_lb_pool_member",
            "values": {

```python
# Issue the HTTP request
response = requests.post(url, auth=(user, pwd), headers=headers, json=payload)

# Check for HTTP status codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:',
          response.content)
    exit()

# Decode the JSON response into a dictionary and use the data
data = response.json()
print(data)

All CIs and relationship CIs are inserted as new records into their respective tables.

Identification and Reconciliation - POST /now/identifyreconcile/queryEnhanced

Determines the CMDB operation (insert/update) to perform with the specified payload (request body), without committing the operations in the database.

Use this endpoint to simulate submission of a payload (request body) to the Identification and Reconciliation - POST /now/identifyreconcile/enhanced endpoint.

This method is similar to the Identification and Reconciliation - POST /now/identifyreconcile/query method, but adds the following functionality:

• Partial payloads
  ◦ In case of an item having a warning or error, indicates if an item operation is INSERT_AS_PARTIAL or INSERT_INCOMPLETE.
  ◦ Returns the sys_ids of partial payloads that were merged with existing partial payloads.
• Supports payload deduplicate feature.
• Generates a summary.

URL format

Versioned URL: /api/now/{api_version}/identifyreconcile/queryEnhanced

Default URL: /api/now/identifyreconcile/queryEnhanced
## Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| options             | Comma-separated list of name-value pairs representing Enhanced IRE options. As an example, to override the default values for the partial payloads, partial commits, deduplicate payloads, and generate summary Enhanced IRE options: partial_payloads:false,partial_commits:false,deduplicate_payloads:

**Note:** By default or if `partial_payloads` is set to true, both `partial_commits` and `deduplicate_payloads` are enabled, even if they are set to false, as those features are essential for partial payloads functionality.

For more on Enhanced IRE options, see [Identification and Reconciliation engine (IRE)](https://go.to/snowdoc).

Valid values for each name-value pair:

- **true**: Enable this Enhanced IRE option.
- **false**: Disable this Enhanced IRE option.

Data type: String |
| sysparm_data_source | Identifies the source of the CI information. This must be one of the choice values defined for the discovery_source field of the Configuration Item [cmdb_ci] table. Data type: String Default: Insert the API payload into the incomplete payloads table. |
**Request body parameters (XML or JSON)**

</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports <code>application/json</code>.</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Only supports <code>application/json</code>.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request.</td>
</tr>
</tbody>
</table>

Error message detail "Chunk [...] is not a valid entry" indicates that the `options` query parameter is not in the correct name-value pair format. For example, specifying an `options` parameter of `partial` produces a 500 status code with "Chunk [partial] is not a valid entry" in the message detail.

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>Array of results produced by the query.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>

</tr>
</tbody>
</table>

Data type: String

result.additionalCommittedItems.identificationAttempts.attributes

Array of CI identifier entry attributes used during this additional CI identification attempt. Data type: Array

Attribute names and types depend on the request body data and the identifier in use, such as:

```json
"attributes": {
  "serial_number": "String",
  "serial_number_type": "String"
}
```

result.additionalCommittedItems.identificationAttempts.hybridEntryCiAttributes

Array of CI identifier entry attributes used during this additional CI identification attempt. Data type: Array

Attribute names and types depend on the request body data and the identifier in use, such as:

```json
"hybridEntryCiAttributes": {
  "name": "String",
  "serial_number": "String"
}
```

result.additionalCommittedItems.identificationAttempts.identifierName

The identifier rule used for this additional CI identification attempt. The identifier rule used for this additional CI identification attempt.
<table>

#### result.additionalCommittedItems.operation

- **DELETE**: An existing CI is removed from the target table.
- **INSERT**: The additional CI is inserted into the target table as a new record.
- **NO_CHANGE**: No operation is performed for the additional CI.
- **UPDATE**: An existing CI in the target table is updated.
- **UPDATE_WITH_DOWNGRADE**: An existing CI in the target table is updated and its class is changed to a more generic class (ancestor class).
- **UPDATE_WITH_SWITCH**: An existing CI in the target table is updated and its class is changed to another class which is not an ancestor or descendent class.
- **UPDATE_WITH_UPGRADE**: An existing CI in the target table is updated and its class is changed to a more specialized class (descendent class).

#### Data type: String

#### The operation performed for this additional CI.

Possible values:

- **DELETE**: An existing CI is removed from the target table.
- **INSERT**: The additional CI is inserted into the target table as a new record.
- **NO_CHANGE**: No operation is performed for the additional CI.
- **UPDATE**: An existing CI in the target table is updated.
- **UPDATE_WITH_DOWNGRADE**: An existing CI in the target table is updated and its class is changed to a more generic class (ancestor class).
- **UPDATE_WITH_SWITCH**: An existing CI in the target table is updated and its class is changed to another class which is not an ancestor or descendent class.
- **UPDATE_WITH_UPGRADE**: An existing CI in the target table is updated and its class is changed to a more specialized class (descendent class).

#### result.additionalCommittedItems.sysId

- **Unknown**: Identification of this additional CI failed. See errors for details.

#### Data type: String

The sys_id found for this additional CI through identification.

Notable values:

- **Unknown**: Identification of this additional CI failed. See errors for details.

</table>

Data type: String
result.relations.warnings

Array of objects in which each object describes a warning encountered while processing this dependent relationship CI.

Data type: Array

```json
"warnings": [
  {
    "error": "String",
    "message": "String"
  }
]
```

result.relations.warnings.error

The type of warning encountered while processing this dependent relationship CI.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result.relations.warnings.message</td>
<td>The warning message encountered while processing this dependent relationship.</td>
</tr>
</tbody>
</table>

**Example: cURL request**

Simulate submission of a partial payload for a computer CI.

```bash
curl "https://instance.servicenow.com/api/now/identifyreconcile/queryEnhanced" \
  --request POST \n  --header "Accept: application/json" \n  --header "Content-Type: application/json" \n  --user "username":"password" \n  --data '{ \n    "items": [ \n      { \n        "className": "cmdb_ci_computer", \n        "sys_object_source_info": { \n          "source_name": "ServiceNow", \n          "source_native_key": "ncomputer3367" \n        }, \n        "values": { \n          "cpu_core_count": "6", \n          "ram": "8192", \n          "manufacturer": "DELL", \n          "company": "My Company" \n        } \n      } \n    ] \n  }'
```

The response shows that the payload would be inserted into the CMDB IRE Partial Payloads [cmdb_ire_partial_payloads] table.

```json
{
  "result": {
    "relations": [],
    "items": [
      {
        "identifierEntrySysId": "Unknown",
        "partialSysIds": [
```
"1aec79151bb45010593876a61a4bcb28",
"sysId": "Unknown",
"errorCount": 0,
"markers": [],
"className": "cmdb_ci_computer",
"inputIndices": [0],
"operation": "INSERT_AS_PARTIAL",
"errors": [],
"identificationAttempts": [
{
"info": "sys_object_source NO_MATCH",
"attemptResult": "NO_MATCH",
"identifierName": "",
"attributes": [],
"hybridEntryCiAttributes": []
},
{
"attemptResult": "SKIPPED",
"identifierName": "Hardware Rule",
"attributes": [
    "serial_number",
    "serial_number_type"
],
"hybridEntryCiAttributes": [],
"searchOnTable": "cmdb_serial_number"
},
{
"attemptResult": "SKIPPED",
"identifierName": "Hardware Rule",
"attributes": [
    "serial_number"

"searchOnTable": "cmdb_ci_hardware"
},
{
"attemptResult": "SKIPPED",
"identifierName": "Hardware Rule",
"attributes": [
    "name"
]
}
Simulate submission of a second partial payload that would complete the description of the computer CI, with the summary generation Enhanced IRE option enabled.
The response shows that the computer CI would be inserted, and displays a summary of operations that would be performed.

```json
{
  "result": {
    "relations": [],
    "hasError": false,

}
}
Example: Python request

Simulate submission of a payload containing entries for three Linux server CIs and generate a summary of operations performed for this payload.

```python
# Need to install requests package for python
import requests

# Set the API endpoint URL for the request
data_url = 'https://instance.servicenow.com/api/now/identifyreconcile/queryEnhanced'

# Set credentials
data_user = 'username'
data_pwd = 'password'

# Set query parameters
query_params = {
    "options": "generate_summary:true"
}

# Set HTTP headers
headers = {
    "Accept": "application/json",
    "Content-Type": "application/json"
}

# Define JSON payload
payload = {
    "items": [
        {
            "className": "cmdb_ci_linux_server",
            "sys_object_source_info": {
                "source_name": "ServiceNow",
                "native_source_key": "linserver273"
            },
            "values": {
                "name": "linuxserver9423",
                "serial_number": "m51ced54747j89ed561n2bn674sa",
                "ram": "16384",
                "ip_address": "92.251.144.62",
                "company": "b7e831bd0a80169015ae101f3c4d6cd",
                "discovery_source": "ServiceNow"
            }
        }
    ]
}
```

# Issue the HTTP request
response = requests.post(url, auth=(user, pwd), params=params, headers=headers,
                        json=payload)

# Check for HTTP status codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:',
          response.content)
    exit()
All three CIs would be updated, and the operation summary is generated.

```json
{
    "result": {
        "items": [
            {
                "className": "cmdb_ci_linux_server",
                "operation": "UPDATE",
                "sysId": "5472d2d1bb85010593876a61a4bcbe6",

Import Set API

The Import Set API allows you to interact with import set tables.

Overview

The API transforms incoming data based on associated transform maps. The import set API supports synchronous transforms. The Import Set API mirrors the existing SOAP interface.

Security

Access to tables via the REST API is restricted by BasicAuth. To allow access to tables without any authentication or authorization, add the table name to sys_public.list. ACLs defined on tables are still enforced, and it is the administrator's responsibility to deactivate ACLs.

Import Set - GET /now/import/{stagingTableName}/{sys_id}

Retrieves the specified import staging record and resulting transformation result.
**URL format**

Versioned URL: `/api/now/{api_version}/import/{stagingTableName}/{sys_id}`

Default URL: `/api/now/import/{stagingTableName}/{sys_id}`

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>stagingTableName</td>
<td>Name of the table from which to obtain the import data. Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the record that contains the data. Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Request body parameters (XML or JSON)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Headers**

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Indicates the specified resource was not available. As import set tables are deleted frequently based on a schedule, GET requests may return 404 NotFound responses if the transformation result no longer exists.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>import_set</td>
<td>Name of the import set. Data type: String</td>
</tr>
<tr>
<td>result</td>
<td>List of objects that contain information on the data sets that were imported.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Data type: Array</td>
<td>&quot;result&quot;: [</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>result.display_name</td>
<td>Display name of the import set.</td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
<tr>
<td>result.display_value</td>
<td>Value of the import set.</td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
<tr>
<td>result.record_link</td>
<td>Table API GET request for the imported record.</td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
<tr>
<td>result.status</td>
<td>Status of the import.</td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
<tr>
<td>result.sys_id</td>
<td>Sys_id of the import record.</td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
<tr>
<td>result.table</td>
<td>Name of the table in which the data was imported.</td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
<tr>
<td>result.transform_map</td>
<td>Name of the transform map.</td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
<tr>
<td>staging_table</td>
<td>Name of the import staging table.</td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
</tbody>
</table>

**Example: Sample cURL request**

```
curl
"https://instance.servicenow.com/api/now/import/imp_user/e2928be64f411200adf9f8e18110c777"
```
Example: Sample Python request

```python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/now/import/imp_user/e2928be64f411200adf9f8e18110c777'

# Eg. User name='username', Password='password' for this code sample.
user = 'username'
pwd = 'password'

# Set proper headers
headers = {'Accept': 'application/xml'}

# Do the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    # Handle error
```
print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.content)
exit()

# Decode the XML response into a dictionary and use the data
print(response.content)

<?xml version="1.0" encoding="UTF-8"?>
<response>
  <import_set>ISET0010001</import_set>
  <staging_table>imp_user</staging_table>
  <result>
    <display_name>name</display_name>
    <display_value>John Public</display_value>
    <status>inserted</status>
    <sys_id>ea928be64f411200adf9e18110c777</sys_id>
    <record_link>https://instance.service-now.com/api/now/table/sys_user/ea928be64f411200adf9e18110c777</record_link>
    <table>sys_user</table>
    <transform_map>User</transform_map>
  </result>
</response>

**Import Set - POST /now/import/{stagingTableName}**

Inserts incoming data into a specified staging table and triggers transformation based on predefined transform maps in the import set table.

Transformation occurs synchronously. For each transform map that you define, the responses include transformation results such as information on the target records.

⚠️ **Note:** The status_message and error_message fields on transformation scripts are processed and returned in response, along with any custom response fields.

**URL format**

Versioned URL: /api/now/{api_version}/import/{stagingTableName}
Default URL: /api/now/import/{stagingTableName}
Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>stagingTableName</td>
<td>Name of the table from which to import the data. Data type: String</td>
</tr>
</tbody>

<td></td>
</tr>
</tbody>
</table>

**Example: Sample cURL request**

```bash
curl "https://instance.servicenow.com/api/now/import/imp_user" \
  --request POST \
  --header "Accept:application/json" \
  --header "Content-Type:application/json" \
  --data "{"first_name":"John","last_name":"Public","user_id":"john.public","email":"john.public@company.com"}" \ 
  --user "username":"password"
```

```json
{
  "import_set": "ISET0010001",
  "staging_table": "imp_user",
  "result": [ 
```
Example: Sample Python request

```python
# Need to install requests package for python
import requests

# Set the request parameters
url = 'https://instance.service-now.com/api/now/import/imp_user'
user = 'username'
pwd = 'password'
headers = {'Content-Type': 'application/xml', 'Accept': 'application/xml'}

# Do the HTTP request
response = requests.post(url, auth=(user, pwd), headers=headers,
                          data='<request><entry><first_name>John</first_name><last_name>Public</last_name><user_id>john.public</user_id><email>john.public@company.com</email></entry></request>"

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)
```

```
<?xml version="1.0" encoding="UTF-8"?>
<response>
    <import_set>ISET0010001</import_set>
</response>
```
Import Set - POST /now/import/{stagingTableName}/insertMultiple

Inserts multiple records into a specified staging table and triggers transformation based on predefined transform maps or Robust Transform Engine (RTE) configurations in a single request.

Transformation is asynchronous by default. To set synchronous transformation, create a new record in the Rest Insert Multiples [sys_rest_insert_multiple] table, select the source table, and set the transformation to synchronous.

This endpoint can send a request body in two possible formats.

**Data source file format**

If you generate a staging table from a JSON data source, match the JSON format of the source file.

**Staging table column format**

Default. Matches the staging table column request body format in key value pairs.

**URL format**

Versioned URL: /api/now/{api_version}/import/{stagingTableName}/insertMultiple

Default URL: /api/now/import/{stagingTableName}/insertMultiple

© 2021 ServiceNow, Inc. All rights reserved.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
## Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>stagingTableName</td>
<td>Name of the import set table from which to import the data. Refer to Import sets key concepts. Data type: String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>multi_import_set_id</td>
<td>Sys_id of an entry in the Multi Import Sets [sys_multi_import_set] table. If specified, adds the current import to this multiple import set instead of adding to a new multiple import set. Data type: String</td>
</tr>
<tr>
<td>run_after</td>
<td>Sys_id of an entry in the Import Sets [sys_import_set] table. Enables running the current import set after the specified import set is complete. You can use this parameter to enforce the sequential order of imports. This parameter is only valid in asynchronous transformations. Data type: String</td>
</tr>
</tbody>
</table>

### Request body (JSON)

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data source file</td>
<td>This request body format matches the JSON file format used to create the data source. Provide the request body in the same format as the JSON in the data source. JSON input varies depending on the properties in your data source. Refer to JSON information in File type data source.</td>
</tr>
</tbody>
</table>
Request body (JSON) (continued)

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• This option is only available if the staging table was created using a JSON data source. Refer to <a href="#">Create a File type data source</a>.</td>
<td></td>
</tr>
<tr>
<td>• You must define the path of the data source in the Data Source [sys_data_source] table in the Path for each row field.</td>
<td></td>
</tr>
<tr>
<td>• To change the default behavior for the REST Insert Multiple user, create an entry in the REST Insert Multiples [sys_rest_insert_multiple] table.</td>
<td></td>
</tr>
<tr>
<td>• Enable the <strong>Use data source format</strong> in the REST insert multiple entry.</td>
<td></td>
</tr>
</tbody>
</table>

**Data type:** Object

**Staging table column (default)**

This request body format matches staging table columns. Use the `records` array of key-value pairs matching the staging table column to insert in the import fields. Each JSON key is maps the table column to a JSON value representing the value to be inserted. JSON input varies depending on what fields are in your staging table.

The column mapping default key value is to the column table.

```
{
  "records": [  
    {  
      "<ColumnLabel1>":"<value>",
      "<ColumnLabel2>":"<value>"
    },  
    {  
      "<ColumnLabel1>":"<value>",
      "<ColumnLabel2>":"<value>"
    }  
  ]
}
```

You can modify mapping settings by adding an entry in the Rest Insert Multiples [sys_rest_insert_multiple] table and changing the **Column mapping** from Label to Column name.

```
{
  "records": [  
    {  
      "<column_name1>":"<value>",
      "<column_name2>":"<value>"
    }  
  ]
}
```
Request body (JSON) (continued)

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>&quot;&lt;column_name1&gt;&quot;:&quot;&lt;value&gt;&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;&lt;column_name2&gt;&quot;:&quot;&lt;value&gt;&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
</tbody>
</table>

The data dictionary provides details on table fields in the system.

Data type: Array

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports application/json.</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Only supports application/json.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.
### Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

### Response body (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>import_set_id</td>
<td>Sys_id of the record added to the Import Sets [sys_import_set] table. For asynchronous requests, you can use this value to run another import set after this import set process is complete. Data type: String</td>
</tr>
<tr>
<td>multi_import_set_id</td>
<td>Sys_id of the record added to the Multi Import Sets [sys_multi_import_set] table. This value can be used to group multiple import sets into one set. Data type: String</td>
</tr>
</tbody>
</table>

### Example: Sample cURL request

The following example shows how to run a transform on an import table called `u_employee_import_set_table` using the staging table column format.

```cURL
curl "https://instance.servicenow.com/api/now/import/u_employee_import_set_table/insertMultiple" \
--request POST \
--header "Accept:application/json" \
--header "Content-Type:application/json" \
--data "{
  "records": [
    {
      "Address": "Hollywood",
      "Name": "Tom",
      "ID": "123"
    }
  ]
"}
```
Results include sys_ids for new records in the Import Sets [sys_import_set] and Multi Import Sets [sys_multi_import_set] tables.

```
}

"import_set_id": "<import_set_sys_id>",
"multi_import_set_id": "<multi_import_set_sys_id>"
```  

**Interaction Management API**

Use the interaction management API to create interactions.

This class requires the Interaction Logging, Routing, and Queueing plugin (com.glide.interaction).

**Interaction - POST /now/interaction**

Inserts or updates a record in the interaction table.

**URL format**

- Versioned URL: /api/now/{api_version}/interaction
- Default URL: /api/now/interaction

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>
### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>channel</td>
<td>Required. Sys_id for the interaction connector you want to create an interaction for. Data type: String</td>
</tr>
<tr>
<td>context</td>
<td>A Map or a table/sys_id pair. By default, interactions have a record in the interaction_json_blob table that stores context data as a JSON object. You can point an interaction to a different record for context. Use context or context_table/context_id to define the context for an interaction. Data type: String</td>
</tr>
<tr>
<td>context_id</td>
<td>Document ID for a record you want to use to store context. The default is a new record in the interaction_json_blob table. If you define the context ID, you also need to define the table. Data type: String</td>
</tr>
<tr>
<td>context_table</td>
<td>Context table you want to use to store interaction context for. The default is interaction_json_blob. If you define the context table, you also need to define the context ID. Data type: String</td>
</tr>
<tr>
<td>channel_metadata</td>
<td>Map or a table/sys_id pair. Channel metadata contains information that a connector can use to communicate through the associated channel. Data type: String</td>
</tr>
<tr>
<td>channel_metadata_id</td>
<td>Document ID for a record you want to use to store channel metadata. The default is a new record in the live_group_profile table. If you define the</td>
</tr>
</tbody>
</table>
Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>channel_metadata_ID</td>
<td>channel metadata ID, you also need to define the table.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>channel_metadata_table</td>
<td>Table you want to use to store channel metadata. The default is the live_group_profile table. If you define the channel metadata table, you also need to define the channel metadata ID.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>queue</td>
<td>Sys_id for the queue you want to associate with the interaction.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json Or application/xml. Default: application/json</td>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>201</td>
<td>Indicates the query ran successfully.</td>
</tr>
<tr>
<td>400</td>
<td>Indicates that one or more mandatory parameters were missing from the request.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>assigned_to</td>
<td>The sys_id of the user the interaction is assigned to. Data type: String</td>
</tr>
<tr>
<td>channelMetadataDocument</td>
<td>The sys_id of the channel metadata document associated with the interaction. Data type: String</td>
</tr>
<tr>
<td>channelMetadataTable</td>
<td>The table name of the channel metadata table associated with the interaction. Data type: String</td>
</tr>
<tr>
<td>channel_metadata</td>
<td>Any channel metadata included for the interaction. Data type: String</td>
</tr>
<tr>
<td>closed_by</td>
<td>The sys_id of the user who closed the interaction. Data type: String</td>
</tr>
<tr>
<td>Element</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>contextDocument</td>
<td>The sys_id for the context document associated with the interaction. Data type: String</td>
</tr>
<tr>
<td>contextTable</td>
<td>The name of the table associated with the interaction. Data type: String</td>
</tr>
<tr>
<td>number</td>
<td>The number of the new interaction. Data type: String</td>
</tr>
<tr>
<td>opened_for</td>
<td>The sys_id of the user who the interaction was opened for. Data type: String</td>
</tr>
<tr>
<td>queue</td>
<td>The sys_id for the queue you create the interaction for. Data type: String</td>
</tr>
<tr>
<td>state</td>
<td>The state the interaction is in. If you assign a queue, the state automatically changes to <strong>Queued</strong>, otherwise the default is <strong>New</strong>. Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>The sys_id of the interaction. Data type: String</td>
</tr>
</tbody>
</table>

**Example: Sample cURL request**

```bash
curl "http://instance.servicenow.com/api/now/interaction" \
   --request POST "
   --header "Accept:application/json" "
   --header "Content-Type:application/json" "
   --data "{"channel":"28a5989387310302ae97e2526cb0b5d","queue":"f3a50867b30303002186a72256a8dcb7"}" "
   --user "username":"password"
```

```json
{
   "result": {
      "channel": "28a5989387310302ae97e2526cb0b5d",
      "context": {
```
Example: Sample Python request

```python
import requests

# Set the request parameters
url = 'http://instance.servicenow.com/api/now/interaction'

# Eg. User name="username", Password="password" for this code sample.
user = 'username'
pwd = 'password'

# Set proper headers
headers = {"Content-Type":"application/json","Accept":"application/json"}

# Do the HTTP request
response = requests.post(url, auth=(user, pwd), headers=headers,
data="{"channel":"28a59893873103002ae97e2526cb0b5d","queue":"f3a50867b3030302186a72256a8dcb7"}")

# Check for HTTP codes other than 200
if response.status_code != 200:
    exit()
```
Interaction - POST /now/interaction/{interaction_id}/close
Changes the state of an interaction to closed or closed complete.

URL format
Versioned URL: /api/now/{api_version}interaction/{interaction_id}/close
Default URL: /api/now/interaction/{interaction_id}/close
## Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

Knowledge Management REST API

The Knowledge Management REST API enables searching, viewing, and fetching lists of most-viewed and featured knowledge articles.

This API can only be used when the Knowledge API (sn_km_api) plugin is activated. The Knowledge Management REST API was originally released in Orlando using the Knowledge API app available in the ServiceNow Store.

To enable other domains to use Knowledge Management REST API endpoints, define a Cross-Origin Resource Sharing (CORS) rule. For more information, see Define a CORS rule.

To view an article from the scoped knowledge base using this REST API, allow the sn_km_api scope read access from the requesting scope in the Restricted Caller
Access Privileges [sys_restricted_caller_access] table. For more information, see Define cross-scope access to an application resource.

By default, this API has a rate limit of 500 per hour for unauthenticated and snc_external users. For more information about rate limiting, see Inbound REST API rate limiting.

**Knowledge Management - GET /knowledge/articles**

Returns a list of knowledge base (KB) articles which can be searched and filtered using various parameters.

**URL format**

Versioned URL: `/api/sn_km_api/{api_version}/knowledge/articles`

Default URL: `/api/sn_km_api/knowledge/articles`

**Supported request parameters**

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| filter | Encoded query to use to filter the result set. Syntax: `filter=<attr><operator><value>`.

- `<attr>`: Name of the table column.
- `<operator>`: Valid values:
  - `=`: Exactly matches `<value>`.
  - `!`: Does not match `<value>`.
  - `∧`: Enables you to specify more than one condition and logically AND them.
**Query parameters (continued)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>^OR:</td>
<td>Enables you to specify more than one condition and logically OR them.</td>
</tr>
<tr>
<td>LIKE:</td>
<td>&lt;attr&gt; contains the specified string. Only works for &lt;attr&gt; fields whose data type is string.</td>
</tr>
<tr>
<td>STARTSWITH:</td>
<td>&lt;attr&gt; starts with the specified string. Only works for &lt;attr&gt; fields whose data type is string.</td>
</tr>
<tr>
<td>ENDSWITH:</td>
<td>&lt;attr&gt; ends with the specified string. Only works for &lt;attr&gt; fields whose data type is string.</td>
</tr>
<tr>
<td>&lt;value&gt;:</td>
<td>Value to match against.</td>
</tr>
</tbody>
</table>

All parameters are case-sensitive. Query can contain more than one entry, such as `filter=<attr><operator><value>[<operator><attr><operator><value>]`.  

**Data type:** String  
**Default:** empty

| fields | Comma-separated list of fields from the Knowledge [kb_knowledge] table to show details in results.  
**Data type:** String  
**Default:** None

| kb | Comma-separated list of knowledge base sys_ids from the Knowledge Bases [kb_knowledge_base] table to restrict results to.  
**Data type:** String

| language | List of comma-separated languages in two-letter ISO 639-1 language code format to restrict results to. Alternatively type 'all' to search in all valid installed languages on an instance.  
**Data type:** String  
**Default:** User's session language or en

| limit | Maximum number of records to return. Unusually large limit values can impact system performance. For requests that exceed this number of records, use the offset parameter to paginate record retrieval.  
**Data type:** Number
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>offset</td>
<td>Starting record index for which to begin retrieving records. Use this value to paginate record retrieval. This functionality enables the retrieval of all records, regardless of the number of records, in small manageable chunks. For example, the first time this endpoint is called, offset is set to &quot;0&quot;. To page through all available records, use offset=offset+limit until the end of the all records is reached. Data type: Number Default: 0</td>
</tr>
<tr>
<td>query</td>
<td>Text to search for, can be empty. Data type: String</td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
## Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>articles</td>
<td>List of articles returned in response. Data type: Array</td>
</tr>
<tr>
<td>articles.fields</td>
<td>Values of requested fields, if any. Data type: Object</td>
</tr>
</tbody>
</table>

```json
"articles": [
  {
    "fields": {Object},
    "link": "String",
    "id": "String",
    "number": "String",
    "rank": Number,
    "score": Number,
    "snippet": "String",
    "title": "String"
  }
]
```

```json
"fields": {
  "<field_name>": {Object}
}
```
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>articles.fields.&lt;field_name&gt;</td>
<td>Lists each field requested using the fields parameter, if any. Data type: Object</td>
</tr>
</tbody>
</table>
|   | ```
   "<field_name>": {
   "display_value": "String",
   "label": "String",
   "name": "String",
   "type": "String",
   "value": "String"
   }
   ``` |
<p>| articles.fields.&lt;field_name&gt;.display_value | Display value of the requested field. Data type: String |
| articles.fields.&lt;field_name&gt;.label | Label representing the requested field. For example, Knowledge. Data type: String |
| articles.fields.&lt;field_name&gt;.name | Name of the requested field. Matches <code>&lt;field_name&gt;</code>. Data type: String |
| articles.fields.&lt;field_name&gt;.type | Data type of requested field. Data type: String |
| articles.fields.&lt;field_name&gt;.value | Value of the requested field. Data type: String |
| articles.id | Knowledge article sys_id from the Knowledge [kb_knowledge] table. Data type: String |
| articles.link | Link to the article. Data type: String |
| articles.number | Knowledge article number. Data type: String |
| articles.rank | Search rank of article specific to this search. Data type: Number (Float) |</p>
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>articles.snippet</td>
<td>Text showing a small portion of the knowledge article.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>articles.score</td>
<td>Relevancy score, results sorted in descending order by score.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>articles.title</td>
<td>Short description or title of the knowledge article.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>meta</td>
<td>Meta information of the results and request parameters.</td>
</tr>
<tr>
<td></td>
<td>Data type: Object</td>
</tr>
<tr>
<td>&quot;meta&quot;: {</td>
<td></td>
</tr>
<tr>
<td>&quot;count&quot;: Number,</td>
<td></td>
</tr>
<tr>
<td>&quot;end&quot;: Number,</td>
<td></td>

<td></td>
</tr>
<tr>
<td>&quot;kb&quot;: &quot;String&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;language&quot;: &quot;String&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;query&quot;: &quot;String&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;start&quot;: Number,</td>
<td></td>
</tr>
<tr>
<td>&quot;status&quot;: {Object},</td>
<td></td>
</tr>
<tr>
<td>&quot;ts_query_id&quot;: &quot;String&quot;</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>meta.count</td>
<td>Number of available KB articles.</td>
</tr>
<tr>
<td></td>
<td>Data type: Number</td>
</tr>
<tr>
<td>meta.end</td>
<td>Ending index of the result set.</td>
</tr>
<tr>
<td></td>
<td>Data type: Number</td>
</tr>
<tr>
<td>meta.fields</td>
<td>Fields in the article.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>meta.filter</td>
<td>Filter used to acquire the data.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>meta.kb</td>
<td>List of knowledge base article sys_ids.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>meta.language</td>
<td>List of comma-separated languages of the KB articles that were requested.</td>
</tr>
<tr>
<td>meta.query</td>
<td>Specified request query.</td>
</tr>
<tr>
<td>meta.start</td>
<td>Starting index of result set.</td>
</tr>
<tr>
<td>meta.status</td>
<td>Status of the call.</td>
</tr>
<tr>
<td>meta.ts_query_id</td>
<td>Sys_id of the query.</td>
</tr>
</tbody>
</table>

**Example: cURL request**

```
curl 
  "https://instance.servicenow.com/api/sn_km_api/knowledge/articles?query=Windows&limit=2&fields=short_description&fields=sys_class_name" 
  --request GET 
  --header "Accept:application/xml" 
  --user "username":"password"
```

```json
{
  "result": {
    "meta": {
      "start": 0,
      "end": 2,
      "fields": "short_description,sys_class_name",
      "query": "Windows",
      "filter": ",",
      "kb": ",",
      "language": "en",
      "count": 19,
      "ts_query_id": "7976f36129c30410f877796e70786991",
      "status": {
        "code": 200
      }
    }
  }
}
```
Should I upgrade to Windows 8.x?

Windows 8.x is designed for using touch, mouse, and keyboard the Windows Store and access apps such as Calendar, Mail, and Messaging. By most accounts, Windows boot times, smaller memory footprint, and more free memory for the programs you run.

What is the Windows key?

The Windows key is a standard key on most keyboards on computers built to use a Windows operating system. It is labeled with a Windows logo, and is usually placed between on the right side as well. Pressing Win (the Windows key) on its own will do the following:

Windows: Toggle
Knowledge Management - GET /knowledge/articles/{article_sys_id}/attachments/{attachment_sys_id}

Returns a knowledge article attachment as a file.

**URL format**

**Versioned URL:** `/api/sn_km_api/{api_version}/knowledge/articles/{article_sys_id}/attachments/{attachment_sys_id}`

**Default URL:** `/api/sn_km_api/knowledge/articles/{article_sys_id}/attachments/{attachment_sys_id}`

**Supported request parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
</tbody>
</table>
Path parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>article_sys_id</td>
<td>Sys_id of the knowledge article with the attachment you intend to retrieve. Located in the Knowledge Bases [kb_knowledge] table.</td>
</tr>
<tr>
<td>attachment_sys_id</td>
<td>Sys_id of record to which the attachment belongs.</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Content-Type</td>
<td>The content type of the response, for example, image/gif or <em>/</em>.</td>
</tr>
</tbody>
</table>
**Status codes**

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not found. The requested item was not found.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

**Response body parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>File is returned as a response.</td>
<td></td>
</tr>
</tbody>
</table>

**Example: Sample cURL request**

```bash
curl "https://instance.service-now.com/api/sn_km_api/knowledge/articles/0b48fd75474321009db4b5b08b9a71c2/attachments/fedf5614294f4010f877796e70786956" \
--request GET \
--header "Accept:*/*" \
--user "username":"password"
```

Binary response not shown (file is returned as a response).

**Knowledge Management - GET /knowledge/articles/featured**

Returns a list of the most-viewed knowledge articles and featured knowledge articles.

**URL format**

*Versioned URL*: `/api/sn_km_api/{api_version}/knowledge/articles/featured`

*Default URL*: `/api/sn_km_api/knowledge/articles/featured`

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>search_id</td>
<td>Optional unless using search_rank. Unique identifier of search that returned this article. You can retrieve search_id using one of the following APIs that returns the articles.id element:</td>
</tr>
</tbody>
</table>
|            | • Knowledge Management - GET /knowledge/articles  
|            | • Knowledge Management - GET /knowledge/articles/featured  
|            | • Knowledge Management - GET knowledge/articles/most_viewed  
|            | Passing the search_id and search_rank parameter increments the article view count and records an entry for the article in the Knowledge Use [kb_use] table. You can also verify incremented view counts in Knowledge Base [kb_view2] page. Data type: String |
| search_rank| Optional unless using search_id. Article search rank by click-rate that you can retrieve using one of the following APIs that returns the articles.rank element:                                           |
|            | • Knowledge Management - GET /knowledge/articles  
|            | • Knowledge Management - GET /knowledge/articles/featured  
|            | • Knowledge Management - GET knowledge/articles/most_viewed  
|            | Data type: Number                                                                                                                                                                                            |
| update_view| Update view count and record an entry for the article in the Knowledge Use [kb_use] table. True whether present as a standalone parameter or set to true.                                                        |
|            | Note: If you pass update_view with search_id and search_rank, update_view is ignored because the view count will already be incremented.                                                                     |
|            | Data type: Boolean that is always handled as true when passed whether set to "true", "false", or not set at all.                                                                                      |

  }
}

Example: Sample cURL request (update_view)

curl "https://instance.servicenow.com/api/sn_km_api/knowledge/KB0000020?update_view=' \ 
  --request GET \ 
  --header "Accept:application/json" \ 
  --user "username":"password"
Should I upgrade to Windows 8.x?

Windows 8.x is designed for using touch, mouse, and keyboard together, on hardware ranging from touch-enabled tablets and laptops to PCs and all-in-one computers...(intentionally truncated)

Knowledge Management - GET knowledge/articles/most_viewed

Returns a list of knowledge articles prioritized by most-viewed.

URL format

Versioned URL: /api/sn_km_api/{api_version}/knowledge/articles/most_viewed

Default URL: /api/sn_km_api/knowledge/articles/most_viewed

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fields</td>
<td>Comma-separated list of fields from the Knowledge [kb_knowledge] table to show details in results.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>

Select Send automatic replies. If desired, select the Only send during this time range check box to schedule when your out of office replies are active. If yo",

MetricBase Time Series API

Use the MetricBase Time Series API to insert data into, retrieve information from, and to run transforms against a MetricBase database.

These APIs can only be used when the MetricBase plugin (com.snc.clotho) is installed and activated.

Role required to write to this API: clotho_rest_put

The examples in this section were created using data in the MetricBase Demo (com.snc.clotho.demo) plugin.

MetricBase Time Series - GET /now/clotho/table/{table}/{subject}/{metric}

Retrieves specified time series data from the MetricBase database.

**URL format**

Versioned URL: /api/now/{api_version}/clotho/table/{table}/{subject}/{metric}

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>

</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports application/json.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.
### Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>label</td>
<td>The label used to identify this metric’s result set. Data type: String</td>
</tr>
<tr>
<td>seriesRef</td>
<td>Data series results. Data type: Array</td>
</tr>
<tr>
<td>seriesRef.metric</td>
<td>The name of the metric from which the data series was obtained. Only appears if the metrics object is passed in the request. Data type: String</td>
</tr>
<tr>
<td>seriesRef.subject</td>
<td>The sys_id of the data series record. Located in the table specified in seriesRef.table. Data type: String</td>
</tr>
<tr>
<td>seriesRef.table</td>
<td>The name of the table from where the data series was obtained. Data type: String</td>
</tr>
<tr>
<td>values</td>
<td>The transformed series values.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>values:</td>
<td>The ISO 8601 timestamp of the value.</td>
</tr>
<tr>
<td>values.timestamp</td>
<td>The ISO 8601 timestamp of the value.</td>
</tr>
<tr>
<td>values.value</td>
<td>The metric values.</td>
</tr>
</tbody>
</table>

**Example: cURL request**

```bash
curl "https://instance.servicenow.com/api/now/v1/clotho/table/mb_demo_drone/626b051787333200a328c5b836cb0b99/mb_demo_mt_altitude?sysparm_start=2019-03-20T17%3A04%3A55&sysparm_end=2019-03-20T17%3A09%3A55" \
   --request GET \
   --header "Accept:application/json" \
   --user "username":"password"
```

```json
{
   "seriesRef": {
      "subject": "626b051787333200a328c5b836cb0b99",
      "table": "mb_demo_drone",
      "metric": "mb_demo_mt_altitude"
   },
   "label": "626b051787333200a328c5b836cb0b99:mb_demo_drone|mb_demo_mt_altitude",
   "values": [
      {
         "timestamp": "2019-03-20T17:05:00Z",
         "value": 83.150185
      },
      {
         "timestamp": "2019-03-20T17:06:00Z",
         "value": 83.46074
      }
   ]
}```
Example: Python request

import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/now/v1/clotho/table/mb_demo_drone/626b051787333200a328c5b836cb0b99/mb_demo_mt_altitude?sysparm_start=2019-03-20T17%3A04%3A55&sysparm_end=2019-03-20T17%3A09%3A55'

# Eg. User name="username", Password="password" for this code sample.
user = 'username'
pwd = 'password'

# Set proper headers
headers = {"Accept":"application/json"}

# Do the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:',response.json())
    exit()

# Decode the JSON response into a dictionary and use the data
data = response.json()
print(data)

{
    "seriesRef": {
        "subject": "626b051787333200a328c5b836cb0b99",
        "table": "mb_demo_drone",
        "metric": "mb_demo_mt_altitude"
    },
    "label": "626b051787333200a328c5b836cb0b99:mb_demo_drone|mb_demo_mt_altitude",
    "values": [
        {
            "timestamp": "2019-03-20T17:05:00Z",
            "value": 83.150185
        },
        {
            "timestamp": "2019-03-20T17:06:00Z",
            "value": 83.46074
        },
        {
            "timestamp": "2019-03-20T17:07:00Z",
            "value": 83.83104
        },
        {
            "timestamp": "2019-03-20T17:08:00Z",
            "value": 84.260635
        },
        {
            "timestamp": "2019-03-20T17:09:00Z",
            "value": 84.749
        }
    ]
}
## Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>metric</td>
<td>Name of the column in the table identified in the subject parameter to use as the metric. Data type: String</td>
</tr>
<tr>
<td>table</td>
<td>Name of the table containing the GlideRecord associated with this series. Data type: String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| sysparm_display_value | Flag that indicates whether the result data is labeled with the subject record display value if no other label is specified. Valid values:  
  • true: Result data is labeled with the subject record display value.  
  • false: Result data is not labeled with the subject record display value.  
  Data type: Boolean  
  Default: false                                                                 |
| sysparm_end           | Required. End time of the evaluation period. An empty or missing value is treated as the current time.  
  Data type: String  
  Format: ISO 8601 (UTC), either:                                                                                     |
### Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_query</td>
<td>Encoded query string for finding the subject records. Data type: String Default: None</td>
</tr>
</tbody>
</table>
| sysparm_start      | Required. Start time of the evaluation period. The special value all can be used to set the start time as the current time minus the maximum retention period for the specified metrics. An empty or missing value is treated as an implicit all. Data type: String Format: ISO 8601 (UTC), either:  
  - Absolute date format [YYYY-MM-DDThh:mm:ss], such as 2019-03-20T17:04:55  
  - Relative to current time duration format [P(n)Y(n)M(n)DT(n)H(n)M(n)S], such as P1M.                                                                                                           |
| sysparm_subject_limit | Limit size of the subject query result. Data type: Number Default: 10,000                                                                                                                                     |
| sysparm_transforms | Comma separated list of transforms. Valid transforms:  
  - add  
  - avg  
  - label  
  - mul  
  - resample  
  - sum  
  - top |
Query parameters (continued)

<table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
</tbody>
</table>
### Status codes (continued)

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>label</td>
<td>The label used to identify this metric’s result set. Data type: String</td>
</tr>
<tr>
<td>seriesRef</td>
<td>Data series results. Data type: Array</td>
</tr>
<tr>
<td></td>
<td>&quot;seriesRef&quot;: [</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&quot;metric&quot;: &quot;String&quot;,</td>

</tr>
<tr>
<td></td>
<td>&quot;table&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>seriesRef.metric</td>
<td>The name of the metric from which the data series was obtained. Only appears if the metrics object is passed in the request. Data type: String</td>
</tr>
<tr>
<td>seriesRef.subject</td>
<td>The sys_id of the data series record. Located in the table specified in seriesRef.table. Data type: String</td>
</tr>
<tr>
<td>seriesRef.table</td>
<td>The name of the table from where the data series was obtained. Data type: String</td>
</tr>
<tr>
<td>values</td>
<td>The transformed series values. Data type: Array</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>&quot;values&quot;: [</td>
<td></td>
</tr>
<tr>
<td>{</td>
<td></td>
</tr>
<tr>
<td>&quot;timestamp&quot;: &quot;String&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;value&quot;: Number }</td>
<td></td>
</tr>
<tr>
<td>]</td>
<td></td>
</tr>
</tbody>
</table>

values.timestamp

The ISO 8601 timestamp of the value.
Data type: String

values.value

The metric values.
Data type: Number

Example: cURL request

}
MetricBase Time Series - POST /now/clotho/transform

Retrieves and optionally groups time series data for one or more metrics after applying a specified list of transforms that form a linear pipeline.

**URL format**

Versioned URL: `/api/now/{api_version}/clotho/transform`

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| sysparm_display_value           | Flag that indicates whether the result data is labeled with the subject record display value if no other label is specified. Valid values:  
• true: Result data is labeled with the subject record display value.  
• false: Result data is not labeled with the subject record display value.  
Data type: Boolean  
Default: false |

**Request body parameters (XML or JSON)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>end</td>
<td>Required. End time of the evaluation period. An empty or missing value is treated as the current time. Data type: String</td>
</tr>
</tbody>
</table>
### Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td><strong>Description</strong></td>
</tr>
</tbody>
</table>
| limit             | Maximum number of records to return. Unusually large values can impact system performance.  
Data type: Number  
Default: 10,000    |
| metrics           | List of metrics objects to use in the transform. For more information on metrics, see [Metrics](#).  
Data type: Array   |
| metrics.groupBy   | Comma-separated list of fields, contained in the table specified in the **table** parameter, to group the series by before collecting or applying aggregated transformations.  
  The order of the items in the list is the order in which the data is grouped by. For example, if there are two items in the list, "state, zip code", then the series is first grouped by state and then by zip code within the state.  
Data type: String  
Default: Data is not grouped. |
| metrics.label     | Label to use for this metric's result set. It replaces any labels generated by the transform chain.  
Data type: String  |

Format: ISO 8601 (UTC), either:
- Absolute date format [YYYY-MM-DDThh:mm:ss], such as 2019-03-20T17:04:55.
- Relative to current time duration format [P(n)Y(n)M(n)DT(n)H(n)M(n)S], such as P1M.
### Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metrics.metric</td>
<td>Required if <code>metrics</code> object is passed. Metric field to use in the transform. This field must be in the table specified in the <code>table</code> parameter. Data type: String</td>
</tr>
<tr>
<td>metrics.transforms</td>
<td>List of transforms (transform chain) to apply to the retrieved time series data. Each transform builds on the results of the previous transform. For a list of available transforms, see Supported Transforms below. Data type: Array</td>
</tr>
</tbody>
</table>
| metrics.transforms.arg | Dependent on the transform. Parameter or parameters to pass into the transform. General guideline:  
  - Do not use the `arg` parameter when specifying transformations that do not take a parameter.  
  - Use Number, String, or Boolean for transforms that take a single parameter.  
  - Use a JSON object, with the appropriate name-value pairs, for transforms that take more than one parameter. Data type: Number, String, Boolean, or JSON object, depending on transform. (For a list of available transforms, refer to the table Supported transforms below.) |
| metrics.transforms.name | Required if a `transforms` object is specified. Name of the transform. |
Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>query</strong></td>
<td>Encoded query to use to filter the result set. You can compose the query using the specified table's filter editor. Once created, select Copy URL from the filter's breadcrumbs context menu. Data type: String Default: None</td>
</tr>
<tr>
<td><strong>start</strong></td>
<td>Required. Start time of the evaluation period. The special value <code>all</code> can be used to set the start time as the current time minus the maximum retention period for the specified metrics. An empty or missing value is treated as an implicit <code>all</code>. Data type: String Format: ISO 8601 (UTC), either: • Absolute date format <code>[YYYY-MM-DDThh:mm:ss]</code>, such as <code>2019-03-20T17:04:55</code> • Relative to current time duration format <code>[P(n)Y(n)M(n)DT(n)H(n)M(n)S]</code>, such as <code>P1M</code>.</td>
</tr>
<tr>
<td><strong>table</strong></td>
<td>Required. Name of the table that contains the GlideRecord associated with this series. Data type: String</td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not found. The requested item was not found.</td>
</tr>
<tr>
<td>405</td>
<td>Invalid method. The functionality is disabled.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>

### Supported transforms

<table>
<thead>
<tr>
<th>Transform</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>add</td>
<td>Adds the specified number to each timestamp value. Arguments:</td>
</tr>
<tr>
<td></td>
<td>• arg (Decimal): The number to add.</td>
</tr>
<tr>
<td>autocorrelate</td>
<td>Calculates the correlation between timestamp values separated by an increasing number of periods starting at 1.</td>
</tr>
<tr>
<td>avg</td>
<td>Aggregates the time series into one series containing the average value for each corresponding timestamp across the input.</td>
</tr>
<tr>
<td>bottom</td>
<td>Returns the specified number of series that have the lowest values. Arguments:</td>
</tr>
<tr>
<td></td>
<td>• arg (Integer): The number of series to return.</td>
</tr>
</tbody>
</table>

**results.series.values.timestamp**

ISO 8601 timestamp of the value.
Data type: String

**results.series.values.value**

Transformed value.
Data type: Number
<table>
<thead>
<tr>
<th>Transform</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>For example, the following returns the two time series that contain the lowest sets of values.</td>
</tr>
<tr>

<tr>
<td></td>
<td>&quot;arg&quot;: 2</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>]</td>
</tr>
<tr>
<td>ceil</td>
<td>Rounds the value in each timestamp up to the specified precision: <code>ceil(value / &lt;arg&gt;) * &lt;arg&gt;)</code></td>
</tr>
<tr>
<td></td>
<td>Arguments:</td>
</tr>
<tr>
<td></td>
<td>• arg: <strong>Decimal</strong>: The decimal precision to round up to.</td>
</tr>
<tr>
<td>collect</td>
<td>Displays the transform results of the transform chain up to the point of the collect transform call. Collect transform results contain a unique marker, but you may want to also define a label.</td>
</tr>
<tr>
<td></td>
<td>For example:</td>
</tr>
</tbody>
</table>
|           | ```

|           |       } |
|           |   } |
```
<table>
<thead>
<tr>
<th>Transform</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>constrainValues</td>
<td>Replaces any value outside the specified range with the corresponding maximum or minimum value. For example, if you specified the following, the transform replaces any value that is less than 0 with 0, and any value that is more than 100 with 100.</td>
</tr>
</tbody>
</table>

```
"transforms": [
  {
    "name": "constrainValues",
    "val1": 0,
    "val2": 100
  }
]
```

Arguments:
- `val1` (**Decimal**): Minimum or maximum value.
- `val2` (**Decimal**): Minimum or maximum value.

| count         | Aggregates the time series into one series. The new series contains the number of values that are not NaN (Not a Number) for each corresponding timestamp across the series. |

| derivative    | Determines the rate of change between timestamps. Divides the difference between the value in each timestamp and the value in the next timestamp by the timestamp’s period.  

**Note:** This transform returns one less value than the number of values in the series.

| div           | Divides the value in each timestamp by the specified number (arg).  
Arguments:
- `arg` (**Decimal**): The number by which to divide the value of each timestamp. |

<p>| envelope      | Returns two time series, where, at any point in time, one contains the largest value and the other contains the smallest value. |</p>
<table>
<thead>
<tr>
<th>Transform</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note</strong>: NaNs are ignored, but are returned if there are no other return values.</td>
<td></td>
</tr>
</tbody>
</table>
| **exp** | Raises the value of the specified base to the power of the value in each timestamp. Arguments:  
- arg (Decimal): The base value. |
| **filter** | Applies an aggregator to the contents of a sliding window, such as producing a moving average. Arguments:  
- aggregator (Aggregator): Type of aggregation to perform.  
- window (Duration): The duration of the sliding window. |
| **floor** | Rounds the value in each timestamp down to the specified precision: floor(value / <arg>) * <arg>  
Arguments:  
- arg (Decimal): The decimal precision to round down to. |
| **fractiles** | Returns a time series for each fraction in the specified array. Each timestamp value is the value at which the specified fraction of values, for the corresponding timestamp across the input series, is below the specified percentage. For example, if the fraction is 0.5, then the value in the timestamp is the value where half the values in the input series are below 0.5. Arguments:  
- arg: (Array of Decimals): The fractions to use on the input series. For example:  
```json
"transforms": [  
  {  
    "name": "fractiles",  
    "arg": [0.25, 0.5, 0.75, 1]  
  }  
]
```
<p>| <strong>groupBy</strong> | Groups data by the specified fields before collecting or applying aggregated transformations. Arguments: |</p>
<table>
<thead>
<tr>
<th>Transform</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>arg</strong> (String): A comma separated list of fields in the table to use to group the transform results.</td>
<td></td>
</tr>
<tr>
<td>For example:</td>
<td></td>
</tr>
<tr>
<td>&quot;transforms&quot;: [</td>
<td></td>
</tr>
<tr>
<td>{</td>
<td></td>
</tr>
<tr>
<td>&quot;name&quot;: &quot;groupBy&quot;</td>
<td></td>

<td></td>
</tr>
<tr>
<td>}</td>
<td></td>
</tr>
<tr>
<td>]</td>
<td></td>
</tr>
<tr>
<td>integrate</td>
<td>Multiplies the value in each timestamp by its period.</td>
</tr>
<tr>
<td>interpolate</td>
<td>Creates a data value for an NaN data item by interpolating from adjacent data values. Arguments:</td>
</tr>
<tr>
<td>• <strong>arg</strong> (Integer): Number of data samples in each direction to check for a non-NaN value. If a non-NaN value is not found, then NaN is used.</td>
<td></td>
</tr>
<tr>
<td>inverse</td>
<td>Computes the inverse of each timestamp value.</td>
</tr>
<tr>
<td>iqr</td>
<td>Performs an interquartile range transform and creates a result set that contains four series:</td>
</tr>
<tr>
<td>1. <strong>-IQR</strong>: The median of all entries below ( Q1 - (1.5 \times IQR) ).</td>
<td></td>
</tr>
<tr>
<td>2. <strong>Q1</strong>: The median of the smallest half of entries.</td>
<td></td>
</tr>
<tr>
<td>3. <strong>Q3</strong>: The median of the largest half of entries.</td>
<td></td>
</tr>
<tr>
<td>4. <strong>+IQR</strong>: The median of all entries above ( Q3 + (1.5 \times IQR) ).</td>
<td></td>
</tr>
<tr>
<td><strong>Note</strong>: ( IQR = Q3 - Q1 )</td>
<td></td>
</tr>
<tr>
<td>label</td>
<td>Labels a transformation chain.</td>
</tr>
<tr>
<td><strong>Note</strong>: Subsequent transformations may modify or replace the label.</td>
<td></td>
</tr>
<tr>
<td>Transform</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>Arguments:</strong></td>
<td></td>

<tr>
<td>• arg (String): Text of the label. Can contain the following formatting expressions:</td>
<td></td>
</tr>
<tr>
<td>◦ %%%: Escape a &quot;%%&quot; literal.</td>
<td></td>
</tr>
<tr>
<td>◦ %l: Current label that is being replaced.</td>
<td></td>
</tr>
<tr>
<td>◦ %%s: Series subject.</td>
<td></td>
</tr>
<tr>
<td>◦ %g: Value of the group by field. If this is a referenced record, then the value of the record’s name field. If multiple groups are specified in the <code>groupBy</code> transform, labels are comma separated.</td>
<td></td>
</tr>
<tr>
<td>◦ %G: Value of the group by field. If this is a referenced record, then the record's sys_id. If multiple groups are selected, values are comma separated.</td>
<td></td>
</tr>
<tr>
<td>For example:</td>
<td></td>
</tr>
<tr>
<td>&quot;transforms&quot;: [</td>
<td></td>
</tr>
<tr>
<td>{</td>
<td></td>
</tr>
<tr>
<td>&quot;name&quot;: &quot;label&quot;,</td>

| } | |
| , | |
| { | |
| "name": "label", | |
| "arg": "Model: %g" | |
| } | |
| ] | |

**limit**

Returns, at most, the specified duration or number of values, starting with the most recently saved value.

**Arguments:**
<table>
<thead>
<tr>
<th>Transform</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• arg (Integer): Number of timestamp values to return for each time series. OR • arg (Duration): Duration to limit each time series to.</td>
</tr>
<tr>
<td>log</td>
<td>Runs a logarithm on the value in each timestamp where the result is the log of the specified base for the timestamp value. Arguments:</td>
</tr>
<tr>
<td></td>
<td>• arg (Decimal): Base for the logarithm calculation.</td>
</tr>
<tr>
<td>mapValues</td>
<td>Replaces any values within the specified range (inclusive) with the specified value. If both lowerBound and upperBound are specified as NaN, then it replaces any NaN value with the targetValue.</td>
</tr>
<tr>
<td></td>
<td>Arguments:</td>
</tr>
<tr>
<td></td>
<td>• lowerBound (Decimal): The lowest value in the range.</td>
</tr>
<tr>
<td></td>
<td>• upperBound (Decimal): The highest value in the range.</td>
</tr>
<tr>
<td></td>
<td>• targetValue (Decimal): Replacement value.</td>
</tr>
<tr>
<td></td>
<td>For example, the following changes all values in the time series that are between .1 and .9 to 1:</td>
</tr>
<tr>
<td></td>
<td>&quot;transforms&quot;: [</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&quot;name&quot;: &quot;mapValues&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;lowerBound&quot;: .1,</td>
</tr>
<tr>
<td></td>
<td>&quot;upperBound&quot;: .9,</td>
</tr>
<tr>
<td></td>
<td>&quot;targetValue&quot;: 1</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>]</td>
</tr>
<tr>
<td>max</td>
<td>Returns a series that contains the maximum value for each corresponding timestamp across the input.</td>
</tr>
<tr>
<td>median</td>
<td>Creates a series that contains the median of values for each timestamp across a set of series. If there are n series:</td>
</tr>
<tr>
<td>Transform</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>Transform</strong></td>
<td><strong>Description</strong></td>
</tr>
</tbody>
</table>
| • If \( n \) is odd, the median is the \( \frac{n}{2} + 1 \) value for a timestamp.  
  • If \( n \) is even, the median is the average of the \( \frac{n}{2} \) and \( \frac{n}{2} + 1 \) values for a timestamp. |
| **min** | Returns a series that contains the minimum value for each corresponding timestamp across the input. |
| **mul** | Multiplies the value in each timestamp by the specified number.  
Arguments:  
• arg (Decimal): Number by which to multiply the value of each timestamp. |
| **partition** | Produces a new series with values filtered by applying a specified aggregator to a non-overlapping window.  
Arguments:  
• aggregator (Aggregator): Type of aggregation to perform.  
• window (Duration): The duration of the non-overlapping window to apply the aggregator.  
• base (DateTime): The zero offset to use for partitioning.  
  For example, to partition by day (24h), set this value to Monday at midnight in your time zone. To partition by a 30-day period, set this value to the first day of the most recent month.  
  Default: Beginning of the EPOCH. |
| **pow** | Raises each timestamp value to the specified power.  
Arguments:  
• arg: (Decimal): Power to which to raise each value. |
| **product** | Aggregates the selected metric series into a single series that contains the product of all values for each timestamp. NaNs are excluded. If all numbers in the series are NaN, the output is also NaN. |
| **resample** | Resamples a time series to either a fixed number of points or from one frequency to another.  
Use the resample transformation to reduce the number of samples in the result set to more closely match the number of samples that you want to display. |
<table>
<thead>
<tr>
<th>Transform</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transform</td>
<td>You can pass various arguments for this transform. Below is a list of each of the possible argument groups. Only one of these argument groups can be passed within a single transform. The following argument groups are delineated by AND/OR. AND meaning the argument is part of the current group; OR meaning it is the start of a new argument group.</td>
</tr>
<tr>
<td></td>
<td>• arg (Integer): Number of samples to include in the result set. If available samples are less than this number, the endpoint uses interpolation to create additional samples. If there are more samples than this number, they are reduced by averaging them. OR</td>
</tr>
<tr>
<td></td>
<td>• arg (Duration): The frequency at which to resample. If available samples are less than this number, the endpoint uses interpolation to create additional samples. If there are more samples than this number, they are reduced by averaging them. OR</td>
</tr>
<tr>
<td></td>
<td>• minValues (Integer): The minimum number of samples to include in the result set. If available samples are less than this number, the endpoint uses interpolation to create additional samples. AND</td>
</tr>
<tr>
<td></td>
<td>• maxValues (Integer): The maximum number of samples to include in the result set. If there are more samples than this number, they are reduced by averaging them. OR</td>
</tr>
<tr>
<td></td>
<td>• aggregator (Aggregator): The aggregator to use when resampling. AND</td>
</tr>
<tr>
<td></td>
<td>• values (Integer): The number of samples to include in the result set. If available samples are less than this number, the endpoint uses interpolation to create additional samples. If there are more samples than this number, they are reduced by applying the specified aggregator to them. OR</td>
</tr>
<tr>
<td>Transform</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>• aggregator (<em>Aggregator</em>): The aggregator to use when resampling. AND • period (<em>Duration</em>): The frequency at which to resample. If available samples are less than this number, the endpoint uses interpolation to create additional samples. If there are more samples than this number, they are reduced by applying the specified <em>aggregator</em> to them. OR • aggregator (<em>Aggregator</em>): The aggregator to use when resampling. AND • minValues (Integer): The minimum number of samples to include in the result set. If available samples are less than this number, the endpoint uses interpolation to create additional samples. AND • maxValues (Integer): The maximum number of samples to include in the result set. If there are more samples than this number, they are reduced by averaging them.</td>
<td></td>
</tr>
</tbody>
</table>

**round**

Rounds the value in each timestamp up to the specified precision: `(value / <arg>) * <arg>`

Arguments:

• arg (*Decimal*): The decimal precision to round up to.

**root**

Calculates the root of each timestamp value using the specified index.

Arguments:

• arg (*Decimal*): The index of the root.

For example, the following returns the square root of each timestamp:

```json
"transforms": [
  {
    "name": "root",
    "arg": "2"
  }
]"transforms": [  
  {
    "name": "root",
    "arg": "2"
  }

<tbody>
<tr>
<td>stddev</td>
<td>Creates a series that contains the standard deviation of values for each timestamp across a set of series.</td>
</tr>
</tbody>
</table>
| sub       | Subtracts the specified number from the value in each timestamp. Arguments:  
|           | • arg (Number): The number to subtract from the value in each timestamp. |
| sum       | Aggregates the selected metric series into one series that contains the sum of all values for each timestamp, excluding any NaNs. If all numbers in the series are NaN, the output is NaN. |
| timeshift | Shifts the time range by adding the specified offset to a value’s timestamp without modifying the value. Use this transform to shift timestamps to another timezone. Arguments:  
|           | • arg: (Duration): The amount of time to shift by. |
| top       | Returns the specified number of series that have the highest values. Arguments:  
|           | • arg (Integer): The number of series to return.  
|           | For example, the following returns the two time series that contain the highest sets of values.  
|           | "transforms": [

#### DateTime

Absolute date/time values are specified by the ISO 8601 date and time format: `YYYY-MM-DDThh:mm:ss`. For example: `2020-02-28T13:10:42`.

Where:

- `[YYYY]`: Four-digit year.
- `[MM]`: Zero-padded month between 01 and 12.
- `[DD]`: Zero-padded day between 01 and 31.
- `T`: Represents time and is mandatory before any of the time components are specified.
- `[hh]`: Zero-padded hour between 00 and 23.
- `[mm]`: Zero-padded minutes between 00 and 59.
- `[ss]`: Zero-padded seconds between 00 and 59. Note that leap seconds are spread out evenly across the previous 1,000 seconds.

Relative date/time values are specified using a `duration`, which is subtracted from the current time.
### Transform data types (continued)

<table>
<thead>
<tr>

| **Decimal** | Decimal value that can either be:  
- A signed decimal number of arbitrary precision that can use exponential notation.  
  Such as:  
  - 2  
  - 1.7  
  - -3.47  
  - 1.0E+2  
- A string representation of:  
  - A signed decimal number that may use exponential notation and is guaranteed to be a double-precision 64-bit IEEE 754 floating-point number.  
  - "NaN"  
  - "-Infinity"  
  - "+Infinity" |
  Where:  
  - P: Duration designator, referred to as "period", and is always placed at the beginning of the duration.  
  - [n]Y: Number of years.  
  - [n]M: Number of months.  
  - [n]D: Number of days.  
  - T: Time designator and is mandatory before any of the time components are specified.  
  - [n]H: Number of hours.  
  - [n]M: Number of minutes.  
  - [n]S: Number of seconds. |

</thead>
<tbody>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Only supports application/json.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>Message that indicates the status of the request, such as ok if the request processed successfully.</td>
</tr>
</tbody>
</table>

Example: cURL request

```
curl "https://instance.servicenow.com/api/now/v1/clotho/put" \
  --request POST \
  --header "Accept:application/json" \
  --header "Content-Type:application/json" \
  --data "{
```
Example: Python request

```python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/now/v1/clotho/put'
```

    }
}

Predictive Intelligence API

Use the Predictive Intelligence API to predict a field value based on one or more input fields and a trained solution.

This API can only be used when the Predictive Intelligence (com.glide.platform_ml) plugin is activated.

Predictive Intelligence - GET /agent_intelligence/solution/{solution_name}/prediction

Predicts an output field value using a specific solution.

URL format

Default URL: /api/now/agent_intelligence/solution/{solution_name}/prediction

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>solution_name</td>
<td>Name of solution to use for predictions. For example, ml_incident_categorization.</td>
</tr>
</tbody>
</table>
Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Solution definition input field key-value pair</td>
<td>Name-value pair of the solution input field. For example, enter the name: short_description and the value: Unable to connect to VPN. Data type: String</td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.
### Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>input</td>
<td>Name-value pairs that were specified as input to the call. Data type: Object</td>
</tr>
<tr>
<td>output</td>
<td>Predicted outcome values based on the specified solution. Data type: Object</td>
</tr>
<tr>
<td>output.confidence</td>
<td>Estimated precision of the prediction as a percentage. For example, <strong>53.84615375762915</strong>. Data type: Number</td>
</tr>
<tr>
<td>output.outcome</td>
<td>Prediction output field value. For example, an incident categorization solution would return an incident category such as <strong>inquiry</strong>. Data type: String</td>
</tr>
<tr>
<td>output.threshold</td>
<td>Value of the configured threshold associated with the prediction. Data type: Number</td>
</tr>
</tbody>
</table>
Example: Sample cURL request

```bash
curl "https://instance.service-now.com/api/now/predictive_intelligence/solution/ml_incident_category/prediction?short_description=unable%20to%20connect%20to%20VPN" \
--request GET \
--header "Accept:application/json" \
--user "username":"password"
{
  "result": {
    "input": {
      "short_description": "unable to connect to VPN",
      "api": "api"
    },
    "output": {
      "outcome": "inquiry",
      "confidence": 53.84615375762915,
      "threshold": 5
    }
  }
}
```

Example: Sample Python request

```python
# Need to install requests package for python
import requests

# Set the request parameters
url = 'https://instance.service-now.com/api/now/agent_intelligence/solution/ml_incident_category/prediction?short_description=unable%20to%20connect%20to%20VPN'

# Eg. User name= "username", Password= "password" for this code sample.
user = 'username'
pwd = 'password'

# Set proper headers
headers = {'Accept': 'application/json'}

# Do the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers )

# Check for HTTP codes other than 200
if response.status_code != 200:
```
print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:',response.json())
exit()

# Decode the JSON response into a dictionary and use the data
data = response.json()
print(data)

{
    "result": {
        "input": {
            "short_description": "unable to connect to VPN",
            "api": "api"
        },
        "output": {
            "outcome": "inquiry",
            "confidence": 53.84615375762915,
            "threshold": 5
        }
    }
}

Predictive Intelligence - GET /agent_intelligence/solution/prediction

Returns predictions for multiple solutions.

⚠️ Note: Outcome result objects are grouped by solution name and sys_id in the format result.<solutionname>.<sys_id>.[{ <result1> },{ <result2> }].

For customization information, see MLSolutionFactory scriptable objects.

URL format

Versioned URL: /now/{api_version}/agent_intelligence/solution/prediction

Default URL: /now/agent_intelligence/solution/prediction

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
</tbody>
</table>
Path parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>input_filter</td>
<td>Required parameter if <code>input_table</code> is used, do not use this parameter with <code>input_maps</code> parameter. Filter to select records on which to run predictions. For example: sys_id 0ef47232db801300864adfea5e961912</td>
</tr>
</tbody>
</table>
| input_maps  | Required unless using `input_table` parameter. Array of input name-value pairs. For example: `[["short_description": "my email is not working"], ["short_description": "need help with password"]]

Data type: Array |
| input_table  | Required unless using `input_maps` parameter. Table name on which you want to run predictions. For example: `incident` |
| options      | JSON object with optional arguments. For example: `{"top_n" : 5, "apply_threshold":false}` |

Valid options:
- `top_n`: Number. If provided, returns the top results, up to the specified number of predictions.
- `apply_threshold`: Boolean. Checks the threshold value for the solution and applies it to the result set. The threshold value is solution threshold for similarity or class-level threshold for classification. Default value is true.
- `custom_results_filter`: String. Similarity solutions only. Specifies the allowed set from which results are returned using an encoded query.
Query parameters (continued)

<table>

```
Product Order Open API

The Product Order Open API provides a standardized mechanism for placing a product order with all of the necessary order parameters. This API is a ServiceNow® implementation of TM Forum TMF622 Product Ordering Management API REST Specification.

A product order is created based on a product offering that is defined and published in a product catalog. The product offering identifies the product or set of products that are available to a customer and includes the relevant product characteristics that capture the unique options of a product, and other relevant attributes such as pricing, contract terms, and availability.

To access this API, the Order Management for Telecommunications (sn_ind_tmt_orm) plugin must be activated.

This API is provided within the sn_ind_tmt_orm namespace.

The calling user must have the sn_ind_tmt_orm.order_integrator role.
Extending the Product Order Open API

The Product Order Open API can be extended using the following script includes. The API should only be extended with an understanding of the consequences of the changes.

- **TMFOrderAPIConstants**: Contains constants and required parameter information.
- **TMFProductOrderAPIUtil**: Contains functions to handle POST requests.
- **TMFProductOrderGetAPIUtil**: Contains functions to handle GET requests.
- **ProductOrderExtensionOOB**: Contains helper functions that support functions in TMFProductOrderAPIUtil and TMFProductOrderGetAPIUtil.
- **ProductOrderProcessor**: An empty script include file. Use this file to define any functions that you want to override from ProductOrderExtensionOOB.

Extend the Product Order Open API to make the following customizations.

**Required parameters**

To change which request body parameters are required or not required, update the TMFOrderAPIConstants script include.

- **TMFOrderAPIConstants.SCHEMA.CREATE_PRODUCT_ORDER**: Sets the required request body parameters to create a product order.

**Request body validation**

To perform additional validation on the request body, override ProductOrderExtensionOOB functions. ProductOrderExtensionOOB contains the following four helper functions that return `true` by default.

- **validatePostRequest()** - Called by processCreateOrder() in TMFProductOrderAPIUtil.
- **validateProductObj()** - Called by processCreateOrder() in TMFProductOrderAPIUtil.
- **validateRelatedPartyObj()** - Called by processCreateOrder() in TMFProductOrderAPIUtil.
- **validateGetRequest()** - Called by processGetOrder() in TMFProductOrderGetAPIUtil.

If a helper function returns `false`, it stops the API operation. To apply custom validation, override ProductOrderExtensionOOB helper functions by creating functions with identical names and parameters in ProductOrderProcessor. These new ProductOrderProcessor functions will be called by
TMFProductOrderAPIUtil and TMFProductOrderGetAPIUtil to replace the default ProductOrderExtensionOOB helper functions. In this example, a function in ProductOrderProcessor overrides a default function in ProductOrderExtensionOOB to perform validation on the productOrderItem attribute.

```javascript
// ProductOrderProcessor
var ProductOrderProcessor = Class.create();
ProductOrderProcessor.prototype =
    Object.extendsObject(ProductOrderExtensionOOB, {
        // Define overriding functions here
        // Function name and parameters must be identical to the function it overrides
        validatePostRequest: function(orderObject, details) {
            // Returning false terminates the POST request
            // Make sure to push error message in details array in case of error
            if (gs.nil(orderObject.productOrderItem)) {
                details.push(new TMFCommonOrderAPIUtil().getErrorDetailsObj(TMFOrderAPIConstants.MESSAGES.MISSING_ORDER_ITEM, '/'));
                return false;
            }
            return true;
        },
        type: 'ProductOrderProcessor'
    });
```

**Additional REST operations**

To create additional operations beyond the existing GET and POST operations, create additional scripted REST resources for the Product Order Open API. The logic of the new scripted REST resources should be consistent with the existing operations. Define functions for the new operations in a new script include.

**Field mapping**

When creating records, the API maps request body parameters to record fields. When retrieving records, the API maps record fields to response object attributes. ProductOrderExtensionOOB contains the following functions to map a POST request body to a GlideRecord.

- `transformOrderGr()`
- `transformOrdLineItemGr()`
ProductOrderExtensionOOB contains the following functions to map a GlideRecord to a response object for GET or POST requests.

- transformPostOrderResponse()
- transformGetOrderResponse()
- transformProductObj()
- transformRelatedPartyCustomerLineItem()
- transformOrderItemRelationship()
- transformGetOrdLineItmResponse()
- transformProductCharacteristics()
- transformProductSpecification()

Customize field mappings to add and retrieve data for additional fields, or to change the default mappings for fields. To customize the field mappings, override ProductOrderExtensionOOB mapping functions by creating functions with identical names and parameters in ProductOrderProcessor. These new ProductOrderProcessor functions will be used by TMFProductOrderAPIUtil and TMFProductOrderGetAPIUtil to replace the default ProductOrderExtensionOOB mapping functions. In this example, two functions in ProductOrderProcessor override the default functions in ProductOrderExtensionOOB to create mappings for the external_id and sys_id fields.

```javascript
// ProductOrderProcessor
var ProductOrderProcessor = Class.create();
ProductOrderProcessor.prototype =
  Object.extendsObject(ProductOrderExtensionOOB, {
    // Define overriding functions here
    // Function name and parameters must be identical to the function it overrides

    transformOrderGr: function(requestObject, orderGr) {
      orderGr.external_id = requestObject.externalId;
      return orderGr;
    }
  });
```
Product Order Open API - GET /productorder/{id}

Retrieves the specified customer order.

It retrieves the order information from the following related tables:

- Customer Order [sn_ind_tmt_orm_order]
- Order Line Item [sn_ind_tmt_orm_order_line_item]
- Order Characteristic [sn_ind_tmt_orm_order_characteristic_value]
- Order Line Item Contact [sn_ind_tmt_orm_order_line_item_contact]

URL format

Default URL: /api/sn_ind_tmt_orm/productorder/{id}

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>Sys_id of the customer order to retrieve. Located in the Customer Order [sn_ind_tmt_orm_order] table. Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| fields| Comma-separated list of fields to return in the response. If this value is not passed in, all fields are returned. Possible values:  
  • channel  
  • expectedCompletionDate |
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td></td>
</tr>
<tr>
<td>note</td>
<td></td>
</tr>
<tr>
<td>productOrderItem</td>
<td></td>
</tr>

Data type: String

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Headers**

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

**Request headers**

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

**Response headers**

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>201</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. Can be for any of the following reasons:</td>
</tr>
<tr>
<td></td>
<td>• Missing query parameter</td>
</tr>
<tr>
<td></td>
<td>• Invalid URI</td>
</tr>
<tr>
<td>404</td>
<td>Not found. The requested item was not found.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>channel</td>
<td>Array of objects that describe the channels to use for selling the products.</td>
</tr>
<tr>
<td>channel.id</td>
<td>Unique identifier of the channel to use to sell the associated products. ID values are located in the external_id field of the DistributionChannel table.</td>
</tr>
<tr>
<td>channel.name</td>
<td>Name of the channel to use to sell the associated products.</td>
</tr>
<tr>
<td>expectedCompletionDate</td>
<td>Date on which the order will be completed.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>note</td>
<td>Array of objects that describe notes made by the customer when ordering.</td>

<tr>
<td>data type: Array</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>note.author</td>
<td>User name of the person that authored the associated note.</td>
</tr>
<tr>
<td>data type: String</td>
<td></td>
</tr>
<tr>
<td>note.date</td>
<td>Date that the note was created.</td>
</tr>
<tr>
<td>data type: String</td>
<td></td>
</tr>
<tr>
<td>note.text</td>
<td>Additional notes/comments made by the customer while ordering.</td>
</tr>
<tr>
<td>data type: String</td>
<td></td>
</tr>
<tr>
<td>ponr</td>
<td>Flag that indicates whether the point of no return for the order has been reached.</td>
</tr>
<tr>
<td>data type: Boolean</td>
<td></td>
</tr>
<tr>
<td>productOrderItem</td>
<td>Array of objects that describe items associated with the product and their associate action.</td>
</tr>
<tr>
<td>data type: Array</td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>productOrderItem.action</td>
<td>Action to carry out on the product. Possible actions are defined on the Choice List tab in the Action Dictionary Entry of the sn_ind_tmt_orm_order_line_item table. Data type: String</td>
</tr>
<tr>
<td>productOrderItem.id</td>
<td>Unique identifier of the line item. Data type: String</td>
</tr>
<tr>
<td>productOrderItem.itemPrice</td>
<td>Array of objects that describe the price associated with the product. Data type: Array</td>
</tr>
<tr>
<td>productOrderItem.itemPrice.price</td>
<td>Description of the price of the associated product. Data type: Object</td>
</tr>
<tr>
<td>productOrderItem.itemPrice.price.taxIncludedAmount</td>
<td>Description of the price of the associated product, including the tax. Data type: Object</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>productOrderItem.itemPrice.price.taxIncludedAmount.unit</td>

Product Order Open API - POST /productorder

Creates the specified customer order and customer order line items.

Once processed, new records are created in the following tables:

- Customer Order [sn_ind_tmt_orm_order]
- Order Line Item [sn_ind_tmt_orm_order_line_item]
- Order Characteristic [sn_ind_tmt_orm_order_characteristic_value]
- Order Line Item Contact [sn_ind_tmt_orm_order_line_item_contact]

URL format

Default URL: /api/sn_ind_tmt_orm/productorder

Supported request parameters

| 201         | Successful. If there are any issues with the characteristics or characteristics option information, the endpoint stores the following comments in the work notes fields of the associated Customer Order Line Item record:  
  • The following Order Item characteristics does not exist: Review specification `<characteristic.name>` and correct the characteristic and characteristic option in the order line item prior to approving the order.  
  • Order Item characteristic: `<characteristic.name>` with characteristic value: `<characteristic.value>` is invalid. Correct the characteristic values before approving the order. |
| 400         | Bad Request. Could be any of the following reasons:  
  • Invalid payload: Request body missing - Payload was not passed in the request body.  
  • Invalid payload: productOrderItem is missing - Product order line item object or JSON is missing.  
  • Invalid payload: productOrderItem id is missing - The `id` parameter is missing in the product order line item of the payload.  
  • Invalid payload: productOrderItem action is missing - The `action` parameter is missing in the product order line item of the payload.  
  • Invalid payload: productOrderItem productOffering is missing - The product offering object or JSON is missing from the product order line item in the payload.  
  • Invalid payload: productOffering id is missing - The `id` parameter is missing in the product order line item of the product offering object in the payload.  
  • Invalid payload: Product offering does not exist - The product offering in the product order line item is not valid. |

Push Installation API

The Push Installation API enables you to register and unregister the tokens that enable mobile devices to receive push notifications from an application.

A push notification is a text message that appears on a user’s mobile device to alert them about something important or to ask them to perform an action.

When creating custom mobile applications, in order to set up Push notifications, you must register the device with the manufacturer’s service. The service must know the address of a user’s device so it can properly send notifications to that device using push tokens. The device also needs to be able to receive the notifications and act on them. For instructions on how to register a device and get a push token, refer to the device’s operating systems developer documentation. For example, for Apple devices, refer to https://developer.apple.com/documentation/usernotifications/registering_your_app_with_apns.
Push Installation - POST /now/push/{pushApplicationName}/installation

Adds or updates tokens that enable devices to receive push notifications from the specified application.

**URL format**

Versioned URL: /api/now/{api_version}/push/{pushApplicationName}/installation

Default URL: /api/now/push/{pushApplicationName}/installation

**Supported request parameters**

<table>
<thead>
<tr>
<th>Path parameters</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>pushApplicationName</td>
<td>Name of the application for which to register the push notifications. This parameter must be the same as the value in the Name column for the associated application in the Push Application [sys_push_application] table. Data type: String</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Query parameters</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Request body parameters (XML or JSON)</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Element</td>
<td>Description</td>
</tr>
<tr>
<td>platform</td>
<td>Platform on which to register the push notification. This parameter must be the Name value from the Push Platform [sys_push_platform] table. Data type: String</td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>token</td>
<td>Token supplied by the device manufacturer, such as Apple, when the mobile application registers to receive push notifications. The endpoint writes the token value to the Push Notification Installation [sys_pushnotif_app_install] table. Data type: String</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Only supports <code>application/json</code>.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
</tbody>
</table>
### Status codes (continued)

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>500</td>
<td>Internal Server Error. A logic error on the server-side code occurred.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Example: Sample cURL request

```bash
curl -X POST \
    https://instance.servicenow.com/api/now/push/ServiceNowPushApp/installation \
    --header "Content-Type: application/json" \
    --user "username":"password" \
    --data 
    '{"platform":"Apple","token":"544836d77ac2e551bbf78204630509a7d494fc87f52e85da52e5b5d42910e2cf"}' \
```

None

### Example: Sample Python request

```python
#Need to install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/now/push/ServiceNowPushApp/installation'

# Eg. User name="username", Password="password" for this code sample.
user = 'username'
pwd = 'password'

# Set proper headers
headers = {"Content-Type":"application/json"}

# Do the HTTP request
response = requests.post(url, auth=(user, pwd), headers=headers, 
data="{"platform":"Apple","token":"544836d77ac2e551bbf78204630509a7d494fc87f52e85da52e5b5d42910e2cf"}")
```
Push Installation - POST /now/push/{pushApplicationName}/removeInstallation
Deactivates the tokens that enable mobile devices to receive push notifications from the specified application.

**URL format**

Versioned URL: /api/now/{api_version}/push/{pushApplicationName}/removeInstallation
Default URL: /api/now/push/{pushApplicationName}/removeInstallation

**Supported request parameters**

**Path parameters**

<td>None</td>
</tr>
</tbody>
</table>

Example: Sample cURL request

```
curl -X POST \  
   https://instance.servicenow.com/api/now/push/ServiceNowPushApp/removeInstallation \  
   --header "Content-Type: application/json" \  
   --user "username":"password" \  
   --data '{"platform":"Apple"}' \
```

Example: Sample Python request

```
# Need to install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/now/push/ServiceNowPushApp/removeInstallation'

# Eg. User name="username", Password="password" for this code sample.
user = 'username'
pwd = 'password'

# Set proper headers
headers = {'Content-Type':'application/json'}

# Do the HTTP request
```
Push Metrics API

The Push Metrics API provides endpoints that enable integrators to push raw Operational Intelligence data from an external source to the MID Server.

This API is based on client-side tools that push the raw data from the external source to the MID Server. The Operational Intelligence Metrics extension is required to be configured with the Enable REST Listener option enabled. For more information on setting up the MID Server, see Get started with Operational Intelligence.

For information on authentication requirements, see Configure the MID Web Server extension.

Push Metrics - POST /mid/sa/metrics

Pushes raw Operational Intelligence data from an external source to the MID Server.

URL format

Default URL: /api/mid/sa/metrics

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ci2metric_id</td>
<td>List of key-value pairs to use to identify the configuration item (CI). It is formerly known as <code>ci_identifier</code>. The script continues to accept <code>ci_identifier</code>. Data type: Object</td>
</tr>
<tr>
<td>metric_type</td>
<td>Name of the metric. Data type: String</td>
</tr>
<tr>
<td>node</td>
<td>IP address, FQDN, name of the CI, or host. In the example below, the name of the Linux server where the disks are installed. Data type: String</td>
</tr>
<tr>
<td>resource</td>
<td>Information about the resource for which metric data is being collected. In the example below, <code>C:\</code> is the resource for which metric data is collected. Data type: String</td>
</tr>
<tr>
<td>source</td>
<td>Data source monitoring the metric type. Data type: String</td>
</tr>
<tr>
<td>timestamp</td>
<td>Epoch time stamp of the metric. Data type: Number, Unit: Milliseconds</td>
</tr>
<tr>
<td>value</td>
<td>Value of the metric. Data type: Number</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Example: Sample cURL request

```bash
curl -X POST "https://servicenow-instance/api/mid/sa/metrics"
-H "Content-Type: application/json"
-U "username":"password"
-d "{
   "metric_type": "Disk C: % Free Space",
}"
```
Remote help request API

The Remote help request API enables creating, viewing, and fetching lists of IT service requests and their details from an electronic medical record (EMR) system. An IT service request is associated with a task type such as an incident in the ServiceNow instance.

You can only use this API when the EMR Help application (sn_ind_rmt_help) is installed from the ServiceNow Store. Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store. For cumulative release notes information for all released apps, see the ServiceNow Store version history release notes.

Role required to access the endpoints of this API: sn_ind_rmt_help.requester.

Remote help request - POST /remote_help_request/{req_defn_id}

Inserts electronic medical record (EMR) system data into the corresponding ServiceNow tables.

You need to specify a request definition ID in addition to the parameters for the task and additional data from the EMR system persisted in the request data table associated with the task. You pass two types of data into this endpoint. The first is the request data, which the endpoint inserts into the Remote Request Data [sn_ind_rmt_help_request_data] table and its associated child tables. The second is the task parameters of the IT service request, which the endpoint inserts into the Remote Request Parameter [sn_ind_rmt_help_request_param] table. Only data or fields that are defined in the request definitions are processed by the endpoint. For additional information on this data model, see EMR Help data model.

Records are identified using the request definition ID.

URL format

Versioned URL: /api/sn_ind_rmt_help/{api_version}/remote_help_request/{req_defn_id}
Default URL: /api/sn_ind_rmt_help/remote_help_request/{req_defn_id}

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>req_defn_id</td>
<td>Unique ID of the request definition. This value corresponds to the ID column in the Remote Request Definition [sn_ind_rmt_help_request_defn] table. Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

**Example: cURL request**

Insert data from a Cerner EMR system.

```bash
curl
  "https://instance.servicenow.com/api/sn_ind_rmt_help/v1/remote_help_request/sn_it_request"
--request POST \
--header "Accept: application/json" \
--header "Content-Type: application/json" \
--data "{
  "source":"Cerner",
  "task_parameters":{
    "short_description":"Unable to load patient data",
    "caller_id":"82d4ecb4db40e8100e28aa594b96195c",
    "impact":"2",
    "contact_type":"email"
  },
  "request_data":{
    "application":"Powerchart",
    "server":"CTXCHSITN453",
    "environment":"CTX24",
    "issue_type":"Helpdesk",
    "millennium_username":"JOHN JASON",
    "position":"Lab Tech",
    "session_recording_id":"s5ds34dd96491b959a35010651896k",
    "user_is_physician":"Yes",
    "work_station":"PC354FLR3STATION7",
    "additional_info":"MRN 222333"
  }
}
"--user "username":"password"
```

The following output shows both a successful response and an error response.

```json
// Successful response
{
  "result": {
    "task_id": "75b09061db2cac100e28aa594b9619fa",
    "error": null
  }
}
```
Remote help request - PUT /remote_help_request/{req_defn_id}/task/{task_id}

Updates a record in the specified remote request data table for the task.

Enables you to specify a request definition ID in addition to the task sys_id to update a remote request that was created earlier.

**URL format**

**Versioned URL:** /api/sn_ind_rmt_help/{api_version}/remote_help_request/{req_defn_id}/task/{task_id}

**Default URL:** /api/sn_ind_rmt_help/remote_help_request/{req_defn_id}/task/{task_id}

<tr>
<td>request_data</td>
<td>Required. Name-value pairs of the request data from the EMR system to update the Remote Request Data [sn_ind_rmt_help_request_data] table or its child table. For example:</td>
</tr>
<tr>
<td></td>
<td>&quot;request_data&quot;: {</td>
</tr>
<tr>
<td></td>
<td>&quot;additional_info&quot; : &quot;Please contact my office for more information.&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>source</td>
<td>Required. Name of the EMR system invoking the endpoint as specified in a request definition. For example:</td>
</tr>
<tr>
<td></td>
<td>&quot;source&quot;: &quot;Cerner&quot;</td>
</tr>
</tbody>
</table>

Data type: Object

- **Note:** Only pass parameters configured in a request definition in the request_data object. Any other parameters are ignored. To learn more, see Configure request definitions for EMR systems.
Request body parameters (JSON) (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| task_parameters  | Required. Name-value pairs that describe the task parameters of the IT service request. Each element in the object corresponds to a column in the corresponding task tables such as the Incident [incident] table. For example:  
```json
"task_parameters": {
  "impact":"1",
  "contact_type":"phone"
}
```

**Note:** Only pass parameters configured in a request definition in the task_parameters object. Any other parameters are ignored. To learn more, see Configure request definitions for EMR systems.

Data type: Object

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>

<td></td>
</tr>
<tr>
<td>result.warningTranslated</td>
<td>Optional localized warning message.</td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
</tbody>
</table>

**Example: cURL request**

Update an IT service request created earlier in a Cerner EMR system

```bash
curl
  "https://instance.servicenow.com/api/sn_ind_rmt_help/v1/remote_help_request/sn_it_request/task/207e57c1db60a410f50fd5b4b96192e"
  --request PUT \n  --header "Accept: application/json" \n  --header "Content-Type: application/json" \n  --data "{
    "source":"Cerner",
    "task_parameters":{
      "impact":"1",
      "contact_type":"phone"
    },
    "request_data":{
      "additional_info" : "Please contact my office for more information."
    }
  }
  --user "username":"password"
```

The following output shows both a successful response and an error response.

```json
// Successful response
{
```
Remote help request - GET /remote_help_request/{req_defn_id}
Fetches a list of tasks that match the specified ID and query filter.

⚠️ Note:
- Reference and choice type fields are always returned as JSON objects with the value and display_value.
- DateTime fields are returned as strings and always in UTC.

URL format

Versioned URL: /api/sn_ind_rmt_help/{api_version}/remote_help_request/{req_defn_id}
Default URL: /api/sn_ind_rmt_help/remote_help_request/{req_defn_id}

Supported request parameters

<table>
<thead>
<tr>
<th>Path parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>
Path parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>req_defn_id</td>
<td>Unique ID of the request definition to update. This value corresponds to the ID column in the Remote Request Definition [sn_ind_rmt_help_request_defn] table. Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>Required. Encoded query used to filter the result set. Data type: String</td>
</tr>
</tbody>
</table>

Request body parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports application/json.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.
### Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>Return results.</td>
</tr>
<tr>
<td></td>
<td>&quot;result&quot;: {</td>
</tr>
</tbody>
</table>
|                     |   "code": "String",
|                     |   "error": "String",
|                     |   "errorTranslated": "String",
|                     |   "status": "String",
|                     |   "task_list": [Array],
|                     |   "warning": "String",
|                     |   "warningTranslated": "String" |
|                     | } |

Data type: Object

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result.code</td>
<td>Application error code when the result.status is returned as failure.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>result.error</td>
<td>Error message that is included if the result.status is failure.</td>
</tr>
<tr>
<td></td>
<td>This message is in English only.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>result.errorTranslated</td>
<td>Optional localized error message.</td>
</tr>
<tr>
<td>result.status</td>
<td>Status of the response.</td>
</tr>
</tbody>
</table>
|               | Possible values:
<table>

</tr>
<tr>
<td>result.warningTranslated</td>
<td>Optional localized warning message.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

**Example: cURL request**

Fetch data from a Cerner EMR system

curl
  "https://instance.servicenow.com/api/remote_help_request/v1/sn_it_request/?query=active=true" \
  --header "Accept: application/json" \
  --header "Content-Type: application/json"
  
  { 
      "source":"Cerner",
  } \
  --user "username":"password"

The following output shows both a successful response and an error response.

```json
// Successful response
{
    "result": {
        "status": "success",
        "task_list": [
            {
                "number": "INC0010096",
                "short_description": "Unable to load data - 1",
                "assigned_to": {
                    "value": "7a381da2dbfb5410f50fdc5b4b9619f2",
                    "display_value": "Abel Tuter (IT agent)"
                }
            }
        ]
    }
}
```

// Error response
{
  "result": {
    "status": "failure",
    "code": "1019",
  }
}
Remote help request - GET /remote_help_request/{req_defn_id}/task/{task_id}

Fetches a single task as specified in the task_id.

Enables you to specify a request definition ID and task ID and retrieve the task details.

⚠️ Note:

- Reference and choice type fields are always returned as JSON objects with the value and display_value.
- DateTime fields are returned as strings and always in UTC.
- Only additional comments are supported in journal type fields.
- Additional comments are passed back as a JSON array of objects. Each object represents a comment with created_on, created_by, and value fields. The latest comments are sent first.

### URL format

**Versioned URL:** /api/sn_ind_rmt_help/{api_version}/remote_help_request/{req_defn_id}/task/{task_id}

**Default URL:** /api/sn_ind_rmt_help/remote_help_request/{req_defn_id}/task/{task_id}

### Supported request parameters

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).
### Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>Return results.</td>
</tr>
<tr>
<td>result.code</td>
<td>Application error code when the result.status is returned as failure.</td>
</tr>
<tr>
<td>result.error</td>
<td>Error message that is included if the result.status is failure. This message is in English only.</td>
</tr>
<tr>
<td>result.errorTranslated</td>
<td>Optional localized error message.</td>
</tr>
<tr>
<td>result.status</td>
<td>Status of the response. Possible values:</td>
</tr>
</tbody>
</table>

Data type: Object

```
"result": {
    "code": "String",
    "error": "String",
    "errorTranslated": "String",
    "status": "String",
    "task_parameters": (Object),
    "warning": "String",
    "warningTranslated": "String"
}
```
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• failure \n• success \nData type: String</td>
</tr>
<tr>
<td>result.task_parameters</td>
<td>Required. Name-value pairs that describe the task parameters of the IT service request. Each element in the object corresponds to a column in the corresponding task tables such as the Incident [incident] table. \nData type: Object</td>
</tr>
<tr>
<td>result.warning</td>
<td>Optional warning message. May be included if the result.status is success. \nThis message is in English only. \nData type: String</td>
</tr>
<tr>
<td>result.warningTranslated</td>
<td>Optional localized warning message. \nData type: String</td>
</tr>
</tbody>
</table>

**Example: cURL request**

Fetch data from a Cerner EMR system

curl
   "https://instance.servicenow.com/api/sn_ind_rmt_help/v1/remote_help_request/sn_it_request/task/207e57c1db60a410f50f5b4b96192e"\n   --request GET \n   --header "Accept: application/json"\n   --user "username":"password"

The following output shows both a successful response and an error response.

```json
// Successful response
{
  "result": {
    "status": "success",
    "task_parameters": {
      "number": "INC0010096",
      "short_description": "Unable to load data - 1",
      "state": {
        "value": "2",
        "display_value": "In Progress"
      }
    }
  }
}
```
Response Templates API

This API requires the Templated Responses plugin (com.sn_templated_snip), which is activated by default. This API is provided within the sn_templated_snip namespace.

For additional information on response templates, see Response templates.

Response Templates - POST /response_templates/get_templates

URL format

Default URL: /api/sn_templated_snip/response_templates/get_templates
# Supported request parameters

## Path parameters

</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

## Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

## Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>errorFormat</td>
<td>HTML formatting to use for errors. Data type: String Default: &quot;&lt;span style='color:#ff0000'&gt;${%s}&lt;/span&gt;&quot;</td>
</tr>
<tr>
<td>includeEvaluatedBody</td>
<td>Flag that indicates whether to render the template variables. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• false: Do not render the template variables. The response contains the message variables. For example:</td>
</tr>
<tr>
<td></td>
<td>Please note that your case ${number} has been escalated to ${assignment_group}.</td>
</tr>
<tr>
<td></td>
<td>• true: Renders the template variables and returns evaluated_response in the return results. For example:</td>
</tr>
<tr>
<td></td>
<td>Please note that your case INC100001 has been escalated to Facilities.</td>
</tr>
<tr>
<td>limit</td>
<td>Maximum number of response templates to return. Data type: Boolean Default: false</td>
</tr>
</tbody>
</table>
### Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Data type: Number</td>
</tr>
<tr>
<td></td>
<td>Default: 50</td>
</tr>
<tr>
<td>offset</td>
<td>For pagination, the index at which to start the search.</td>
</tr>
<tr>
<td></td>
<td>Data type: Number</td>
</tr>
<tr>
<td></td>
<td>Default: 0</td>
</tr>
<tr>
<td>opts</td>
<td>Parameters to pass to the <code>sn_tempated_snip.response_template</code> extension point. The format and content of these parameters are dependent on the implementation of the extension point. For additional information on extension points, see <a href="#">Using extension points to extend application functionality</a>.</td>
</tr>
<tr>
<td></td>
<td>Data type: Object</td>
</tr>
<tr>
<td>recordId</td>
<td>Required. Sys_id of the record to use to render the variables in the response template.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>searchTerm</td>
<td>Text to use to filter the list of matching response templates. The endpoint performs a CONTAINS search of this text on the name and body fields and a STARTS WITH search on the short name field. For example, if the search term is &quot;crash&quot;, the endpoint returns any response template that matches the query criteria and has crash in the name or body or the short name starts with crash. Response templates with exact matches on short name appear first in the return results. All other returned response templates are sorted by name.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td></td>
<td>Default: Return all matching response templates.</td>
</tr>
<tr>
<td>tableName</td>
<td>Required. Name of the table to use to search the Response Templates table to locate corresponding response templates. For example, &quot;incident&quot; or &quot;sn_hr_core_case&quot;.</td>
</tr>
</tbody>
</table>
Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>

```
SAM-Software Usage Data Integration API

The SAM-Software Usage Data Integration API enables you to create and update records in the Software Usage [samp_sw_usage] table.

This API requires activation of the Software Asset Management Professional (com.snc.samp) plugin. It also requires that you have either the sam_admin or sam_developer role to access the endpoint.

SAM-Software Usage Data Integration - POST /sam_software_usage_integration/createOrUpdate

Creates or updates a specified record in the Software Usage [samp_sw_usage] table.

You can create/update one or more software usage records in a single call.

URL format

Versioned URL: /api/now/{api_version}/sam_software_usage_integration/createOrUpdate

Default URL: /api/now/sam_software_usage_integration/createOrUpdate
# Supported request parameters

## Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>

## Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

## Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| items | List of column names and values for each field to store in the software usage record. The column information that you must pass depends on the value you specify for reclamation_type (which is a required field): Possible reclamation_type values and the column information that must be passed:  
  • total_usage:  
    ◦ configuration_item  
    ◦ last_used_time  
    ◦ month_used  
    ◦ norm_product  
    ◦ year  
  • last_used_date:  
    ◦ configuration_item  
    ◦ norm_product |

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The combination of these fields uniquely identify a record. If the record is not found in the table, a new record with the specified fields is created; otherwise the existing record is updated.</td>
</tr>
<tr>
<td></td>
<td>Data type: Array</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
</tbody>
</table>
Status codes (continued)

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not found. The requested item was not found.</td>
</tr>
<tr>
<td>405</td>
<td>Invalid method. The functionality is disabled.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>items</td>
<td>Name-value pair list of all fields in the software usage record. Data type: Array (content varies)</td>
</tr>
</tbody>
</table>

Example: cURL request

The following example illustrates how to create a new software usage record.

```bash
curl -X POST
    "https://instance.servicenow/api/now/sam_software_usage_integration/createOrUpdate"
    -H "Accept: application/json"
    -H "Content-Type: application/json"
    -d "{"items": [
        {
            'configuration_item': 'eaa9604d3790200044e0bfc8bcbe5dc1',
            'month_used': 2,
            'norm_product': '40209c060b3022002d6c650d37673a89',
            'norm_publisher': '24dccc20b3022002d6c650d37673ab3',
            'reclamation_type': 'total_usage',
            'usage_count': 13,
            'total_usage_time': 13,
            'year': 2020
        }
    ]}
```

{ "result": {} }
The following example illustrates how to update multiple software usage records in a single call.

curl -X POST
  "https://instance.servicenow/api/now/sam_software_usage_integration/createOrUpdate" \
  -H "Accept: application/json" \
  -H "Content-Type: application/json" \

'year': 2020}]}
Scorecards API

The Scorecards REST API enables you to query data about Performance Analytics indicators. The query parameters equate to the functions available on the Analytics Hub for drilling down into an indicator.

This API requires the Performance Analytics (com.snc.pa.analytics_center) application.

Scorecards - GET /now/pa/scorecards

Retrieves details about indicators from the Analytics Hub.

Access to tables through the REST API is restricted by BasicAuth. Access control lists defined for tables are enforced to restrict access to data.

To make queries using the Performance Analytics API, you must also have the pa_viewer role.
Almost all queries use the `sysparm_uuid` parameter. This parameter consists of the indicator `sys_id` followed by a colon-separated list of additional, optional `sys_ids`. The `sysparm_uuid` is always the first parameter.

**URL format**

Versioned URL: `/api/now/{api_version}/pa/scorecards`

Default URL: `/api/now/pa/scorecards`

**Supported request parameters**

<table>
<thead>
<tr>

### Query parameters (continued)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| sysparm_display_value            | Data retrieval operation for reference and choice fields. Based on this value, retrieves the display value and/or the actual value from the database. Data type: String Valid values:  
  - true: Returns the display values for all fields.  
  - false: Returns the actual values from the database.  
  - all: Returns both actual and display values.  
  Default: false |

**Note:** There is no preferred method for setting this parameter. However, specifying the display value may cause performance issues since it is not reading directly from the database and may include referencing other fields and records. For more information on display values and actual values, see [Table API FAQs (KB0534905)](https://www.servicenow.com/kb/KB0534905). |

| sysparm_elements_filter          | Sys_id of an elements filter to apply to the returned data. You cannot obtain the sys_id of an indicator group through this API. Instead, get the sys_id from the indicator group record. For more information about obtaining sys_ids from records, see [Unique record identifier (sys_id)](https://www.servicenow.com/kb/KB0534905). Data type: String |

| sysparm_exclude_reference_link   | Flag that indicates whether to hide additional information provided for reference fields, such as the URI to the reference resource. Valid values: |

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| sysparm_include_score_notes  | Flag that indicates whether to return all notes associated with the score. The note element contains the note text as well as the author and timestamp when the note was added. Valid values:  
  • true: Return all notes associated with the score.  
  • false: Do not return all notes associated with the score.  
  Data type: Boolean  
  Default: false |
| sysparm_include_scores       | Flag that indicates whether to return indicator scores for the entire time range selected on the Analytics Hub. If a value is not specified, this parameter defaults to false and returns only the most recent score value.  
  To constrain the date range of the scores that are returned, combine this parameter with `sysparm_from` and `sysparm_to`.  
  Valid values:  
  • true: Return indicator scores for the entire selected time range.  
  • false: Do not return indicator scores for the entire time range.  
  Data type: Boolean  
  Default: false |
| sysparm_include_target_color_scheme | Flag that indicates whether to return the target_color_scheme element that contains the minimum and maximum values, and the color of each section of the target color scheme for the Analytics Hub. Valid values:  
  • true: Return the realtime_enabled element.  
  • false: Do not return the realtime_enabled element.  
  Data type: Boolean  
  Default: false |
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| sysparm_include_trendline_scores  | Flag that indicates whether to return the `trendline_scores` element that contains an array of date-value pairs that define the Analytics Hub trendline. This parameter requires that the `sysparm_include_scores` parameter is also set to `true`. Valid values:  
  - true: Return the `trendline_scores` element.  
  - false: Do not return the `trendline_scores` element.  
  Data type: Boolean  
  Default: false                                                                                                                                                                                                 |
| sysparm_key                       | Flag that indicates whether to return results only for key indicators. Valid values:  
  - true: Return the `trendline_scores` element.  
  - false: Do not return the `trendline_scores` element.  
  Data type: Boolean  
  Default: false                                                                                                                                                                                                                                                                 |
| sysparm_limit                     | Maximum number of scores to return.  
  Data type: Number                                                                                                                                                                                                                                                                                                                             |
| sysparm_page                      | Page number. For example, when querying 20 indicators with the default `sysparm_per_page` value (10), specify a `sysparm_page` value of 2 to retrieve indicators 11-20.  
  Data type: Number                                                                                                                                                                                                                                                                 |
<p>| sysparm_per_page                  | Maximum number of indicators each query can return on a page.                                                                                                                                                                                                                                                                                  |</p>

### Query parameters (continued)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_step</td>
<td>Numeric value to skip scores, based on the indicator frequency. For example, specify a value of 3 to return scores from every third day for a daily indicator, or every third week for a weekly indicator.</td>
</tr>
<tr>
<td>sysparm_tags</td>
<td>Indicator group sys_id in which to return the indicators of that group. Do not use <code>sysparm_uuid</code> with this parameter. You cannot obtain the sys_id of an indicator group through this API. Instead, get the sys_id from the indicator group record. For more information about obtaining sys_ids from records, see Unique record identifier (sys_id).</td>
</tr>
</tbody>
</table>
| sysparm_target   | Flag that indicates whether to return results only for indicators that have a target set on the Analytics Hub. Valid values:  
  - true: Only return results for indicators that have a target set.  
  - false: Return results for all applicable indicators. |
| sysparm_to       | Latest date from which to return scores. Only scores from this date or earlier are returned.  
  This parameter requires that `sysparm_include_scores` be `true`. |
| sysparm_uuid     | Colon-separated list of sys_id values to specify which indicators, breakdowns, aggregates, and domains to query. The parameter follows this format: `<indicator_sys_id>:<breakdown_sys_id>:<element_sys_ids>:<lvl-2 breakdown_sys_id>:<lvl-3 breakdown_sys_id>:...` |
Query parameters (continued)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>elements_filter_sys_id or element_sys_ids:&lt;aggregate_sys_id&gt;;&lt;domain_sys_id&gt;</td>
<td>The parameter must begin with the sys_id of an indicator record. Optionally, you can append the sys_id values of a breakdown and breakdown element to group the response based on the breakdown, and the sys_id of an aggregate to apply that aggregate. You can use a breakdown aggregate, or use only one.</td>
</tr>
</tbody>
</table>

**Note**: If an indicator is configured to use a Default time series, all values that this API retrieves for that indicator use the selected aggregate.

For examples of fully-constructed sysparm_uuid values, see Performance Analytics REST API examples.

</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Depends on request parameters.</td>
</tr>
</tbody>
</table>

Example: Return an indicator filtered by a breakdown and element

```bash
# The GET request gets the details for
# the indicator Number of open
# incidents, where the Priority of the
# incident is 1 - Critical. The sys_id
# values for the indicator, the
# Priority breakdown, and the 1 -
# Critical element are all passed in
# the sysparm_uuid parameter.

curl --verbose --user "username":"password" \
     --header "Accept: application/json" \
     "https://instance.servicenow.com/api/now/v1/pa/scorecards?sysparm_uuid=fb007202d7130100b96d45a3ce6103b4:0df47e02d7130100b96d45a3ce610399:e5900140200331007665978299a805f3"
```
{  
    // The request is made Dec 12. The score is 76, which is unchanged from Dec 11, and which exceeds the target of 70.

Script Debugger API

The Script Debugger API enables you to debug lines of server-side JavaScript code, such as business rules and script includes.

For more information about the Script Debugger, see Script Debugger and Session Log.

This API is available by default.

Script Debugger - GET /js/debugpoints/script/{tableName}/{sysId}/{fieldName}

Retrieve a list of breakpoints or logpoints in a server-side script, such as a business rule or script include.

URL format

Default URL: /api/now/js/debugpoints/script/{tableName}/{sysId}/{fieldName}

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>Name of the table that contains the server-side script, such as sys_script or sys_script_include. Data type: String</td>
</tr>
<tr>
<td>sysId</td>
<td>Sys_id for the server-side script. Data type: String</td>
</tr>
<tr>
<td>fieldName</td>
<td>Name of the field that contains the server-side script content. Data type: String</td>
</tr>
</tbody>
</table>
Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

Example cURL request

Example: cURL request

Retrieves a list of logpoints and breakpoints for a server-side script. This script has a logpoint on line 2, a breakpoint on line 11, and a conditional breakpoint on line 18.

curl
"https://instance.servicenow.com/api/now/js/debugpoints/script/sys_script_include/d65f78c40a0a0b6900196656f35913d3/script" \ 
--request GET \ 
--header "Accept:application/json" \ 
--header "Content-Type:application/json" \ 
--user 'username':'password"

{
    "result": {
        "canWrite": true,
        "debugpoints": {
            "LOGPOINT": {
                "2": {
                    "evaluationString": "A log message",
                    "sysId": "ba28b0fa739310101c233096fbf6a75e"
                }
            },
            "BREAKPOINT": {
                "11": {
                    "evaluationString": "",
                    "sysId": "dc5f5bf341256010f877587fbdf5ec1d"
                },
                "18": {
                    "evaluationString": "a == true",

    }
}
Script Debugger - POST js/debugpoints/process

Add, update, or remove breakpoints or logpoints in a server-side script, such as a business rule or script include. Process several breakpoints or logpoints at a time.

URL format

Default URL: /api/now/js/debugpoints/process

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fetchAll</td>
<td>When true, returns a list of all the breakpoints or logpoints added or updated by the user. Data type: Boolean Default: false</td>
</tr>
</tbody>
</table>
| fetchAllFilter     | Returns a filtered list of all the breakpoints or logpoints added or updated by the user. Valid values:  
• debugpointType. Set to either breakpoint or logpoint.  
• scriptId. Set to the sys_id of the script in which to search for debug points.  
• scope. Set to the name of the scope in which to search for debug points.  
Use the caret (^) symbol as a separator for multiple properties. For example, fetchAllFilter=debugpointType=logpoint^scope=MyApp Data type: String |
### Request body parameters (XML or JSON)

<tr>
<td></td>
<td>• It requests to add a breakpoint or logpoint identical to one that already exists.</td>
</tr>
<tr>
<td>requestedDebugpoints.lineNumber</td>
<td>Line number in the server-side script specifying where the breakpoint or logpoint was added, deleted, or updated. Data type: Number</td>
</tr>
<tr>
<td>requestedDebugpoints.debugpointType</td>
<td>Type of debug point added, deleted, or updated. Possible values: breakpoint, logpoint</td>
</tr>
</tbody>
</table>
Example: cURL request

This example adds a conditional breakpoint at line 12 in the script.

```
curl "https://instance.servicenow.com/api/now/js/debugpoints/process" \
  --request POST \
  --header "Accept: application/json" \
  --header "Content-Type: application/json" \
  --data "\n  {\n    "tableName": "sys_script_include",\n    "scriptId": "d65f78c40a0b6900196656f35913d3\",\n    "fieldname": "script\",\n    "lineNumber": 12,\n    "evaluationString": "a == false\",\n    "debugpointType": "breakpoint\",\n    "operation": "add\"\n  }\n  "\n  --user 'username': 'password'
```

```json
{
  "result": {
    "requestedDebugpoints": [
    {
      "scriptId": "d65f78c40a0b6900196656f35913d3\",\n      "evaluationString": "a == false\",\n      "operation": "add\",\n      "tableName": "sys_scriptInclude\",\n      "fieldName": "script\",\n      "status": "success\",\n      "lineNumber": 12,\n      "debugpointType": "breakpoint\"
    }],
    "status": 200
  }
}```
Service Catalog API

The Service Catalog API provides access Service Catalog configuration and actions from within a Service Portal.

Service Catalog - DELETE /sn_sc/servicecatalog/cart/{cart_item_id}
Deletes the specified item from the current cart.

URL format

Versioned URL: /api/sn_sc/{api_version}/servicecatalog/cart/{cart_item_id}
Default URL: /api/sn_sc/servicecatalog/cart/{cart_item_id}

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>cart_item_id</td>
<td>Sys_id of the item to delete from the current cart. Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>
Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>204</td>
<td>Indicates that the request completed successfully and the specified item was deleted from the cart.</td>
</tr>
<tr>
<td>400</td>
<td>Indicates that either the specified cart_item_id is invalid or the user does not have access to the cart item.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>
### Example: cURL request
```
curl
  "https://instance.servicenow.com/api/sn_sc/v1/servicecatalog/cart/1f4cc597db21120064301150f0b8f5fc" \n  --request DELETE \n  --user "username":"password"
```

### Example: Python request
```
# Install requests package for python
import requests

# Set the request parameters
url =
  'https://instance.servicenow.com/api/sn_sc/v1/servicecatalog/cart/1f4cc597db21120064301150f0b8f5fc'

# Set the user credentials
user = 'username'
pwd = 'password'

# Make the HTTP request
response = requests.delete(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 204
if response.status_code != 204:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:',
          response.json())
    exit()

# Decode the JSON response into a dictionary and use the data
data = response.json()
print(data)
```

### Service Catalog - DELETE /sn_sc/servicecatalog/cart/{sys_id}/empty

Deletes a specified cart, and the contents of the cart.

The capabilities of what a user can delete (items and/or cart) depends on the role in which they use to authenticate.

User roles needed to delete cart and cart contents:
• admin/catalog_admin: Can empty any user cart.
• admin: Can delete the cart after all the contents of the cart are deleted.
• catalog_admin: Can delete all the items in the cart.

**URL format**

Versioned URL: `/api/sn_sc/{api_version}/servicecatalog/cart/{sys_id}/empty`
Default URL: `/api/sn_sc/servicecatalog/cart/{sys_id}/empty`

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the cart to empty and delete. Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

**Request body parameters (XML or JSON)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

**Headers**

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>204</td>
<td>Request completed successfully and the items in the cart are successfully checked out.</td>
</tr>
</tbody>
</table>
| 400          | Indicates an error for one of the following reasons:  
|              | • Invalid cartId.  
|              | • User does not have admin/catalog_admin role, or is trying to empty another user cart. |
| 401          | Unauthorized. The user credentials are incorrect or have not been passed. |
| 500          | Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error. |

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
**Example: cURL request**

curl
  "https://instance.servicenow.com/api/sn_sc/servicecatalog/cart/dde34ad713426300027879d96144b072/empty" \
  --request DELETE \ 
  --user 'username':'password'

None

**Example: Python request**

```python
# Install requests package for python
import requests

# Set the request parameters
url =
  'https://instance.servicenow.com/api/sn_sc/servicecatalog/cart/dde34ad713426300027879d96144b072/empty'

# Set the user credentials
user = 'username'
pwd = 'password'

# Make the HTTP request
response = requests.delete(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 204
if response.status_code != 204:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:',
          response.json())
    exit()

# Decode the JSON response into a dictionary and use the data
data = response.json()
print(data)
```

None

**Service Catalog - GET /sn_sc/servicecatalog/cart**

Retrieves the details of the items within the logged in user's cart.

**URL format**

Versioned URL: /api/sn_sc/{api_version}/servicecatalog/cart
Default URL: /api/sn_sc/servicecatalog/cart

Supported request parameters

### Path parameters

<table>

## Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).

### Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Indicates that the request completed successfully. If there is no item in the cart, it returns basic cart information and pricing for user. If the cart contains any items, then the information about the items and their individual pricing is also included.</td>
</tr>
<tr>
<td>400</td>
<td>Indicates that the cart is empty and cannot check out.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cart_id</td>
<td>Sys_id of the cart. Data type: String</td>
</tr>
</tbody>
</table>
| <recurring_frequency>   | List of items in the cart having a specific recurring frequency. Possible values include:  
  • daily  
  • monthly  
  • yearly  
  • none (no recurring fees)  
  Data type: Object  

```json
"<recurring_frequency>": {  
  "frequency_label": "String",  
  "items": [Array],  
  "show_subtotal_price": "String",  
```

</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Request completed successfully; returns the shipping address of the specified user.</td>
</tr>
<tr>
<td>400</td>
<td>User sys_id is invalid.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>Address of the specified user. Data type: String</td>
</tr>
</tbody>
</table>
Example: cURL request

curl
   "https://instance.servicenow.com/api/sn_sc/servicecatalog/cart/delivery_address/62826bf03710200044e0bfc8bcbe5df1" \
   --request GET \
   --header "Accept:application/json" \
   --user "username":"password"

{
   'result': '25 New Chardon Street, Boston\n   Boston, MA, 02114-1801\n   USA'
}

Example: Python request

# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/sn_sc/servicecatalog/cart/delivery_address/62826bf03710200044e0bfc8bcbe5df1'

# Set the user credentials
user = 'username'
pwd = 'password'

# Set the proper headers
headers = {'Accept':"application/json"}

# Make the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
   print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.json())
   exit()

# Decode the JSON response into a dictionary and use the data
data = response.json()
print(data)
Service Catalog - GET /sn_sc/servicecatalog/catalogs

Retrieves a list of catalogs to which the user has access based on the passed in parameters.

**URL format**

**Versioned URL:** /api/sn_sc/{api_version}/servicecatalog/catalogs

**Default URL:** /api/sn_sc/servicecatalog/catalogs

**Supported request parameters**

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_limit</td>
<td>Maximum number of records to return. For requests that exceed this number of records, use the sysparm_offset parameter to paginate record retrieval. This limit is applied before ACL evaluation. If no records return, including records you have access to, rearrange the record order so records you have access to return first.</td>
</tr>
<tr>
<td>sysparm_text</td>
<td>Keyword to search for in the &quot;title&quot; field of the available service catalogs.</td>
</tr>
</tbody>
</table>

[i] **Note:** Unusually large sysparm_limit values can impact system performance.

Data type: Number

Default: 1000
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_view</td>
<td>Device on which the item can display:</td>
</tr>
<tr>
<td></td>
<td>• desktop: On the desktop.</td>
</tr>
<tr>
<td></td>
<td>• mobile: On a mobile device.</td>
</tr>
<tr>
<td></td>

### Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Indicates that the request completed successfully. If a valid query returns no results, the response body only contains an empty result array.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td>Description of the catalog. Data type: String</td>
</tr>
<tr>
<td>desktop_image</td>
<td>Image that appears on the desktop for this catalog. Data type: String</td>
</tr>
<tr>
<td>has_categories</td>
<td>Flag that indicates whether the catalog contains categories. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: Catalog contains categories.</td>
</tr>
<tr>
<td></td>
<td>• false: Catalog does not contain categories. Data type: Boolean</td>
</tr>
<tr>
<td>has_items</td>
<td>Flag that indicates whether the catalog contains items. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: Catalog contains items.</td>
</tr>
<tr>
<td></td>
<td>• false: Catalog does not contain items. Data type: Boolean</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the catalog. Data type: String</td>
</tr>
<tr>
<td>title</td>
<td>Catalog title. Data type: String</td>
</tr>
</tbody>
</table>
Example: cURL request

```bash
curl "https://instance.servicenow.com/api/sn_sc/servicecatalog/catalogs?sysparm_limit=10" \
--request GET \
--header "Accept:application/json" \
--user "username":"password"
```

```json
{
  "result": [
    {
      "title": "Technical Catalog",

        },
        {
            "title": "Service Catalog",
            "sys_id": "e0d08b13c3330100c8b837659bba8fb4",
            "has_categories": true,
            "has_items": true,
            "description": "Service Catalog - IT Now",
            "desktop_image": "adbcc271475211002ee987e8dee49001.iix"
        }
    ]
}

**Service Catalog - GET /sn_sc/servicecatalog/catalogs/{sys_id}/categories**

Retrieves the list of available categories for the specified catalog.

**URL format**

Versioned URL: /api/sn_sc/{api_version}/servicecatalog/catalogs/{sys_id}/categories

Default URL: /api/sn_sc/servicecatalog/catalogs/{sys_id}/categories
## Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the catalog whose categories are requested. Data type: String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| sysparm_limit   | Maximum number of records to return. For requests that exceed this number of records, use the sysparm_offset parameter to paginate record retrieval.  
This limit is applied before ACL evaluation. If no records return, including records you have access to, rearrange the record order so records you have access to return first. 

⚠️ **Note:** Unusually large sysparm_limit values can impact system performance.  
Data type: Number  
Default: 1000 |
| sysparm_offset  | Starting record index for which to begin retrieving records. Use this value to paginate record retrieval.  
This functionality enables the retrieval of all records, regardless of the number of records, in small manageable chunks.  
For example, the first time you call this endpoint, sysparm_offset is set to "0". To simply page through all available records, use sysparm_offset=sysparm_offset+sysparm_limit, until you reach the end of all records. |
### Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_offset</td>
<td>Do not pass a negative number in the <code>sysparm_offset</code> parameter. Data type: Number Default: 0</td>
</tr>
<tr>
<td>sysparm_top_level_only</td>
<td>Only return those categories whose parent is a catalog. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Only return those categories whose parent is a catalog.</td>
</tr>
<tr>
<td></td>
<td>• false: Return all categories.</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
<tr>
<td>sysparm_view</td>
<td>UI view for which to render the data. Determines the fields returned in the response. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• desktop</td>
</tr>
<tr>
<td></td>
<td>• mobile</td>
</tr>
<tr>
<td></td>
<td>• both</td>
</tr>
<tr>
<td></td>
<td>If you also specify the <code>sysparm_fields</code> parameter, it takes precedent.</td>
</tr>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: <code>application/json</code> or <code>application/xml</code>. Default: <code>application/json</code></td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
### Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
</tbody>
</table>
| 400         | Indicates that request is invalid for one of the following reasons:  
  - User does not have access to the category.  
  - Invalid sys_id. |
| 401         | Unauthorized. The user credentials are incorrect or have not been passed. |
| 500         | Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error. |

### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| child_categories          | List of objects that describe the child categories that belong to this category.  
  Data type: Array          |
|                           |                                                                                          |
|                           | "child_categories": [

        "sys_id": "2809952237b1300054b6a3549dbe5dd4",
        "child_categories": []
    }
}
Service Catalog - GET /sn_sc/servicecatalog/items

Retrieves a list of catalog items based on the specified parameters.

**URL format**

Versioned URL: /api/sn_sc/{api_version}/servicecatalog/items

Default URL: /api/sn_sc/servicecatalog/items

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_catalog</td>
<td>Catalog sys_id of the item. Use this parameter to locate items in a specific catalog. Data type: String</td>
</tr>
<tr>
<td>sysparm_category</td>
<td>Category sys_id of the item. Use this parameter to locate catalog items in a specific category. Data type: String</td>
</tr>
<tr>
<td>sysparm_limit</td>
<td>Maximum number of records to return. For requests that exceed this number of records, use the sysparm_offset parameter to paginate record retrieval. This limit is applied before ACL evaluation. If no records return, including records you have access to, rearrange the record order so records you have access to return first.</td>
</tr>
</tbody>
</table>

**Note:** Unusually large sysparm_limit values can impact system performance.
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_offset</td>
<td>Data type: Number, Default: 1000. Starting record index for which to begin retrieving records. Use this value to paginate record retrieval. This functionality enables the retrieval of all records, regardless of the number of records, in small manageable chunks. For example, the first time you call this endpoint, sysparm_offset is set to &quot;0&quot;. To simply page through all available records, use sysparm_offset=sysparm_offset + sysparm_limit, until you reach the end of all records. Do not pass a negative number in the sysparm_offset parameter. Data type: Number, Default: 0.</td>
</tr>
<tr>
<td>sysparm_text</td>
<td>Data type: String, Specific text for which to search for in the category items. For example, sysparm_text=&quot;iPhone&quot; or sysparm_text=&quot;Mobile devices&quot;.</td>
</tr>
<tr>
<td>sysparm_type</td>
<td>Data type: String, Type of item. Valid search values: Record Producer, Order Guide. If any other value is passed, the information is ignored.</td>
</tr>
<tr>
<td>sysparm_view</td>
<td>Data type: String, UI view for which to render the data. Determines the fields returned in the response. Valid values: desktop, mobile, both.</td>
</tr>
</tbody>
</table>
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>If you also specify the <code>sysparm_fields</code> parameter, it takes precedence.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.
### Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Returns a list of catalogs and items based on the specified parameters. If a valid query results in no items, then the response body contains only an empty result array.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>catalogs</td>
<td>List of objects that describe the catalogs that contain this item. Data type: Array</td>
</tr>
<tr>
<td></td>
<td>&quot;catalogs&quot;: [{ &quot;sys_id&quot;: &quot;String&quot;, &quot;title&quot;: &quot;String&quot; }]</td>
</tr>
<tr>
<td>catalogs.sys_id</td>
<td>Sys_id of the catalog. Data type: String</td>
</tr>
<tr>
<td>catalogs.title</td>
<td>Catalog title. Data type: String</td>
</tr>
<tr>
<td>category</td>
<td>Describes the category that contains this item. Data type: Object</td>
</tr>
<tr>
<td></td>
<td>&quot;catalogs&quot;: { &quot;sys_id&quot;: &quot;String&quot;, &quot;title&quot;: &quot;String&quot; }</td>
</tr>
<tr>
<td>category.sys_id</td>
<td>Sys_id of the category.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>category.title</strong></td>
<td>Category title</td>
</tr>
<tr>
<td><strong>content_type</strong></td>
<td>Type of content.</td>
</tr>
<tr>
<td><strong>description</strong></td>
<td>Detailed description of the item.</td>
</tr>
<tr>
<td><strong>icon</strong></td>
<td>Source of the small icon displayed beside the item name.</td>
</tr>
<tr>
<td><strong>kb_article</strong></td>
<td>Knowledge based article associated with the item.</td>
</tr>
<tr>
<td><strong>local_currency</strong></td>
<td>Country currency code for the local currency.</td>
</tr>
<tr>
<td><strong>localized_price</strong></td>
<td>Price of the item expressed in the currency defined by <code>local_currency</code>.</td>
</tr>
<tr>
<td><strong>localized_recurring_price</strong></td>
<td>Price of the recurring fee expressed in the currency defined by <code>local_currency</code>.</td>
</tr>
<tr>
<td><strong>name</strong></td>
<td>Name of the item.</td>
</tr>
<tr>
<td><strong>order</strong></td>
<td>Pre-defined order to which the item belongs.</td>
</tr>
<tr>
<td><strong>picture</strong></td>
<td>Path to the image to display for the item.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>price</td>
<td>Price of item expressed in the currency defined by <code>price_currency</code>. Data type: String</td>
</tr>
<tr>
<td>price_currency</td>
<td>Country currency code for which the item price is expressed. Data type: String</td>
</tr>
<tr>
<td>recurring_frequency</td>
<td>Frequency at which the recurring fees are applied, such as daily, monthly, or yearly; null if there are no fees for the item. Data type: String</td>
</tr>
<tr>
<td>recurring_price</td>
<td>Amount of the recurring fee associated with the item. Data type: String</td>
</tr>
<tr>
<td>recurring_price_currency</td>
<td>Country currency code for which the recurring fees are expressed. Data type: String</td>
</tr>
<tr>
<td>short_description</td>
<td>Brief description of the item. Data type: String</td>
</tr>
<tr>
<td>show_price</td>
<td>Flag that indicates whether to show item pricing in the cart. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: Name-value pairs are returned in the response parameters.</td>
</tr>
<tr>
<td></td>
<td>• false: Name-value pairs are not returned in the response parameters.</td>
</tr>
<tr>
<td>show_quantity</td>
<td>Flag that indicates whether to display the item quantity in the cart. Possible values:</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| • true: Display the item quantity in the cart.  
• false: Do not display the item quantity in the cart. |
| sys_class_name    | Table to which the record belongs, such as sc_cat_item_producer. Data type: String                                                        |
| sys_id            | Sys_id of the item. Data type: String                                                                                                     |
| type              | Type of item. Data type: String                                                                                                             |
| url               | URL of the item. Data type: String                                                                                                         |

**Example: cURL request**

```bash
curl  
"https://instance.servicenow.com/api/sn_sc/servicecatalog/items?sysparm_catalog=e0d08b13c3330100c8b837659bba8fb4&sysparm_limit=2" 
--request GET 
--header "Accept:application/json" \  
--user "username":"password"
```

```json
{
  "result": [
    {
      "short_description": null,
      "kb_article": ",
      "icon": "images/icons/catalog_item.gifx",
      "description": "<p class="p1"><font size="2"><span class="s1">Request an existing Standard Change Template is made unavailable when it is no longer required or no longer acceptable as a Standard Change. This will be confirmed by your Change Management team.</span></font></p>",
      "show_price": false,
      "type": "record_producer",
      "show_quantity": true,
```

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
        </font>"
      }
    ]
}
```
A slim and stylish design makes the Apple iPhone 5 smartphone lightweight and easy-to-carry around.

Key Features:

- Storage Capacity: 64 GB
- Color: Black and Slate
- Network Generation: 2G, 3G, 4G
- Style: Smartphone
- Camera: 8.0 MP
- Operating System: iOS

Service Catalog - GET /sn_sc/servicecatalog/items/{sys_id}
Retrieves a specified catalog item.

URL format
Versioned URL: /api/sn_sc/{api_version}/servicecatalog/items/{sys_id}
Default URL: /api/sn_sc/servicecatalog/items/{sys_id}

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
</tbody>
</table>
Path parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sys_id</td>
<td>Sys_id of the catalog item to return. Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_view</td>
<td>UI view for which to render the data. Determines the fields returned in the response. Valid values: desktop, mobile, both. If you also specify the sysparm_fields parameter, it takes precedent. Data type: String</td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml.</td>
</tr>
</tbody>
</table>
Request headers (continued)

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Indicates that the request has completed successfully and returns the details of the catalog item.</td>
</tr>
</tbody>
</table>
| 400         | Indicates that request is invalid for one of the following reasons:  
  • User does not have access to the catalog item.  
  • Invalid sys_id. |
| 401         | Unauthorized. The user credentials are incorrect or have not been passed. |
| 500         | Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error. |

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| catalogs | List of objects that describe the catalogs that contain this item.  
Data type: Array |

```json
"catalogs": [
  "sys_id": "String",

**Service Catalog - GET /sn_sc/servicecatalog/wishlist/{cart_item_id}**

Retrieves the details of the specified item stored in the wish list cart.

**URL format**

Versioned URL: /api/sn_sc/v1/servicecatalog/wishlist/{cart_item_id}

Default URL: /api/sn_sc/servicecatalog/wishlist/{cart_item_id}
Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cart_item_id</td>
<td>Sys_id of the wish list cart item to retrieve.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.
### Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Indicates a failed request. Incorrect cart item id or the item does not exist in the wish list cart.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cart_item_id</td>
<td>Sys_id of the item.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>catalog_item_id</td>
<td>Sys_id of the catalog identifier for this item in the wish list cart.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>delivery_time</td>
<td>Amount of time that it takes to deliver the item.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>item_name</td>
<td>Name of the item.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>localized_price</td>
<td>Price of the item expressed in the local currency.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>localized_recurring_price</td>
<td>Price of the recurring fee expressed in the local currency.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>price</td>
<td>Price of item.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>quantity</td>
<td>Number of this item in the wish list cart.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>recurring_frequency</td>
<td>Frequency at which the recurring fees are applied, such as daily, monthly, or yearly. Null if no recurring fees for this item.</td>
</tr>
<tr>
<td>recurring_price</td>
<td>Amount of the recurring fee associated with the item.</td>
</tr>
<tr>
<td>variables</td>
<td>Name-value pairs of the variables associated with the item.</td>
</tr>
</tbody>
</table>

**Example: cURL request**

```bash
curl
   "http://instance.servicenow.com/api/sn_sc/servicecatalog/wishlist/774906834fbb4200086eeed18110c737" \
   --request GET \
   --header "Accept:application/json" \
   --user "username":"password"
{
   "result": {
      "catalog_item_id": "04b7e94b4f7b4200086eeed18110c7fd",
      "variables": {
         "Adobe Photoshop": ",",
         "Adobe Acrobat": ",",
         "Optional Software": ",",
         "Additional software requirements": ","
      },
      "quantity": "1",
      "localized_price": "$1,100.00",
      "price": "$1,100.00",
      "recurring_frequency": "Annually",
      "localized_recurring_price": "$100.00",
      "recurring_price": "$100.00",
      "item_name": "Standard Laptop ",
      "cart_item_id": "d31be364c3012200d68d3b0ac3d3aecc",
      "delivery_time": "5 Days"
   }
}
Example: Python request

```python
# Install requests package for python
import requests

# Set the request parameters
url =
'http://instance.servicenow.com/api/sn_sc/servicecatalog/wishlist/d31be364c3012200d68d3b0ac3d3aece'

# Set the user credentials
user = 'username'
pwd = 'password'

# Set the proper headers
headers = {'Accept': 'application/xml'}

# Make the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:',
          response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)
```

```xml
<?xml version="1.0" encoding="UTF-8"?>
<response>
    <result>
        <catalog_item_id>04b7e94b4f7b4200086eeed18110c7fd</catalog_item_id>
        <quantity>1</quantity>
        <variables>
            <Adobe Photoshop/></Adobe Photoshop>
            <Adobe Acrobat/></Adobe Acrobat>
            <Optional Software/></Optional Software>
            <Additional software requirements/></Additional software requirements>
        </variables>
        <localized_price>$1,100.00</localized_price>
    </result>
</response>
```
Service Catalog - POST /sn_sc/servicecatalog/cart/checkout

Retrieves and processes the checkout for the current cart based on whether the two-step checkout process is enabled.

If one-step checkout, the method checks out (saves) the cart and returns the request number and the request order ID. If two-step checkout, the method returns the cart order status and all the information required for two-step checkout.

URL format

Versioned URL: /api/sn_sc/{api_version}/servicecatalog/cart/checkout
Default URL: /api/sn_sc/servicecatalog/cart/checkout

Supported request parameters

<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Indicates that the request completed successfully and the items in the cart are successfully checked out.</td>
</tr>
<tr>
<td>400</td>
<td>Indicates that the user cart is empty.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>parent_id</td>
<td>If available, sys_id of the parent record from which the request is created. For more information, see Configure a parent mapping for a request.</td>
</tr>
<tr>
<td>parent_table</td>
<td>Name of the parent table.</td>
</tr>
<tr>
<td>request_id</td>
<td>Sys_id of the order request generated.</td>
</tr>
<tr>
<td>request_number</td>
<td>Number of the request generated.</td>
</tr>
</tbody>
</table>

Example: cURL request

```bash
curl "https://instance.servicenow.com/api/sn_sc/v1/servicecatalog/cart/submit_order " \
--request POST \
--header "Accept:application/json" \
--user "username":"password"
```
Example: Python request

```python
# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/sn_sc/v1/servicecatalog/cart/submit_order '

# Set the user credentials
user = 'username'
pwd = 'password'

# Set the proper headers
headers = {'Accept': 'application/json'}

# Make the HTTP request
response = requests.post(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.json())
    exit()

# Decode the JSON response into a dictionary and use the data
data = response.json()
print(data)
```

Service Catalog - POST /sn_sc/servicecatalog/items/{sys_id}/add_to_cart

Adds the specified item to the cart of the current user.
**URL format**

Versioned URL: `/api/sn_sc/{api_version}/servicecatalog/items/{sys_id}/add_to_cart`

Default URL: `/api/sn_sc/servicecatalog/items/{sys_id}/add_to_cart`

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, <code>v1</code> or <code>v2</code>. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the item to add to the current cart. Data type: String</td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.
### Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>The following errors can occur:</td>
</tr>
<tr>
<td></td>
<td>• <em>Invalid quantity value</em>: Indicates that either the <code>sysparm_quantity</code> parameter is not provided or contains an invalid value.</td>
</tr>
<tr>
<td></td>
<td>• <em>Security constraints prevent ordering of Item</em>: Indicates that either the cart item <code>sys_id</code> specified in the path parameters is invalid or the user does not have access to the item.</td>
</tr>
<tr>
<td></td>
<td>• <em>Mandatory Variables are required</em>: Indicates that one or more of the mandatory variables is not provided in the request.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cart_id</td>
<td>Cart sys_id. Cart sys_id. Data type: String</td>
</tr>
<tr>
<td>items</td>
<td>Details of all of the items in the cart. Data type: Array</td>
</tr>
</tbody>
</table>

```json
"items": [
  {
    "cart_item_id": "String",
    "catalog_item_id": "String",
    "item_name": "String",
    "localized_recurring_price": "String",
    "localized_price": "String",
    "price": "String",

**Service Catalog - POST /sn_sc/servicecatalog/items/{item_sys_id}/get_invalid_delegated_users**

Returns a list of users whose request for the specified item cannot be delegated (requested by another user.)

You can call this endpoint prior to calling an endpoint such as Service Catalog API - POST /sn_sc/servicecatalog/items/{sys_id}/add_to_cart or Service Catalog API - POST /sn_sc/servicecatalog/items/{sys_id}/order_now that allow the requisition of a service catalog item on behalf of another person. These calls fail if you pass in a user that is not authorized for the associated item. This endpoint allows you to verify your list of users prior to calling an endpoint that orders the item or tries to add the item to a cart.

**URL format**

Versioned URL: /api/sn_sc/{api_version}/servicecatalog/items/{item_sys_id}/get_invalid_delegated_users
Default URL: /api/sn_sc/servicecatalog/items/{item_sys_id}/
get_invalid_delegated_users

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
<tr>
<td>item_sys_id</td>
<td>Sys_id of the service catalog item to verify whether the specified user has acquisition rights. Located in the Service Catalog [sc_catalog] table.</td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_also_request_for</td>
<td>Comma separated string of valid user sys_ids. The endpoint verifies that these users have acquisition rights to the specified service catalog item. Located in the Users [sys_user] table.</td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Request failed. Bad request given for processing. Refer to the message in the return results for additional information on the error.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>errCode</td>
<td>Number associated with the error. Only returned if the endpoint fails.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>errMsg</td>
<td>Description of the error that the endpoint encountered when it failed.</td>
</tr>
<tr>
<td>invalidUsers</td>
<td>Names of the users that are not able to request the specified catalog item.</td>
</tr>
<tr>
<td>Data type: Array</td>
<td></td>
</tr>
</tbody>
</table>

### Example: cURL request

```bash
curl
  "https://instance.servicenow.com/api/sn_sc/servicecatalog/items/04b7e94b4f7b4200086eeed1810c7fd/get_invalid_delegated_users"
  --request POST
  --header "Accept:application/json"
  --header "Content-Type:application/json"
  --data
  "\"sysparm_also_request_for\":\"a8f98bb0eb32010045e1a5115206fe3a,62826bf03710200044e0bfc8bcbe5df1\""
  --user "username":"password"

{
  "result": {
    "invalidUsers": [
      "Abel Tuter"
    ]
  }
}
```

### Example: cURL request

```bash
curl
  "https://instance.servicenow.com/api/sn_sc/servicecatalog/items/04b7e94b4f7b4200086eeed18110c7fd/get_invalid_delegated_users"
  --request POST
  --header "Accept:application/json"
  --header "Content-Type:application/json"
  --data
  "\"sysparm_also_request_for\":\"a8f98bb0eb32010045e1a5115206fe3a,62826bf03710200044e0bfc8bcbe5df1\""
  --user "username":"password"
```
Service Catalog - POST /sn_sc/servicecatalog/items/{sys_id}/order_now

Orders the specified catalog item.

**URL format**

Versioned URL: /api/sn_sc/{api_version}/servicecatalog/items/{sys_id}/order_now

Default URL: /api/sn_sc/servicecatalog/items/{sys_id}/order_now

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the service catalog item. Located in the Catalog Item [sc_cat_item] table. Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_also_request_for</td>
<td>Comma-separated string of user sys_ids of other users for which to order the specified item. User sys_ids are located in the User [sys_user] table.</td>
</tr>
<tr>
<td></td>
<td>• You cannot specify more than 50 additional users to receive the item.</td>
</tr>
<tr>
<td></td>
<td>• If any person in the list doesn’t qualify for the item, the entire request is rejected.</td>
</tr>
<tr>
<td></td>
<td>• If the associated item does not have the requested_for variable set, the request is rejected.</td>
</tr>
<tr>
<td></td>
<td>• If the associated item has the requested_for variable set, but the Enable also Request for variable is not configured, or the calling user doesn’t have the proper roles, the request is rejected.</td>
</tr>
<tr>
<td>sysparm_quantity</td>
<td>Required. Quantity of the item. Cannot be a negative number.</td>
</tr>
<tr>
<td></td>
<td>Data type: Number</td>
</tr>
<tr>
<td>variables</td>
<td>Name-value pairs of all mandatory cart item variables. Mandatory variables are defined on the associated form.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

**Headers**

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

**Request headers**

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Indicates that the quantity value is invalid and the request is not placed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>number</td>
<td>Number of the generated request.</td>
</tr>
<tr>
<td>parent_id</td>
<td>If available, the sys_id of the parent record from which the request is created. For more information, see Configure a parent mapping for a request. Data type: String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>parent_table</td>
<td>If available, the name of the parent table from which the request is created. Data type: String</td>
</tr>
<tr>
<td>request_id</td>
<td>Sys_id of the order request.                                                Data type: String</td>
</tr>
<tr>
<td>request_number</td>
<td>Request number.                                                              Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the order.                                                        Data type: String</td>
</tr>
<tr>
<td>table</td>
<td>Table name of the request.                                                   Data type: String</td>
</tr>
</tbody>
</table>

**Example: Sample cURL request**

```bash
curl "https://instance.servicenow.com/api/sn_sc/servicecatalog/items/d82ea08510247200964f77ffeec6c4ee/order_now" \
    --request POST \
    --header "Accept:application/json" \
    --header "Content-Type:application/json" \
    --data "{
        sysparm_quantity: 1,
        variables: {
            replacement: 'Yes',
            originalnumber: '1640000',
            data_plan: '500MB'
        }
    }
"
    --user "username":"password"
```

```json
{
    "result": {
        "sys_id": "cf56a3fcdb3a2300e890f71fbf9619ac",
        "number": "REQ0010012",
        "request_number": "REQ0010012",
        "request_id": "cf56a3fcdb3a2300e890f71fbf9619ac",
        "table": "sc_request"
    }
}
```
Example: Sample Python request

```python
# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/sn_sc/servicecatalog/items/d82ea08510247200964f77ffe
c6c4ee/order_now'

# Set the user credentials
user = 'username'
pwd = 'password'

# Set the proper headers
headers = {"Content-Type":"application/json","Accept":"application/json"}

# Make the HTTP request
response = requests.post(url, auth=(user, pwd), headers=headers, data="{
    sysparm_quantity: 1,
    variables: {
        replacement: 'Yes',
        originalnumber: '1640000',
        data_plan: '500MB'
    }
}
"

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error
Response:',response.json())
    exit()

# Decode the JSON response into a dictionary and use the data
data = response.json()
print(data)

Service Catalog - POST /sn_sc/servicecatalog/items/{sys_id}/submit_producer

Creates a record and returns the Table API relative path and redirect URL to access the created record.

**URL format**

Versioned URL: /api/sn_sc/{api_version}/servicecatalog/items/{sys_id}/submit_producer

Default URL: /api/sn_sc/servicecatalog/items/{sys_id}/submit_producer

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the table in which to create the record producer.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_view</td>
<td>UI view for which to render the data. Determines the fields returned in the response. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• desktop</td>
</tr>
<tr>
<td></td>
<td>• mobile</td>
</tr>
<tr>
<td></td>
<td>• both</td>
</tr>
</tbody>
</table>
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>If you also specify the <code>sysparm_fields</code> parameter, it takes precedent.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>variables</td>
<td>Name-value pairs of the variables of the producer record to define.</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>

</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.
## Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Indicates successful request and returns the response object consisting of Table API and URL to access the created record.</td>
</tr>
<tr>
<td>400</td>
<td>Request is not processed due to incorrect request message.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Requested resource cannot be found.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

## Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>number</td>
<td>Number of the ticket associated with the record producer. Data type: String</td>
</tr>
<tr>
<td>parent_id</td>
<td>If available, sys_id of the parent record from which the request is created. For more information, see Configure a parent mapping for a request. Data type: String</td>
</tr>
<tr>
<td>parent_table</td>
<td>Name of the parent table. Data type: String</td>
</tr>
<tr>
<td>record</td>
<td>Table API relative path of the newly created record producer. Data type: String</td>
</tr>
<tr>
<td>redirect_portal_url</td>
<td>URL to which to redirect the Service Portal. Data type: String</td>
</tr>
<tr>
<td>redirect_to</td>
<td>Redirect value. Data type: String</td>
</tr>
<tr>
<td>redirect_url</td>
<td>Redirect URL to access the created record producer. Data type: String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the record created.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>table</td>
<td>Name of the table on which the request was made.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

**Example: cURL request**

```
curl
"https://instance.servicenow.com/api/sn_sc/servicecatalog/items/3f1dd0320a0a0b99000a53f7604a2ef9/submit_producer" \
--request POST \--header "Accept:application/json" \--header "Content-Type:application/json" \--data "{'variables':"'urgency':2',"'comments':"This is sample incident'"}"
--user "username":"password"
```

```
{
  "result": {
    "sys_id": "6baf4e1ddba2300e890f71fbf961963",
    "number": "INC0010006",
    "parent_id": null,
    "record": "api/now/table/incident/6baf4e1ddba2300e890f71fbf961963",
    "redirect_portal_url": "",
    "parent_table": "task",
    "redirect_url": "incident.do?sys_id=6baf4e1ddba2300e890f71fbf961963&sysparm_view=ess",
    "table": "incident",
    "redirect_to": ""
  }
}
```

**Example: Python request**

```python
# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/sn_sc/servicecatalog/items/3f1dd0320a0a0b99000a53f7604a2ef9/submit_producer'

# Set the user credentials
user = 'username'
```
pwd = 'password'

# Set the proper headers
headers = {"Content-Type":"application/json","Accept":"application/xml"}

# Make the HTTP request
response = requests.post(url, auth=(user, pwd), headers=headers,
                          data="{"variables":{"urgency":"2","comments":"This is sample incident"}}")

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:',
          response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)

Service Catalog - POST /sn/sc/servicecatalog/variables/{sys_id}/display_value
Returns the display value of the specified variable.

URL format

Versioned URL: /api/sn_sc/{api_version}/servicecatalog/variables/{sys_id}/display_value
Default URL: /api/sn_sc/servicecatalog/variables/{sys_id}/display_value
Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the variable for which to return the display value.</td>
</tr>
</tbody>
</table>

Query parameters

<table>

Service Catalog - PUT /sn_sc/servicecatalog/items/{sys_id}/submit_guide
Retrieves a list of items based on the needs described for an order guide.

URL format
Versioned URL: /api/sn_sc/{api_version}/servicecatalog/items/{sys_id}/submit_guide
Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the order guide whose items are to be retrieved. Located in the Order guide [sc_cat_item_guide] table. Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>variables</td>
<td>Variables requested for an item. Each variable is a JSON object consisting of name-value pairs. Data type: Array</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>
Request headers (continued)

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Indicates that the request has completed successfully. Returns a list of items based on the passed-in variable list. If the result set does not contain any items, then an empty array is returned.</td>
</tr>
</tbody>
</table>
| 400         | Indicates that the request is invalid. Could be due to one of the following reasons:  
- User does not have access to the item.  
- Mandatory variables of one or more items have not been answered. (Only variables defined as mandatory are honored.) |
| 401         | Unauthorized. The user credentials are incorrect or have not been passed. |
| 500         | Internal error while calculating items depending on options chosen. |
## Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>catalogs</td>
<td>List of objects the catalogs to which the item belongs and each catalog title and sys_id of the catalog.</td>
</tr>
<tr>
<td>catalogs.sys_id</td>
<td>Sys_id of the catalog.</td>
</tr>
<tr>
<td>catalogs.title</td>
<td>Catalog title.</td>
</tr>
<tr>
<td>category</td>
<td>Describes the category that contains this item.</td>
</tr>
<tr>
<td>category.sys_id</td>
<td>Sys_id of the category.</td>
</tr>
<tr>
<td>category.title</td>
<td>Category title</td>
</tr>
<tr>
<td>client_script</td>
<td>List of all the catalog client scripts defined on the catalog item.</td>
</tr>
</tbody>
</table>

**Data type examples:**

```
"catalogs": [{
  "sys_id": "String",
  "title": "String"
}]
```

```
"client_script": {
  "onChange": [Array],
  "onLoad": [Array],
  "onSubmit": [Array]
}
```
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>client_script.onChange</td>
<td>List of onChange client scripts associated with the item.</td>
</tr>
<tr>
<td></td>
<td>Data type: Array</td>
</tr>
<tr>
<td>client_script.onLoad</td>
<td>List of onLoad client scripts associated with the item.</td>
</tr>
<tr>
<td></td>
<td>Data type: Array</td>
</tr>
<tr>
<td>client_script.onSubmit</td>
<td>List of onSubmit client scripts associated with the item.</td>
</tr>
<tr>
<td></td>
<td>Data type: Array</td>
</tr>
<tr>
<td>data_lookup</td>
<td>Data lookups defined on the catalog item.</td>
</tr>
<tr>
<td></td>
<td>Data type: Array</td>
</tr>
<tr>
<td>description</td>
<td>Full description of catalog item.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>icon</td>
<td>Path of the image that appears as an icon beside the catalog item.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>name</td>
<td>Name of the catalog item.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>short_description</td>
<td>Text on the service catalog homepage or search results page, or the title on the order form of the catalog item.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>show_price</td>
<td>Indicates whether to show the price details. If true, returns the following details.</td>
</tr>
<tr>
<td></td>
<td>• local_currency</td>
</tr>
<tr>
<td></td>
<td>• localized_price</td>
</tr>
<tr>
<td></td>
<td>• localized_recurring_price</td>
</tr>
<tr>
<td></td>
<td>• price</td>
</tr>
<tr>
<td></td>
<td>• price_currency</td>
</tr>
<tr>
<td></td>
<td>• recurring_frequency</td>
</tr>
<tr>
<td></td>
<td>• recurring_price</td>
</tr>
<tr>
<td></td>
<td>• recurring_price_currency</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the catalog item.</td>
</tr>
<tr>
<td>type</td>
<td>Item type. Possible values: catalog item, order guide, record producer item</td>
</tr>
<tr>
<td>variables</td>
<td>Name-value pairs of all the variables associated with the catalog item.</td>
</tr>
<tr>
<td>ui_policy</td>
<td>List of all catalog UI policies defined on the catalog item.</td>
</tr>
</tbody>
</table>

**Example: cURL request**

Corp VPN Account

Corp VPN provides VPN (Virtual Private Network) access to all Internal Corporate Systems and to IP Restricted Customer Instances. By utilizing Corp VPN, users will be provided a similar experience to being within one of the Corporate office locations, while offsite.

Please reference the CORP VPN Installation and Support Documentation for instructions on installation, usage and FAQ’s. For all other questions, please contact IT Support.

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.json())
    exit()

# Decode the JSON response into a dictionary and use the data
data = response.json()
print(data)
```

Same as above

---

Service Order Open API

The Service Order Open API provides a standardized mechanism for placing a service order with all of the necessary order parameters.

To access this API, the Order Management for Telecommunications (sn_ind_tmt_orm) plugin must be activated. For related information, see Service order management. This API is a ServiceNow® implementation of the Open API TMForum TMF641 Service Ordering Management API specification.

This API is provided within the sn_ind_tmt_orm namespace.
The calling user must have the sn_ind_tmt.orm.order_integrator role.

**Extending the Service Order Open API**

The Service Order Open API can be extended using the following script includes. The API should only be extended with an understanding of the consequences of the changes.

- **TMFOrderAPIConstants**: Contains constants and required parameter information.
- **TMFServiceOrderAPIUtil**: Contains functions to handle POST requests.
- **TMFServiceOrderGetAPIUtil**: Contains functions to handle GET requests.
- **ServiceOrderExtensionOOB**: Contains helper functions that support functions in TMFServiceOrderAPIUtil and TMFServiceOrderGetAPIUtil.
- **ServiceOrderProcessor**: An empty script include file. Use this file to define any functions that you want to override from ServiceOrderExtensionOOB.

Extend the Service Order Open API to make the following customizations.

**Required parameters**

To change which request body parameters are required or not required, update the TMFOrderAPIConstants script include.

- **TMFOrderAPIConstants.SCHEMA.CREATE_SERVICE_ORDER**: Sets the required request body parameters to create a service order.

**Request body validation**

To perform additional validation on the request body, override ServiceOrderExtensionOOB functions. ServiceOrderExtensionOOB contains the following four helper functions that return `true` by default.

- **validatePostRequest()** - Called by `processPostOrder()` in TMFServiceOrderAPIUtil.
- **validateServiceObj()** - Called by `processPostOrder()` in TMFServiceOrderAPIUtil.
- **validateRelatedPartyObj()** - Called by `processPostOrder()` in TMFServiceOrderAPIUtil.
- **validateGetRequest()** - Called by `processGetOrder()` in TMFServiceOrderGetAPIUtil.

If a helper function returns `false`, it stops the API operation. To apply custom validation, override ServiceOrderExtensionOOB helper functions by creating functions with identical
names and parameters in ServiceOrderProcessor. These new ServiceOrderProcessor functions will be called by TMFServiceOrderAPIUtil and TMFServiceOrderGetAPIUtil to replace the default ServiceOrderExtensionOOB helper functions. In this example, a function in ServiceOrderProcessor overrides a default function in ServiceOrderExtensionOOB to perform validation on the serviceOrderItem attribute.

```javascript
// ServiceOrderProcessor
var ServiceOrderProcessor = Class.create();
ServiceOrderProcessor.prototype =
Object.extendsObject(ServiceOrderExtensionOOB, {
  // Define overriding functions here
  // Function name and parameters must be identical to the function it overrides
  validatePostRequest: function(orderObject, details) {
    // Returning false terminates the POST request
    // Make sure to push error message in details array in case of error
    if (gs.nil(orderObject.serviceOrderItem)) {
      details.push(new TMFCommonOrderAPIUtil().getErrorDetailsObj(TMFOrderAPIConstants.MESSAGES.MISSING_ORDER_ITEM, '/'));
      return false;
    }
    return true;
  },

type: 'ServiceOrderProcessor'
});
```

**Additional REST operations**

To create additional operations beyond the existing GET and POST operations, create additional scripted REST resources for the Service Order Open API. The logic of the new scripted REST resources should be consistent with the existing operations. Define functions for the new operations in a new script include.

**Field mapping**

When creating records, the API maps request body parameters to record fields. When retrieving records, the API maps record fields to response object attributes.

ServiceOrderExtensionOOB contains the following functions to map a POST request body to a GlideRecord.
• transformOrderGr()
• transformOrdLineItemGr()
• transformCustLineItmContact()
• transformOrderItemChar()

ServiceOrderExtensionOOB contains the following functions to map a GlideRecord to a response object for GET or POST requests.

• transformPostOrderResponse()
• transformGetOrderResponse()
• transformServiceObj()
• transformRelatedPartyCustomerLineItem()
• transformOrderItemRelationship()
• transformGetOrdLineItmResponse()
• transformServiceCharacteristics()
• transformServiceSpecification()

Customize field mappings to add and retrieve data for additional fields, or to change the default mappings for fields. To customize the field mappings, override ServiceOrderExtensionOOB mapping functions by creating functions with identical names and parameters in ServiceOrderProcessor. These new ServiceOrderProcessor functions will be used by TMFServiceOrderAPIUtil and TMFServiceOrderGetAPIUtil to replace the default ServiceOrderExtensionOOB mapping functions. In this example, two functions in ServiceOrderProcessor override the default functions in ServiceOrderExtensionOOB to create mappings for the external_id and sys_id fields.

```javascript
// ServiceOrderProcessor
var ServiceOrderProcessor = Class.create();
ServiceOrderProcessor.prototype =
Object.extendsObject(ServiceOrderExtensionOOB, {
    // Define overriding functions here
    transformOrderGr: function(requestObject, orderGr) {
        orderGr.external_id = requestObject.externalId;
        return orderGr;
    }
});
```
Service Order Open – GET sn_ind_tmt_orm/serviceorder/{id}

Retrieves information for a specified service order.

This operation retrieves a customer order record with related records as dictated by query parameters and filter criteria.

This API retrieves service order information from the following related tables:

- Order [sn_ind_tmt_orm_order]
- Order Line Item [sn_ind_tmt_orm_order_line_item]
- Order Characteristic Value [sn_ind_tmt_orm_order_characteristic_value]
- Order Line Item Contact [sn_ind_tmt_orm_order_line_item_contact]

**URL format**

/api/sn_ind_tmt_orm/serviceorder/{id}

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>Sys_id of the service order to retrieve. Located in the Order [sn_ind_tmt_orm_order] table. Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fields</td>
<td>Comma-separated list of fields to return in the response. If this value is not passed in, all fields are returned. Possible values:</td>
</tr>
</tbody>
</table>
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expectedCompletionDate</td>
<td></td>
</tr>
<tr>
<td>id</td>
<td></td>
</tr>
<tr>
<td>orderDate</td>
<td></td>
</tr>
<tr>
<td>ponr</td>
<td></td>
</tr>
<tr>
<td>serviceOrderItem</td>
<td></td>

<td></td>
</tr>
<tr>
<td>requestedStartDate</td>
<td></td>
</tr>
</tbody>
</table>

Data type: String

Request body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports application/json.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.
### Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>201</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. Can be for any of the following reasons:</td>
</tr>
<tr>
<td></td>
<td>- Missing query parameter</td>
</tr>
<tr>
<td></td>
<td>- Invalid URI</td>
</tr>
<tr>
<td>404</td>
<td>Not found. The requested item was not found.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expectedCompletionDate</td>
<td>Date on which the order is to be completed.</td>
</tr>
<tr>
<td>id</td>
<td>Sys_id of the requested service order.</td>
</tr>
<tr>
<td>note</td>
<td>Array of objects that describe additional notes made by the customer when ordering.</td>
</tr>
<tr>
<td>note.author</td>
<td>User name of the person that authored the associated note.</td>
</tr>
<tr>
<td>note.date</td>
<td>Date that the note was created.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>note.text</td>
<td>Additional notes/comments made by the customer while ordering.</td>
</tr>
<tr>
<td>ponr</td>
<td>Flag that indicates whether the point of no return for the order has been reached. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Point of no return for the order has been reached. The order can't be modified or canceled while fulfillment is in progress.</td>
</tr>
<tr>
<td></td>
<td>• false: Point of no return for the order has not been reached. The order can be modified or canceled.</td>
</tr>
<tr>
<td>relatedParty</td>
<td>Array of objects that describe the role linked to an OrderLineItemContact. Data type: Array</td>
</tr>
<tr>
<td>relatedParty.id</td>
<td>Sys_id of the account or customer contact associated with the order. Located in the account [customer_account], contact [customer_contact], or Order line item contact [sn_ind_tmt_orm_order_line_item_contact] table. Data type: String</td>
</tr>
<tr>
<td>relatedParty.name</td>
<td>Name of the account or customer. Data type: String</td>
</tr>
</tbody>
</table>

Example: cURL request

The following example shows how to specify a service order to retrieve data.

curl
  "https://instance.service-now.com/api/sn_ind_tmt_orm/serviceorder/5e3dee59db74f0504ae3c9db13961944" \
  --request GET \
  --header "Accept:application/json" \
  --user 'username':'password'

The response body provides details of the specified service order.

```json

Service Order Open – POST sn_ind_tmt_orm/serviceorder

Enables creating, updating, or deleting a customer order or customer order line item for service orders.

Use this API to create, update, or disconnect a customer order.

When an add action is received and accepted, a new record is created in the following tables:

- Order [sn_ind_tmt_orm_order]
- Order Line Item [sn_ind_tmt_orm_order_line_item]
- Order Characteristic Value [sn_ind_tmt_orm_order_order_characteristic_value]
- Order Line Item Contact [sn_ind_tmt_orm_order_line_item_line_item_contact]

URL format

/api/sn_ind_tmt_orm/serviceorder

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
</tbody>
</table>
| 201         | Successful. If there are any issues with the characteristics or characteristics option information, the endpoint stores the following comments in the work notes fields of the associated Customer Order Line Item record:  
  - The following Order Item characteristics does not exist: Review specification `<specification.name>` and correct the characteristic and characteristic option in the order line item prior to approving the order.  
  - Order Item characteristic: `<characteristic.name>` with characteristic value: `<characteristic.value>` is invalid. Correct the characteristic values before approving the order. |
| 400         | Bad Request. Could be any of the following reasons:  
  - Invalid payload: Request body missing. - Payload was not passed in the request body.  
  - Invalid payload: serviceOrderItem missing. - Service order line item object or JSON is missing.  
  - Invalid payload: serviceOrderItem ID is missing. – The ID is missing from the service order line item.  
  - Invalid payload: serviceOrderItem action is missing. – The service object or JSON is missing from the payload.  
  - Invalid payload: serviceOrderItem service is missing. – The service property is missing from the service order line item. |
### Status codes (continued)

**Example: cURL request**

The following example shows how to create a customer service order.

```bash
curl "https://instance.service-now.com/api/sn_ind_tmt_orm/serviceorder" \
  --request POST \
  --header "Accept: application/json" \
  --header "Content-Type: application/json" \
  --data "{
    "externalId": "BSS748",
    "requestedStartDate": "2018-01-15T09:37:40.508Z",
    "requestedCompletionDate": "2018-01-15T09:37:40.508Z",
    "@type": "ServiceOrder"
  }"
```
"note": [
  {
    "text": "This is a TMF service order illustration"
  },
  {
    "text": "This is a TMF service order illustration no 2"
  }
],
"serviceOrderItem": [
  {
    "id": "100",
    "action": "add",
    "@type": "ServiceOrderItem",
    "service": {
      "@type": "CFS",
      "serviceCharacteristic": [
        {
          "name": "Firewall Security",
          "value": "Standard"
        },
        {
          "name": "Firewall coverage",
          "value": "Premium(Up to 50 sites)"
        },
        {
          "name": "Administration Support",
          "value": "Basic( Customer Managed)"
        }
      ],
      "serviceSpecification": {
        "id": "f99546ff07266010a7955b7e0ad300a8",

```
SG Services API

Creates and manages application services and upstream relationships between them.

Request apps on the Store

Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store. For cumulative release notes information for all released apps, see the ServiceNow Store version history release notes.

This API can only be used when the CMDB Application API and CLI (sn_service_graph) plugin is activated. This API is used within the sn_service_graph namespace.

Using this API does not require details regarding source tables or relationship types.

To script critical operations which support automation across the enterprise, you can leverage APIs or run command line operations that the CMDB Application CLI and API store app provide instead of using the user interface. The CMDB Application CLI and API store app provides a robust framework
which consolidates all the APIs that are related to application services and the command lines that let you access the interface to those APIs.

CMDB Application CLI and API commands enable the following tasks:

• Registering and creating an application service and establishing upstream relationships
• Getting details of a given application service and its upstream relationships
• Connecting higher level constructs such as business applications and business service offerings
• Populating an application service with a given population type
• Changing the state of an application service

For the command line solution, see CMDB Application CLI and API available commands.

**SG Services – POST – `/sg_services/app_service/convert`**

Converts a manual or empty type application service to a calculated application service. During conversion, the application service record moves into the `[cmdb_ci_service_calculated]` table with the newly assigned class.

The following properties for identifying a CI take precedence as follows:

1. `sys_id` – If `sys_id`, the system only uses the `sys_id` and ignores any additional values.
2. `number` – If provided without the `sys_id`, the system only uses the number and ignores any additional values.
3. `<IRE field name>` – The system only uses these values if the `sys_id` or `number` are not provided.

**URL format**

Versioned URL: `/api/sn_service_graph/{api_version}/sg_services/app_service/convert`

Default URL: `/api/sn_service_graph/sg_services/app_service/convert`
Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Request body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;IRE field name&gt;</td>
<td>One or more IRE fields identifying the application service. For example, name or version.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>levels</td>
<td>Number of levels to include in the conversion.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>number</td>
<td>Unique number that identifies the application service.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the application service listed in the Application Service [cmdb_ci_service_auto] table.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports application/json.</td>
</tr>
</tbody>
</table>

### Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or the user does not have the app_service_admin role.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>status</td>
<td>Indicates success or failure. Data type: String</td>
</tr>
</tbody>
</table>

### Example: cURL request

The following example shows how to convert an application service type.

```bash
curl
"https://instance.service-now.com/api/sn_service_graph/sg_services/app_service/convert"
--request POST
```
--header "Accept:application/json" \
--header "Content-Type:application/json" \
--data "{
  "name": "Test Register",
  "environment": "Test",
  "version": "1.0",
  "levels": 8
}" \
--user 'username':'password'

Results indicating a successful conversion to a calculated application service.

```
{
  "result": {
    "status": "success"
  }
}
```

SG Services – POST – /sg_services/app_service/delete

Deletes an application service.

The following properties for identifying a CI take precedence as follows:

1. sys_id – If sys_id, the system only uses the sys_id and ignores any additional values.
2. number – If provided without the sys_id, the system only uses the number and ignores any additional values.
3. <IRE field name> – The system only uses these values if the sys_id or number are not provided.

URL format

Versioned URL: /api/sn_service_graph/{api_version}/sg_services/app_service/delete

Default URL: /api/sn_service_graph/sg_services/app_service/delete

Supported request parameters

<table>
<thead>
<tr>
<th>Path parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
</tbody>
</table>
Path parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Request body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;IRE field name&gt;</td>
<td>One or more IRE fields identifying the application service. For example, name or version. Data type: String</td>
</tr>
<tr>
<td>number</td>
<td>Unique number that identifies the application service. Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the application service listed in the Application Service [cmdb_ci_service_auto] table. Data type: String</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports application/json.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or the user does not have the app_service_admin role.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>status</td>
<td>Indicates success or failure. Data type: String</td>
</tr>
</tbody>
</table>

Example: cURL request

The following example shows how to delete an application service.

curl "https://instance.service-now.com/api/sn_service_graph/sg_services/app_service/delete"
   --request POST
   --header "Accept:application/json"
   --header "Content-Type:application/json"
   --data "{
       "name": "Test Register",
       "environment": "Test",
       "version": "1.0"
   }"
   --user 'username': 'password'

Results indicating a successful removal of an application service.

{ "result": { |
SG Services – POST – /sg_services/app_service/find

Finds the details of a given application service and its upstream relationships.

Users with the app_service_user role can use this API, but results are restricted to application services in Operational status. The app_service_admin role provides unlimited viewing of application services.

The following properties for identifying a CI take precedence as follows:

1. sys_id – If sys_id, the system only uses the sys_id and ignores any additional values.
2. number – If provided without the sys_id, the system only uses the number and ignores any additional values.
3. <IRE field name> – The system only uses these values if the sys_id or number are not provided.

**URL format**

Versioned URL: /api/sn_service_graph/{api_version}/sg_services/app_service/find

Default URL: /api/sn_service_graph/sg_services/app_service/find

**Supported request parameters**

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Request body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;IRE fields&gt;</td>
<td>One or more IRE fields identifying the application service. For example, name or version.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>number</td>
<td>Unique number that identifies the application service.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the application service listed in the Application Service [cmdb_ci_service_auto] table.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

<td>&quot;relationship&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>]</td>
</tr>
<tr>
<td>relationships.class_name</td>
<td>Name of the class that contains the application service.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>relationships.name</td>
<td>Name of the relationship.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>relationships.number</td>
<td>Unique number of the relationship.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>relationships.relationship</td>
<td>The relationship rule.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>relationships.sys_id</td>
<td>Sys_id of the relationship.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the application service listed in the Application Service [cmdb_ci_service_auto] table.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

**Example: cURL request**

The following example shows how to find details of an application service.

```
curl "https://instance.service-now.com/api/sn_service_graph/sg_services/app_service/find" \
--request POST \ 
--header "Accept:application/json" \ 
--header "Content-Type:application/json" \ 
--data "{
   "name": "Test App Service1"
}" \ 
--user 'username':'password'
```

The response body includes the application service and relationship information.

```json
{
   "result": {
      "aliases": null,
      "asset": null,
      "asset_tag": null,
      "assigned": "",
      "assigned_to": null,
      "assignment_group": null,
      "attestation_score": null,
      "attested": "0",
      "attested_by": null,
```

SG Services – POST – /sg_services/app_service/populate

Populates an application service with a service population method.

The following properties for identifying a CI take precedence as follows:

- **Name**
- **System ID**
- **Number**
- **Class Name**
- **Relationship**
1. sys_id – If sys_id, the system only uses the sys_id and ignores any additional values.
2. number – If provided without the sys_id, the system only uses the number and ignores any additional values.
3. <IRE field name> – The system only uses these values if the sys_id or number are not provided.

**URL format**

Versioned URL: /api/sn_service_graph/{api_version}/sg_services/app_service/populate

Default URL: /api/sn_service_graph/sg_services/app_service/populate

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Request body parameters (JSON)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;IRE field name&gt;</td>
<td>One or more IRE fields identifying the application service. For example, name or version. Data type: String</td>

</tbody>
</table>

**Example: cURL request**

The following example shows how to populate an application service with a dynamic_service type.

```bash
curl
  "https://instance.service-now.com/api/sn_service_graph/sg_services/app_service/populate" \
  --request POST \
  --header "Accept:application/json" \
  --header "Content-Type:application/json" \
  --data "{
    "name": "Test Register",
    "environment": "Test",
    "version": "1.0",
  }"

  \"population_method\": {  
    \"type\": \"dynamic_service\",
    \"levels\": 8
  }"

  --user 'username': 'password'
```

Results indicating a successful population of an application service.

```json
{
  "result": {
    "status": "success"
  }
}
```

**SG Services – POST – /sg_services/app_service/register**

Creates an application service, tags and constructs upstream relationships such as business applications, business service offerings, and other application services.

The following properties for identifying a CI take precedence as follows:
1. sys_id – If sys_id, the system only uses the sys_id and ignores any additional values.
2. number – If provided without the sys_id, the system only uses the number and ignores any additional values.
3. <IRE field name> – The system only uses these values if the sys_id or number are not provided.

**URL format**

Versioned URL: `/api/sn_service_graph/{api_version}/sg_services/app_service/register`

Default URL: `/api/sn_service_graph/sg_services/app_service/register`

**Supported request parameters**

**Path parameters**

  }
}
```

**SG Services – POST – /sg_services/app_service/relationship/create**

Constructs upstream relations such as business applications, business service offerings, and other application services.

This API creates a relationship, taking input with a single parent and a corresponding child object.

The following properties for identifying a CI take precedence as follows:

1. sys_id – If sys_id, the system only uses the sys_id and ignores any additional values.
2. number – If provided without the sys_id, the system only uses the number and ignores any additional values.
3. <IRE field name> – The system only uses these values if the sys_id or number are not provided.

**URL format**

*Versioned URL:* /api/sn_service_graph/{api_version}/sg_services/app_service/relationship/create

*Default URL:* /api/sn_service_graph/sg_services/app_service/relationship/create
Supported request parameters

Example: cURL request

The following example shows how create a relationship from an application service.

```c
curl  
"https://instance.service-now.com/api/sn_service_graph/sg_services/app_service/relationship/create"  
--request POST  
--header "Accept:application/json"  
--header "Content-Type:application/json"  
--data 
"{  
"child": {  
"name": "wdfsdf",  
"environment": "Test",  
"version": "1.0"  
},  
"parent": {  
"sys_id": "abcdefg",  
"name": "business App1",  
"class_name": "service_offering" 
} 
}"  
--user 'username':'password'
```

Results indicating a successful creation of an application service relationship.

```
{
  "result": {
    "status": "success"
  }
}
```

**SG Services – POST – /sg_services/app_service/relationship/delete**

Deletes an application service upstream relationship.

The following properties for identifying a CI take precedence as follows:

1. `sys_id` – If `sys_id`, the system only uses the `sys_id` and ignores any additional values.
2. `number` – If provided without the `sys_id`, the system only uses the number and ignores any additional values.
3. `<IRE field name>` – The system only uses these values if the `sys_id` or number are not provided.

**URL format**

*Versioned URL:* `/api/sn_service_graph/{api_version}/sg_services/app_service/relationship/delete`

*Default URL:* `/api/sn_service_graph/sg_services/app_service/relationship/delete`

**Supported request parameters**

curl "https://instance.service-now.com/api/sn_service_graph/sg_services/app_service/state"
  \   
  --request POST \
  --header "Accept:application/json" \
  --header "Content-Type:application/json" \
  --data "{
   \"name\": \"Test Register\",\n   \"environment\": \"Test\",\n   \"version\": \"1.0\",\n   \"state\": \"activate\"
   }
} \
--user 'username':'password'

Results indicating a successful operation.

{
  "result": {
    "status": "success"
  }
}

SG Services – POST – /sg_services/app_service/update

Updates an existing application service provided and creates tags for the given application service.

The following properties for identifying a CI take precedence as follows:

1. sys_id – If sys_id, the system only uses the sys_id and ignores any additional values.
2. number – If provided without the sys_id, the system only uses the number and ignores any additional values.
3. <IRE field name> – The system only uses these values if the sys_id or number are not provided.

URL format

Versioned URL: /api/sn_service_graph/{api_version}/sg_services/app_service/update
Default URL: /api/sn_service_graph/sq_services/app_service/update

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>

Request body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;fields or tags to update&gt;</td>
<td>Use key-value pairs to identify each field or tag to be updated. Only basic information can be updated, no upstream relationships can be updated. Data type: String</td>
</tr>
<tr>
<td>&lt;IRE field name&gt;</td>
<td>One or more IRE fields identifying the application service. For example, name or version. You can send the sys_id, number or IRE to identify an application service; however, none of these fields can be updated when used as an identifier. To update the IRE fields, input should include the sys_id or number as an identifier. Data type: String</td>
</tr>
<tr>
<td>number</td>
<td>Unique number that identifies the application service. Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the application service listed in the Application Service [cmdb_ci_service_auto] table. Data type: String</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports application/json.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or the user does not have the app_service_admin role.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;IRE field name&gt;</td>
<td>One or more IRE fields identifying the application service. For example, name or version. Data type: String</td>
</tr>
<tr>
<td>number</td>
<td>Unique number that identifies the application service. Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the application service listed in the Application Service [cmdb_ci_service_auto] table.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>&lt;updated fields&gt;</td>
<td>If the update is successful, each modified field sent in the payload is listed in the response body.</td>
</tr>
</tbody>
</table>

**Example: cURL request**

The following example shows how to update an application service, using name as an IRE field.

```bash
curl "https://instance.service-now.com/api/sn_service_graph/sg_services/app_service/update"
  
--request POST 
--header "Accept:application/json"
--header "Content-Type:application/json"
--data "{
   
   
   "name": "Test Register",
   "environment": "Test",
   "version": "1.0"
   
   }
   
--user 'username':'password'
```

Response includes application service identification information and updated fields.

```json
{  
"result": {  
  "sys_id": "123456",
  "number": "SVCKji0w9e",
  "name": "Test Register",
  "environment": "Test",
  "version": "1.0"
}
}
```

**Syntax Editor API**

The Syntax Editor API enables you to access context menu options in the JavaScript syntax editor. Use this API to retrieve type definitions for script includes, find references to script includes or tables, and retrieve a list of cached tokens.

For more information about the syntax editor, see JavaScript syntax editor.
This API is available by default.

**Syntax Editor - GET /syntax_editor/cache/{token_type}**
Retrieves a list of cached tokens by token type.

**URL format**

Versioned URL: /api/now/{api_version}/syntax_editor/cache/{token_type}
Default URL: /api/now/syntax_editor/cache/{token_type}

**Supported request parameters**

<table>
<thead>
<tr>
<th>Path parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
</tr>
<tr>
<td>api_version</td>
</tr>
</tbody>
</table>
| token_type | Type of token. Valid values:  
- sys_db_object. The table containing a record of each table in the database.  
- sys_script_include. The table containing script includes. Data type: String |

<table>
<thead>
<tr>
<th>Query parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
</tr>
<tr>
<td>name</td>
</tr>
</tbody>
</table>

**Request body parameters (XML or JSON)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>Result of the request. An object containing the flush time for the cache, and a list of cached tokens based on the requested token type. The token type can be either sys_script_include or sys_db_object.</td>
</tr>
</tbody>
</table>

```json
"result": {
  "flushTime": Number,
```

</tr>
<tr>
<td>Data type: Object</td>
<td></td>
</tr>
</tbody>
</table>
| result.flushTime | Time since the cache was last flushed.  
Data type: Number  
Unit: milliseconds  |
| result.sys_script_include | List of all the cached script includes. Each list item has the name of the script include and its sys_id.  
"sys_script_include": {  
  <name>: <sys_id>  
}  
Data type: Object | |
| result.sys_script_include.<name> | Name of the script include and its sys_id.  
Data type: String | |
| result.sys_db_object | List of all the cached database objects. Each list item has the name of the database object and a Boolean indicating whether it's cached.  
"sys_db_object": {  
  <name>: Boolean  
}  
Data type: Object | |
| result.sys_db_object.<name> | Name of the database object with a flag indicating whether it's cached.  
Possible values:  
• true. The object is cached.  
• false. The object is not cached.  
Data type: Boolean | |

**Example: cURL request**

This example retrieves a list of cached tokens with a sys_script_include token type.
curl "https://instance.servicenow.com/api/now/syntax_editor/cache/sys_script_include" \
--request GET \n--header "Accept:application/json" \n--user 'username':'password'

{
    "result": {

</tr>
</tbody>
</table>

**Example: cURL request**

This example searches the sys_script_include table for all references to the ListFinder script include.

```bash
curl "https://instance.servicenow.com/api/now/syntax_editor/getReferences" \
   --request POST \
   --header "Accept:application/json" \
   --header "Content-Type:application/json" \
   --data "{
   "searchWord":"ListFinder",
   "searchWordType":"script_include",
   "searchTables":["sys_script_include"]
}" \
   --user 'username':'password
```

```json
{
   "result":{
      {
         "name":"SysList",
         "sysId":"7d8f32c3c0a8016400e609be97b11s98",
         "tableName": "sys_script_include",
         "tableDisplayName": "Script Include",
         "applicationLabel": "Global",
         "fields":{
```

Syntax Editor - POST /syntax_editor/intellisense/{tableName}

Returns the type definition for a script include.

**URL format**

Versioned URL: /api/now/{api_version}/syntax_editor/intellisense/{tableName}

Default URL: /api/now/syntax_editor/intellisense/{tableName}

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>tableName</td>
<td>Name of the table that contains the script includes, such as sys_script_include. Data type: String</td>
</tr>
</tbody>
</table>
### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scriptIncludes</td>
<td>Required. List of sys_ids for the script includes. For example, a list of sys_ids from the Script Includes [sys_script_include] table. Data type: Array</td>
</tr>
</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see [Supported REST API headers](#)

#### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

#### Response headers

</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#)
### Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>Key/value pairs for each script include. The key is the sys_id of the script include. The value is the type definition. Both the key and value are strings.</td>
</tr>
<tr>
<td>result.&lt;sys_id&gt;</td>
<td>The script include, identified by its sys_id, followed by its type definition.</td>
</tr>
</tbody>
</table>

Data type: String

Example: cURL request

This example retrieves the type definition for two script includes.

```bash
curl "https://instance.servicenow.com/api/now/syntax_editor/intellisense/sys_script_include" \
   --request POST \
   --header "Accept:application/json" \
   --header "Content-Type:application/json" \
   --data "{
   "scriptIncludes": [
    "8e7bfa6c0a8002700f0e559b09de474",
    "b1ed0f5c3b23300daa79624a1d3ae0b"
   ]
}
   --user 'username':'password'
```

```json
| "result": { |
```
Table API

The Table API allows you to perform create, read, update, and delete (CRUD) operations on existing tables.

**Table - DELETE /now/table/{tableName}/{sys_id}**

Deletes the specified record from the specified table.

**URL format**

Versioned URL: /api/now/{api_version}/table/{tableName}/{sys_id}

Default URL: /api/now/table/{tableName}/{sys_id}

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the record to delete. Data type: String</td>
</tr>
<tr>
<td>tableName</td>
<td>Name of the table from which to delete the specified record, such as &quot;incident&quot; or &quot;asset&quot;. Data type: String</td>
</tr>
</tbody>
</table>
### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| sysparm_query_no_domain     | Flag that indicates whether to restrict the record search to only the domains for which the logged in user is configured. Valid values:  
  - false: Exclude the record if it is in a domain that the currently logged in user is not configured to access.  
  - true: Include the record even if it is in a domain that the currently logged in user is not configured to access.  
  Data type: Boolean  
  Default: false |

**Note:** The `sysparm_query_no_domain` parameter is available only to system administrators or users who have the `query_no_domain_table_api` role.

### Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see [Supported REST API headers](#).

### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
</table>
| Accept | Data format of the response body. Supported types: `application/json`  
  Of `application/xml`.  
  Default: `application/json` |
Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>204</td>
<td>Indicates that the request completed successfully.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Example: cURL request

Delete a record from the Incident table.

```bash
curl "https://instance.servicenow.com/api/now/table/incident/d977b66a4f411200adf9f8e18110c7b2" \
--request DELETE \
--header "Accept:application/json" \
--user 'username':'password'
```

There is no response body.

None

Example: Python request

Delete a record from the Incident table.

```python
# Need to install requests package for python
import requests

# Set the request parameters
```
url =
'https://instance.servicenow.com/api/now/table/incident/d977b66a4f411200adf9f8e18110c7b2'

# Eg. User name="username", Password="password" for this code sample.
user = 'username'
pwd = 'password'

# Set proper headers
headers = {'Accept':"application/json"}

# Do the HTTP request
response = requests.delete(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 204
if response.status_code != 204:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:',
    response.json())
    exit()

# Decode the JSON response into a dictionary and use the data
data = response.json()
print(data)

There is no response body.

None

Table - GET /now/table/{tableName}

Retrieves multiple records for the specified table.

For basic instructions, see Retrieve existing incidents.

URL format

Versioned URL: /api/now/{api_version}/table/{tableName}
Default URL: /api/now/table/{tableName}
## Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| api_version    | Optional. Version of the endpoint to access. For example, `v1` or `v2`. Only specify this value to use an endpoint version other than the latest. Depending on the version, this endpoint returns different results on a valid query.  
  • Version 1 returns error code 404 with no results.  
  • Version 2 returns success code 200 and an empty array as the response body.                                                                 |
|                | Data type: String                                                                                                                                                                                            |
| tableName      | Name of the table from which to retrieve the records.                                                                                                                                                        |
|                | Data type: String                                                                                                                                                                                            |

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| name-value pairs | Name-value pairs to use to filter the result set. This parameter is mutually exclusive with `sysparm_query`. For example, instead of using `&sysparm_query=active=true`, you can simplify the calling statement by using `&active=true`.  
  Based on this value, retrieves the display value and/or the actual value from the database.  
  • true: Returns the display values for all fields.  
  • false: Returns the actual values from the database.  
  • all: Returns both actual and display values.                                                                                             |
|                | Data type: String                                                                                                                                                                                            |
| sysparm_display_value | Data retrieval operation for reference and choice fields. Based on this value, retrieves the display value and/or the actual value from the database.                                                                 |
|                | Data type: String                                                                                                                                                                                            |
### Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| sysparm_exclude_reference_link | Flag that indicates whether to exclude Table API links for reference fields.  
Valid values:  
- true: Exclude Table API links for reference fields.  
- false: Include Table API links for reference fields.  
Data type: Boolean  
Default: false |
| sysparm_fields              | Comma-separated list of fields to return in the response.  
Data type: String |
| sysparm_limit               | Maximum number of records to return. For requests that exceed this number of records, use the **sysparm_offset** parameter to paginate record retrieval.  
This limit is applied before ACL evaluation. If no records you have access to return, rearrange the record order so records you have access to return first.  
⚠️ **Note:** Unusually large **sysparm_limit** values can impact system performance.  
Data type: Number  
Default: 1000 |
| sysparm_no_count            | Flag that indicates whether to execute a `select count(*)` query on the table to return the number of rows in the associated table.  
Valid values:  
- true: Do not execute a `select count(*)`.  
- false: Execute a `select count(*)`.  
Data type: Boolean  
Default: false |

Note: There is no preferred method for setting the `sysparm_no_count` parameter. Specifying the display value may cause performance issues since it is not reading directly from the database and may include referencing other fields and records. For more information on display values and actual values, see Table API FAQs (KB0534905).
## Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sysparm_offset</code></td>
<td>Starting record index for which to begin retrieving records. This functionality enables you to paginate record retrieval. This functionality enables the retrieval of all records, regardless of the number of records, in small manageable chunks. For example, the first time you call this endpoint, <code>sysparm_offset</code> is set to &quot;0&quot;. To simply page through all available records, use <code>sysparm_offset=sysparm_offset+sysparm_limit</code>, until you reach the end of all records. Do not pass a negative number in the <code>sysparm_offset</code>. Data type: Number Default: 0</td>
</tr>
</tbody>
</table>
| `sysparm_query`       | Encoded query used to filter the result set. Syntax: `sysparm_query=<col_name><operator><value>`.  
  • `<col_name>`: Name of the table column to filter against.  
  • `<operator>`: Supports the following values:  
    - `=`: Exactly matches `<value>`.  
    - `!`: Does not match `<value>`.  
    - `^`: Logically AND multiple query statements.  
    - `^OR`: Logically OR multiple query statements.  
    - `LIKE`: `<col_name>` contains the specified string. Only works for `<col_name>` fields whose data type is string.  
    - `STARTSWITH`: `<col_name>` starts with the specified string. Only works for `<col_name>` fields whose data type is string.  
    - `ENDSWITH`: `<col_name>` ends with the specified string. Only works for `<col_name>` fields whose data type is string.  
  `<value>`: Value to match against. All parameters are case-sensitive. Queries can contain more than one entry, such as `sysparm_query=<col_name><operator><value>[<operator><col_name><operator><value>]`. For example:  
  ```javascript
  (sysparm_query=caller_id=javascript:gs.getUserID()^active=true)
  ```  
  Encoded queries also supports order by functionality. To sort responses based on certain fields, use the `ORDERBY` and `ORDERBYDESC` clauses. |
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Syntax:</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>For example: sysparm_query=active=true^ORDERBYnumber^ORDERBYDESCcategory</td>
</tr>
<tr>
<td></td>
<td>This query filters all active records and orders the results in ascending order by number, and then in descending order by category.</td>
</tr>
<tr>
<td></td>
<td>If part of the query is invalid, such as by specifying an invalid field name, the instance ignores the invalid part. It then returns rows using only the valid portion of the query. You can control this behavior using the glide.invalid_query.returns_no_rows property. Set this property to true to return no rows on an invalid query.</td>
</tr>
<tr>
<td></td>
<td>Note: The glide.invalid_query.returns_no_rows property controls the behavior of all queries across the instance, GlideRecord.query(), and web service APIs.</td>
</tr>
</tbody>
</table>

Data type: String

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_query_category</td>
<td>Name of the category to use for queries.</td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_query_no_domain</td>
<td>Flag that indicates whether to restrict the record search to only the domains for which the logged in user is configured. Valid values: false: Exclude the record if it is in a domain that the user is not configured to access. true: Include the record even if it is in a domain that the user is not configured to access.</td>
</tr>
<tr>
<td>Data type: Boolean</td>
<td></td>
</tr>
<tr>
<td>Default: false</td>
<td></td>
</tr>
</tbody>
</table>

Note: The sysparm_query_no_domain parameter is available only to system administrators or users who have the query_no_domain_table_api role.
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| sysparm_suppress_pagination_header          | Flag that indicates whether to remove the Link header from the response. The Link header provides various URLs to relative pages in the record set which you can use to paginate the returned record set.  
Valid values:  
• true: Remove the Link header from the response.  
• false: Do not remove the Link header from the response.  
Data type: Boolean  
Default: false |
| sysparm_view                                 | UI view for which to render the data. Determines the fields returned in the response.  
Valid values:  
• desktop  
• mobile  
• both  
If you also specify the `sysparm_fields` parameter, it takes precedence.  
Data type: String |

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

### Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Link</td>
<td>Relative URLs, based on the previous request, that you can use to page through the available record set. For example:</td>
</tr>
<tr>
<td></td>
<td>https://&lt;instance name&gt;.servicenow.com/api/now/table/cmdb_ci?sysparm_offset=40&amp;sysparm_limit=10000&gt;;rel=&quot;next&quot;,</td>
</tr>
<tr>
<td></td>
<td>https://&lt;instance name&gt;.servicenow.com/api/now/table/cmdb_ci?sysparm_offset=40&amp;sysparm_limit=10000&gt;;rel=&quot;prev&quot;,</td>
</tr>
<tr>
<td></td>
<td>https://&lt;instance name&gt;.servicenow.com/api/now/table/cmdb_ci?sysparm_offset=0&amp;sysparm_limit=10000&gt;;rel=&quot;first&quot;,</td>
</tr>
<tr>
<td></td>
<td>https://&lt;instance name&gt;.servicenow.com/api/now/table/cmdb_ci?sysparm_offset=2780&amp;sysparm_limit=10000&gt;;rel=&quot;last&quot;</td>
</tr>
<tr>
<td></td>
<td>For additional information on the rel parameter, refer to <a href="https://html.spec.whatwg.org/multipage/links.html#linkTypes">https://html.spec.whatwg.org/multipage/links.html#linkTypes</a>.</td>
</tr>
<tr>
<td>X-Total-Count</td>
<td>Total count of records returned by the query.</td>
</tr>
</tbody>
</table>

### Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](https://service-now.com).

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Request completed successfully. If a valid query returned no results, the response body contains only an empty result array.</td>
</tr>
</tbody>
</table>
Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name-value pairs</td>
<td>Field names and values of all parameters within the specified record or those specified in the query parameters.</td>
</tr>
</tbody>
</table>

Example: cURL request

Retrieve the first record from the Problem table.

```
curl "https://instance.servicenow.com/api/now/table/problem?sysparm_limit=1" \
--request GET \
--header "Accept:application/json" \
--user 'username':'password'
```

The response contains the name-value pairs for the requested record.

```
{
    "result": [ 
        {

Example: Python request
Retrieve the first record from the Problem table.

```python
# Need to install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/now/table/problem?sysparm_limit=1'

# Eg. User name="username", Password="password" for this code sample.
user = 'username'
pwd = 'password'

# Set proper headers
headers = {'Accept':"application/xml"}

# Do the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)
```

The response contains the name-value pairs for the requested record.

Table - GET /now/table/{tableName}/{sys_id}

Retrieves the record identified by the specified sys_id from the specified table.

**URL format**

Versioned URL: /api/now/{api_version}/table/{tableName}/{sys_id}

Default URL: /api/now/table/{tableName}/{sys_id}

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the record to retrieve.</td>
</tr>
<tr>
<td>tableName</td>
<td>Name of the table from which to retrieve the record.</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_display_value</td>
<td>Data retrieval operation for reference and choice fields. Based on this value, retrieves the display value and/or the actual value from the database.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td></td>
<td>Valid values: ____________________________________________________________________________</td>
</tr>
</tbody>
</table>
### Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_exclude_reference_link</td>
<td>Flag that indicates whether to exclude Table API links for reference fields.</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Exclude Table API links for reference fields.</td>
</tr>
<tr>
<td></td>
<td>• false: Include Table API links for reference fields.</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
<tr>
<td></td>
<td>Default: false</td>
</tr>
<tr>
<td>sysparm_fields</td>
<td>Comma-separated list of fields to return in the response.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>sysparm_query_no_domain</td>
<td>Flag that indicates whether to restrict the record search to only the</td>
</tr>
<tr>
<td></td>
<td>domains for which the logged in user is configured.</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
</tbody>
</table>

Note: There is no preferred method for setting this parameter. However, specifying the display value may cause performance issues since it is not reading directly from the database and may include referencing other fields and records. For more information on display values and actual values, see Table API FAQs (KB0534905).
**Query parameters (continued)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Headers**

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>404</td>
<td>Not found. The requested item was not found.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name-value pairs</td>
<td>Field names and values of all parameters within the specified record or those specified in the query parameters.</td>
</tr>
</tbody>
</table>

Example: cURL request

Retrieve a record from the Incident table.

curl
  "https://instance.servicenow.com/api/now/table/incident/a9e30c7dc61122760116894de7bcc7bd"
  --request GET
  --header "Accept:application/json"
  --user 'username':'password"
The response contains the name-value pairs for the requested record.

```json
{
    "result": {
        "upon_approval": "",
        "location": {
            "link": "https://instance.servicenow.com/api/now/table/cmn_location/105cf7f3c611227501e75e08b14a38ba",

Example: Python request

Retrieve the first record from the Incident table.

```python
# Need to install requests package for python
import requests

# Set the request parameters
url =
'https://instance.servicenow.com/api/now/table/incident/a9e30c7dc61122760116894de7bdc7bd'

# Eg. User name="username", Password="password" for this code sample.
user = 'username'
pwd = 'password'
```
# Set proper headers
headers = {'Accept': 'application/xml'}
# Do the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)
# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.content)
    exit()
# Decode the XML response into a dictionary and use the data
print(response.content)
The response contains the name-value pairs for the requested record.

<?xml version="1.0" encoding="UTF-8"?>
<response>
    <result>
        <upon_approval />
        <location>
            <link>https://instance.servicenow.com/api/now/table/cmn_location/105cf7f3c611227501e75e08b14a38ba</link>
            <value>105cf7f3c611227501e75e08b14a38ba</value>
        </location>
        <expected_start />
        <reopen_count />
        <close_notes />

        <impact>1</impact>
        <urgency>3</urgency>
        <correlation_id />
        <priority>3</priority>
        <sys_tags />
        <sys_domain>
            <link>https://instance.servicenow.com/api/now/table/sys_user_group/global</link>
            <value>global</value>
        </sys_domain>
        <description />
        <group_list />
        <delivery_plan />
        <sys_mod_count>4</sys_mod_count>
    </result>
</response>
Table - PATCH /now/table/{tableName}/{sys_id}
Updates the specified record with the name-value pairs included in the request body.

**URL format**

Versioned URL: /api/now/{api_version}/table/{tableName}/{sys_id}
Default URL: /api/now/table/{tableName}/{sys_id}

**Supported request parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the record to update.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>tableName</td>
<td>Name of the table in which the specified record is located.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_display_value</td>
<td>Data retrieval operation for reference and choice fields. Based on this value, retrieves the display value and/or the actual value from the database.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
</tbody>
</table>
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• true: Returns the display values for all fields.</td>
</tr>
<tr>
<td></td>
<td>• false: Returns the actual values from the database.</td>
</tr>
<tr>
<td></td>
<td>• all: Returns both actual and display values.</td>
</tr>
<tr>
<td></td>

Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_query_no_domain</td>
<td>Flag that indicates whether to restrict the record search to only the domains for which the logged in user is configured.</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• false: Exclude the record if it is in a domain that the currently logged in user is not configured to access.</td>
</tr>
<tr>
<td></td>
<td>• true: Include the record even if it is in a domain that the currently logged in user is not configured to access.</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
<tr>
<td></td>
<td>Default: false</td>
</tr>
</tbody>
</table>

Note:
- If this parameter is set to true, pay attention to input values, especially date values, as these are interpreted as being supplied via the user time zone preference and are transformed into UTC format.
- To set the value of an encrypted field, you must set this parameter to true. If this parameter is not set to true, values submitted to encrypted fields are not saved. Additionally, the requesting user must have the appropriate encryption context prior to submitting the request. Encrypted fields are hidden for users without the appropriate encryption context. For more information on display values and actual values, see Table API FAQs (KB0534905). For more information on field encryption see Encryption support.
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Note: The sysparm_query_no_domain parameter is available only to system administrators or users who have the query_no_domain_table_api role.</td>
<td></td>
</tr>
</tbody>
</table>
| sysparm_view          | UI view for which to render the data. Determines the fields returned in the response. Valid values:  
  • desktop  
  • mobile  
  • both  
  If you also specify the sysparm_fields parameter, it takes precedent.  
  Data type: String |

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| name-value pairs| Field name and the new value for each parameter to update in the specified record.  
  Note: All fields within a record may not be available for update. For example, fields that have a prefix of "sys_" are typically system parameters that are automatically generated and cannot be updated. |

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
<tr>
<td>X-no-response-body</td>
<td>By default, responses include body content detailing the modified record. Set this request header to true to suppress the response body.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Indicates that the request completed successfully.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name-value pairs</td>
<td>Field names and values of all parameters within the specified record or those specified in the query parameters.</td>
</tr>
</tbody>
</table>

Example: cURL request

Update a record in the Incident table.
The response contains the name-value pairs for the updated record.

Table - POST /now/table/{tableName}

Inserts one record in the specified table. Multiple record insertion is not supported by this method.

URL format

Versioned URL: /api/now/{api_version}/table/{tableName}
Default URL: /api/now/table/{tableName}
## Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>tableName</td>
<td>Name of the table in which to save the record.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_display_value</td>
<td>Data retrieval operation for reference and choice fields. No retrieval of display values required.</td>
</tr>
<tr>
<td></td>
<td>Based on this value, retrieves the display value and/or the actual value from the database.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Returns the display values for all fields.</td>
</tr>
<tr>
<td></td>
<td>• false: Returns the actual values from the database.</td>
</tr>
<tr>
<td></td>
<td>• all: Returns both actual and display values.</td>
</tr>
<tr>
<td></td>
<td>Default: false</td>
</tr>
</tbody>
</table>

**Note:** There is no preferred method for setting this parameter. However, specifying the display value may cause performance issues since it is not reading directly from the database and may include referencing other fields and records. For more information on display values and actual values, see Table API FAQs (KB0534905).
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_exclude_reference_link</td>
<td>Flag that indicates whether to exclude Table API links for reference fields.</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Exclude Table API links for reference fields.</td>
</tr>
<tr>
<td></td>
<td>• false: Include Table API links for reference fields.</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
<tr>
<td></td>
<td>Default: false</td>
</tr>
<tr>
<td>sysparm_fields</td>
<td>Comma-separated list of fields to return in the response.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>sysparm_input_display_value</td>
<td>Flag that indicates whether to set field values using the display value or</td>
</tr>
<tr>
<td></td>
<td>the actual value.</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Treats input values as display values and they are manipulated so</td>
</tr>
<tr>
<td></td>
<td>they can be stored properly in the database.</td>
</tr>
<tr>
<td></td>
<td>• false: Treats input values as actual values and stored them in the</td>
</tr>
<tr>
<td></td>
<td>database without manipulation.</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
<tr>
<td></td>
<td>Default: false</td>
</tr>
</tbody>
</table>
### Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| **sysparm_view** | UI view for which to render the data. Determines the fields returned in the response. Valid values:  
  - desktop  
  - mobile  
  - both  
  If you also specify the `sysparm_fields` parameter, it takes precedent.  
  Data type: String |

**Note:**

- If this parameter is set to `true`, pay attention to input values, especially date values, as these are interpreted as being supplied via the user time zone preference and are transformed into UTC format.

- To set the value of an encrypted field, you must set this parameter to `true`. If this parameter is not set to `true`, values submitted to encrypted fields are not saved. Additionally, the requesting user must have the appropriate encryption context prior to submitting the request. Encrypted fields are hidden for users without the appropriate encryption context. For more information on display values and actual values, see Table API FAQs (KB0534905). For more information on field encryption see Encryption support.
Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name-value pairs</td>
<td>Field name and the associated value for each parameter to define in the specified record.</td>
</tr>
</tbody>
</table>

**Note:** All fields within a record may not be available for update. For example, fields that have a prefix of "sys_" are typically system parameters that are automatically generated and cannot be updated.

Fields that are not specified and not auto generated by the system are set to the associated data type's null value.

**Headers**

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

**Request headers**

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
<tr>
<td>X-no-response-body</td>
<td>By default, responses include body content detailing the new record. Set this header to true in the request to suppress the response body.</td>
</tr>
</tbody>
</table>

**Response headers**

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Location</td>
<td>Location of the created resource.</td>
</tr>
</tbody>
</table>
Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>201</td>
<td>Indicates that the request completed successfully.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name-value pairs</td>
<td>Field names and values of all parameters within the newly created record or those specified in the query parameters.</td>
</tr>
</tbody>
</table>

Example: cURL request

Insert a new record into the Incident table.

curl "https://instance.servicenow.com/api/now/table/incident" \
    --request POST \
    --header "Accept:application/json" \
    --header "Content-Type:application/json" \
    --data "{"short_description":'Unable to connect to office wifi',
             "assignment_group":'287ebd7da9fe198100f92cc8d1d2154e',
             "urgency":'2',
             "impact":'2'}" \
    --user 'username':'password'

The response contains the name-value pairs for the new record.

```json

Example: Python request

Insert a new record into the Incident table.

# Need to install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/now/table/incident'

# Eg. User name="username", Password="password" for this code sample.
user = 'username'
pwd = 'password'

# Set proper headers
headers = {"Content-Type":"application/xml","Accept":"application/json"}

# Do the HTTP request
response = requests.post(url, auth=(user, pwd), headers=headers,
data="<request><entry><short_description>Unable to connect to office wifi</short_description><assignment_group>287ebd7da9fe198100f92cc8d1d2154e</assignment_group><urgency>2</urgency><impact>2</impact></entry></request>"
)

# Check for HTTP codes other than 201
if response.status_code != 201:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.json())
    exit()

# Decode the JSON response into a dictionary and use the data
data = response.json()
print(data)

The response contains the name-value pairs for the new record.

{ "result": { "upon_approval": "proceed", "location": "", "expected_start": "", "reopen_count": "0", "close_notes": "", "additional_assignee_list": "", "impact": "2", "urgency": "2", "correlation_id": "" }}
Table - PUT /now/table/{tableName}/{sys_id}
Updates the specified record with the request body.

**URL format**

Versioned URL: /api/now/{api_version}/table/{tableName}/{sys_id}
Default URL: /api/now/table/{tableName}/{sys_id}

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td>sys_id</td>
<td>Unique identifier of the record to update.</td>
</tr>
<tr>
<td>tableName</td>
<td>Name of the table in which the record is located.</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_display_value</td>
<td>Data retrieval operation for reference and choice fields. Based on this value, retrieves the display value and/or the actual value from the database.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Returns the display values for all fields.</td>
</tr>
<tr>
<td></td>
<td>• false: Returns the actual values from the database.</td>
</tr>
<tr>
<td></td>
<td>• all: Returns both actual and display values.</td>
</tr>
</tbody>
</table>
### Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_exclude_reference_link</td>
<td>Flag that indicates whether to exclude Table API links for reference fields.</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Exclude Table API links for reference fields.</td>
</tr>
<tr>
<td></td>
<td>• false: Include Table API links for reference fields.</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
<tr>
<td></td>
<td>Default: false</td>
</tr>
<tr>
<td>sysparm_fields</td>
<td>Comma-separated list of fields to return in the response.</td>
</tr>
<tr>
<td>sysparm_input_display_value</td>
<td>Flag that indicates whether to set field values using the display value or the actual value.</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Treats input values as display values and they are manipulated so they can be stored properly in the database.</td>
</tr>
<tr>
<td></td>
<td>• false: Treats input values as actual values and stored them in the database without manipulation.</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
</tbody>
</table>

**Note:** There is no preferred method for setting this parameter. However, specifying the display value may cause performance issues since it is not reading directly from the database and may include referencing other fields and records. For more information on display values and actual values, see [Table API FAQs (KB0534905)](KB0534905).
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_query_no_domain</td>
<td>Flag that indicates whether to restrict the record search to only the domains for which the logged in user is configured.</td>
</tr>
</tbody>
</table>

**Default**: false

**Note:**
- If this parameter is set to `true`, pay attention to input values, especially date values, as these are interpreted as being supplied via the user time zone preference and are transformed into UTC format.
- To set the value of an encrypted field, you must set this parameter to `true`. If this parameter is not set to `true`, values submitted to encrypted fields are not saved. Additionally, the requesting user must have the appropriate encryption context prior to submitting the request. Encrypted fields are hidden for users without the appropriate encryption context. For more information on display values and actual values, see Table API FAQs (KB0534905). For more information on field encryption see Encryption support.

Data type: Boolean

**Default**: false
### Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_view</td>
<td>UI view for which to render the data. Determines the fields returned in the response. Valid values: desktop, mobile, both. If you also specify the sysparm_fields parameter, it takes precedence. Data type: String</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> The <code>sysparm_query_no_domain</code> parameter is available only to system administrators or users who have the <code>query_no_domain_table_api</code> role.</td>
</tr>
</tbody>
</table>

### Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name-value pairs</td>
<td>Name-value pairs for the field(s) to update in the associated table. For example, to update the short description file, enter a name-value pair similar to the following: --data &quot;{&quot;&quot;short_description&quot;: &quot;my short desc&quot;}&quot; .</td>
</tr>
</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

#### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: <code>application/json</code> or <code>application/xml</code>.</td>
</tr>
</tbody>
</table>
Request headers (continued)

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default:</td>
<td>application/json</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Supported types: application/json or</td>
</tr>
<tr>
<td></td>
<td>application/xml.</td>
</tr>
<tr>
<td>X-no-response-</td>
<td>By default, responses include body content detailing the modified record.</td>
</tr>
<tr>
<td>body</td>
<td>Set this header to true in the request to suppress the response body.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Indicates the request completed successfully.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name-value pairs</td>
<td>All fields (not just modified) with their associated values for the change request.</td>
</tr>
</tbody>
</table>

Example: cURL request

Update a record in the Incident table.

curl
   "https://instance.servicenow.com/api/now/table/incident/ef43c6d40a0b5700c77f9bf387afe3"
   --request PUT
   --header "Accept:application/json"
The response contains the name-value pairs for the updated record.

```json
{
    "result": {
        "upon_approval": "proceed",
        "location": {
            "link": "https://instance.servicenow.com/api/now/table/cmn_location/108752c8c611227501d4ab0e392ba97f",
            "value": "108752c8c611227501d4ab0e392ba97f"
        },
        "expected_start": "",
        "reopen_count": "",
        "close_notes": "",
        "additional_assignee_list": "",
        "impact": "1",
        "urgency": "1",
        "correlation_id": "",
        "sys_tags": "",
        "sys_domain": {
            "link": "https://instance.servicenow.com/api/now/table/sys_user_group/global",
            "value": "global"
        },
        "description": "",
        "group_list": "",
        "priority": "1",
        "delivery_plan": "",
        "sys_mod_count": "7",
        "work_notes_list": "",
        "business_service": "",
        "follow_up": "",
        "closed_at": "",
        "sla_due": "2017-07-05 05:58:24",
        "delivery_task": "",
        "sys_updated_on": "2016-01-22 14:12:37",
        "parent": "",
        "work_end": "",
        "number": "INC0000050",
    }
}
```
Example: Python request

Update a record in the Incident table.
# Need to install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/now/table/incident/ef43c6d40a0b5700c77f9bf387afe3'

# Eg. User name="username", Password="password" for this code sample.
user = 'username'
pwd = 'password'

# Set proper headers
headers = {'Content-Type': 'application/xml', 'Accept': 'application/xml'}

# Do the HTTP request
response = requests.put(url, auth=(user, pwd), headers=headers,
data='"<request><entry><assigned_to>681b365ec0a80164000fb0b05854a0cd</assigned_to><urgency>1</urgency><comments>Elevating urgency, this is a blocking issue</comments></entry></request>"

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)

The response contains the name-value pairs for the updated record.

<?xml version="1.0" encoding="UTF-8"?>
<response>
    <result>
        <upon_approval>proceed</upon_approval>
        <location>
            <link>https://instance.servicenow.com/api/now/table/cmn_location/108752c8c611227501d4ab0e392ba97f</link>

Trouble Ticket Open API

Creates, updates, and retrieves data from the Case [sn_customerservice_case] and Incident [incident] tables.

Use this API to manage ticket information between external ticketing systems and the Now Platform. The Trouble Ticket Open API is a ServiceNow® implementation of the TM Forum Trouble Ticket Management API REST specification. This implementation is based on the TMF621 Trouble Ticket Management API REST Specification Release 19, June 2019.

This API is included in the Telecommunications Assurance Workflows application, which is available on the ServiceNow Store. The Customer Service (com.sn_customerservice) and Customer Service Install Base Management (com.snc.install_base) applications are required to use this API with the Case [sn_customerservice_case] table.

This API is provided within the sn_ind_tsm_sdwan namespace.

The calling user must have the ticket_integrator role.
Extending the Trouble Ticket Open API

The Trouble Ticket Open API can be extended by editing the following script includes. These script includes should only be edited with an understanding of the consequences of the changes.

- **TMFTroubleTicketAPIConstants**: Contains constants and required parameter information.
- **TMFTroubleTicketAPIUtil**: Contains functions to handle POST, GET, and PATCH requests.
- **TroubleTicketProcessorOOB**: Contains helper functions that support functions in TMFTroubleTicketAPIUtil.
- **TroubleTicketProcessor**: An empty script include file. Use this file to define any functions that you want to override from TroubleTicketProcessorOOB.

Extend the Trouble Ticket Open API to make the following customizations.

**Required parameters**

To change which request body parameters are required or not required, update the TMFTroubleTicketAPIConstants script include. By default, the request body to create a ticket (POST) requires the parameters **description**, **severity**, and **ticketType**. By default, the request body to update a ticket (PATCH) doesn't have required parameters.

- **TMFTroubleTicketAPIConstants.TROUBLE_TICKET_CREATION_SCHEMA**: Sets the required request body parameters to create a ticket.
- **TMFTroubleTicketAPIConstants.TROUBLE_TICKET_UPDATE_SCHEMA**: Sets the required request body parameters to update a ticket.

In this example, the **description**, **severity**, **status**, and **ticketType** parameters are required to create a ticket.

```javascript
// TMFTroubleTicketAPIConstants
TMFTroubleTicketAPIConstants.TROUBLE_TICKET_CREATION_SCHEMA = {
  "title": "CreateTroubleTicket",
  "type": "object",
  "properties": {
    "description": {
      "type": "string"
    },
    "severity": {
      "type": "string"
    },
    "status": {
```

Request body validation

To perform additional validation on the request body, override TroubleTicketProcessorOOB functions. TroubleTicketProcessorOOB contains the following six helper functions that return true by default. These functions are called in TMFTroubleTicketAPIUtil.

- verifyGetRequestForCase() - Called by processGetRequestForCase().
- verifyPatchRequestForCase() - Called by processPatchRequestForCase().
- verifyPostRequestForCase() - Called by processPostRequestForCase().
- verifyGetRequestForIncident() - Called by processGetRequestForIncident().
- verifyPatchRequestForIncident() - Called by processPatchRequestForIncident().
- verifyPostRequestForIncident() - Called by processPostRequestForIncident().

If a helper function returns false, it stops the API operation. To apply custom validation, override TroubleTicketProcessorOOB helper functions by creating functions with identical names and parameters in TroubleTicketProcessor. These new TroubleTicketProcessor functions will be called by TMFTroubleTicketAPIUtil to replace the default TroubleTicketProcessorOOB helper functions.

In this example, a function in TroubleTicketProcessor overrides a default function in TroubleTicketProcessorOOB to perform validation on the name attribute.
// TroubleTicketProcessor
var TroubleTicketProcessor = Class.create();
TroubleTicketProcessor.prototype =
Object.extendObject(TroubleTicketProcessorOOB, {
    // Define overriding functions here
    // Function name and parameters must be identical to the function it
    // overrides

    verifyPostRequestForCase: function(caseObject, apiResponseProcessor){
        // Returning false terminates the POST request
        // Make sure to assign error message and reason
        if (caseObject.name != "Hello world") {
            apiResponseProcessor.setMessage(TMFTroubleTicketAPIConstants.MESSAGES.CASE_CREATION_FAILURE);
            apiResponseProcessor.setReason("No reason needed");
            return false;
        }
    },

    type: 'TroubleTicketProcessor'
});

### Additional REST operations

To create additional operations beyond the existing GET, PATCH, and POST operations, create additional scripted REST resources for the Trouble Ticket Open API. The logic of the new scripted REST resources should be consistent with the existing operations. Define functions for the new operations in TMFTroubleTicketAPIUtil.

### Field mapping

When creating or updating records, the API maps request body parameters to case and incident record fields. When retrieving records, the API maps record fields to response object attributes. TroubleTicketProcessorOOB contains the following functions to map a PATCH or POST request body to a case or incident GlideRecord.

- `mapPatchRequestToCase()`
- `mapPostRequestToCase()`
- `mapPatchRequestToIncident()`
- `mapPostRequestToIncident()`
TroubleTicketProcessorOOB contains the following functions to map a case or incident GlideRecord to a JSON response object for GET, PATCH, or POST requests.

- `createGetResponseForCase()`
- `createPatchResponseForCase()`
- `createPostResponseForCase()`
- `createGetResponseForIncident()`
- `createPatchResponseForIncident()`
- `createPostResponseForIncident()`

Customize field mappings to add and retrieve data for additional case and incident fields, or to change the default mappings for fields. To customize the field mappings, override TroubleTicketProcessorOOB mapping functions by creating functions with identical names and parameters in TroubleTicketProcessor. These new TroubleTicketProcessor functions will be used by TMFTroubleTicketAPIUtil to replace the default TroubleTicketProcessorOOB mapping functions.

In this example, two functions in TroubleTicketProcessor override the default functions in TroubleTicketProcessorOOB to change the Description field mapping and add a mapping for the Contract field.

```javascript
// TroubleTicketProcessor
var TroubleTicketProcessor = Class.create();
TroubleTicketProcessor.prototype = Object.extendsObject(TroubleTicketProcessorOOB, {
  // Define overriding functions here
  // Function name and parameters must be identical to the function it overrides
  mapPostRequestToCase: function(caseGr, caseObject){
    // Override default mapping for the Description field
    caseGr.description = "All cases will be created with this description";
    // Add new mapping to the Contract field
    caseGr.contract = caseObject.contract;
  },
  createPostResponseForCase: function(caseGr, caseObject){
    // Override default mapping for the description attribute
```
Mapping logic for choice fields

The State, Priority, and contact_type fields are choice fields, where each choice is composed of a label and a corresponding value. For example, if the State field is set to New, the label is New and the value is 1. The mapping between choice labels and values can be changed by overriding the choice field mapping functions.

TroubleTicketProcessorOOB contains the following choice field mapping functions.

- transformCaseSeverity()
- transformCaseChannel()
- transformCaseStatus()
- transformIncidentSeverityToUrgency()
- transformIncidentSeverityToImpact()
- transformIncidentChannel()
- transformIncidentStatus()

Override TroubleTicketProcessorOOB choice field mapping functions by creating functions with identical names and parameters in TroubleTicketProcessor. These new TroubleTicketProcessor functions will be used by TMFTroubleTicketAPIUtil to replace the default TroubleTicketProcessorOOB choice field mapping functions. In this example, a function in TroubleTicketProcessor overrides a default function in TroubleTicketProcessorOOB to change the choice mapping for the Status field.

```javascript
// TroubleTicketProcessor
var TroubleTicketProcessor = Class.create();
TroubleTicketProcessor.prototype =
    Object.extendsObject(TroubleTicketProcessorOOB, {
        // Define overriding functions here
```

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
```javascript
// Function name and parameters must be identical to the function it overrides

transformCaseStatus: function(status) {
    if (status == "Draft")
        return 1;
    else return 10;
},

type: 'TroubleTicketProcessor'
});
```

**Trouble Ticket - GET /sn_ind_tsm_sdwan/troubleticket/{ticketType}/{id}**

Gets a record from the Case or Incident table.

**URL format**

Default URL: /api/sn_ind_tsm_sdwan/troubleticket/{ticketType}/{id}

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| ticketType | The type of ticket. This value determines whether a record is retrieved from the Case [sn_customerservice_case] or Incident [incident] table. Valid values:  
  • case  
  • incident |

Data type: String

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>Sys_id of the case or incident record to retrieve. Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fields</td>
<td>Comma-separated list of fields to return in the response. Invalid fields are ignored. If this value is not passed in, all fields are returned. Valid fields:</td>
</tr>
</tbody>
</table>
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• channel</td>
<td></td>
</tr>
<tr>
<td>• creationDate</td>
<td></td>
</tr>
<tr>
<td>• description</td>
<td></td>
</tr>
<tr>
<td>• id</td>
<td></td>
</tr>
<tr>
<td>• lastUpdate</td>
<td></td>
</tr>
<tr>
<td>• name</td>
<td></td>
</tr>
<tr>
<td>• note</td>
<td></td>
</tr>
<tr>
<td>• relatedParty</td>
<td></td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td>• status</td>
<td></td>
</tr>
<tr>
<td>• ticketType</td>
<td></td>
</tr>
<tr>
<td>• @type</td>
<td></td>
</tr>
</tbody>
</table>

Data type: String

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports application/json.</td>
</tr>
</tbody>
</table>
## Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

## Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
</tbody>
</table>
| 400         | Bad Request. A bad request type or malformed request was detected for one or more of the following reasons.  
  • Invalid path parameter.  
  • Invalid URI. |
| 404         | Record not found. A record associated with the ID is not found in the Case [sn_customerservice_case] or Incident [incident] table. |

## Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@type</td>
<td>This value is always TroubleTicket. Data type: String</td>
</tr>
<tr>
<td>channel</td>
<td>The method of contact that the ticket was created through. Data type: Object</td>
</tr>

</tr>
<tr>
<td></td>
<td>&quot;@referredType&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>relatedParty.@referredType</td>
<td>The type of related party. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• customer: Related party is a company or account.</td>
</tr>
<tr>
<td></td>
<td>• customer_contact: Related party is a caller or contact.</td>
</tr>
<tr>
<td>relatedParty.id</td>
<td>The sys_id for the related party. For cases, the sys_id is from the Contact [customer_contact] or Account [customer_account] tables. For incidents, the sys_id is from the User [sys_user] or Company [core_company] tables. Data type: String</td>
</tr>
<tr>
<td>relatedParty.name</td>
<td>The name of the related party. For cases, maps to the Contact or Account field. For incidents, maps to the Caller or Company field. Data type: String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>severity</td>
<td>The severity of the issue described by the trouble ticket. Maps to the <strong>Priority</strong> field.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>status</td>
<td>The current status of the trouble ticket. Maps to the <strong>State</strong> field.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>ticketType</td>
<td>The type of ticket (case or incident).</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

**Example: cURL request**

This example gets the name, description, severity, and status of a case.

```bash
curl
   "https://instance.servicenow.com/api/sn_ind_tsm_sdwan/troubleticket/case/a78e2c8cdb68b41015364c9b0b96193e?fields=name%2Cdescription%2Cseverity%2Cstatus"
   --request GET \
   --header "Accept:application/json" \
   --user 'username':'password'

{
   "name": "Short description of issue",
   "description": "Example description of an issue",
   "severity": "2 - High",
   "status": "Open"
}
```

**Trouble Ticket - PATCH /sn_ind_tsm_sdwan/troubleticket/{ticketType}/{id}**

Updates a record in the Case or Incident table.

**URL format**

Default URL: /api/sn_ind_tsm_sdwan/troubleticket/{ticketType}/{id}
### Supported request parameters

#### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| ticketType| The type of ticket. This value determines whether a record is updated in the Case [sn_customerservice_case] or Incident [incident] table. Valid values:  
  - `case`  
  - `incident`  
  Data type: String |
| id        | The sys_id of the case or incident record to update.                         |
|           | Data type: String                                                           |

#### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

#### Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>channel</td>
<td>The method of contact that the ticket was created through.</td>
</tr>
<tr>
<td></td>
<td>Data type: Object</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>channel.name</td>
<td>The name of the contact method. Maps to the Channel [contact_type] field for cases and the Contact type [contact_type] field for incidents. Valid values are the choices for the contact_type field. You can provide the choice label or value. For example, Virtual Agent or virtual_agent.</td>
</tr>

<td>• Invalid ticketType or ticketType does not match path parameter ticketType. For example, ticketType is case but path parameter is incident.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@type</td>
<td>This value is always TroubleTicket. Data type: String</td>
</tr>
<tr>
<td>channel</td>
<td>The method of contact that the ticket was created through. Data type: Object</td>
</tr>
<tr>
<td>channel.name</td>
<td>The name of the contact method. Data type: String</td>
</tr>
<tr>
<td>creationDate</td>
<td>The date that the case or incident record was created. Data type: String</td>
</tr>
<tr>
<td>description</td>
<td>The description of the issue from the ticket. Data type: String</td>
</tr>
<tr>
<td>id</td>
<td>The sys_id of the case or incident record that was created. Data type: String</td>
</tr>
<tr>
<td>lastUpdate</td>
<td>The date that the case or incident record was last updated.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>name</td>
<td>The name of the trouble ticket, typically a short description of the issue. Data type: String</td>
</tr>
<tr>
<td>note</td>
<td>A list of the comments and work notes that were added to the ticket by the POST request. Data type: Array</td>
</tr>
<tr>
<td>note.@type</td>
<td>The type of note. Valid values: work_notes, comments                        Data type: String</td>
</tr>
<tr>
<td>note.author</td>
<td>The name of the ServiceNow integration user who made the POST request that created the note. Data type: String</td>
</tr>
<tr>
<td>note.date</td>
<td>The date the note was created in the ServiceNow instance. Data type: String</td>
</tr>
<tr>
<td>note.text</td>
<td>The note text. Data type: String</td>
</tr>
<tr>
<td>relatedParty</td>
<td>Details about the companies and contacts associated with the ticket. Data type: Array</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>relatedParty.id</td>
<td>The sys_id for the related party. For cases, the sys_id is from the Contact [customer_contact] or Account [customer_account] tables. For incidents, the sys_id is from the User [sys_user] or Company [core_company] tables. Data type: String</td>
</tr>
<tr>
<td>relatedParty.referredType</td>
<td>The type of related party. Valid values: • customer: Related party is a company or account. • customer_contact: Related party is a caller or contact. Data type: String</td>
</tr>
<tr>
<td>severity</td>
<td>The severity of the issue described by the trouble ticket. Data type: String</td>
</tr>
<tr>
<td>status</td>
<td>The current status of the trouble ticket. Data type: String</td>
</tr>
<tr>
<td>ticketType</td>
<td>The type of ticket (case or incident). Data type: String</td>
</tr>
</tbody>
</table>

**Example: cURL request**

This example creates a case with high priority and open state.

```bash
curl "https://instance.servicenow.com/api/sn_ind_tsm_sdwan/troubleticket/case" \
   --request POST \   
   --header "Accept:application/json" \   
   --header "Content-Type:application/json" \   
   --data "{
     "description":"Example description of an issue",
   }
```

User Role Inheritance API

The User Role Inheritance API allows you to see the roles that a specific user inherited.

This API requires the Contextual Security: Role Management V2 REST API (com.glide.role_management.inh_count.rest_api) plugin, automatically activated on new instances starting with the Jakarta release, or the Contextual Security: Role Management Enhancements REST API plugin, automatically activated starting with the Geneva release. The Contextual Security: Role Management V2 REST API is dependent on the Contextual Security: Role Management V2 (com.glide.role_management.inh_count) plugin.

A user’s role can be directly granted, inherited from other roles, or inherited from groups. You must have the user_admin role to access this API.

User Role Inheritance - GET /global/user_role_inheritance

Returns a specified user's granted and inherited roles.

URL format

Versioned URL: /api/global/{api_version}/user_role_inheritance
Default URL: /api/global/user_role_inheritance
Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_sysid</td>
<td>Required. Sys_id of the user for which to return role information.</td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Status codes
The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not found. The requested item was not found.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>from_group</td>
<td>List of roles that are inherited from groups that have roles. Data type: Array</td>
</tr>
<tr>
<td>from_role</td>
<td>List of roles that are either granted directly or inherited from other roles. Data type: Array</td>
</tr>
<tr>
<td>user_name</td>
<td>Full name of user. Data type: String</td>
</tr>
</tbody>
</table>

Example: Sample cURL request

```
curl -H "Accept:application/json" -u "username:'password" "https://instance.service-now.com/api/global/user_role_inheritance?user_sysid=62826bf03710200044e0bfc8bcbbe5df1" 
```
Example: Sample Python request

```python
#easy_install requests
import requests

# Set the request parameters
url = 'https://instance.service-now.com/api/global/user_role_inheritance?user_sysid=62826bf037120044e0bfc8bcbe5df1'

# Eg. User name="username", Password="password" for this code sample.
user = 'username'
pwd = 'password'

# Set proper headers
headers = {'Accept': 'application/json'}

# Do the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.json())
    exit()
```

Virtual Agent Bot Integration API

The Virtual Agent Bot Integration API allows users to integrate any chat interface or a bot ecosystem with the ServiceNow Virtual Agent and/or Live Agent. This API is built on the conversational custom chat integration framework provided with Virtual Agent and operates in the `sn_va_as_service` namespace.

For additional information on installing and configuring the Virtual Agent Bot Integration API, see Virtual Agent API.

VA Bot Integration - POST /sn_va_as_service/bot/integration

Sends a specified message, attachment, or URL to a specified secondary ServiceNow Virtual Agent (VA) bot.

A customer's site can have one or more secondary ServiceNow bots. In addition to passing messages to a ServiceNow VA secondary bot, the primary bot or chat client can use this endpoint to pass messages to an agent through Live Agent chat. Use the `action` parameter passed in the request body to specify how the specified content should be handled.
Note: This endpoint can be either synchronous or asynchronous depending on how it is configured. If asynchronous, when the request is received by the endpoint, it validates the request and responds with a call status of success or failure and the appropriate HTTP status code. The VA then processes the request and sends a second response to the configured response endpoint. For example, for a bot-to-bot integration, this would be to the URL of your primary bot. Both of these responses are defined below. For additional information on this configured response endpoint, see Configure the response endpoint for Virtual Agent API.

Note: The responses in the code examples for this endpoint show what is sent from the VA to the configured response endpoint. They do not show the actual response to this endpoint which is a simple success or failure response.

URL format
Default URL: /api/sn_va_as_service/bot/integration

</table>

Data type: String
Default: Null
### Request body parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| botToBot         | Flag that indicates whether the conversation is between bots, such as between a primary bot and secondary bot. Possible values:  
  - true: Bot-to-bot conversation.  
  - false: Standalone ServiceNow bot conversation.  
  
  Data type: Boolean  
  Default: true       |
| clientSessionId  | Unique client session identifier of the application/service that the end-user is using to communicate with the ServiceNow bot. This ID helps identify the set of request/responses for a specific user conversation. The format of this parameter is determined by the implementer.  
  Data type: String  
  Default: Null       |
| clientVariables  | Pass-through JSON-formatted name-value pairs that are sent back in the response. These values are not processed by the endpoint, but can be used to keep specific customer information attached to the conversation.  
  Data type: Object  
  Default: Null       |
| contextVariables | JSON-formatted name-value pairs that provide addition                                                                                      |

<tr>
<td>message.text</td>
<td>Required if attachment parameter is not specified. Message text. The language of the message should be passed in the contextVariables parameter. Data type: String Maximum length: Unlimited</td>
</tr>
</tbody>
</table>
| message.typed               | Required. Flag that indicates whether the message was typed in or was an option selection (clicked). Valid values:  

- true: Message was typed in by the user.  
- false: Message was an option selection.  

Data type: Boolean                                                                                                                                         |
| requestId                   | Required. Unique alphanumeric identifier for this request.                                                                                                                                                                                                                                                                                   |
Request body parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| silentMessage  | Flag that indicates whether this is a silent message. A silent message is a message that does not require a response. Valid values:  
  • true: Silent message, no response message expected.  
  • false: Regular message, response message expected.  

  Note: If a request with `silentMessage = true` is sent, all subsequent bot messages remain suppressed until a request to turn-off silent mode is sent by passing `silentMessage = false`.  

  Data type: Boolean  
  Default: false  

| timestamp      | Unix epoch time when the message was sent from the end-user of the chat client.  

  Data type: Number  
  Unit: Milliseconds  
  Default: Current time  

| timezone       | GMT time zone of the end-user of the chat client.  

  For example:  

  "timezone":"Asia/Kolkata"
### Request body parameters (continued)

<td>For a list of the available time zone values, see <a href="https://en.wikipedia.org/wiki/List_of_tz_database_time_zones">https://en.wikipedia.org/wiki/List_of_tz_database_time_zones</a>. Data type: String Default: GMT time zone of the ServiceNow instance.</td>
</tr>
</tbody>
</table>

**topic**

Required if the user wants to switch to a particular topic by specifying a topic name. Name-value pair of the topic to switch to. You can either specify the topic name or the topic sys_id.

#### Note:

You can only specify a single topic name or id in the object.

Data type: Object

```json
"topic": {
  "name": "String",
  "id": "String"
}
```

For example:

```json
{
  "requestId": "xxxx-xxxx-xxxx-xxxx",
  "clientSessionId": "xxx-xxx-xxx-xxx",
  "action": "SWITCH",
  "topic": {
    "name": "Topic Name"
  },
  "userId": "beth"
}
```

</thead>
</table>
| 200         | Successful. The request was successfully processed. If you receive a 200 status code, but do not receive a response back, check the following things:  
• Whether the request is failing in Static, JWT, or Hash Based Token validation which generally happens in the worker thread of Virtual Agent.  
• Whether the request body format is correct. If incorrect, the conversion does not happen correctly.  
• Whether the request body is missing some mandatory parameters. Exceptions and errors can be traced in logs.  
• Whether the site defined in the REST Message to receive the response is operational; able to detect in logs.  
• Ensure the REST Message that defines where to post the response is set correctly. |
| 400         | Bad Request. A bad request type or malformed request was detected. |
| 401         | Unauthorized. The user credentials are incorrect or have not been passed. |
| 405         | Invalid method. The functionality is disabled. |
| 500         | Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error. |

**Response body parameters**

Status of the endpoint call. This is sent in response when the initial call request is received. The request has not yet been processed.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>error</td>
<td>Description of the detected error. Only returned if an error occurs.</td>
</tr>

Data type: String

**body.value**

Data to use to process the body element. The type of information that is passed back depends on the type of body element.

OutputLink: Object.

```
"value": {
  "action": "String"
}
```

OutputImage: String. Image URL.

OutputHtml: String. HTML that the client needs to render.

Data type: String or Object

**body.value.action**

Only returned for DefaultOutputLink. URL of returned link.

Data type: String

**body.waitTime**

Amount of time that the user has to wait before being connected to a live agent.
<table>
<thead>
<tr>

</tbody>
</table>

**Example:** Start a conversation using the **START_CONVERSATION** action to start a conversation.

The following example shows how to use the **START_CONVERSATION** action to start a conversation with Virtual Agent. This call directs the user to the greeting topic.

```bash
curl "https://instance.servicenow.com/api/sn_va_as_service/bot/integration" \
--request POST \
--header "Accept:application/json" \
--header "Content-Type:application/json" \
--data "{
  "requestId": "asd2423-sda23-qwe23-we23",
  "action": "START_CONVERSATION",
  "enterpriseId": "ServiceNow",
  "nowBotId": "A85PWLERF",
  "clientSessionId": ",",
  "nowSessionId": ",",
  "message":{
    "text": ",",
    "typed": true,
    "clientMessageId": "ABC-123"
  },
  "userId": "beth.anglin",
  "emailId": "beth.anglin@example.com",
  "timestamp": 1588824102,
  "timezone": "America/New_York"
}"
--user "username":"password"
```

The following is the response body sent from the VA to the configured response endpoint.

```json
{
  "requestId": "asd2423-sda23-qwe23-we23",
  "clientSessionId": ",",
  "nowSessionId": ",",
```

Example: Transfer a conversation to Live Agent using utterance

The following example illustrates how to transfer a conversation to Live Agent, bypassing the greeting topic, by passing agent as an utterance in the message.text parameter. Possible utterance values are defined in the sys_cs_contextual_action table. For additional information on contextual actions, see Contextual actions for custom chat integrations.
The following is the response body sent from the VA to the configured response endpoint.

```json
{
  "requestId": "322bas2be70-sadsa-we32-3eq2-1231ra9",
  "clientSessionId": "",
  "message": {
    "text": "agent",
    "typed": true
  },
  "userId": "abel.tuter",
  "emailId": "abel.tuter@servicenow.com",
  "timestamp": 1588824102,
  "timezone": "America/New_York"
}
```
Example: Transfer a conversation to Live Agent Support based on the user's selection

The following example shows transferring the conversation to Live Agent Support based on the user's selection from the prior interaction.

curl "https://instance.servicenow.com/api/sn_va_as_service/bot/integration" \
  --request POST \
  --header "Accept:application/json" \
  --header "Content-Type:application/json" \
  --header "token: ORANGE" \
  --data "{
    "requestId": "322bas2be70-sadsa-we32-3eq2-1231ra9",
    "botToBot": true,
    "clientSessionId": "",
    "silentMessage": false,
    "message": {
      "text": "Live Agent Support.",
      "typed": true
    },
    "userId": "abel.tuter",
    "score": 1
  }"
The following is the response body sent from the VA to the configured response endpoint.

```
{
  "requestId": "322bas2be70-sadsa-we32-3eq2-1231ra9",
  "clientSessionId": "",
  "message": {
    "text": "Live Agent Support.",
    "typed": true
  },
  "userId": "abel.tuter",
  "body": [
    {
      "uiType": "OutputText",
      "group": "DefaultText",
      "value": "Please stand by while I connect you to a live agent."
    }
  ],
  "agentChat": true,
  "score": 1
}
```

**Example: End a Virtual Agent conversation by setting the action parameter.**

The following example shows how to end a Virtual Agent conversation by setting the `action` parameter to `END_CONVERSATION`.

```
curl "https://instance.servicenow.com/api/sn_va_as_service/bot/integration" \
  --request POST \
  --header "Accept:application/json" \
  --header "Content-Type:application/json" \
  --data "{
  "requestId": "s345ew-sjg554-qwe23-we23",
  "action": "END_CONVERSATION",
  "enterpriseId": "ServiceNow",
  "nowBotId": "A85PWLERF",
  "clientSessionId": "",
  "nowSessionId": "",
  "message": {
  ```
The following is the response body sent from the VA to the configured response endpoint showing the conversation ended.

```json
{
    "requestId": "s345ew-sjg554-qwe23-we23",
    "clientSessionId": "",
    "nowSessionId": "",
    "message": {
        "text": "",
        "typed": true,
        "clientMessageId": "ABC-123"
    },
    "userId": "beth.anglin",
    "body": [
        {
            "uiType": "OutputText",
            "group": "DefaultText",
            "value": "The conversation has ended. If you need help again, type hi."
        }
    ],
    "score": 1
}
```

Example: End a Live Agent conversation by setting the action parameter

The following example shows how to end a Live Agent conversation by setting the `action` parameter to `END_CONVERSATION`.

```
curl "https://instance.servicenow.com/api/sn_va_as_service/bot/integration" \
  --request POST \
  --header "Accept:application/json" \
  --header "Content-Type:application/json" \
```

Example: Use commands defined in the sys_cs_contextual_action table as an utterance to start a conversation with Virtual Agent

The following example shows how to use the **hi** command defined in the sys_cs_contextual_action table as an utterance to start a conversation with Virtual Agent instead of setting the action parameter to START_CONVERSATION as shown in prior examples. This example shows using one of the language variants of the **hi** command, "hola".

```bash
curl "https://instance.servicenow.com/api/sn_va_as_service/bot/integration" \
  --request POST \ 
  --header "Accept:application/json" \ 
  --header "Content-Type:application/json" \ 
  --header "token: ORANGE" \ 
  --data "{
    "requestId": "302bas2be70-sadsa-we32-3eq2-1231ra9",
    "botToBot": true,
    "clientSessionId": "",
    "silentMessage": false,
    "message": {
      "text": "hola",
      "typed": true
    },
    "userId": "fred.ludy",
    "emailId": "abel.tuter@servicenow.com",
    "timestamp": 1588824102,
    "timezone": "America/New_York"
  }"
```

The following is the response body sent from the VA to the configured response endpoint.

```json
{
    "requestId": "302bas2be70-sadsa-we32-3eq2-1231ra9",
    "clientSessionId": "",
    "message": {
      "text": "hola",
      "typed": true
    },
    "userId": "fred.ludy",
    "body": {
      "uiType": "OutputText",
      "group": "DefaultText",
      "value": "Hi, I'm your Virtual Agent. Let me know how I can help you today.",
      "maskType": "NONE"
    }
}
```
uiType":"TopicPickerControl",
"group":"DefaultPicker",
"nluTextEnabled":false,
"promptMsg":"Hi guest, please enter your request or make a selection of what I can help with. You can type helllllp! any time when you need help.",
"label":"Show me everything",
"options":[
{
"label":"boolean check",
"value":"1b5257a1db712010d3d6d9595e9619f3",

Example: Use commands defined in the sys_cs_contextual_action table as an utterance to end a conversation

The following example shows how to use the `Bye` command defined in the sys_cs_contextual_action table as an utterance to end a conversation with Virtual Agent instead of setting `action` to `END_CONVERSATION` as shown in prior examples. This example shows using one of the language variants of the `Bye` command, "choa".

```
curl "https://instance.servicenow.com/api/sn_va_as_service/bot/integration" \
  --request POST \
  --header "Accept:application/json" \
  --header "Content-Type:application/json" \
  --header "token: ORANGE" \
  --data "{
    "requestId": "302bas2be70-sadsa-we32-3eq2-1231ra9",
    "botToBot": true,
    "clientSessionId": "",
    "silentMessage": false,
    "message": {
      "text": "choa",
      "typed": true
    },
    "userId": "fred.ludy",
    "emailId": "abel.tuter@servicenow.com",
    "timestamp": 1588824102,
    "timezone": "America/New_York"
  }"
```
The following is the response body sent from the VA to the configured response endpoint.

```json
{
    "requestId":"302bas2be70-sadsa-we32-3eq2-1231ra9",
    "clientSessionId":"",
    "message":{
        "text":"chao",
        "typed":true
    },
    "userId":"fred.ludy",
    "body":{
        "uiType":"Picker",
        "group":"DefaultPicker",
        "required":true,
        "nluTextEnabled":false,
        "label":"Please make a selection.",
        "itemType":"ID",
        "style":"list",
        "multiSelect":false,
        "options":{
            "label":"End conversation",
            "value":"1",
            "renderStyle":"data",
            "enabled":false
        },
        "scriptedData":null
    },
    "score":1
}
```
Example: Change an ongoing conversation using the SWITCH action parameter.

The following example shows how to use the **SWITCH** action parameter to change an ongoing conversation to the topic that matches what is specified in the **intent.id** parameter.

```bash
curl "https://instance.servicenow.com/api/sn_va_as_service/bot/integration" \
--request POST \
--header "Accept:application/json" \
--header "Content-Type:application/json" \
--data "{
  "requestId": "adfsfs-hgfhg-34fssd-zxcz-sd43",
  "enterpriseId": "ServiceNow",
  "nowBotId": "A85PWLERF",
  "clientSessionId": "",
  "nowSessionId": "",
  "action": "SWITCH",
  "intent": {
    "id": "Saloon Vehicle"
  },
  "message":{
    "typed": true,
    "clientMessageId": "ABC-123"
  },
  "userId": "Guest",
  "timestamp": 1588824102,
  "timezone": "America/New_York"
}"
--user "username":"password"
```

The following is the response body sent from the VA to the configured response endpoint showing the VA switched to the new topic.

```json
{
  "requestId": "adfsfs-hgfhg-34fssd-zxcz-sd43",
  "clientSessionId": "",
  "nowSessionId": "",
  "message":{
    "typed": true,
    "clientMessageId": "ABC-123"
  },
  "userId": "Guest",
  "body":{
    "uiType": "InputText",
    "body": "Please enter your vehicle details.
```

   },
   "userId": "Guest",
   "timestamp": 1588824102,
   "timezone": "America/New_York"
}"
   --user "username":"password"
```

The following is the response body sent from the VA to the configured response endpoint showing the NLU confidence score.

```
{
   "requestId":"sdfsfs-hgfhg-34fssd-zxcz-sd43",
   "clientSessionId":"",
   "nowSessionId":"",
   "message":{
```
Example: Transfer a conversation to Live Agent in a specific queue.

The following example shows how to transfer a conversation to Live Agent in a specific queue. You must first set up your queues with specific conditions. You then pass those conditions as contextVariables in the request body. For additional information on creating a work item queue, see Create a work item queue.

curl "https://instance.servicenow.com/api/sn_va_as_service/bot/integration" \ 
--request POST \ 
--header "Accept:application/json" \ 
--header "Content-Type:application/json" \ 
--data "{
  "requestId": "34re-dasd-qwe23-dsds", // Unique value for a message (hash)
  "enterpriseId": "ServiceNow", // ServiceNow (Optional)
  "nowBotId": "A85PWLERF", // In case of multiple ServiceNow secondary bots (one for HR, one for ITSM)
  "action": "AGENT", // Actions to close conversation. Other possible value is END_CONVERSATION
  "clientSessionId": ", // Client conversation id
  "nowSessionId": ", // ServiceNow conversation id
  "message": {
    "text": "How are you?", // User passed message
    "typed": true, // typed or clicked
    "clientMessageId": "ABC-123"
  },
  "userId": "abraham.lincoln", // User’s id in their system
}
The following is the response body sent from the VA to the configured response endpoint.

```json
{
  "requestId": "34re-dasd-qwe23-dsds",
  "clientSessionId": "",
  "nowSessionId": "",
  "message": {
    "text": "How are you?",
    "typed": true,
    "clientMessageId": "ABC-123"
  },
  "userId": "abraham.lincoln",
  "body": [
    {
      "uiType": "OutputText",
      "group": "DefaultText",
      "value": "I am sorry but I didn't understand your request.",
      "maskType": "NONE"
    },
    {
      "uiType": "OutputText",
      "group": "DefaultText",
      "value": "Please try giving me your request in a different way. I'm currently better at understanding short sentences.",
      "maskType": "NONE"
    },
    {
      "uiType": "TopicPickerControl",
      "group": "DefaultPicker",
      "nluTextEnabled": false,
      "promptMsg": "Hi guest, please enter your request or make a selection of what I can help with. You can type help any time when you need help.",
      "label": "Show me everything",
      "options": [
```
Example: Transfer a public application/pdf attachment file

This example shows how to transfer a public application/pdf attachment.

curl "https://instance.servicenow.com/api/sn_va_as_service/bot/integration" \
   --request POST \
   --header "Accept:application/json" \
   --header "Content-Type:application/json" \
   --header "token:BOT_Token" \
   --data "{
   "requestId": "f42f3550-5b44-4cde-aa52-9b6756b3131c",

   "headers": {
   "Authorization": "Basic amFzbWluZS55YS9WbGRod2FuaW9VZzdGluZ0AxMkJM="
   } 
   }
Scripted REST APIs

The scripted REST API feature allows application developers to build custom web service APIs.

You can define service endpoints, query parameters, and headers for a scripted REST API, as well as scripts to manage the request and response.

Scripted REST APIs generally follow the REST architecture, but you can customize them to use different conventions. You define scripted REST APIs using the
Scripted REST Service form found under **Scripted Web Services → Scripted REST APIs**.

The following podcast offers additional information on the use of scripted REST APIs.

**Scripted REST APIs Podcast**

**Scripted REST API URIs**

Scripted REST API URIs have the following format:

- ![https://<instance.service-now.com>/api/<name_space>/<version>/<api_id>/<relative_path>](https://<instance.service-now.com>/api/<name_space>/<version>/<api_id>/<relative_path>)

In this URI:

- `<instance.service-now.com>`: Path to the ServiceNow instance where users access the scripted REST API.

- `<name_space>`: For web services in the global scope, the name space is the value of the property `glide.appcreator.company.code`. For web services in a scoped application, the name space is the scope name, such as

---

© 2021 ServiceNow, Inc. All rights reserved.

x_company_appname. For additional information on name spaces, see
Application scope.

• <version>: Optional. Version of the endpoint to access if the API uses
  versioning, such as v1. You can access the default version of a versioned API
  by specifying the URI without a version number.

• <api_id>: Value of the API ID field on the Scripted REST Service form. By default
  this value is based on the service name.

• <relative_path>: Relative path defined for the resource in the Scripted REST
  Service form. Specifying a relative resource path allows you to have multiple
  resources using the same HTTP method, such as GET, in one web service. For
  example, a resource may specify the path /{id} when the web service has
  only one GET resource, or /user/{id} and /message/{id} when the web service
  has different resources for requesting user and message records.

Scripted REST API versioning

Scripted REST API URIs may include a version number, such as /api/management/
  v1/table/{tableName}. Version numbers identify the endpoint version that a URI
  accesses. By specifying a version number in your URIs, you can test and deploy
  changes without impacting existing integrations.

Default API version

A version may be marked as default. Specifying a default version allows users to
  access that version using a scripted REST endpoint without a version number. If
  no version is marked as default, the latest version is used as the default.

Scripted REST API resources

A scripted REST API resource is equivalent to a REST endpoint. It defines the HTTP
  method to execute, the processing script, and any override settings from the
  parent API. You can define one or more resources per API.

Scripted REST API query parameters

Query parameters define values that requesting users can pass in a request.
  When creating a scripted REST API, you can specify which parameters are
  available and which are mandatory for each request. You can also associate a
  query parameter with multiple resources.

Access request parameters in scripts using the request object params field.

Scripted REST API roles

To work with scripted REST APIs, you must have the web service administrator
  [web_service_admin] role. Users with this role can read, create, modify, and
  delete scripted REST APIs and web service resources.
Note: These roles are not required to access a scripted REST API endpoint.

Request and response formats
By default, all resources in an API support the following request and response formats: application/json, application/xml, and text/xml. You can override the default formats at the API level. The new formats apply to all resources belonging to the API, unless an individual resource overrides the defaults.

Scripted REST API security
You can configure your scripted REST APIs with the necessary level of security. From public APIs/endpoints that don’t require any security to highly secure APIs/endpoints that require user authentication with tight access control to all resources.

Scripted REST API access controls
Access control lists (ACLs) define criteria, such as the roles needed and conditions that a user must meet to access a scripted REST API or endpoint. A requesting user must satisfy at least one of the ACLs. It is not necessary to satisfy all selected ACLs. You can define a single ACL for an entire REST API or for an individual endpoint.

Note: By default, scripted REST APIs contain an ACL that prohibits users with the snc_external role from making requests to the API.

When defining a scripted REST API ACL, it must have the Type value REST_Endpoint.

For additional information on ACLs, see Access control list rules and Configure a scripted REST API resource to require an ACL.

Scripted REST API security matrix
There are multiple possible security configurations for scripted REST APIs. Use this table to identify the scripted REST API security configuration that best suits your needs, and the field values to implement that configuration.
### Scripted REST API security

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Scripted REST API</th>
<th>Scritped REST Resource</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Default ACLs</td>
<td>Requires authentication</td>
</tr>
<tr>
<td>The resource is public. No authentication or ACL is required.</td>
<td>Any value</td>
<td>False</td>
</tr>
<tr>
<td>The resource requires basic authentication only. No ACL is required.</td>
<td>Any value</td>
<td>True</td>
</tr>
<tr>
<td>The resource requires basic authentication only. ACL is required.</td>
<td>No ACL selected</td>
<td>True</td>
</tr>
<tr>
<td>An ACL selected in the resource record is required.</td>
<td>Any value</td>
<td>True</td>
</tr>
<tr>
<td>An ACL selected in the scripted REST API record is required.</td>
<td>One or more ACLs selected</td>
<td>True</td>
</tr>
</tbody>
</table>

### Scripted REST API error objects

Scripted REST APIs include error objects that allow you to respond to a request with a standard HTTP error message when an error occurs during request processing. You can use error objects in scripted REST API resources to alert requesting clients of errors. Use error objects to respond to incoming requests, not to catch errors within your server-side code.

### Error response format

The content type of the response depends on the request Accept header. If the Accept header specifies an unsupported format, such as image/jpeg, the error response uses JSON.

Error responses follow this format:

```json
{
    "error": {
        "message": "My error message"
    }
}
```
The numeric status code, such as 404, is included in the response Status code header, not in the response body.

**Automated Test Framework support**

The Automated Test Framework (ATF) supports Inbound REST test steps. You can create automated tests for custom Inbound REST APIs that you create. Creating tests for your custom REST APIs simplifies upgrade testing, and makes it possible to verify that modifications to a REST API are backward compatible. See Administering REST test step configurations and ATF REST test step configurations.

**Developer training**

In the ServiceNow® Developer Site, you can find training for **Scripted REST APIs**.

**Create a scripted REST API**

Create a scripted REST API to define web service endpoints.

**Before you begin**
Role required: web_service_admin

**About this task**
By default, scripted REST APIs contain an ACL that prohibits users with the snc_external role from making requests to the API.

**Procedure**

1. Navigate to **System Web Services > Scripted REST APIs**.
2. Click **New**.
3. Enter a **Name** for the service.
   - The **API ID** is set automatically based on the **Name**. You can modify the **API ID** if needed.
4. Click **Submit**.

**What to do next**
After you create the API, configure the service as needed such as by creating resources, assigning ACLs, or specifying supported request and response formats.
Create a scripted REST API resource

Create a scripted REST API resource to define the HTTP method, the processing script, and to override settings from the parent service.

**Before you begin**
There must be a scripted REST API defined before you can create resources.
Role required: web_service_admin

**About this task**
By default, any new Scripted REST API resource you create contains an ACL that prohibits users with the snc_external role from making requests to the API.

**Procedure**
1. Navigate to **System Web Services > Scripted REST APIs**.
2. Select a scripted REST API record.
3. In the **Resources** related list, click **New**.
4. Enter a **Name**.
   - The resource name affects the URI for sending requests to the API.
5. Select the **HTTP method** this resource implements, such as **GET**.
6. In the **Script** field, define how the operation parses and responds to requests.
7. **Optional:** Override settings from the parent REST API as needed, such as by specifying different security settings or valid content types.
8. **Optional:** On the **Documentation** tab, provide a **Short description** explaining how to access the resource.
   - This information appears when exploring this resource using the REST API Explorer.
9. Click **Submit**.

**What to do next**
After creating the resource, you can associate headers and query parameters. For details, see **Define scripted REST API headers** and **Define available query parameters**.

**Define scripted REST API headers**
Define scripted REST API headers to control which headers the API accepts and can respond with.

**Before you begin**
There must be a scripted REST API defined before you can create headers.
Role required: web_service_admin

Procedure
1. Navigate to System Web Services > Scripted REST APIs.
2. Select a scripted REST API record.
3. In the Request Headers related list, click New.
4. Enter a Header name.
5. Enter a Short description and Example value to explain how to use the header.
6. Click Submit.
7. Optional: From the Request Headers tab, locate the header name and set Is required to "true" to make this header mandatory for all requests to associated scripted REST resources.

What to do next
After defining available headers, associate the headers with a scripted REST resource.

Define available query parameters
Define available query parameters to control what values a requesting user can pass in the request URI.

Before you begin
Role required: web_service_admin

Procedure
1. Navigate to System Web Services > Scripted REST APIs.
2. Select a scripted REST API record.
3. In the Query Parameters related list, click New.
4. Specify the Query parameter name.
5. Enter a Short description and Example value to explain how to use the parameter.
6. Click Submit.
7. Optional: From the Query Parameters tab, locate the query parameter and set Is required to "true" to make this query parameter mandatory for all requests to associated scripted REST resources.
What to do next
After defining available query parameters, associate the parameters to a scripted REST resource. For details, see Associate query parameters to a resource.

Associate query parameters to a resource
Associate scripted REST API query parameters to a resource.

Before you begin
Role required: web_service_admin

Procedure
1. Navigate to System Web Services > Scripted REST APIs.
2. Select a scripted REST API record.
3. In the Resources related list, click New
4. In the API query parameter, select or enter the query parameter to associate with the resource.
5. In the API resource, select or enter the scripted REST API resource to associate with the query parameter.
6. Click Submit.

What to do next
After associating the parameters with a scripted REST resource, configure any required ACLs for the API or endpoint. For details, see Configure a scripted REST API resource to require an ACL.

Configure a scripted REST API to require an ACL
Requests to scripted REST APIs respect platform ACLs, and the requesting user must meet any table ACL requirements to access instance data. Additionally, you can configure the scripted REST API to require a specific ACL.

Before you begin
Role required: web_service_admin

About this task
The ACLs selected in this task apply to all API endpoints.

Procedure
1. Navigate to System Web Services > Scripted REST APIs.
2. Select a scripted REST API.
3. In the **Default ACLs** field, select one or more ACLs that meet the security needs for the API. Select only those ACLs that have a **Type** of **REST_Endpoint**. A requesting user must satisfy at least one of the selected ACLs. It is not necessary to satisfy all selected ACLs.

4. Click **Update**.

**What to do next**
You can override the API security settings for each individual API resource/endpoint. For details, see **Configure a scripted REST API resource to require an ACL**.

**Configure a scripted REST API resource to require an ACL**
By default, API resources/endpoints inherit security settings from the parent API. Define custom ACLs for a specific resource/endpoint to override the inherited settings.

**Before you begin**
Role required: web_service_admin or admin

**About this task**
ACLs are checked for an authenticated user only.

**Procedure**
1. Navigate to **System Web Services > Scripted REST APIs**.
2. Select a scripted REST API.
3. In the **Resources** related list, select a resource.
4. In the **Security** tab, select the **Requires authentication** check box. You must select this check box to require an ACL for the resource. If you clear this check box, the resource becomes public and requires no credentials. Clear this check box only if you want to allow unauthenticated requests to access the resource, even if the parent REST service requires an ACL.
5. Select the **Requires ACL authorization** check box.
6. In the **ACL** field, select one or more ACLs that meet the security needs for the endpoint. Select only those ACLs that have a **Type** of **REST_Endpoint**. Only users who have roles defined in the selected REST_Endpoint type ACL are granted access to this resource. Selecting an ACL for a resource overrides any ACLs selected for the parent web service. Leave this field blank to use the ACLs selected for the parent web service.
Related information

Configure a scripted REST API to require an ACL

Enable versioning for a scripted REST API

Enable versioning for a scripted REST API to provide multiple versions of the API while maintaining compatibility with existing integrations.

Before you begin
There must be a scripted REST API defined before you can enable versioning.
Role required: web_service_admin

Procedure

1. Navigate to System Web Services > Scripted REST APIs.
2. Select a scripted REST API.
3. Under Related Links, click Enable versioning.
   The Enable versioning pop up appears. The Make version v1 default check box is selected by default.
4. Optional: Clear the Make version v1 default check box to enable versioning without a default version.
   Versioned APIs without a default version are accessible only by using the version-specific URI. Make version v1 default, or select a different version as default after you enable versioning.
5. Click OK.
   The Versioning embedded list is added to the Scripted REST Service form. You can add new versions or control which version is default from this list.

Add a version to a scripted REST API

Add a new version to a versioned scripted REST API to define new API behavior without impacting older versions.

Before you begin
There must be a scripted REST Service that has versioning enabled before you can add a new version.
Role required: web_service_admin

Procedure

1. Navigate to System Web Services > Scripted REST APIs.
2. Select a scripted REST API.
   The Add new version pop up appears.

4. Optional: Select Make this version the default to configure the REST service to 
   use the new version as the default version.

5. Optional: In the Copy existing resources from version choice list, select an 
   existing version to copy all resources from that version to the new version.

6. Click OK.

Control request and response content type
Controls which content types are allowed in scripted REST API requests and 
responses.

By default, scripted REST APIs support application/json, application/xml, and 
text/xml. User-defined custom content types (with json or xml subtypes) are 
also supported. For example, application/vnd.collection+json and application/
vnd.adobe.xdp+xml are treated as JSON and XML, respectively.

Important: If the request body format is not of a json or xml subtype, use 
only the request body dataStream field to access the request body. Using 
request body data, dataString, nextEntry(), or hasNext() with a non-json or 
non-xml format results in a 500 error response.

Setting defaults
You can set default values for the API using the Default supported request 
formats and Default supported response formats fields. These fields define 
acceptable values users can pass in the Content-Type and Accept request 
headers, respectively. If a requesting user specifies an Accept or Content-Type 
header not supported by the API or resource, the instance responds with an 
HTTP error code of 406 or 415.

You can override these values for each resource using the Supported request 
formats and Supported response formats on the Scripted REST Service form.

Note: The Supported request formats field appears only for PUT, POST, and 
PATCH resources.

Using wildcard values
You can use wildcard values when specifying valid content types.

• To perform a single-character wildcard search, use the percent sign (%) 
  character. This wildcard finds words that contain any one character in place 
  the percent-sign-character. For example, to find words such as text or test, 
  search for: te%t.
• To perform a multiple-character wildcard search, use the asterisk (*) character. This wildcard finds words that contain zero or more characters in place of the asterisk-character. For example, to find words such as planned or placed, search for: `pl*d`.

**Using the x-www-form-urlencoded content type**

If a REST API or resource accepts the application/x-www-form-urlencoded Content-type, you can retrieve the urlencoded values provided in the request as a JSON map. You can then supply these urlencoded key-value pairs as query parameters, in the request body, or both. They are combined and stored in the request parameters. Access these parameters through the `request.queryParams` object.

For example, if your API is defined to accept the application/x-www-form-urlencoded content-type and your API is implemented as follows,

```javascript
(function process(/*RESTAPIRequest*/ request, /*RESTAPIResponse*/ response) {
    response.setBody(request.queryParams);
})(request, response);
```

... then the following request yields the respective response:

POST to localhost:8080/api/now/some_api/some_resource?name3=value3&name4=value4

**Body:**

name1=value1&name2=value2

**Response:**

```
{
    "result":
    {
        "name4": [ "value4" ],
        "name3": [ "value3" ],
        "name2": [ "value2" ],
        "name1": [ "value1" ]
    }
}
```

**Sending binary type in a response**

When sending a binary type in a response, you must set the response content type and write the binary stream directly using a `RESTAPIResponseStream` object. You can access this object by calling `getStreamWriter()` on the response object. For more information, see `RESTAPIResponse - Scoped, Global`. 
Controlling maximum request size

You can specify the maximum file size allowed in a scripted REST API request payload.

The file size limit applies when accessing any of the following variables or functions from a RESTAPIRequestBody object.

- `data`
- `dataString`
- `nextEntry()`
- `hasNext()`

Accessing these variables or functions with a request payload that exceeds the maximum size causes the service to respond with error code 400.

The file size limit does not apply when accessing the `dataStream` variable.

Maximum request size properties

Several properties control the maximum allowed request size. Add these properties to the System Properties [sys_properties] table to specify a maximum request size.

<table>
<thead>
<tr>
<th>Property</th>
<th>Default value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.rest.scripted.max_inbound_content_length_mb</td>
<td>10</td>
<td>The maximum size, in megabytes, for a scripted REST request body that is not gzip compressed.</td>
</tr>
<tr>
<td>glide.rest.scripted.max_inbound_gzip_content_length_mb</td>
<td>1</td>
<td>The maximum size, in megabytes, for a scripted REST request body that is gzip compressed.</td>
</tr>
<tr>
<td>glide.rest.max_content_length</td>
<td>10</td>
<td>The maximum size, in megabytes, for a scripted REST request body, whether or not it is gzip compressed.</td>
</tr>
</tbody>
</table>

- Maximum: 25

As a result, even if `glide.rest.scripted.max_inbound_content_length_mb` or `glide.rest.scripted.max_inbound_gzip_content_length_mb` are set, the request body is limited to the value of `glide.rest.max_content_length`.

Scripted REST APIs good practices

Follow these guidelines when designing and implementing scripted REST APIs.

Follow REST API conventions

Use REST API standards to provide a consistent and easy to use interface for clients. REST API conventions define specific behavior for each type of method. Use the following guidelines as a starting point for designing your API.

- **GET** operations only query data. A GET request should never modify data.
- **POST** operations create new records but do not modify existing records.
- **PUT** and **PATCH** operations modify existing records.
- **DELETE** operations destroy records.

Use versioning to control changes to your API

Use versioning to implement new functionality and avoid breaking existing integrations. When you introduce significant functionality changes to your API, create a new version of the API first. Do not introduce behavior that will break existing integrations in a published version.

Using versioning allows you to implement significant changes to your API without breaking existing clients. You can then release the new version of the API for new clients while allowing existing clients to upgrade at their own pace.

Encourage clients to use a version-specific API, or configure the API without a default version to force clients to specify a version. You can also make new, optional behavior available by adding an optional parameter to an existing version.

Return an informative HTTP status code

Return a status code that informs the requestor of the success or failure of the request. Return an HTTP status code that helps the client understand the result of the request. Use the following guidelines for common status codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Indicates that the request was completed successfully.</td>
</tr>
<tr>
<td>201</td>
<td>Indicates that a record was created successfully.</td>
</tr>
<tr>
<td>204</td>
<td>Indicates that a record was deleted successfully.</td>
</tr>
</tbody>
</table>
Common status codes (continued)

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>40X</td>
<td>Status codes in the 400 range indicate a client error, such as 400 for invalid request syntax.</td>
</tr>
<tr>
<td>(401, 404)</td>
<td></td>
</tr>
<tr>
<td>50X</td>
<td>Status codes in the 500 range indicate that a server error occurred. The client request may have been valid or invalid, but a problem occurred on the server that prevented it from processing the request.</td>
</tr>
<tr>
<td>(500, 503)</td>
<td></td>
</tr>
</tbody>
</table>

Return useful error information

Provide the client with enough information in error messages to allow them to understand the problem without having to refer to your API documentation. An error response should include a helpful error message, as well as an error status code.

For example, when a client queries a record that does not exist, you can return the error message "The specified record does not exist. Ensure that a record with the ID of <id value> exists in the application." along with a 404 status code.

The scripted REST API feature includes several preconfigured error objects you can use for commonly-encountered errors, and a customizable ServiceRequest error object you can use when the preconfigured error objects do not meet your needs.

Enforce and test access controls

Enforce existing access controls and require additional access to modify data. In addition to requiring authentication to access the API, require authorization to access data. Use the GlideRecordSecure API in your scripted REST API scripts. This API ensures that access controls defined on the underlying data are applied for the requesting user.

Require additional access controls for operations that modify data. Requests such as PUT, POST, and DELETE should require a higher level of access than GET. Configure these API resources to require a more strict ACL.

Test your access controls, both authentication and authorization, before releasing the API.

Build tests to verify functionality

Build tests that verify your scripted REST web services functionality as part of your development process. Use repeatable tests to ensure that your API functions
the way you expect it to. Testing also helps ensure that changes you make do not affect the expected API behavior after you release a version. You can use a REST client application that supports automated testing, such as Postman, to facilitate testing.

Tests should validate the response code, headers, and body content as appropriate for each resource you implement. You can also use tests to validate authentication requirements, and to confirm that errors return useful responses.

**Scripted REST API examples**

Multiple examples are available demonstrating how to create and use scripted REST APIs.

**Scripted REST API example - script samples**

These examples demonstrate how to create various resource scripts for a scripted REST API.

**Query parameters GET example**

This example demonstrates how to get query parameter values from a request.

```javascript
/**
 * GET - Sample Request API - Query Params
 */
(function process(/*RESTAPIRequest*/ request, /*RESTAPIResponse*/ response) {
    var uri = request.uri;
    var url = request.url;
    var queryParams = request.queryParams;
    var customHeader = request.getHeader('X-Custom');

    return {
        "uri": uri,
        "url": url,
        "queryParams": queryParams,
        "customHeader": customHeader
    };
})(request, response);
```

**Path parameters GET example**

This example demonstrates how to get path parameter values from a request.
/**
* GET - Sample Request API - Path Params
*/
(function process(/*RESTAPIRequest*/ request, /*RESTAPIResponse*/ response) {
    var uri = request.uri;
    var url = request.url;
    var path = request.pathParams;

    return {
        "uri": uri,
        "url": url,
        "path_params": path,
        "path.id": path.id
    };
})(request, response);

**Script include GET example**

This example demonstrates how to use a script include to provide a response. By using a script include you can reuse common code and maintain readability in the REST service scripts.

/**
* GET - Sample Request API - Script Include
*/
(function process(/*RESTAPIRequest*/ request, /*RESTAPIResponse*/ response) {
    var responseObj = global.SampleDataUtil.getSampleJSON();
    return responseObj;
})(request, response);

**String POST example**

This example demonstrates how to parse a POST message with a string body and send a response based on the request.

/**
* POST - Sample Request API - dataString
* sample usage:
* var requestBody = request.body;
* var requestString = requestBody.dataString;
*/
(function process(/*RESTAPIRequest*/ request, /*RESTAPIResponse*/ response) {
    var requestBody = request.body;
    var requestString = requestBody.dataString;

Binary POST example
This example demonstrates how to parse a POST message with a binary body and send a response based on the request.

```javascript
/**
 * POST - Sample Request API - Body
 */
(function process /*RESTAPIRequest*/ request, /*RESTAPIResponse*/ response) {
    var body = request.body.data;
    //do any additional processing on the request body, such as inserting a new record.
    return {
        "body.id": body.id
    }
})(request, response);
```

Not acceptable error example
This example demonstrates how to respond with a not acceptable error. Use this error type when the request Accept header value is not supported by the web service.

```javascript
/**
 * Sample Not Acceptable Error Sample
 */
(function process /*RESTAPIRequest*/ request, /*RESTAPIResponse*/ response) {
    response.setError(new sn_ws_err.NotAcceptableError('sample error message'));
})(request, response);
```

Bad request error example
This example demonstrates how to respond with a bad request error. Use this error type to indicate a mistake in the request syntax.

```javascript
/**
 * Bad Request Error Sample
 */
(function process /*RESTAPIRequest*/ request, /*RESTAPIResponse*/ response) {
    response.setError(new sn_ws_err.BadRequestError('sample error message'));
})(request, response);
```
Conflict error example
This example demonstrates how to respond with a conflict error. Use this error type in the event of multiple conflicting requests, such as multiple updates to the same record.

```javascript
/**
 * Error Response: Conflict Error Sample
 */
(function process(/*RESTAPIRequest*/ request, /*RESTAPIResponse*/ response) {
  response.setError(new sn_ws_err.ConflictError('sample error message'));
})(request, response);
```

Not found error example
This example demonstrates how to respond with a not found error. Use this error type if the requested resource does not exist or is unavailable.

```javascript
/**
 * Error Response: Not Found Error Sample
 */
(function process(/*RESTAPIRequest*/ request, /*RESTAPIResponse*/ response) {
  response.setError(new sn_ws_err.NotFoundError('sample error message'));
})(request, response);
```

Unsupported media type error example
This example demonstrates how to respond with an unsupported media type error. Use this error type to indicate that the Content-Type of the request is unsupported.

```javascript
/**
 * Error Response: Unsupported Media Type Error Sample
 */
(function process(/*RESTAPIRequest*/ request, /*RESTAPIResponse*/ response) {
  response.setError(new sn_ws_err.UnsupportedMediaTypeError('sample error message'));
})(request, response);
```

Service error example
This example demonstrates how to respond with a generic service error. The ServiceError object allows you to define the status code, message, and error detail. Use a ServiceError if the predefined error types do not meet your needs.

```javascript
/**
 * Error Response: Custom Error Sample
 */
(function process(/*RESTAPIRequest*/ request, /*RESTAPIResponse*/ response) {
```

© 2021 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
var myError = new sn_ws_err.ServiceError();
myError.setStatus(418);
myError.setMessage("I am a Teapot");
myError.setDetail("Here are the details about this error");
response.setError(myError);
})((request, response);

**Scripted REST resource script example**
This sample REST API resource script parses the name and id values from the request body and returns those values in the response.

```javascript
/**
 * POST - Sample Request API - Body
 */
(function process(/*RESTAPIRequest*/ request, /*RESTAPIResponse*/ response) {
var body = request.body.data,
id0,name0,id1,name1;
name0 = body[0].name; // 'user0'
id0 = body[0].id; // '1234'
namel = body[1].name; // 'user1'
id1 = body[1].id; // '5678'

return {
"id": id0,
"name": name0,
"id1": id1,
"name1": namel
};
})((request, response);

**Requests**
The API can accept both XML and JSON requests.

<table>
<thead>
<tr>
<th>JSON Request</th>
<th>XML Request</th>
</tr>
</thead>
<tbody>
<tr>
<td>POST /api/sn_demo_api/v1/example/body HTTP/1.1 Content-Type: application/json Accept: application/json Host: &lt;instance&gt;.service-now.com Connection: close Content-Length: 91</td>
<td>POST /api/sn_demo_api/v1/example/body HTTP/1.1 Content-Type: application/xml Accept: application/json Host: &lt;instance&gt;.service-now.com Connection: close Content-Length: 152</td>
</tr>
</tbody>
</table>
Requests (continued)

<table>
<thead>
<tr>
<th>JSON Request</th>
<th>XML Request</th>
</tr>
</thead>
</table>
| \[
|   { "name": "user0",  
|      "id": 1234    
| },
|   {  
|      "name": "user1",  
|      "id": 5678    
| }\] | <request><entry>
| |   <name>user0</name>
| |     <id>1234</id>
| | </entry>
| | <entry>
| |   <name>user1</name>
| |     <id>5678</id>
| | </entry>
| | </request> |

Responses

Both requests specify application/json as the Accept header value. This causes either response to use JSON formatting, even if the request content type is XML.

HTTP/1.1 200 OK
Content-Type: application/json; charset=UTF-8
Transfer-Encoding: chunked
Date: Tue, 04 Aug 2015 15:20:44 GMT
Server: ServiceNow
Connection: close
Set-Cookie: BIGipServerpool_<Instance>=880838154.47166.0000; path=/

{"result":{"id":1234,"id1":5678,"name":"user0","name1":"user1"}}

Scripted REST API example - streaming vs object serialization

These examples demonstrate how to send a JSON response using streaming and using default object serialization.

Streaming vs object serialization

When sending a response, you can send a response as a stream or serialize an object. There are advantages and disadvantages to either approach. Pick a technique based on the needs of your integration.

Generally, if the response object is simple, can be represented as XML or JSON, and is a consistent size, use object serialization. If using a format other than XML or JSON, or if the size of the response varies, use streaming.
Streaming the response

Using a streaming responses provides advantages in response time, instance performance, and content flexibility, but adds additional complexity to the script. When using streaming, you are responsible for formatting the response, setting the response status, and setting the Content-Type header. When streaming a response, the requesting user receives a response quickly because the entire response does not need to be created before starting streaming.

This example demonstrates a Scripted REST Resource script that returns an array of incident records using streaming.

```javascript
/**
 * Sample Scripted REST Resource that returns custom JSON objects with properties from Incident GlideRecords
 * This sample uses ServiceNow JavaScript API to query incident records and then iterates over those records to build and stream a custom JSON object that includes some values from the incidents
 */
(function runOperation(/*RESTServiceRequest*/ request, /*RESTServiceResult*/ response) {
    var writer = response.getOutputStream(),
        hdrs = {},
        table = 'incident',
        record_limit = 100,
        gr = new GlideRecord(table);

    hdrs['Content-Type'] = 'application/json';
    response.setStatus(200);
    response.setHeaders(hdrs);

    gr.setLimit(record_limit);
    gr.query();

    // start building response object
    writer.writeString('{"results":[');

    // iterate over incident records and build JSON representations to be streamed out.
    while (gr.next()) {
        var incidentObj = {};

        incidentObj.number = gr.number + '';
        incidentObj.short_description = gr.short_description + '';
        writer.writeString(global.JSON.stringify(incidentObj));
    }

    writer.writeString(']}
```
if (gr.hasNext()) {
    writer.writeString("",");
}

// close the response object
writer.writeString("})");
})/(request, response);

A request to this resource returns the following response.

// sample response
/*
HTTP/1.1 200 OK
Content-Type: application/json
Server: ServiceNow

// sample response number of records returned has been truncated for this example

{
  "results": [
  {
    "number": "INC0011301",
    "short_description": "lorem ipsum short description 0 my new incident"
  },
  {
    "number": "INC0011302",
    "short_description": "lorem ipsum short description 1 my new incident"
  },
  {
    "number": "INC0011303",
    "short_description": "lorem ipsum short description 2 my new incident"
  },
  {
    "number": "INC0011304",
    "short_description": "lorem ipsum short description 3 my new incident"
  },
  {
    "number": "INC0011309",
    "short_description": "lorem ipsum short description 8 my new incident"
  }
]
Building an object

Using object serialization allows you to take advantage of ServiceNow provided serialization and content negotiation. When serializing an object instead of streaming, the entire object must be created and serialized before the client receives a response. This may delay the response, or require a large amount of system resources if the response object is very large. Object serialization is available only for XML or JSON responses. Responses using a different format must use streaming.

This example returns the same Incident data as the streaming example, but collects all of the response data in an array before sending the response.
/**
 * Sample Scripted REST Resource returns an array of custom JSON objects that include 2 incident properties.
 * This sample uses ServiceNow JavaScript API to query incident records and then iterates over those records building a custom JSON object that includes 2 values from the incident records.
 * Note that because we are returning a simple JSON object we can rely on built in serialization to set the content-type header as well as response status. The 'result_arr' object will not be returned until it has been completely built and stored
 */
(function runOperation(/*RESTServiceRequest*/ request, /*RESTServiceResult*/ response) {
    var table = 'incident',
        record_limit = 100,
        result_arr = [],
        gr = new GlideRecord(table);

    gr.setLimit(record_limit);
    gr.query();

    // iterate over incident records and build JSON representations to be streamed out.
    while (gr.next()) {
        var incidentObj = {};

        incidentObj.number = gr.number + '';
        incidentObj.short_description = gr.short_description + '';

        result_arr.push(incidentObj);
    }

    return result_arr;
})(request, response);

A request to this resource returns the following response.

/*
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Server: ServiceNow
*/
Scripted REST API example - streaming file attachments

This example demonstrates how to send an image attachment to a requesting user as a binary stream.
A request to this resource returns the following response.

// sample response
/*
HTTP/1.1 200 OK
Set-Cookie: glide_session_store=SYSTEM; Expires=Fri, 30-Oct-2015 21:57:00 GMT; Path=/;
HttpOnly
Content-Type: image/jpeg
Transfer-Encoding: chunked
Date: Fri, 30 Oct 2015 21:26:59 GMT
Connection: close
Server: ServiceNow

<binary response body excluded from this sample>
*/

GraphQL API framework

Create a custom GraphQL API to query record data from a component or a third-party system.

For example, you can create a component that displays the cases associated with an SLA. You can use the Now® Experience UI Framework to develop the component you need, and access case data from the platform by creating a GraphQL schema that defines data in the Case table.
To learn more about developing components, see Developing components for Workspace.

**Benefits of GraphQL**

GraphQL is a web query language optimized for client-side development. Using scripted GraphQL, you can:

- Discover fields and objects available to query through introspection.
- Query the exact data you need from a component.
- Manage multiple possible queries from a single API, as opposed to multiple endpoints for a REST request.
- Integrate with third-party systems by making the schema public.
- Generate the GraphQL query from your component and handle the response.

**What to know before you begin**

Before you start creating custom GraphQL APIs, make sure you have:

- GraphQL knowledge to create a schema.
- JavaScript knowledge to define the API behavior.
- General knowledge of web component concepts.
- A custom Workspace component to consume record data.
- Understanding of the ServiceNow data model that you want to expose in the schema.
- GlideRecord knowledge to map fields to record data in your resolver scripts.

**GraphQL overview**

Creating a scripted GraphQL API includes these parts:

**GraphQL Schema Definition Language (SDL)**

Define the structure and data type of fields available in a GraphQL query. You can define the SDL using the Schema script field in the GraphQL Scripted Schemas [sys_graphql_schema] table. The SDL only supports Query and Mutation operations.

**Resolvers**

Define the data returned by each field. You can define the resolvers for each field in the GraphQL Scripted Resolvers related list on the GraphQL Scripted Schemas form.
Typeresolvers
Resolve interfaces and unions into concrete GraphQL types. For example, you might define a union between an incident type and a problem type. Use the typeresolver script to define when to return which. You can define the typeresolvers in the GraphQL Scripted Typeresolvers related list on the GraphQL Scripted Schemas form.

Resolver mappings
Map resolvers to fields in the schema. You can define resolver mappings in the GraphQL Scripted Resolver Mappings related list on the GraphQL Scripted Schemas form.

To learn more about the GraphQL query language, see the GraphQL website.

Limitations
The following GraphQL features are not supported:

- Subscription operations
- Custom scalar types

Introspection
By default, introspective queries into your custom schemas are not allowed. To allow introspection, set a system property. See GraphQL system properties.

Namespaces
GraphQL APIs have two different namespaces:

- **Application namespace**
  The namespace for the custom application. To learn more about application namespaces, see Application scope.

- **Schema namespace**
  The namespace for the schema to ensure that all queries are unique. You can have multiple schema namespaces in a single application.

When querying data, you must include both namespaces in your query. For example, the following query is searching for data with the following namespaces:

- Application namespace: x_graph_scope
- Schema namespace: planet
query {
  x_graph_scope {
    planet {
      findAll {
        name
        mass
        distance
      }
    }
  }
}

Directives and global functions

@source schema directive
Maps a GraphQL field to the value of a property of the parent object. If the field has a separate resolver script, the system uses the record that it resolves to instead of the parent object.
Use in your schema script.

Resolver functions

These functions are available on the global env object.

• getArguments(): Returns the arguments of the previous field.
• getSource(): Returns the parent object.

Use in your resolver script.

Typersolver functions

These functions are available on the global env object.

• getArguments(): Returns the arguments of the previous field.
• getobject(): Returns the parent object.
• getTypeName(): Returns the name of the interface or union type.

Use in your typersolver script.

Demo application

To see a demo GraphQL PTO calendar schema with mutations and queries, enable the GraphQL Framework Demo Application plugin (com.glide.graphql.framework.demo).
Create a GraphQL schema

Create a GraphQL schema to make data available to GraphQL queries.

Before you begin
Role required: admin

Procedure
1. Navigate to System Web Services > GraphQL > Schemas.
2. Click New.
3. Complete these fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the schema.</td>
</tr>
<tr>
<td>Schema namespace</td>
<td>Must be unique within the name of the application.</td>
</tr>
<tr>
<td>Application</td>
<td>Read-only application that the schema is a part of.</td>
</tr>
<tr>
<td>Application namespace</td>
<td>Read-only. Works with the Schema namespace to prevent conflict with schemas with the same name.</td>
</tr>
<tr>
<td>Active</td>
<td>Checked if active, unchecked if not active.</td>
</tr>
<tr>
<td>Schema</td>
<td>Schema definition that adheres to the GraphQL SDL format. Must be GraphQL valid syntax. Otherwise, error messages appear on save to indicate the syntax problem.</td>
</tr>
</tbody>
</table>

Note: The following GraphQL features are not supported:
- Subscription operations
- Custom scalar types

You can use these directives in your schema:
- `@source`: Maps a GraphQL field to the value of a property of the parent object. If the field has a separate resolver script, the system uses the record that it resolves to instead of the parent object.

Example
This example defines an Incident object type in the schema and uses a resolver script to map the type to a GlideRecord from the Incident table. Using
the @source directive maps the fields within the Incident type to the value or display_value in the Incident GlideRecord.

```graphql
type Incident {
  id: String @source(value: "sys_id.value")
  active: Boolean @source(value: "active.display_value")
  state: String @source(value: "state.display_value")
  priority: String @source(value: "priority.display_value")
  severity: String
  description: DisplayableString
  resolvedBy: User @source(value: "resolved_by.value")
  openedBy: User @source(value: "opened_by.value")
  child_incidents: String
  opened_at: String
  resolved_at: String
  closed_at: String
  work_notes: String
  comments: String @source(value: "comments.display_value")
  parent_incident: String
}
```

4. Select the **Security** tab and complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Requires authentication</td>
<td>Checked if the schema requires authentication, unchecked if the schema doesn’t require authentication and is available publicly.</td>
</tr>
<tr>
<td>Requires SNC internal</td>
<td>Appears only if the Explicit Roles plugin is enabled. Checked if the schema requires the SNC internal role, unchecked if the schema doesn’t require the SNC internal role.</td>
</tr>
<tr>
<td>Requires ACL authorization</td>
<td>Checked if the schema requires ACL authorization, unchecked if the schema doesn’t require ACL authorization.</td>
</tr>
<tr>
<td>ACLs</td>
<td>Appears only if Requires ACL authorization is checked. Checks incoming queries against ACLs of type <strong>GraphQL</strong>.</td>
</tr>
</tbody>
</table>

**Note:** The API returns clear error messages to users who do not have access to a schema, or who are not authenticated when the API requires authentication to access.
5. Save the form.

6. **Optional:** Create a resolver script to define what value the schema returns when a component queries a specific field. If you don’t define a resolver for a field, the query returns any matching field value from the parent object type. For example, suppose you have an Incident object type in your schema with a worknotes field. The Incident object type has a resolver that maps to a GlideRecord from the Incident table. If you do not create a resolver mapping for the worknotes field, the system searches the parent object’s data source, which is the GlideRecord from the Incident table, for a worknotes field and assigns the associated value.

   a. Select the GraphQL Scripted Resolvers tab and click **New**.

   b. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the resolver.</td>
</tr>
<tr>
<td>Schema</td>
<td>Read-only schema namespace.</td>
</tr>
<tr>
<td>Application</td>
<td>Read-only application that the schema is a part of.</td>
</tr>
<tr>
<td>Script</td>
<td>Define the value returned when the field is queried. Functions available on the global <code>env</code> object:</td>
</tr>
<tr>
<td></td>
<td>• <code>getArguments()</code>: Returns the arguments of the previous field.</td>
</tr>
<tr>
<td></td>
<td>• <code>getSource()</code>: Returns the parent object.</td>
</tr>
<tr>
<td></td>
<td>This script has access to GlideRecord.</td>
</tr>
</tbody>
</table>

**Example**

(Optional) This example returns a record from the User table when the associated field is queried:

```javascript
(function process(/*ResolverEnvironment*/ env) {
  var userid = env.getArguments().id != null ? env.getArguments().id : env.getSource();
  var now_GR = new GlideRecord('sys_user');
  gr.addQuery('sys_id', userid);
  gr.query();
```

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
c. Click Submit.

7. Optional: Define the typeresolvers for your schema to resolve interfaces and unions into concrete types.

a. Select the GraphQL Scripted Typeresolvers tab and click **New**.

b. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schema</td>
<td>Read-only schema namespace.</td>
</tr>
<tr>
<td>Type</td>
<td>The interface or union type defined in the schema.</td>
</tr>
<tr>
<td>Application</td>
<td>Read only application that the schema is a part of.</td>
</tr>
<tr>
<td>Script</td>
<td>Define the value returned for union and interface types. Functions available on the global <code>env</code> object:</td>
</tr>
<tr>
<td></td>
<td>• <code>getArguments()</code>: Returns the arguments of the previous field.</td>
</tr>
<tr>
<td></td>
<td>• <code>getObject()</code>: Returns the parent object.</td>
</tr>
<tr>
<td></td>
<td>• <code>getTypeName()</code>: Returns the name of the interface or union type.</td>
</tr>
<tr>
<td></td>
<td>This script has access to GlideRecord.</td>
</tr>
</tbody>
</table>

c. Click Submit.

8. Optional: Map the resolver and typeresolver records to fields in the schema. This mapping lets the system know what value to return when a component queries a specific field.

a. Select the GraphQL Scripted Resolver Mappings tab and click **New**.

b. Complete the form.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Path</td>
<td>Path to the field in the schema you want to map.</td>
</tr>
<tr>
<td>Resolver</td>
<td>Resolver to use to define the data returned by the field.</td>
</tr>
<tr>
<td>Application</td>
<td>Read-only application that the schema is a part of.</td>
</tr>
<tr>
<td>Schema</td>
<td>Read-only schema namespace.</td>
</tr>
</tbody>
</table>

**c. Click Submit.**

**Test a GraphQL schema**

Test your GraphQL schema using a third-party tool.

**Before you begin**

Role required: admin

- Create a GraphQL schema.
- Download a third-party GraphQL tool, such as GraphiQL or Insomnia.

**Procedure**

1. Open the third-party tool on your machine.
2. Set the endpoint to query your custom schema: `https://<your-instance>.servicenow.com/api/now/graphql`.
3. Add any authentication headers required.
4. **Optional:** If introspection is enabled, you can send introspective queries to learn more about what the schema includes. To turn on introspection, see GraphQL system properties.

ℹ️ **Note:** Do not use introspective queries in a production environment.

5. Send test queries to the schema.

   Include both the application and schema namespaces. This example includes both namespaces:

   - Application namespace: `x_graph_scope`
   - Schema namespace: `planet`

   ```
   query {
     x_graph_scope {
       planet {
   ```
What to do next
Query a GraphQL schema from a component.

Query a GraphQL schema from a component
Access record data in a component by querying your scripted GraphQL schema.

Before you begin
Role required: admin
1. Create a GraphQL schema.
2. Test a GraphQL schema.
3. Create a custom component.

Procedure
1. Navigate to your component directory.
2. Define the query in your component's index.js file.

⚠️ Note: Do not use introspective queries in a production environment.

Example
```javascript
const incidentQuery = `query ($sys_id: String!) {
  query (sys_id: $sys_id) {
    incident {
      _results {
        sys_id {
          displayValue
        }
      }
    }
  }
}
`;
```
3. Add the following line to the top of the script to import the `createGraphQLEffect` API into your component.

```javascript
import {createGraphQLEffect} from '@servicenow/ui-effect-graphql';
```

4. Call the query using the `createGraphQLEffect` API. To learn more about this API, see the Developer Site.

5. Create action handlers to manage the result of the query.

**Example**

```javascript
actionHandlers: {
  [DATA_FETCH_REQUESTED]: dataFetchHandler,
  [DATA_FETCH_STARTED]: ({updateState}) => updateState({loading: true}),
  [DATA_FETCH_SUCCEEDED]: ({action, updateState}) => updateState({data: action.payload}),
  [DATA_FETCH_FAILED]: () => { /* handle network error */ },
}
```

**Example:**
This example shows a complete component including the query, the GraphQL API call, and action handlers to manage the response.

```javascript
import {createCustomElement} from '@servicenow/ui-core';
import snabbdom from '@servicenow/ui-renderer-snabbdom';
import {createGraphQLEffect} from '@servicenow/ui-effect-graphql';

const GQL_QUERY = `query query ($active: Boolean) {
  now {
    mySchema (active: $active) {
      myField {
        value
      }
    }
  }
}`;

const DATA_FETCH_REQUESTED = 'DATA_FETCH_REQUESTED';
const DATA_FETCH_STARTED = 'DATA_FETCH_STARTED';
const DATA_FETCH_SUCCEEDED = 'DATA_FETCH_SUCCEEDED';
const DATA_FETCH_FAILED = 'DATA_FETCH_FAILED';

const dataFetchHandler = createGraphQLEffect(GQL_QUERY, {
  variableList: ['active'],
});
```
GraphQL system properties

Configure GraphQL API framework behavior. For example, you can configure whether to allow introspective queries into your schema.

Navigate to **System Web Services > GraphQL > Properties** to change your GraphQL settings.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.graphql.introspection_enabled</td>
<td>Enables introspective queries to discover the supported GraphQL queries and types.</td>
</tr>
<tr>
<td></td>
<td>• Type: Boolean</td>
</tr>
<tr>
<td></td>
<td>• Default: False</td>
</tr>
</tbody>
</table>
SOAP web service

Simple Object Access Protocol (SOAP) is an XML-based protocol for accessing web services over HTTP.

You can use SOAP to access data on your instance. Available SOAP web services are WS-I compliant, as outlined in the WS-I Basic Profile 1.0.

Web service provider

ServiceNow publishes its underlying table structures and associated data using the following web service methods:

- **Direct web services**: Use a URL query to request a table’s WSDL.
- **SOAP web service import sets**: Use import tables and transform maps to automate web service requests for tables.
- **Scripted SOAP web services**: Use custom JavaScript to execute SOAP web services requests.

⚠️ **Note**: SOAP messages are sent with the assumption that the recipient is XML compliant. No encoding is applied to a SOAP message. SOAP always decodes responses as UTF-8, the XML encoding header is not used.

WSDL

All tables and import sets dynamically generate Web Service Definition Language (WSDL) XML documents that describe its table schema and available operations.

You can obtain a table’s WSDL by issuing a URL call to your instance that contains the name of the table and the **WSDL** parameter. For example:

```plaintext
https://myinstance.service-now.com/incident.do?WSDL
```

All dynamically generated and served ServiceNow WSDLs accessible via HTTP are available for use under the terms defined in the Open Source Initiative OSI - Apache License, Version 2.0 license agreement.

Long-running SOAP request support

The Now Platform supports long-running SOAP requests by preventing socket timeouts due to inactivity of the network connection while the requests are in process.

This functionality improves the efficiency of the ODBC driver when requesting large numbers of records, doing aggregate queries, or using order by expressions that require sorting.
By default, the system provides timeout protection for web services clients provided by ServiceNow such as the ODBC driver and the MID Server. You can add timeout protection to your custom web services with system properties.

**Timeout protection**

Web services clients receive a 307-Temporary Redirect to keep long sessions alive and prevent a timeout due to socket inactivity. A 307-Temporary Redirect causes web services clients which support the status code to repeat their last request to the location specified in the HTTP location header. The value of the location header is the same URL that the web services client originally specified. The use of 307-Temporary Redirects is WS-I compliant.

A web service request that exceeds the timeout limit specified in `glide.soap.request_processing_timeout` can only receive a 307-Temporary Redirect when all of these conditions are met:

- The value of `glide.soapprocessor.allow_long_running_threads` is true.
- The request includes a `redirectSupported=true` URL parameter.
- The request is session-aware (supports HTTP cookies).
- The number of redirects has not exceeded the value set by `glide.soap.max_redirects`.

If any of these conditions is not met, the web service client receives a 408 Request Timeout error.

**Note:** To ensure that applications experience a socket timeout rather than a 408 Request Timeout, set the `glide.soap.request_processing_timeout` property to a value larger than the shortest socket timeout setting in effect for the connection between the application and the instance (300 seconds for hosted instances).

**SOAP web services security**

An instance enforces web service security using a combination of basic authentication challenge/response over the HTTPS protocol and system-level access control lists (ACLs) using contextual security. Administrators can control what system resources web services users can access by granting them one of the SOAP roles.

**SOAP roles**

To use SOAP web services, you must have the appropriate role for the operation you want to perform. Also, you must have any other roles required to access the target tables.
### SOAP Roles

<table>
<thead>
<tr>
<th>Role</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>soap</td>
<td>Can perform all SOAP operations.</td>
</tr>
<tr>
<td>soap_create</td>
<td>Can insert new records.</td>
</tr>
<tr>
<td>soap_delete</td>
<td>Can delete existing records.</td>
</tr>
<tr>
<td>soap_ecc</td>
<td>Can query, insert, and delete records on the Queues [ecc_queue] table.</td>
</tr>
<tr>
<td>soap_query</td>
<td>Can query record information.</td>
</tr>
<tr>
<td>soap_query_update</td>
<td>Can query record information and update records.</td>
</tr>
<tr>
<td>soap_script</td>
<td>Can run scripts that specify a .do endpoint. This role is required for running scripted web services.</td>
</tr>
<tr>
<td>soap_update</td>
<td>Can update records.</td>
</tr>
<tr>
<td>import_admin</td>
<td>Can manage all aspects of import sets and imports. Required for access to the Import Set Row [sys_import_set_row] table.</td>
</tr>
</tbody>
</table>

### Default web services role requirements

By default, a set of processor ACL rules require users to have the soap_query role to make WSDL, XSD, and XML schema requests.

If you want to change these role requirements, you can deactivate the ACL rules.
Basic authentication

To enforce basic authentication for the user associated with the instance for each WSDL or SOAP message request, administrators can set the property glide.basicauth.required to true.

When enabled, each WSDL and SOAP request must contain an "Authorization" header as specified in the Basic Authentication protocol.

Because web services requests are non-interactive, the Authorization header is always required during a request.

⚠️ Note: If configured, basic authentication refers to local credentials or LDAP authentication.

Supplying basic authentication information with every request (whether or not it is required) has the added advantage that the user supplied in the basic authentication credentials can be associated with web service invocation. For example, when creating an Incident record, the journal field lists the user ID contained in the basic authentication header instead of the default guest user.

SOAP security policies

The Enhanced Web Service Provider - Common plugin adds the SOAP Security Policies module to the System Web Services application. This module allows administrators to set the following security policies:

- Enable or disable signing SOAP requests when consuming an external web service
- Specify the authentication requirements SOAP requests must meet when communicating over WS-Security.

© 2021 ServiceNow, Inc. All rights reserved.
**Certificates required for signed SOAP requests**

To sign SOAP requests for WS-Security communications, the following certificates are required:

- X.509 certificate from the requester
- X.509 CA certificate of the certificate authority who signed the requester’s certificate

**SOAP default security policy**

Administrators can specify the SOAP security policy an instance uses with the system property `glide.soap.default_security_policy`. The `glide.soap.default_security_policy` system property specifies the name of the SOAP security policy the instance uses when enforcing Web Services-Security (WSS) for inbound requests.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default value</td>
<td>Default Security Policy</td>
</tr>
<tr>
<td>Location</td>
<td>Add to the System Properties [sys_properties] table</td>
</tr>
</tbody>
</table>

**WS-Security**

You can validate signed web services requests using WS-security. Enable WS-Security to:

- Verify that SOAP messages originate from a known sender
- Verify that SOAP messages have not been altered in transit

ServiceNow supports **WS-Security 1.1** to validate signed web services requests.

⚠️ **Note:** WS-Security is not used as an encryption mechanism. HTTPS protocol is used to encrypt all communications.

WS-Security is intended to work with basic authentication. When an instance receives a SOAP message, it reviews the basic authentication header to determine if the SOAP user has rights to the instance. It reviews the WS-Security header to determine the validity of the incoming message. Requests affected by attacks, such as a man-in-the-middle attack, have an invalid WS-Security header and are blocked.
WS-Security profiles

A WS-security profile determines how a web services message is authenticated when WS-security is enabled. The following mechanisms can be used to authenticate web services requests:

**Web service authentication mechanisms**

<table>
<thead>
<tr>
<th>Authentication mechanism</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Certificate verification</td>
<td>Verifies the certificate associated with the request. Verifying the request's certificate requires uploading the requester's certificate and certificate authority.</td>
</tr>
<tr>
<td>User credentials</td>
<td>Authenticates the web services request by verifying the user credentials associated with the request. This type of authentication can either verify that the request's credentials match an existing user's credentials or that the request's credentials match a user name and password provided in the profile record.</td>
</tr>
</tbody>
</table>

Specify the authentication mechanism you want to use when you create a new WS-security profile.

The WS-Security Profiles module lists the WS-Security profiles that are currently in effect.

**WS-Security Profiles module**

<table>
<thead>
<tr>
<th>Type</th>
<th>Active</th>
<th>Order</th>
<th>Bind session</th>
</tr>
</thead>
<tbody>
<tr>
<td>X509</td>
<td>true</td>
<td>100</td>
<td>false</td>
</tr>
<tr>
<td>Username</td>
<td>true</td>
<td>200</td>
<td>true</td>
</tr>
</tbody>
</table>

**WS-Security error logging**

The glide.processor.debug.SOAPProcessor system property allows error messages about WS-security to be displayed in the transaction log.

The system property glide.processor.debug.SOAPProcessor enables (true) or disables (false) debugging messages for SOAP processing such as certificate and keystore checks.
### glide.processor.debug.SOAPProcessor fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>true</td>
</tr>
<tr>
<td>Default value</td>
<td>false</td>
</tr>
<tr>
<td>Location</td>
<td>Add to the System Properties [sys_properties] table</td>
</tr>
</tbody>
</table>

### WSS X.509 Token Profile

Use the X.509 framework for a WSS X.509 security profile. An X.509 certificate is used to validate a public key that is then used to sign the incoming SOAP message. It specifies a binding between a public key and a set of attributes that includes at least the following:

- subject name
- issuer name
- serial number
- validity interval

Use the X.509 authentication framework as defined by the Web Services Security: SOAP Message Security specification.

Upload the certificate and reference it in the **X509 Certificate** field. If a bound session, select the user to impersonate when the WS-Security authentication succeeds.

### WSS X.509 Security Profile

![WSS X.509 Security Profile](image)

### WSS UsernameToken Profile

When specifying the X.509 Token Profile, you can also supply a UsernameToken in the SOAP request.

A UsernameToken is used as a means of identifying the requester by "user name", and optionally using a password, shared secret, or password equivalent, to authenticate that identity.

There are two ways to authenticate a UsernameToken.
1. Authenticate with existing user credentials.

Authenticate with existing user credentials

Use the user name of the incoming SOAP request to look up a user by the specified User field to match the UserName value. The system uses the password value in the incoming UsernameToken to authenticate the request. When the Bind session option is selected, the user that authenticates successfully is used for the session.

2. Authenticate with specified user credentials.

Authenticate with specified user credentials

Authenticate using login credentials unrelated to users in the User table. When the Bind session option is selected, the user that is specified in the Run as user field is used for the session.

Note: The UsernameToken Profile cannot be used independent of the X.509 Token Profile.

Strict security for web services

By default, basic authentication for web services only determines whether a user is authorized to access the instance with a SOAP connection. Once authorized, any user can access any table published as a web service.

The system property Enforce strict security on incoming SOAP requests changes this behavior and requires that users meet Contextual Security requirements to access instance resources from web services.

With this property enabled, only users that have the proper SOAP role and also meet the ACL conditions the table and operation can perform that operation from a SOAP connection.

Mutual authentication for web services

Mutual authentication is supported for outbound web services.
SOAP session management and reporting

A SOAP session is a Glide session established with an instance by any external SOAP client, such as a web services client application, a ServiceNow MID Server, or the ServiceNow ODBC driver. SOAP sessions are included in the list of user sessions at User Administration > Logged in users. The ?SOAP URLs identify SOAP sessions.

SOAP session properties

Certain properties control how SOAP sessions are maintained.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.soap.invalidate_session_timeout</td>
<td>Duration, in seconds, that an active session remains open. After this duration is reached, the instance deactivates the session and reclaims any system resources. If the client sends another request after the timeout duration is reached, the instance establishes a new session. This property accepts values from 5 to 1200 seconds (20 minutes).</td>
</tr>
</tbody>
</table>

- Type: integer
- Default value: 60
- Location: Add to the System Properties [sys_properties] table

Note: To learn more about properties that affect SOAP web services processing, see the following topics in Instance Security Hardening Settings:

- Access control (instance security hardening)
- Basic auth: SOAP requests

Direct web services

A direct web service is available for any table in the system if the correct access control list is configured.
The supported format of the incoming message is document style literal XML SOAP documents (Document/Literal). To retrieve a direct web service WSDL description and XML schema, point to the relative URL `<tablename>.do?WSDL`. For example, to retrieve the WSDL for the Incident table on the online demo system, use the following URL: https://<instance name>.service-now.com/incident.do?WSDL.

**Extended query parameters**

Extended query parameters enable you to filter and modify the return results of a SOAP query when using the `get`, `getKeys`, and `getRecords` functions.

**Note:** Extended query element names are preceded by two underscore characters.

### Available extended query parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>__encoded_query</code></td>
<td>Specify an encoded query string to be used in filtering the returned results. The encoded query string format is similar to the value that may be specified in a <code>sysparm_query</code> URL parameter. See the encoded query building example in the RSS feed generator examples.</td>
<td><code>&lt;__encoded_query&gt;active=true^category='hardware'&lt;/__encoded_query&gt;</code></td>
</tr>
<tr>
<td><code>__order_by</code></td>
<td>Instruct the returned results to be ordered by the specified field.</td>
<td><code>&lt;__order_by&gt;priority&lt;/__order_by&gt;</code></td>
</tr>
</tbody>
</table>
### Available extended query parameters (continued)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>__order_by_desc</td>
<td>Instruct the returned results to be ordered by the specified field, in descending order.</td>
<td><code>&lt;__order_by_desc&gt;opened_date&lt;/__order_by_desc&gt;</code></td>
</tr>
<tr>
<td>__exclude_columns</td>
<td>Specify a list of comma delimited field names to exclude from the result set.</td>
<td><code>&lt;__exclude_columns&gt;sys_created_on,sys_created_by,caller_id&lt;/__exclude_columns&gt;</code></td>
</tr>
<tr>
<td>__limit</td>
<td>Limit the number of records that are returned.</td>
<td><code>&lt;__limit&gt;100&lt;/__limit&gt;</code></td>
</tr>
<tr>
<td>__first_row</td>
<td>Instruct the results to be offset by this number of records from the beginning of the set. When used with __last_row has the effect of querying for a window of results. The results are inclusive of</td>
<td><code>&lt;__first_row&gt;250&lt;/__first_row&gt;</code></td>
</tr>
</tbody>
</table>
# Available extended query parameters (continued)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>__last_row</td>
<td>Instruct the results to be limited by this number of records from the beginning of the set, or the __start_row value when specified. When used with __first_row has the effect of querying for a window of results. The results are less than the last row number, and does not include the last row.</td>
<td>__last_row&gt;500&lt;/__last_row&gt;</td>
</tr>
<tr>
<td>__use_view</td>
<td>Specify a Form view by name, to be used for limiting and expanding the results returned. When the form view contains deep referenced fields such as __use_view&gt;soap_view&lt;/__use_view&gt;</td>
<td></td>
</tr>
</tbody>
</table>
Available extended query parameters (continued)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>caller_id.email</td>
<td>this field will be returned in the result as well.</td>
<td></td>
</tr>
</tbody>
</table>

**Direct web services namespace**

**Specifying a unique namespace for each table**

The `glide.wsdl.definition.use_unique_namespace` property ensures that each table's direct web service WSDL has a unique `targetNamespace` attribute. This property is `true` by default, which requires a table's direct web service WSDL to use a `targetNamespace` value of `http://www.service-now.com/<table name>`. When `false` (or when the property is not present), all tables use the same `targetNamespace` value of `http://www.service-now.com`. Since all tables also share the same operation names, a web service client attempting to consume more than one ServiceNow web service would be unable to differentiate between requests between multiple tables. Using a unique `targetNamespace` value allows web service clients to distinguish requests between multiple tables.

For example, the direct web service WSDL for the incident table uses this `targetNamespace` value:

```xml
<xsd:schema elementFormDefault = "unqualified" targetNamespace = "http://www.service-now.com/incident" >
```

**Setting namespace requirements**

ServiceNow's WSDL schema by default declares an attribute of `elementFormDefault="unqualified"`. This attribute indicates whether or not locally declared elements must be qualified by the `targetNamespace` in an instance document. If the value of this attribute is `unqualified`, then locally declared elements should not be qualified by the `targetNamespace`. If the value of this
attribute is **qualified**, then locally declared elements must be qualified by the `targetNamespace`.

However, this is incompatible with the way clients generated from WSDL (for example, .NET, Axis2, webMethods) process the embedded schema. It removes the schema namespace as a result, making the web service response unparsable.

To overcome this compatibility issue, a boolean property called `glide.wsdl.schema.UnqualifiedElementFormDefault` is introduced. This property has the value of **true** by default. Setting it to **false** enables clients generated from WSDL to parse the return value of the web service invocation. You can modify this property using the Web Services properties page at **System Properties > Web Services**.

**Allowing duplicate service names**

By default, service names from dynamically generated WSDL are unique and have the following format:

```
ServiceNow_<table name>
```

To allow duplicate service names, administrators can set the `glide.wsdl.unique_service_name` property to **false**. Create the property if it does not exist.

**Related information**

**SOAP web service**

**Use forms to limit or extend the query response**

On occasion, there is a need to limit the number of field values that a SOAP query returns.

You can use a form view to limit the number of field values returned by a SOAP query. Specifying a form view has the effects of:

1. Limiting the response elements to contain only the fields on the view.
2. Specifying reference record field values from referenced fields such as `caller_id.email`. This causes the value of the caller's email to be returned in the SOAP response.

To enable form views for SOAP queries, configure the `com.glidesoapview` property to contain the name of the view that you want to use for all SOAP query responses. The default is `soap_response`. You can also specify the view name as a URL parameter, `sysparm_view=<view name>`, when making the SOAP call. For example:
By default, if a specified view name does not exist, the response contains all fields.

**Return the display value for reference variables**

When you query a record using a `get` or `getRecords` function, the instance returns all fields associated with that record. The fields are often reference fields that contain a sys_id for a record on another table.

Use one of these options if you want the display value for the field to be returned instead of the sys_id:

1. Add the `glide.soap.return_displayValue` property to your system properties, and every SOAP request will return a display value for a reference field.

2. Add the `displayvalue=true` parameter to your SOAP request URL, and SOAP requests with that parameter will return a display value for a reference field as a string, instead of the sys_id. The SOAP URL would look as follows: `https://<instance name>.service-now.com/incident.do?displayvalue=true&SOAP`.

3. Add the `displayvalue=all` parameter to your SOAP request URL, and SOAP requests with that parameter will return a display value for a reference field, in addition to the sys_id. The response element name for the display value field will be prefixed with `dv`, such as `dv_caller_id`.

**Clear values from a target instance**

You can pass an empty value through a SOAP parameter to clear the respective value in the target instance.

You can also pass an empty (null) value through the `&allow_empty_value=true` SOAP query parameter to clear the respective value in the target instance.

For example, `https://<instance name>.service-now.com/incident.do?SOAP&allow_empty_value=true` lets you pass an empty value to the incident record in an instance.

You can then enter lines like the following in the SOAP request:

```xml
<assigned_to>value</assigned_to>
<assignment_group>value</assignment_group>
<category></category>
```

In the above example,
• `<assigned_to>value</assigned_to>` changes the value in the **Assigned to** field to the value specified in the SOAP request.

• `<assignment_group>value</assignment_group>` changes the value in the **Assignment group** field to the value specified in the SOAP request.

• `<category></category>` clears the value in the **Category** field.

**Retrieve journal entries using direct web services**

To get the contents of a journal field, make a second soap request against the `sys_journal_field` table to pull the appropriate journal records back for the record in question.

The URL for the WSDL would be in the following format.

```plaintext
https://instance-name.service-now.com/sys_journal_field.do?WSDL
```

To retrieve the journal entries, you will first need to query the incident for its `sys_id` value, and then supply it as the `element_id` value in a `getRecords` call. To specify records only for the `comments` field, specify the value `comments` for the `element` field. For example, a SOAP request would look like the following:

```xml
<soapenv:Envelope xmlns:soapenv= "http://schemas.xmlsoap.org/soap/envelope/"
xmlns:sys= "http://www.service-now.com/sys_journal_field"
><soapenv:Header />
<soapenv:Body><sys:getRecords><element>comments</element><element_id>9d385017c611228701d22
104cc95c371</element_id></sys:getRecords></soapenv:Body></soapenv:Envelope>
```

**Retrieve choice fields using direct web services**

To retrieve or set choice fields, use the choice **Value**, not the **Label**.

For example, if you want to retrieve a list of all closed incidents, use the numerical value for **Closed**, which is 7 by default.

```xml
<state>7</state>
```

To see a list of choice values:

1. Navigate to the form containing the choice field. For example, navigate to **Incident > Open** and select an incident.

2. Right-click the choice value field and select **Configure Dictionary**. For example, configure the dictionary for the **State** field.

3. From the Choices related list, note the value for the label you want to query. For example, note that the **Closed** choice has a value of 7.
Persist an HTTP session across all SOAP calls

In circumstances when a SOAP client makes many calls in a short amount of time, you may want to re-use a single HTTP session for all SOAP calls.

Each SOAP call creates a new user session that persists until it expires. To create a single user session and re-use it for all inbound SOAP calls, develop your SOAP client following these guidelines:

- Use a module like HTTP::Cookies to create a "cookie jar."
- Save the cookies returned by ServiceNow after each request (handled automatically by HTTP::Cookies).
- Re-send the cookies in the cookie jar with each subsequent request.

⚠️ Note: If you have enabled the session rotation high security setting, it will immediately invalidate the JSESSIONID returned from the server with the first response header. The second response includes a new JSESSIONID.

In perl, you can automatically save and send cookies with the following code:

```perl
use HTTP::Cookies;

# we want to store and re-send cookies
my $cookies = HTTP::Cookies->new(ignore_discard => 1);
```
my $soap = SOAP::Lite->proxy('http://localhost:8080/glide/ecc_queue.do?SOAP');

# Set the cookie jar
$soap->transport->cookie_jar($cookies);

**SOAP direct web service API functions**

The standard SOAP API is a set of small, globally defined functions that can be performed on a targeted resource.

The targeted resource (or table) is defined in the URL by the format https://<instance name>.service-now.com/<table name>.do.

### Data Retrieval API

<table>
<thead>
<tr>
<th>Method Summary</th>

Related reference

Data Modification API

getKeys
Query the targeted table by example values and return a comma delimited sys_id list.

Input fields
Any field value in the targeted table.

Output fields
A SOAP response element sys_id that contains a comma delimited list of sys_id values.
Sample SOAP messages

Sample SOAP request

```xml
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
    xmlns:inc="http://www.service-now.com/incident">
  <soapenv:Header/>
  <soapenv:Body>
    <inc:getKeys>
      <category>hardware</category>
    </inc:getKeys>
  </soapenv:Body>
</soapenv:Envelope>
```

Sample SOAP response

```xml
<soapenv:Envelope xmlns:inc="http://www.service-now.com/incident"
    xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
  <soapenv:Header/>
  <soapenv:Body>
    <getKeysResponse>
      <sys_id>46e18c0fa9fe19810066a0083f76bd56,46e57642a9fe198100b96a5dca501ff,46f1784ba9fe19810018aa27fbb23482</sys_id>
      <count>7</count>
    </getKeysResponse>
  </soapenv:Body>
</soapenv:Envelope>
```

Language-specific sample messages

For language-specific `getKeys` samples, refer to the following topics:

- Perl SOAP::Lite
- Java Apache Axis2
- Python

`getRecords`

Query the targeted table by example values and return all matching records and their fields.

**Input fields**

Any field value in the targeted table.
Output fields

The getRecordResponse element may contain one or more getRecordsResult elements that encapsulate elements representing the field values of records matching the query.

Sample SOAP messages

Sample SOAP request

```xml
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
     xmlns:inc="http://www.service-now.com/incident">
  <soapenv:Header/>
  <soapenv:Body>
    <inc:getRecords>
      <number>INC0000002</number>
    </inc:getRecords>
  </soapenv:Body>
</soapenv:Envelope>
```

Sample SOAP request using an encoded query to filter where incident number is INC0000001 or INC0000002

```xml
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
     xmlns:inc="http://www.service-now.com/incident">
  <soapenv:Header/>
  <soapenv:Body>
    <inc:getRecords>
      <__encoded_query>number=INC0000001^ORnumber=INC0000002</__encoded_query>
    </inc:getRecords>
  </soapenv:Body>
</soapenv:Envelope>
```

Sample SOAP response that contains 1 record

```xml
<soapenv:Envelope xmlns:inc="http://www.service-now.com/incident"
     xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
  <soapenv:Header/>
  <soapenv:Body>

        <caller_id.email>david.loo@service-now.com</caller_id.email>
        <closed_at/>
        <number>INC0000002</number>
        <opened_at>2009-12-14 23:07:12</opened_at>
      </getRecordsResult>
    </getRecordsResponse>
  </soapenv:Body>
</soapenv:Envelope>
```
Sample SOAP response that contains more than 1 record

```xml
<soapenv:Envelope xmlns:inc="http://www.service-now.com/incident"
xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
  <soapenv:Header/>
  <soapenv:Body>
    <getRecordsResponse>
      <getRecordsResult>
        <caller_id>5137153cc611227c000bbd1bd8cd2006</caller_id>
        <caller_id.email>rick.berzle@yourcompany.com</caller_id.email>
        <closed_at>2009-12-17 22:55:16</closed_at>
        <number>INC0000009</number>
        <opened_at>2009-12-16 22:50:23</opened_at>
        <short_description>Reset my password</short_description>
      </getRecordsResult>
      <getRecordsResult>
        <caller_id>5137153cc611227c000bbd1bd8cd2005</caller_id>
        <caller_id.email>fred.luddy@yourcompany.com</caller_id.email>
        <closed_at>2009-12-15 22:54:55</closed_at>
        <number>INC0000010</number>
        <opened_at>2009-12-10 22:53:02</opened_at>
        <short_description>Need Oracle 10GR2 installed</short_description>
      </getRecordsResult>
    </getRecordsResponse>
  </soapenv:Body>
</soapenv:Envelope>
```

Language-specific sample messages

For language-specific `getRecords` samples, refer to the following topics:

- Perl SOAP::Lite
- Java Apache Axis2
- Microsoft .NET web services client examples
- Python

© 2021 ServiceNow, Inc. All rights reserved.
**get**

Query a single record from the targeted table by *sys_id* and return the record and its fields.

**Input fields**

An element `<sys_id>` identifying the sys_id of the record to be retrieved.

**Output fields**

A `getResponse` element encapsulating all field values for the record retrieved.

**Sample SOAP messages**

**Sample SOAP request**

```xml
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
  <soapenv:Header/>
  <soapenv:Body>
    <inc:get>
      <sys_id>46e18c0fa9fe19810066a0083f76bd56</sys_id>
    </inc:get>
  </soapenv:Body>
</soapenv:Envelope>
```

The resulting response of a `get` function call looks like this:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<soap:Envelope xmlns:soap="http://schemas.xmlsoap.org/soap/envelope/">
  <soap:Header/>
  <soap:Body>
    <getResponse xmlns="http://www.service-now.com/incident">
      <active>1</active>
      <approval>not requested</approval>
      <assigned_to>46c6f9efa9fe198101dd5eed9ad6e7</assigned_to>
      <caller_id>46b673a6a9fe19810007ab03cbd5849d</caller_id>
      <category>network</category>
      <cmdb_ci>0c43f35dc61122750182c195a29e3243</cmdb_ci>
      <comments>Testing</comments>
      <contact_type>phone</contact_type>
      <due_date>2007-10-28 13:29:45</due_date>
      <escalation>0</escalation>
      <impact>3</impact>
      <incident_state>1</incident_state>
    </getResponse>
  </soap:Body>
</soap:Envelope>
```
aggregate

Query a table using an aggregate function including SUM, COUNT, MIN, MAX, LAST, and AVG.

⚠️ **Note:** Functionality described here requires the Aggregate Web Service plugin.

**Input fields**

Any element of the target table. In addition, one or more of the aggregate functions (SUM, COUNT, MIN, MAX, LAST, and AVG).

A GROUP BY and a HAVING clause may also be added.

**Output fields**

An aggregateResponse element encapsulating all field values for the record retrieved.

**Sample SOAP messages**

Sample SOAP request using COUNT aggregate function.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<soap:Envelope xmlns:soap="http://schemas.xmlsoap.org/soap/encoding/"
    xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/"
    xmlns:m="http://www.service-now.com"
    xmlns:tns="http://www.service-now.com/map"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
```
The resulting response of a COUNT aggregate function call looks like this:

```xml
<?xml version="1.0" encoding="UTF-8"?>
xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding/
xmlns:m="http://www.service-now.com"
xmlns:tns="http://www.service-now.com/map"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
<SOAP-ENV:Body>
<aggregateResponse>
<aggregateResult>
<avg>2.7200</avg>
</aggregateResult>
</aggregateResponse>
</SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

Sample SOAP request using AVG aggregate function with a GROUP BY clause.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<aggregate xmlns="http://www.service-now.com">
<GROUP_BY>category</GROUP_BY>
<active>true</active>
<AVG>severity</AVG>
</aggregate>
```
The resulting response of a AVG aggregate function call with a GROUP BY clause looks like this:

```xml
<?xml version="1.0" encoding="UTF-8"?
xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding/"
xmlns:m="http://www.service-now.com"
xmlns:tns="http://www.service-now.com/map"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
  <SOAP-ENV:Body>
    <aggregateResponse>
      <aggregateResult>
        <avg>1.0000</avg>
        <category>database</category>
      </aggregateResult>
      <aggregateResult>
        <avg>3.0000</avg>
        <category>hardware</category>
      </aggregateResult>
      <aggregateResult>
        <avg>3.0000</avg>
        <category>inquiry</category>
      </aggregateResult>
      <aggregateResult>
        <avg>2.0000</avg>
        <category>network</category>
      </aggregateResult>
      <aggregateResult>
        <avg>2.6923</avg>
        <category>software</category>
      </aggregateResult>
    </aggregateResponse>
  </SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

Sample SOAP request using an encoded query to filter the aggregate:

```xml
<?xml version="1.0" encoding="UTF-8"?
<SOAP-ENV:Envelope xmlns:soap="http://schemas.xmlsoap.org/soap/encoding/"
xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/">
  <SOAP-ENV:Body>
    <aggregateResponse>
      <aggregateResult>
        <avg>1.0000</avg>
        <category>database</category>
      </aggregateResult>
      <aggregateResult>
        <avg>3.0000</avg>
        <category>hardware</category>
      </aggregateResult>
      <aggregateResult>
        <avg>3.0000</avg>
        <category>inquiry</category>
      </aggregateResult>
      <aggregateResult>
        <avg>2.0000</avg>
        <category>network</category>
      </aggregateResult>
      <aggregateResult>
        <avg>2.6923</avg>
        <category>software</category>
      </aggregateResult>
    </aggregateResponse>
  </SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```
Sample aggregate request using HAVING to narrow the results.

HAVING takes four fields. Each field is delimited by "^": the aggregate type, the field of the aggregate, the operation type, and the value to compare.

More than one HAVING can be added to the request, so you can use HAVING expressions, but there is no support for OR.

<th>Output fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>Regular</td>
<td>The <code>sys_id</code> field and the display value of the target table (<code>table</code>) are returned.</td>
</tr>
<tr>
<td>Import set</td>
<td>The <code>sys_id</code> of the import set row, the name of the transformed target table (<code>table</code>), the <code>display_name</code> for the transformed target table, the <code>display_value</code> of the transformed target row, and a <code>status</code> field, which can contain <code>inserted</code>, <code>updated</code>, or <code>error</code>. There can be an optional <code>status_message</code> field or an <code>error_message</code> field value when <code>status=error</code>.</td>
</tr>
</tbody>
</table>
## Insert method output fields (continued)

<table>
<thead>
<tr>
<th>Table type</th>
<th>Output fields</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>When an insert did not cause a target row to be transformed (skipped because a key value is not specified), the sys_id field will contain the sys_id of the import set row, rather than the targeted transform table.</td>
</tr>
<tr>
<td>Import set with multiple transforms</td>
<td>The response from this type of insert will contain multiple sets of fields from the regular import set table insert wrapped in a multiInsertResponse parent element. Each set will contain a map field, showing which transform map created the response.</td>
</tr>
</tbody>
</table>

### Sample SOAP messages for a regular table

The following example shows an insert that specifies the short description only:

```xml
<?xml version="1.0" encoding="ISO-8859-1"?>
 xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding/
 xmlns:m="http://www.service-now.com"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xmlns:xsd="http://www.w3.org/2001/XMLSchema"
 SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
 <SOAP-ENV:Body>
  <insert xmlns="http://www.service-now.com">
   <short_description xsi:type="xsd:string">This is a test</short_description>
  </insert>
 </SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

The resulting response looks like this:

```xml
<?xml version="1.0" encoding="ISO-8859-1"?>
 xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding/
 xmlns:m="http://www.service-now.com"
 xmlns:tns="http://www.service-now.com/incident"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xmlns:xsd="http://www.w3.org/2001/XMLSchema"
 SOAP-ENV:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
 <SOAP-ENV:Body>
  <insertResponse xmlns="http://www.service-now.com">
  </insertResponse>
 </SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```
Language-specific sample messages

For language-specific insert samples, refer to the following topics:

- Perl SOAP::Lite
- Java Apache Axis2
- Microsoft .NET
- Python

**insertMultiple**

Creates multiple new records for the table targeted in the URL.

**Input fields**

The `insertMultiple` element may contain 1 or more record tags that contains all fields from the targeted table, excluding system fields. Limit the number of records inserted in a single operation to no more than 200. You can gradually increase this number with subsequent exports if the increase does not negatively impact instance performance.

**Output fields**

The `insertMultipleResponse` tag is followed by 1 or more record tags that contains:

**Insert method output fields**

<table>
<thead>
<tr>
<th>Table type</th>
<th>Output fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>Regular</td>
<td>The <code>sys_id</code> field and the display value of the target table (<code>table</code>) are returned.</td>
</tr>
<tr>
<td>Import set</td>
<td>The <code>sys_id</code> of the import set row, the name of the transformed target table (<code>table</code>), the <code>display_name</code> for the transformed target table, the <code>display_value</code> of the transformed target row, and a <code>status</code> field, which can contain <code>inserted</code>, <code>updated</code>, or <code>error</code>. There can be an optional <code>status_message</code> field or an <code>error_message</code> field value when <code>status=error</code>.</td>
</tr>
</tbody>
</table>
Insert method output fields (continued)

<table>
<thead>
<tr>
<th>Table type</th>
<th>Output fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>When an insert did not cause a target row to be transformed (skipped because a key value is not specified), the <strong>sys_id</strong> field will contain the sys_id of the import set row, rather than the targeted transform table.</td>
<td></td>
</tr>
<tr>
<td>Import set with multiple transforms</td>
<td>The response from this type of insert will contain multiple sets of fields from the regular import set table insert wrapped in a <strong>multiInsertResponse</strong> parent element. Each set will contain a <strong>map</strong> field, showing which transform map created the response.</td>
</tr>
</tbody>
</table>

Sample SOAP messages for a regular table

The following example shows an insert that specifies the short description only:

```xml
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
  xmlns:inc="http://www.service-now.com/incident">
  <soapenv:Header/>
  <soapenv:Body>
    <inc:insertMultiple>
      <record>
        <short_description>this is test 1</short_description>
      </record>
      <record>
        <short_description>this is test 2</short_description>
      </record>
      <record>
        <short_description>this is test 3</short_description>
      </record>
    </inc:insertMultiple>
  </soapenv:Body>
</soapenv:Envelope>
```

The resulting response looks like this:

```xml
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
  xmlns:inc="http://www.service-now.com/incident">
  <soapenv:Header/>
  <soapenv:Body>
    <insertMultipleResponse>
      <insertResponse>
        <sys_id>168160ad4a36231200a89091281dc803</sys_id>
      </insertResponse>
    </insertMultipleResponse>
  </soapenv:Body>
</soapenv:Envelope>
```
Sample SOAP messages for an import set table

The following example shows an insert that specifies the short description only:

```xml
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/
xmlns:imp="http://www.service-now.com/imp_notification">
  <soapenv:Header/>
  <soapenv:Body>
    <imp:insertMultiple>:
      <imp:record>
        <imp:message>one</imp:message>
        <imp:uuid>a</imp:uuid>
      </imp:record>
      <imp:record>
        <imp:message>two</imp:message>
        <imp:uuid>b</imp:uuid>
      </imp:record>
      <imp:record>
        <imp:message>three</imp:message>
        <imp:uuid>c</imp:uuid>
      </imp:record>
    </imp:insertMultiple>
  </soapenv:Body>
</soapenv:Envelope>
```

The resulting response looks like this:

```xml
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/
xmlns:imp="http://www.service-now.com/imp_notification">
  <soapenv:Header/>
  <soapenv:Body>
  </soapenv:Body>
</soapenv:Envelope>
```
update

Updates an existing record in the targeted table in the URL, identified by the mandatory sys_id field.

Input fields

All fields from the targeted table, excluding system fields, which will be used for updating the existing record. The sys_id field is used to locate the existing record.

Output fields

Returns the sys_id of the record that was updated.
Sample SOAP messages

Sample SOAP request

```xml
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
    xmlns:inc="http://www.service-now.com/incident">
  <soapenv:Header/>
  <soapenv:Body>
    <inc:update>
      <sys_id>46e18c0fa9fe19810066a0083f76bd56</sys_id>
      <short_description>this is updated</short_description>
    </inc:update>
  </soapenv:Body>
</soapenv:Envelope>
```

Sample SOAP response

```xml
<soapenv:Envelope xmlns:inc="http://www.service-now.com/incident"
    xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
  <soapenv:Header/>
  <soapenv:Body>
    <updateResponse>
      <sys_id>46e18c0fa9fe19810066a0083f76bd56</sys_id>
    </updateResponse>
  </soapenv:Body>
</soapenv:Envelope>
```

Language-specific sample messages

For language-specific update samples, refer to the following topics:

- **Perl SOAP::Lite**
- **Java Apache Axis2**
- **Microsoft .NET**
- **Python**

**deleteRecord**
Delete a record from the targeted table by supplying its `sys_id`.

**Input fields**
An element `<sys_id>` identifying the `sys_id` of the record to be retrieved.
Output fields

A `<count>` element within the `deleteRecordResponse` parent element indicating the number of records deleted, this will always equal to "1" for `deleteRecord`.

Sample SOAP messages

Sample SOAP request

```xml
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:inc="http://www.service-now.com/incident">
  <soapenv:Header/>
  <soapenv:Body>
    <inc:deleteRecord>
      <sys_id>46e18c0fa9fe19810066a0083f76bd56</sys_id>
    </inc:deleteRecord>
  </soapenv:Body>
</soapenv:Envelope>
```

Sample SOAP response

```xml
<soapenv:Envelope xmlns:inc="http://www.service-now.com/incident"
xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
  <soapenv:Header/>
  <soapenv:Body>
    <deleteRecordResponse>
      <count>1</count>
    </deleteRecordResponse>
  </soapenv:Body>
</soapenv:Envelope>
```

Language-specific sample messages

For language-specific `deleteRecord` samples, refer to the following topics:

- Perl SOAP::Lite
- Java Apache Axis2
- Microsoft .NET
- Python

**deleteMultiple**

Delete multiple records from the targeted table by example values.
Input fields
All fields from the targeted table, including system fields, are used in query-by-example (QBE) fashion to locate records to be deleted. Query example fields can have special prefixes to constrain the search function.

Output fields
A `<count>` element within the `deleteRecordResponse` parent element indicating the number of records deleted.

Sample SOAP messages

Sample SOAP request
```
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"

xmlns:inc="http://www.service-now.com/incident">

<soapenv:Header/>

<soapenv:Body>

<inc:deleteMultiple>

  <category>hardware</category>

</inc:deleteMultiple>

</soapenv:Body>

</soapenv:Envelope>
```

Sample SOAP response
```
<soapenv:Envelope xmlns:inc="http://www.service-now.com/incident"

xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">

<soapenv:Header/>

<soapenv:Body>

<deleteMultipleResponse>

  <count>6</count>

</deleteMultipleResponse>

</soapenv:Body>

</soapenv:Envelope>
```

Language-specific sample messages
For language-specific `deleteRecord` samples, refer to the following topics:

Perl SOAP::Lite

Microsoft .NET
Python
SOAP web service import sets

Web service import sets complement direct web services and scripted SOAP web services by providing a web service interface to import sets tables.

By default, this type of web service synchronously transforms the incoming data based on the associated transform maps. If the associated import set mode is set to Asynchronous, the behavior is to save the data for transformation at a later time. Web service import sets tables publish all default web service functions in the WSDL.

You can access a web service import set WSDL by specifying the import set table name + ".do?WSDL" on the URL.

For example:

http://<instance name>.service-now.com/imp_notification.do?WSDL.

Related information
- Web service import sets
- Import sets key concepts

Scripted SOAP web services

Scripted SOAP web services allow a ServiceNow administrator to create custom SOAP web services.

You can define input and output parameters for the SOAP web service and use JavaScript to perform operations. Though this feature is very powerful, use direct web services or SOAP web service import sets whenever possible since they are simpler to implement and maintain.

Security

Scripted SOAP web services have the same base security options as all SOAP web services. For details on SOAP web services security, see SOAP web services security.

When strict security is enforced on a system, the HTTP authenticated user must have the soap_script role to execute the scripted web service.

WSDL

All ServiceNow tables and import sets dynamically generate Web Service Definition Language (WSDL) XML documents that describe its table schema and available operations.
Enforcing WSDL compliance

You can force the response to list output values in the same order as defined in the WSDL.

When you create a scripted SOAP web service, the generated WSDL is based on the Input Parameters and Output Parameters related lists. The actual SOAP response sent by the scripted service is determined by the Script. This behavior can cause the script to return output values in a different order than defined in the WSDL.

To enforce the order of output parameters as defined in the related list, select the WSDL Compliance check box. When this check box is selected, the web service reorders the parameters returned by the script to match the order in the WSDL.

**Note:** If additional response parameters are returned by the script, but are not defined in the Response Parameters related list, those parameters are excluded from the response when WSDL Compliance is selected.

### Output Parameters related list

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Order</th>
</tr>
</thead>
<tbody>
<tr>
<td>Param 1</td>
<td>200</td>
</tr>
<tr>
<td>Param 2</td>
<td>300</td>
</tr>
<tr>
<td>Param 3</td>
<td>100</td>
</tr>
</tbody>
</table>

The following is the script that sets values for the defined output parameters. Note that in this example script the parameters are set in a different order than defined in the Output Parameters related list. Also note the additional parameter `param4` that is not defined in the related list.

```java
Response.param1 = 1;
Response.param4 = 4;
Response.param3 = 3;
```

When the WSDL Compliance check box is false, the SOAP response generated by the script is the following:

```xml
<response>
  <param1>1</param1>
  <param4>4</param1>
  <param3>3</param1>
</response>
```
When the **WSDL Compliance** check box is **true**, the SOAP response generated by the script is the following:

```xml
<response>
  <param3>3</param3>
  <param1>1</param1>
</response>
```

**Static WSDL**

Some web service clients require SOAP access to your instance through a specific WSDL format. This required format may differ from the standard ServiceNow WSDL format. In these cases you can create a static WSDL that matches the required format. For details on creating a static WSDL, see **Global variables**

To facilitate custom processing of incoming SOAP requests, the following global variables are available in the script context:

- `soapRequestDocument`: Java org.w3c.dom.Document object representing the incoming SOAP envelope.
- `soapRequestXML`: String object representing the incoming SOAP envelope XML.
- `request`: Javascript object that contains mapped values (mapped to input parameter names) of the incoming SOAP envelope.
- `response`: Javascript object that allows you to customize the response values. See **Customize Response**

**Create a new scripted SOAP web service**

Follow these examples to create a new scripted SOAP web service.

When the Web Services Provider - Scripted plugin is activated, a new module **Scripted Web Services** is available under the **System Web Services** application.
**Example 1: Retrieving a system property**

The first step is to define the incoming and return parameters. This is done by adding an entry to the *Input Parameters* and *Output Parameters*. These parameters are used to construct and present a meaningful WSDL, and they do not add to the functionality of processing the actual Web Service itself.

The parameters are referenced in the script of the Web Service. Any of the input parameters are retrieved using the following syntax:

```javascript
var a = request.property;
```

The output parameters are set by using the following syntax:

```javascript
response.property = "ABC";
```
The following example demonstrates how to retrieve a system property and return it as part of the SOAP response. The example shows how to create a custom scripted web service to do something specific that the base ServiceNow system direct Web Services cannot.

GetProperty web service

Example 2: Ordering a Blackberry

Direct web services operate on tables and their data. The following example shows how to initiate a business solution, such as ordering a Blackberry, by invoking a scripted web service. The following input and output parameters support the Blackberry example:
This script shows how to use the above parameters to add a Blackberry to the service catalog shopping cart and order it. The request number is returned in the `request_number` field of the SOAP response.

```javascript
var cart = new Cart();
var item = cart.addItem('e2132865c0a8016500108d9cee411699');
cart.setVariable(item, 'original', request.phone_number);

// set the requested for
var gr = new GlideRecord("sys_user");
gr.addQuery("user_name", request.requested_for);
gr.query();
if (gr.next()) {
    var cartGR = cart.getCart();
cartGR.requested_for = gr.sys_id;
cartGR.update();
}

var rc = cart.placeOrder();
response.request_number = rc.number;
```

**Customize response**

Follow this example to customize and control the XML payload of a SOAP response.

**Procedure**

1. Create a customized XML document using the `XMLDocument` script include object.

   **Note:** When creating a scripted web service in a scoped application you must use the `XMLDocument2` API.
2. Set its document element to the variable `response.soapResponseElement` in a scripted web service.
For example, the following scripted web service script:

```javascript
var xmldoc = new XMLDocument2();
xmldoc.parseXML("<myResponse></myResponse>");
xmldoc.createElementWithTextValue("element_one", "test");
xmldoc.createElementWithTextValue("element_two", "new2 value");

var el = xmldoc.createElement("element_three");
xmldoc.setCurrentElement(el);
xmldoc.createElementWithTextValue("newChild", "test child element");

response.soapResponseElement = xmldoc.getDocumentElement();
```

Is used to accept the following request:

```xml
<soapenv:Envelope
    xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
    xmlns:tes="http://www.service-now.com/TestCustomResponse">
    <soapenv:Header/>
    <soapenv:Body>
        <tes:execute/>
    </soapenv:Body>
</soapenv:Envelope>
```

Which will respond with the following SOAP response:

```xml
<soapenv:Envelope
    xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
    xmlns:tes="http://www.service-now.com/TestCustomResponse">
    <soapenv:Header/>
    <soapenv:Body>
        <myResponse>
            <element_one>test</element_one>
            <element_two>new2 value</element_two>
            <element_three>
                <newChild>test child element</newChild>
            </element_three>
        </myResponse>
    </soapenv:Body>
</soapenv:Envelope>

WSDL support will need to be created externally. The SOAP endpoint will need to be referred back to the scripted web service in question.
Create a scripted SOAP web service using a static WSDL

Follow these examples to create a scripted SOAP web service using a static WSDL.

Create a scripted web service using a static WSDL

To use a static WSDL, create a scripted web service.

Before you begin
Role required: web_service_admin or admin

Procedure
1. Navigate to System Web Service > Scripted Web Services.
2. Click New.
3. Enter a Name for the scripted SOAP web service such as FakeStockValue.
4. Enter a Script for the web service to run.
5. Click Submit.

Scripted web service example

This example demonstrates the processing script for the FakeStockValue web service.

```
var vProcessor = new FakeStockValue(soapRequestXML);

var responseElement = vProcessor.process();
if(responseElement != null) {
    response.soapResponseElement = responseElement;
} else {
    response.soapResponseElement = vProcessor.generateSoapFault("unknown error");
}
```

Create a static WSDL

Create a static WSDL with the required format to override the standard WSDL for your scripted web service.

Before you begin
Role required: web_service_admin or admin

Procedure
1. Navigate to System Web Services > Static WSDL.
2. Create a static WSDL record using the same name as the scripted web service, such as FakeStockValue.
3. Enter the custom WSDL into the WSDL field.
4. Click Submit.

Static WSDL example
This example demonstrates the FakeStockValue WSDL.

```xml

<types><schema targetNamespace = "http://example.com/stockquote.xsd" xmlns = "http://www.w3.org/2000/10/XMLSchema" ><element name = "TradePriceRequest" ><complexType><all><element name = "tickerSymbol" type = "string" /></all></complexType></element><element name = "TradePrice" ><complexType><all><element name = "price" type = "float" /></all></complexType></element></schema></types>

<message name = "GetLastTradePriceInput" ><part name = "body" element = "xsd1:TradePriceRequest" /></message>

<message name = "GetLastTradePriceOutput" ><part name = "body" element = "xsd1:TradePrice" /></message>

<portType name = "StockQuotePortType" ><operation name = "GetLastTradePrice" ><input message = "tns:GetLastTradePriceInput" /><output message = "tns:GetLastTradePriceOutput" /></operation></portType>

<binding name = "StockQuoteSoapBinding" type = "tns:StockQuotePortType" ><soap:binding style = "document" transport = "http://schemas.xmlsoap.org/soap/http" /><operation name = "GetLastTradePrice" ><soap:operation soapAction = "" /><input><soap:body use = "literal" /></input><output><soap:body use = "literal" /></output></operation></binding>

<service name = "StockQuoteService" ><documentation>My first service</documentation><port name = "StockQuotePort" binding = "tns:StockQuoteSoapBinding" ><soap:address location = "https://myinstance.service-now.com/FakeStockValue.do?SOAP" /></port></service>

</definitions>
```
Create a static WSDL script include
Create a script include to define the majority of the code used to process static WSDL requests.

Before you begin
Role required: script_include_admin or admin

About this task
By implementing the majority of the custom functionality in a script include, you can reuse the script include in multiple areas.

Procedure
1. Navigate to System UI > Script Includes.
2. Click New.
3. Enter a Name for the script include that matches the name of the static WSDL, such as FakeStockValue.
4. Enter the script include code in the Script field.
5. Click Submit.

Static WSDL script include example
This example demonstrates the FakeStockValue script include that implements much of the static WSDL behavior.

```javascript
var FakeStockValue = Class.create();

FakeStockValue.prototype = { 
    initialize : function(requestXML) { 
        //Use some backend XML utilities...you could use string tools if you wish 
        this.xmlutil = Packages.com.glide.util.XMLUtil; 
        //converting the string to an XML Document 
        this.fSoapDoc = new XMLDocument(requestXML); },

    process : function() { 
        var soapBody = this.fSoapDoc.getNode("/Envelope/Body"); 
        //Our WSDL was formatted to have the only first child element be the function 
        var funcNode = this.xmlutil.getFirstChildElement(soapBody); 
        var nodeName = this.xmlutil.getNodeNameNS(funcNode); 
```
// If the function for this SOAP request is TradePriceRequest, perform the necessary actions
if (nodeName == "TradePriceRequest") {
    return this.fakeOutTradePriceRequest(funcNode);
}

// Couldn't find any supported functions in this SOAP request
return this.generateSoapFault("un-supported API call: " + nodeName);

fakeOutTradePriceRequest : function (funcNode) {

    // Create the beginnings of our XML response
    var r = new XMLDocument("<GetLastTradePriceOutput
xmlns='https://www.service-now.com/vws/FakeStockValue'/>");

    // Do the necessary actions here... we're going to get the USER ID of the user
    // used to make this SOAP call. Then we will return the stock symbol they were asking about
    var usersysid = gs.getUserID();
    var now_GR = new GlideRecord("sys_user");
    gr.get(usersysid);
    var username = gr.user_name;
    var quoteSymbol = this.xmlutil.getText(funcNode);
    // Create a "message" element to store our response message
    r.createElement("message", username + ", You were looking for a quote on " + quoteSymbol);
    return r.getDocumentElement();

}

generateSoapFault : function (str) {
    var f = "<SOAP-ENV:Fault>" +
             "<faultcode xsi:type='xsd:string'>SOAP-ENV:FakeStockValue</faultcode>" +
             "<faultstring xsi:type='xsd:string'>" + str +
             "</faultstring>" +
             "</SOAP-ENV:Fault>"
    var s = new XMLDocument(f);
    return s.getDocumentElement();
}
}
initialize function
The initialize function takes the XML request string and converts it to an XML Document object that you can navigate and manipulate using libraries. Alternatively, you can leave the XML request as a string and navigate it using regular expressions.

process function
The process function is called by the scripted web service. This function grabs the first child element in the XML after the body element. The WSDL uses this child element to determine which function to use. In this WSDL there is only one possible function but most WSDLs provide many functions. If more functions were available, there would be more "if" statements that tested the first child element for the various function names.

fakeOutTradePriceRequest function
The fakeOutTradePriceRequest function is the implementation of the only available function in the WSDL. This function looks up the user that the SOAP request authenticated as and retrieves the user_name then returns it to the SOAP client. The fakeOutTradePriceRequest function could be expanded to perform useful activities, such as looking up a stock symbol and returning the last traded price.

generateSoapFault function
The generateSoapFault function returns a SOAP error that can be called if there are problems.

Use the static WSDL
Load the static WSDL into a SOAP client to make requests to the SOAP web service.

The web service client provides
• The FakeStockValue project.
• The StockQuoteBinding web service.
• The GetLastTradePrice SOAP function. This function generates request records when run.
You can change the default request XML in the static WSDL to include a stock symbol.

```xml
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
                  xmlns:stoc="http://example.com/stockquote.xsd">
  <soapenv:Header/>
  <soapenv:Body>
    <stoc:TradePriceRequest>IBM</stoc:TradePriceRequest>
  </soapenv:Body>
</soapenv:Envelope>
```

Submitting a SOAP request to this web service endpoint returns the following to the requesting SOAP client.

```xml
                    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
                    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <SOAP-ENV:Body>
    <GetLastTradePriceOutput xmlns="https://www.service-now.com/vws/FakeStockValue">
      <message>admin2, You were looking for a quote on IBM</message>
    </GetLastTradePriceOutput>
  </SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

**AttachmentCreator SOAP web service**

Attach documents to records in ServiceNow by sending a SOAP message targeting the `ecc_queue` table.

**Important:** The AttachmentCreator SOAP web service is not recommended. Instead, use the REST Attachment API to manage attachments with web services.

Using the AttachmentCreator SOAP web service, you can attach a single document to a message that is a maximum of 5 MB. The following is an example of a URL or target end point: https://instance_name.service-now.com/ecc_queue.do?WSDL

**ecc_queue Fields for Attachment Creation**

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>agent</td>
<td>The name of the agent sending in the request, this</td>
<td>AttachmentCreator</td>
</tr>
</tbody>
</table>
### ecc_queue Fields for Attachment Creation (continued)

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>can be any value since it is not used for processing.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>topic</td>
<td>The topic of the queue record, this value must be set to &quot;AttachmentCreator&quot; to trigger the attachment creation</td>
<td>AttachmentCreator</td>
</tr>
<tr>
<td>name</td>
<td>This field must contain a &quot;:&quot; delimited value of the file name, and its content-type</td>
<td>file_name.xls:application/vnd.ms-excel</td>
</tr>
<tr>
<td>source</td>
<td>This field must contain a &quot;:&quot; delimited value of the target table and its sys_id</td>
<td>incident:dd90c5d70a0a0b39000aac5ae6704ae8</td>
</tr>
<tr>
<td>payload</td>
<td>This field must contain the Base 64 encoded string representing the object to be attached</td>
<td>the base 64 encoded string</td>
</tr>
</tbody>
</table>

Sending in the values described in the table above will attach an Excel file to the incident table for the record located by the sys_id `dd90c5d70a0a0b39000aac5ae6704ae8`

### Security

Like all other HTTP based web services available on the platform, the AttachmentCreator SOAP web service is required to authenticate using basic authentication by default. The user ID that is used for authentication will be subjected to access control in the same way as an interactive user.

To create attachments, the SOAP user must have any roles required to create Attachment [sys_attachment] records, as well as the soap_create role, and
any roles required to read and write records on the target table, such as the itil role to add attachments to incident records. By default there is no single role allowing you to add attachments. You can create a role to explicitly allow adding attachments, then assign this role to the SOAP user.

File type security
You can control what file types users can attach by setting the glide.attachment.extensions and glide.security.file.mime_type.validation properties.

For these properties to apply to the AttachmentCreator web service, the property glide.attachment.enforce_security_validation must be set to true. This property is true by default.

Example SOAP Message
The following is an example of a SOAP message that would take a text file “john1.txt” of mime-type: text/plain and attach it to an Incident with a GUID of: e6eed6950a0a3c59006f32c8e3ff3cf9. Note the payload is the base64 encoding of the file itself.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:ecc="http://www.service-now.com/ecc_queue">
  <soapenv:Header />
  <soapenv:Body>
    <ecc:insert>
      <agent>AttachmentCreator</agent>
      <topic>AttachmentCreator</topic>
      <name>john1.txt:text/plain</name>
      <source>incident:e6eed6950a0a3c59006f32c8e3ff3cf9</source>
      <payload>SSB3b25kZXIgaWYgc2hlIGtub3ducyB3aGF0IHNoZSdzIGRvaW5nIG5vdy4K</payload>
    </ecc:insert>
  </soapenv:Body>
</soapenv:Envelope>
```

Example Node.js Script
The following example Node.js script adds an attachment to an incident record. Run this script from a client computer, not an instance.

```javascript
/**
 * Node.js to ServiceNow attachment upload via SOAP
 * 
 * Andrew Venables andrew.venables@servicenow.com
 * 
 * July 2014
 */
```
var soap = require('soap'), // https://github.com/vpulim/node-soap
mime = require('mime'), // https://github.com/broofa/node-mime
fs = require("fs");

var WSDL_FILENAME = 'ecc_queue.xml'; // Goto https://instancename.service-now.com/ecc_queue.do?WSDL and save a copy of the WSDL locally for simplicity
var DIRECTORY_CONTAINING_FILES = '/Users/andrew.venables/Documents/Uploads'; // Local path to the directory containing all the files we want to upload
var USERNAME = 'andy.venables'; // An admin user account on the instance
var PASSWORD = 'MY_PASSWORD'; // Password for above account
var TARGET_TABLE = 'incident'; // Target table to attach the files to
var TARGET_SYS_ID = '9d385017c611228701d22104cc95c371'; // Target record / sys_id to attach the files to. OOTB INC0000002

var files_to_upload; // Global that will contain our list of files to be uploaded
var pos = 0; // Global pointer for our position in the files_to_upload list

// Create a SOAP client to use to post to the instance
soap.createClient(WSDL_FILENAME, function(err, client) { // Node uses callbacks
if (err) console.error(err);

// Set the username and password
client.setSecurity(new soap.BasicAuthSecurity(USERNAME, PASSWORD));

// Read all the files in our source directory, will include . and ..
files_to_upload = fs.readdirSync(DIRECTORY_CONTAINING_FILES);

console.log('Files to upload: ' + files_to_upload.length + '\n');

// Start iterating through the list of files to upload
next(client);
});

// Process the next file in the files_to_upload array
// This is a neat way of dealing with Node and its expectation of callbacks
function next(client) {

// Check we haven't reached the end
if (pos >= files_to_upload.length) return;

// Get the next file to upload
var file_name = files_to_upload[pos];

// Increment the pointer to the next file
pos++;

console.log(pos + '/' + files_to_upload.length + ' - Uploading file: ' + file_name);

// A blank file is the end of the list
if (file_name == '') return;

// Skip to the next file as this one is invalid
if (file_name == '.' || file_name == '..' || file_name.indexOf('.') == 0)
  next(client);

// Get the file type using a module called mime
var file_type = mime.lookup(file_name);
console.log(' of type: ' + file_type);

var file_payload;
// Load the file into a buffer
fs.readFile(DIRECTORY_CONTAINING_FILES + '/' + file_name, function(err, the_data) {
  if (err) console.error(err);

  // Encode the buffer to base64
  file_payload = new Buffer(the_data, 'binary').toString('base64');

  // Set the parameters before we call the Web Service
  var parameters = {
    'agent': 'AttachmentCreator',
    'topic': 'AttachmentCreator',
    'name': file_name + ':+' + file_type,
    'source': TARGET_TABLE + ':TARGET_SYS_ID,'
    'payload': file_payload
  };

  console.log('      sending...')
  // Make the Web Service call, remember node likes callbacks
  client.insert(parameters, function(err, result) {
    if (err) console.error(err);
  });
Example Perl Script
The following example Perl script will create an attachment to an incident record.

```perl
use MIME::Base64;
use strict;
use SOAP::Lite;

# the ServiceNow instance
my $SNC_HOST = "https://instance_name.service-now.com";
my $base64;
my $buf;

# upload and attach a file on the local disk, base 64 encode it into a string first
open(FILE, "'/Users/davidloo/Desktop/test_files/number_test.xls") or die "$!";
binmode FILE; #preserves file formatting on Windows
while (read(FILE, $buf, 60*57)) {
    $base64 .= encode_base64($buf);
}

# call the sub routine to attach
attach_incident();

sub attach_incident {
    # target the ecc_queue table
    my $soap = SOAP::Lite->proxy("$SNC_HOST/ecc_queue.do?SOAP");
    $soap->(_transport)->(_proxy)->(ssl_opts)->(verify_hostname) = 0;
    my $method = SOAP::Data->name('insert')->attr({xmlns => 'http://www.service-now.com/'});

    # set the ecc_queue parameters
    my @params = (SOAP::Data->name(agent => 'AttachmentCreator'));
    push(@params, SOAP::Data->name(topic => 'AttachmentCreator') );

    # identify the file name and its mime type
    push(@params, SOAP::Data->name(name => 'number_test.xls:application/vnd.ms-excel') );
}
```
# attach to the incident, specifying its sys_id
push(@params, SOAP::Data->name(source => 'incident:dd90c5d70a0a0b39000aac5ae704ae8'));

# set the payload to be the base 64 encoded string representation of the file
push(@params, SOAP::Data->name(payload => $base64));

# invoke the web service
my $result = $soap->call($method => @params);

print_fault($result);

print_result($result);

sub print_result {
    my ($result) = @_; 

    if ($result->body && $result->body->{'insertResponse'}) {
        my %keyHash = %{ $result->body->{'insertResponse'} }; 
        foreach my $k (keys %keyHash) {
            print "name=$k   value=$keyHash{$k}\n";
        }
    }
}

sub print_fault {
    my ($result) = @_; 

    if ($result->fault) {
        print "faultcode=" . $result->fault->{'faultcode'} . "\n";
        print "faultstring=" . $result->fault->{'faultstring'} . "\n";
        print "detail=" . $result->fault->{'detail'} . "\n";
    }
}

# use the itil user for basic auth credentials
sub SOAP::Transport::HTTP::Client::get_basic_credentials {
    return 'itil' => 'itil';
}
Override a SOAP endpoint

The SOAP endpoint address where the SOAP message is posted is consistent with the endpoint of the WSDL.

In some cases, however, the WSDL may reference an incorrect endpoint URL. If this happens, it is necessary to over-ride the generated URL by creating the property `com.glide.soap_address_base_url` to contain the new URL. You may have to add the property manually as this is not an base system property.

For instance, a generated SOAP endpoint may look like this:

```
https://instance.service-now.com/incident.do?SOAP
```

You can specify a property to define the endpoint such that it goes through a proxy by setting the property:

```
com.glide.soap_address_base_url = "https://myproxy.mycompany.com/service-now/"
```

This will result in the endpoint being generated to appear as:

```
https://myproxy.mycompany.com/service-now/incident.do?SOAP
```

Enable HTTP compression

By default, the SOAP request is accepted un-compressed and the result of the request is returned un-compressed.

To enable HTTP compression using [gzip] when sending in your SOAP request, set the following HTTP header:

```
Content-Encoding: gzip
```

To receive the SOAP response compressed using [gzip] send in your SOAP request with the following HTTP header:

```
Accept-Encoding: gzip
```

Prevent empty elements in SOAP messages

By default, an instance does not omit empty elements, elements with NULL or NIL values, from SOAP messages.

To prevent SOAP responses from containing empty elements, an administrator can create a system property called `glide.soap.omit_null_values` and set the value to `true`. This behavior is compliant with the WSDL as all elements in a SOAP message have a minOccurs=0 attribute and are therefore optional. In addition, this behavior prevents the instance from creating inefficient SOAP messages containing a large number of empty elements.
Set this property to `false` to allow SOAP messages to search for existing fields with empty values. For example, if an administrator wants to search for incidents with an empty `Assigned to` field from a SOAP message, then the SOAP message must be able to send an empty value for this field.

**Note:** Changing the value of this property may cause unintended actions in existing web service integrations. Administrators are strongly encouraged to carefully test the new behavior to ensure that existing integrations process empty elements as expected.

**Insert related records using SOAP**

Support is available for inserting hierarchical data into tables or web service import set tables. The hierarchical data in the Insert API is automatically mapped to related records of the targeted table.

**Before you begin**

Role required: admin

**Procedure**

Create and set the property `glide.web_service.hierarchical` to `true`. The client of the API can also override this value by invoking the SOAP web service with the URL parameter `hierarchical=true`.

**Example:**

For example, when a related list is created for the incident table called `u_custom_comments`:

And `u_comment_items` is created as a related list for `u_custom_comments`:

© 2021 ServiceNow, Inc. All rights reserved.

Related reference

WSDL Schema with related records
Hierarchical SOAP Message

WSDL Schema with related records

When a WSDL for the target Incident table is requested with an additional parameter of \texttt{hierarchical=true}, the WSDL schema for the \texttt{Insert} function will reflect available related records that may participate in the hierarchical data payload.

For example, the insert portion of the schema of the incident table, when requested with \texttt{hierarchical=true} displays its hierarchy as follows:

\begin{verbatim}
https://instance.service-now.com/incident.do?WSDL\&hierarchical=true
\end{verbatim}
The WSDL above shows the incident table having a related table `u_custom_comments` that itself has a related table `u_comment_items`.

**Hierarchical SOAP Message**

When the SOAP message is constructed from the hierarchical web service described by the WSDL and invoked, it will create the `incident`, `u_custom_comments`, and `u_comment_items` records.

**Endpoint URL**

https://instance.service-now.com/incident.do?SOAP&hierarchical=true

**Request**

```
<soapenv:Envelope
   xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
   xmlns:inc="http://www.service-now.com/incident">
  <soapenv:Header/>
  <soapenv:Body>
    <inc:insert>
      <short_description>test hierarchical</short_description>
      <u_custom_comments>
        <u_comment>comment 1</u_comment>
        <u_comment_type>travel</u_comment_type>
      </u_custom_comments>
    </inc:insert>
  </soapenv:Body>
</soapenv:Envelope>
```
Specify requirement for signed SOAP requests

Use a SOAP security policy to specify whether the instance requires signed SOAP requests for all inbound SOAP traffic.

Before you begin
Role required: web_service_admin or admin

About this task
By default, all inbound SOAP traffic must be signed. Administrators may want to disable this policy and allow unsigned SOAP requests to ServiceNow web services.

Procedure
2. Select the Default Policy.
3. Clear the Required to Sign SOAP Request check box (selected by default) to disable the requirement.
4. Click Update.
Activate the Enhanced Web Service Provider - Common plugin

Administrators can activate the Enhanced Web Service Provider - Common plugin to enable unsigned WS-Security requests and specify what authentication requirements SOAP requests have.

Before you begin
Role required: admin

Procedure

1. Navigate to System Applications > All Available Applications > All.
2. Find the Enhanced Web Service Provider - Common plugin (com.glide.web_service_provider_v2) using the filter criteria and search bar.
   
   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel. For more information, see Request a plugin.
3. Click Install, and then in the Activate Plugin dialog box, click Activate.

   Note: When domain separation and delegated admin are enabled in an instance, the administrative user must be in the global domain. Otherwise, the following error appears: Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.

Installed with the Enhanced Web Service Provider - Common plugin

The following components installed with the Enhanced Web Service Provider - Common plugin.

The Enhanced Web Service Provider - Common plugin installs the following components:

<table>
<thead>
<tr>
<th>Component Type</th>
<th>Component Installed</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Module</td>
<td>Web Services Security Profiles</td>
<td>The plugin adds this module to the System Web Services application.</td>
</tr>
<tr>
<td>System Property</td>
<td>glide.soap.default_security_policy</td>
<td>Specifies the default security policy to use when enforcing</td>
</tr>
</tbody>
</table>
Components installed with the Enhanced Web Service Provider - Common plugin (continued)

<table>
<thead>
<tr>
<th>Component Type</th>
<th>Component Installed</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Web Services-Security (WSS) for inbound requests.</td>
</tr>
</tbody>
</table>

**Configure SOAP security**

Administrators can configure web service security for inbound SOAP requests made to the ServiceNow instance.

**Before you begin**

Role required: admin

**About this task**

You can also set up web service security to use different certificates for different web service clients. By enabling web service security, you can prevent man-in-the-middle attacks.

ℹ️ **Note:** After you configure a WS-security profile or a security policy, validation is performed on all incoming SOAP requests, including from the MID Server or ODBC driver. Disable validation for these types of requests by marking the service accounts as internal integration users.

**Procedure**

1. Upload a certificate to the instance.
2. Create a WS-security profile.
3. Create a security policy.
   Security policies define which WS-security profiles are used to evaluate a particular web service request. If no policy is defined, all WS-security profiles are used to evaluate all requests.
4. Set the value of the property `glide.soap.default_security_policy` to the name of the new security policy.

**Set the SOAP default security policy**

Set the SOAP default security policy.

**Before you begin**

Role required: web_service_admin or admin
Procedure

1. Navigate to **System Web Services > Properties**.

2. In the **Security Policy to enforce if WS-Security is enabled** field, enter the default security policy to use when enforcing WS-security.

3. Click **Save**.

Create a new security policy

Administrators can specify which security profiles WS-Security communications must meet by creating a new security policy.

Before you begin

Role required: web_service_admin or admin

Procedure

1. Navigate to **System Web Services > SOAP Security Policies**.

2. Click **New**.

3. Fill out the SOAP Security Policy form (see table).

### SOAP Security Policy form fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a unique name for the security policy. Use this name to set the default security policy with the glide.soap.default_security_policy property.</td>
</tr>
<tr>
<td>Type</td>
<td>Select whether the SOAP security policy applies to inbound or outbound traffic.</td>
</tr>
<tr>
<td>Required to Sign SOAP Request</td>
<td>Select this checkbox to require signed SOAP requests. Clear the checkbox to allow unsigned SOAP requests. When enabled, the instance will produce an error for any SOAP request that does not include a valid signature. When disabled, the instance still verifies any signature included with a SOAP request.</td>
</tr>
<tr>
<td>Authenticate</td>
<td>Select if a SOAP request must authenticate against all security profiles or at least one security profile.</td>
</tr>
</tbody>
</table>
4. Click **Submit**.

**Create a new WS-Security profile**

Create a new WS Security profile to define how to authenticate a web services message when WS-Security is enabled.

**Before you begin**

Role required: web_service_admin or admin

**Procedure**

1. Navigate to **System Web Services > WS Security Profiles**.
2. Click **New**.
3. Fill in the WS-Security Profile form (see table).  

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Security Profiles</td>
<td>Select the security profiles you want to apply to this SOAP security policy. You must select at least one security profile.</td>
</tr>
</tbody>
</table>

**WS-Security Profile form fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a unique name for the security profile.</td>
</tr>
<tr>
<td>Type</td>
<td>Select <strong>X509</strong> to verify the request's certificate. Select <strong>Username</strong> to verify the request's user credentials.</td>
</tr>
<tr>
<td>Run as user</td>
<td>Select the ServiceNow user the instance will impersonate if authentication succeeds and the <strong>Bind Session</strong> field is selected. All web services requests will be attributed to this user. For example, if you select the <strong>System Administrator</strong> user then the instance treats all web services operations as being done by the system administrator. Make sure the user you select has appropriate SOAP privileges if you are using the <code>glide.soap.strict_security</code> high security setting. This field is only visible when the type is <strong>X509</strong>.</td>
</tr>
<tr>
<td>Order</td>
<td>Enter the order in which the instance checks security profiles. The instance checks all security profiles when processing an incoming SOAP request. If a request fails any security profile authentication requirement, the instance stops processing additional security profiles and fails the request.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Bind Session</td>
<td>Select this check box to have the instance impersonate the user listed in the <strong>Run as user</strong> field. You should only set this field for one profile at a time. If multiple profiles have this field selected, ServiceNow impersonates the user from the last successfully authenticated WS-Security profile. If no profile has this field selected, ServiceNow impersonates the user provided with the basic authentication headers or impersonates the default user (Guest).</td>
</tr>
<tr>
<td>X509 Certificate</td>
<td>Select the certificate record containing the certificate for web service requests. ServiceNow only validates the request signature. It automatically trusts the certificate’s certificate authority (CA). This field is only visible when the type is <strong>X509</strong>.</td>
</tr>
<tr>
<td>Profile action</td>
<td>Select how you want the instance to authenticate the user credentials. Select <strong>Authenticate with user</strong> if you want the instance to authenticate the request based on an existing user record. The request’s credentials must match values in an existing user record. Select <strong>Specify user to authenticate</strong> if you want to list a user name and password combination that all web services requests must meet. The request’s credentials must match the user name and password you list. This field is only visible when the type is <strong>Username</strong>.</td>
</tr>
<tr>
<td>User field to match</td>
<td>Select the column from the User [sys_user] table containing the value you want match against the request’s UserName. For example, if you select <strong>Email</strong> then the request UserName header must contain an email address matching an existing ServiceNow user. This field is only visible when the profile action is <strong>Authenticate with user</strong>.</td>
</tr>
<tr>
<td>User name</td>
<td>Enter the user name that all web services requests must contain. This field is only visible when the profile action is <strong>Username</strong>.</td>
</tr>
<tr>
<td>User password</td>
<td>Enter the password that all web services requests must contain. This field is only visible when the profile action is <strong>Username</strong>.</td>
</tr>
</tbody>
</table>

4. Click **Submit**.

Enforce strict security for inbound SOAP
Strict security for web services requires that users meet Contextual Security requirements to access instance resources.

Before you begin
Role required: admin

About this task
Note: ServiceNow does not support digital certificates, digital signatures, or other digested token methods in SOAP web service calls.

To enforce strict security for web services connections:

Procedure
1. Navigate to System Properties > Web Services.
2. Select Yes for Enforce strict security on incoming SOAP requests.

Note: To learn more about this property, see SOAP request strict security (instance security hardening) in Instance Security Hardening Settings.

Enable WS-Security verification
Administrators can enable Web Services Security (WSS) verification from the Web Services system properties.

Before you begin
Role required: web_service_admin or admin
Procedure

1. Navigate to System Web Services > Properties.
2. For Require WS-Security header verification for all incoming SOAP requests, select Yes.

   ![Require WS-Security header verification for all incoming SOAP requests]

   Yes | No

   **Note:** Selecting this option enables WS-Security for all inbound SOAP requests. It is not possible to enable WS-Security for only some requests.

3. Click Save.

4. Create a WS-security profile.

5. Update the user record for the MID Server and ODBC driver to mark these users as internal integration users.

6. Download and install the latest MID Server and ODBC driver.

7. To validate SOAP request signatures, upload the remote web service's certificate as a JKS and create the web service's WSS Username Token Profile.

   **Note:** Because ServiceNow's WSS implementation does not verify the CA certificate, you do not need to upload the web service's CA certificate.

Related information

Basic authentication

Mark service accounts as internal integration users

Allow internal integration communications to bypass the WSS authentication requirement by marking their user accounts as internal integration users.

Before you begin

Role required: admin

About this task

When WS-Security is enabled, authentication is required for all SOAP requests including internal integration communications such as the MID Server, ODBC Driver, Remote Update Sets, and high availability cloning. SOAP requests for these internal integration communications cannot implement WS-Security due to technical implications. If your instance uses these SOAP interfaces, you can allow them to bypass the WS-Security authentication requirement by marking their user accounts as internal integration users.
Note: Any web services other than ODBC, MID Server, Remote Update Sets, or high availability cloning must implement WS-Security headers when WS-Security is enabled.

Procedure
1. Navigate to User Administration > Users.
2. Select the user account for the MID Server or ODBC Driver.
3. Configure the form to add the Internal Integration User field.
4. Select the Internal Integration User check box.
5. Click Update.

Related information
Enable WS-Security verification
WS-Security

Debug incoming SOAP envelope
To capture incoming SOAP envelope XML in the system log, add the property glide.processor.debug.SOAPProcessor with a value of true.

When enabled, this property adds the incoming SOAP envelope in the Message field of the system log (System Logs > All). Disable this debugging feature as soon as you are finished so that the log is not overwhelmed with excessive and unnecessary debugging information.

View a SOAP session log
You can view a user's log from a SOAP session.

Before you begin
Role required: admin

Procedure
1. Navigate to User Administration > Logged in users.
2. Open an active SOAP session to see the transactions log. The SOAP session is marked as inactive within 60 seconds of the last transaction.

**Basic authentication code samples**
Samples of basic authentication code for several programming languages and versions.

**Perl and the SOAP::Lite libraries**
To supply basic authentication when using Perl and the SOAP::Lite libraries, you can implement the following function:

```perl
sub SOAP::Transport::HTTP::Client::get_basic_credentials {
    return 'user_name' => 'password';
}
```

**C# .NET VS 2005 or older**
When using C# .NET VS 2005 or older, you can take advantage of the Credentials object. For example:

```csharp

service.ServiceNow proxy = new service.ServiceNow();
service.get getService = newservice.get();
service.getResponse getServiceResponse = new service.getResponse();

try {
    proxy.Credentials = cred;
    getService.sys_id = "bf522c350a0a140701972dbf876f1610";
    getServiceResponse = proxy.get(getService);
} catch (Exception ex) { }
```

**C# .NET VS 2008**
When using C# .NET VS 2008, you can take advantage of the ClientCredentials object. For example:

```csharp
Demo_Incident.ServiceNowSoapClient client = new
test08WebService.Demo_Incident.ServiceNowSoapClient();
client.ClientCredentials.UserName.UserName = "admin";
client.ClientCredentials.UserName.Password = "admin";
```
Then in your `app.config` file look for the following and change "None" to "Basic":

```
<transport clientCredentialType="None" proxyCredentialType="None" realm="" />
```

**VB .NET**

When using VB .NET taking advantage of the Credentials object would look like the following:

```vbnet
Sub Main()
    Dim cred As New System.Net.NetworkCredential("user_name", "password")
    Dim proxy As New VB_Democm.incident.ServiceNow
    Dim getIncident As New VB_Democm.incident.get
    Dim getResponse As New VB_Democm.incident.getResponse

    proxy.Credentials = cred

    getIncident.sys_id = "[your sysID here]"

    getResponse = proxy.get(getIncident)

End Sub
```

The resulting response when Basic Authentication is turned on and no credentials are supplied looks like this:

```
<html>
<head>
<title>Apache Tomcat/5.0.28 - Error report</title>

WS-Security error messages

An instance produces one of the following error messages when it encounters an issue with a WS-security SOAP message.

### WS-security error messages

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Invalid Security Policy Selected. Select an Inbound policy for Inbound Requests.</td>
<td>The default policy name is set to an outbound policy. Set the default policy name to an inbound security policy.</td>
</tr>
<tr>
<td>SOAP request not Signed. Policy requires signing.</td>
<td>The SOAP security policy requires signing and the inbound SOAP request is not signed. Either specify a different SOAP security policy or provide the SOAP request with a proper signature.</td>
</tr>
<tr>
<td>No profiles to authenticate.</td>
<td>The selected Security policy either does not have any security profiles (X509 or UserNameToken) or the security profiles are inactive. Verify at least one security profile is active.</td>
</tr>
<tr>
<td>Unable to verify signed request.</td>
<td>The inbound SOAP request contains an invalid signature. The SOAP request changed after being signed.</td>
</tr>
<tr>
<td>Failed to extract principal(s) from request.</td>
<td>The SOAP request has either been tampered or was not well formed. ServiceNow cannot extract credentials to authenticate the request.</td>
</tr>
<tr>
<td>Failed to authenticate WS-security, unknown type.</td>
<td>The SOAP request contains an unsupported security profile. Resend the request with a supported security profile type: X509 or UsernameToken.</td>
</tr>
<tr>
<td>Failed to authenticate WS-security.</td>
<td>ServiceNow failed to authenticate against the provided profile credentials. Verify that the SOAP request is using the proper credentials.</td>
</tr>
</tbody>
</table>

**LongRunningSOAPRequestProps**

The following properties are available for long-running SOAP requests.
### Long-running SOAP request properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>glide.http.connection_timeout</code></td>
<td>Specify the maximum number of milliseconds an outbound HTTP request (such as Web Services) will wait to establish a connection.</td>
</tr>
<tr>
<td></td>
<td>• Type: integer</td>
</tr>
<tr>
<td></td>
<td>• Default value: 10000 (10 seconds)</td>
</tr>
<tr>
<td></td>
<td>• Location: system properties [sys_properties] table</td>
</tr>
<tr>
<td><code>glide.http.timeout</code></td>
<td>Specifies the maximum number of milliseconds to wait before an outbound transaction times out.</td>
</tr>
<tr>
<td></td>
<td>• Type: integer</td>
</tr>
<tr>
<td></td>
<td>• Default value: 175000 (175 seconds)</td>
</tr>
<tr>
<td></td>
<td>• Location: Add to system properties [sys_properties] table</td>
</tr>
<tr>
<td><code>glide.soap.max_redirects</code></td>
<td>Specifies the maximum number of redirects the server sends to the client before the soap request is timed out.</td>
</tr>
<tr>
<td></td>
<td>• Type: integer</td>
</tr>
<tr>
<td></td>
<td>• Default value: 20</td>
</tr>
<tr>
<td></td>
<td>• Location: system properties [sys_properties] table</td>

</thead>
<tbody>
<tr>
<td></td>
<td>necessary to change this value.</td>
</tr>
</tbody>
</table>

Inbound web service examples

Inbound web service examples demonstrate how to access ServiceNow web services.

Java Apache Axis2 web services client examples

Examples demonstrating an integration with Axis2 Version 1.4.

Requirements

- An "elementFormDefault" value of qualified means that an unqualified element is in the default namespace defined on an ancestor. If it is "unqualified" then an unqualified element is in the empty namespace (xmlns=""). The default is "unqualified".
- To Resolve the Axis Client deserialization failure you should go to System Properties > Web Services and uncheck the property that sets the elementFormDefault attribute of the embedded XML schema to the value of unqualified. Save the property setting and regenerate your Axis2 client code if your client code was generated before changing this property.

Java Apache Axis2 web services client examples insert

An example class to insert an incident record.

```java
public class Insert {
    public static void main ( String args [ ] ) { try {
        HttpTransportProperties. Authenticator basicAuthentication  = new HttpTransportProperties. Authenticator ( ) ;
        basicAuthentication. setUsername ( "admin" ) ;
        basicAuthentication. setPassword ( "admin" ) ;
```
ServiceNowStub proxy = new ServiceNowStub () ; 

proxy._getServiceClient ( ) . getOptions ( ) . setProperty (org. apache. axis2. transport. 
http. HTTPConstants. CHUNKED, Boolean. FALSE ) ; 
proxy._getServiceClient ( ) . getOptions ( ) . setProperty (org. apache. axis2. transport. 
http. HTTPConstants. AUTHENTICATE, basicAuthentication ) ; 

ServiceNowStub. Insert inc = new ServiceNowStub. Insert ( ) ; 
ServiceNowStub. InsertResponse resp = new ServiceNowStub. InsertResponse ( ) ; 

inc. setAssigned_to ( "Christen Mitchell" ) ; 
inc. setCategory ( "hardware" ) ; 
inc. setPriority ( BigInteger. ONE ) ; 
inc. setDescription ( "The WI_FI in the reception area is down" ) ; 
inc. setCaller_id ( "Joe Employee" ) ; 

resp = proxy. insert (inc ) ; 

System. out. println ( "New Incident: " + resp. getNumber ( ) ) ; } catch ( Exception 
e ) { System. out. println ( e. toString ( ) ) ; }

} 

Java Apache Axis2 web services client examples update
An example of an Axis Client program that calls the getKeys function to query all incidents where the category is Hardware.

getKeys
A list of sys_id is returned as a result:

package com.service_now.www ;

public class DemoClient { 

public static void main ( String args [ ] ) { try { 
ServiceNowStub proxy = new ServiceNowStub () ; 
ServiceNowStub. GetKeys getInc = new ServiceNowStub. GetKeys ( ) ; 
ServiceNowStub. GetKeysResponse resp = new ServiceNowStub. GetKeysResponse ( ) ;

getInc. setActive ( true ) ; 
getInc. setCategory ( "hardware" ) ;
http. HTTPConstants. CHUNKED,  Boolean. FALSE ) ;

resp  = proxy. getKeys (getInc ) ;

String [ ] keys  = resp. getSys_id ( ) ;

System. out. println ( "Key: " + keys [ 0 ] ) ; } catch ( Exception e ) { System. out.
println (e. toString ( ) ) ; }

} }

getRecords

package com.service_now.www ;

import com.service_now.www.ServiceNowStub.GetRecordsResult_type0 ;

public class GetRecords {  

/**
 * @param args
 */
* / public static void main ( String [ ] args ) { try {
ServiceNowStub proxy  = new ServiceNowStub ( ) ;
ServiceNowStub. GetRecords incidents  = new ServiceNowStub. GetRecords ( ) ;
ServiceNowStub. GetRecordsResponse result  = new ServiceNowStub. GetRecordsResponse ( ) ;

incidents. setActive ( true ) ;
incidents. setCategory ( "hardware" ) ;
incidents. setSys_created_on ( "> 2009-06-08 10:30:00" ) ;

http. HTTPConstants. CHUNKED,  Boolean. FALSE ) ;

result  = proxy. getRecords (incidents ) ;

GetRecordsResult_type0 [ ] keys  = result. getGetRecordsResult ( ) ;

for ( int key  = 0 ; key  < keys. length ; key ++ ) { System. out. println ( "Key: 
" + keys [ 0 ]. getSys_id ( ) ) ; } catch ( Exception e ) { System. out. println (e.
toString ( ) ) ; }
Java Apache Axis2 web services client examples advanced

Examples showing how to construct and use an Axis2 client to consume a ServiceNow Web Service.

Axis is essentially a SOAP engine -- a framework for constructing SOAP processors such as clients, servers, or gateways. The current version of Axis is written in Java. This content is intended for system admins with a light development background in Java. To begin you would need Java JDK version 1.4.2 or higher and Axis2 version 1.0 or higher.

Create a Java Project
This example uses Eclipse SDK Version: 3.4.2 for managing the source code and executing the web request. Eclipse is not required.

• Open Eclipse and from the menu select File > New > Project > Java Project.
• Give the project a name.
• Verify that the correct JRE is specified.
◦ If using wsdl2java run "java -version" on the command line and this will be the version to specify for the project specific JRE.
◦ If using the Axis2 Codegen plugin use default JRE.
Generate your Axis2 client code

- From a command line in the bin directory of the axis folder:

```
./wsdl2java.sh -uri https://<instance name>.service-now.com/incident.do?WSDL
-o /glide/workspace/TestWebService/
```

- In the above example:
  - The "-uri" is either the path where you have saved a copy of the wsdl to either ".wsdl" or ".xml", or the URL the WSDL resides at.
  - The "-o" is the path where you want the files to be written out to. If not specified, the files will be written out to the current bin location.

- In Eclipse refresh the project and the generated Stub and CallbackHandler should now be displayed

<table>
<thead>
<tr>
<th>Axis Stub</th>
<th>src</th>
<th>com.service_now.www</th>
<th>ServiceNowCallbackHandler.java</th>
<th>ServiceNowStub.java</th>
</tr>
</thead>
</table>

Basic Authentication

```
HttpTransportProperties.Authenticator basicAuthentication = new HttpTransportProperties.Authenticator();
basicAuthentication.setUsername("admin");
basicAuthentication.setPassword("admin");
...
ServiceNowStub proxy = new ServiceNowStub();
...
proxy._getServiceClient().getOptions().setProperty(org.apache.axis2.transport.http.HTTPConstants.AUTHENTICATE, basicAuthentication);
```

Compatibility with Axis2 Versions 1.1 and higher

Chunking support is only available in HTTP Version 1.1. By default chunking is enabled in Axis2.xml for versions 1.1 and higher. ServiceNow does not support Chunking, so you will need to disable chunking at deployment time or at runtime.
• Deployment time: One can disable HTTP chunking by removing or commenting out the following element from Axis2.xml

```xml
<parameter name= "Transfer-Encoding" >chunked</parameter>
```

• Runtime: User can disable the chunking using following property set in Client or Stub, versions 1.1.1 and higher only

```java
options.setProperty (org.apache.axis2.transport.http.HTTPConstants.CHUNKED, Boolean.FALSE );
```

Creating Unique Packages
You can use the Axis2 parameter namespace2package (ns2p) to create unique package names. The parameter uses this format:

```bash
<Axis path>\bin\wsdl2java.bat -u -p cr2 -ns2p <namespace>=<package name> -uri <wsdl to convert>
```

For example:

```bash
<Axis path>\bin\wsdl2java.bat -u -p cr2 -ns2p
http://www.service-now.com/change_request=my.change_request -uri change_request
```

Microsoft .NET web services client examples
Examples demonstrating an integration with Microsoft .NET Web Services Client.

Requirements
.NET 2.0 Versions and Higher:

• An "elementFormDefault" value of qualified means that an unqualified element is in the default namespace defined on an ancestor. If it is "unqualified" then an unqualified element is in the empty namespace (xmlns=""). The default is "unqualified".

• To Resolve the .NET Client deserialization failure you should go to System Properties > Web Services and uncheck the property that sets the elementFormDefault attribute of the embedded XML schema to the value of unqualified. Save the property setting and recreate your WSDL Reference.cs class. See Also "Compatibility with Clients generated from WSDL" below.
Example insert using Visual Basic .NET

A sample Visual Basic .NET program that inserts a core_company record.

```vbnet
Public Class Class1
    Shared Sub Main()
        Dim proxyCompany As New core_company.localhost.ServiceNow()

        Dim companyInsert As New core_company.localhost.insert()

        Dim companyInsertResponse As core_company.localhost.insertResponse

        With companyInsert
            .name = "Test Company SKF 2"
            .contact = "SKF"
            .customer = True
            .customerSpecified = True
        End With

        companyInsertResponse = proxyCompany.insert(companyInsert)

        Console.WriteLine(companyInsertResponse.sys_id)
    End Sub
End Class
```

Sample Visual Basic .NET project
Perl web services client examples

Examples demonstrating an integration with a Perl web services client.

Note: The following examples require the usage of the Perl language and the SOAP::Lite package.

System Requirements

- Perl 5.8
  - SOAP::Lite (prerequisites http://soap-lite.com/prereqs.html)
  - Crypt::SSLeay
  - IO::Socket::SSL

insert

The following example will insert a record into the Incident table.
insert (With XML payload)
The following is an example of inserting a record into the ecc_queue table where the payload field is an XML document. This is done using the Perl language and the SOAP::Lite package, the XML document creation uses the XML::Writer package:

```
#!/usr/bin/perl -w
use SOAP::Lite { +trace => all, maptype => {} };use SOAP::Lite;
use XML::Writer;use XML::Writer::String;
```
## Get parameters passed by OVO

```perl
notification#$OVMSG{id}=$ARGV[0];$OVMSG{node_name}=$ARGV[1];$OVMSG{node_type}=$ARGV[2];$OVMSG{date_created}=$ARGV[3];$OVMSG{time_created}=$ARGV[4];$OVMSG{date_received}=$ARGV[5];$OVMSG{time_received}=$ARGV[6];$OVMSG{application}=$ARGV[7];$OVMSG{msg_group}=$ARGV[8];$OVMSG{object}=$ARGV[9];$OVMSG{severity}=$ARGV[10];$OVMSG{operator_list}=$ARGV[11];$OVMSG{msg_text}=$ARGV[12];$OVMSG{instruction}=$ARGV[13];
```

```perl
sub SOAP::Transport::HTTP::Client::get_basic_credentials{return 'itil' =>'itil';}
```

```perl
my $soap= SOAP::Lite->proxy('http://<instance name>.service-now.com/ecc_queue.do?SOAP');
```

```perl
my $method= SOAP::Data->name('insert')->attr({xmlns =>$http://www.service-now.com/});
```

```perl
# get all incidents with category Network
my @params=( SOAP::Data->name(agent =>'OVO_Notification'));push(@params, SOAP::Data->name(queue =>'input'));push(@params, SOAP::Data->name(name =>'HP Openview OVO Notification'));push(@params, SOAP::Data->name(source =>$OVMSG{id}));
```

```perl
my $s= XML::Writer::String->new();my $writer=new XML::Writer(OUTPUT =>$s);
```

```perl
#$writer->xmlDecl();$writer->startTag('notification');
```

```perl
write_element('id');
write_element('node_name');
write_element('node_type');
write_element('date_created');
write_element('time_created');
write_element('date_received');
write_element('time_received');
write_element('application');
write_element('msg_group');
write_element('object');
write_element('severity');
write_element('operator_list');
write_element('msg_text');
write_element('instruction');
```

```perl
$writer->endTag('notification');
```

```perl
$writer->end;
```

**getRecords**

To query for an Incident using its incident number value:

```perl
#!/usr/bin/perl -w
use SOAP::Lite ( +trace => all, maptype => {} );
use SOAP::Lite;

sub SOAP::Transport::HTTP::Client::get_basic_credentials{return 'itil' => 'itil';}

my $soap = SOAP::Lite->proxy('http://<instance name>.service-now.com/incident.do?SOAP');

my $method = SOAP::Data->name('getRecords')->{'xmlns' => 'http://www.service-now.com/'};

get incident by number

my @params = (SOAP::Data->name(number => 'INC10001'));

my %keyHash = %{$soap->call($method => @params)->body->{'getRecordsResponse'}->{'getRecordsResult'});

# iterate through all fields and print them
foreach my $k (keys %keyHash)
{print "$k=$keyHash{$k}\n";
}
```

**getRecords (Returning Multiple Results)**

The following is an example of retrieving and displaying an array of Incident records by querying all Incidents that have a "Category" of "Network"

```perl
#!/usr/bin/perl -w
use SOAP::Lite ( +trace => all, maptype => {} );
use SOAP::Lite;

sub SOAP::Transport::HTTP::Client::get_basic_credentials{return 'itil' => 'itil';}

my $soap = SOAP::Lite->proxy('http://<instance name>.service-now.com/incident.do?SOAP');

my $method = SOAP::Data->name('getRecords')->{'xmlns' => 'http://www.service-now.com/'};

# get incident by sys_id
my @params = (SOAP::Data->name(category => 'Network'));

my %keyHash = %{$soap->call($method => @params)->body->{'getRecordsResponse'});

my $i = 0;
my $size = @{$keyHash{'getRecordsResult'}};
for ($i = 0; $i < $size; $i++)
{
    my $record = @{$keyHash{'getRecordsResult'}}[$i];
    print "------------------------------ $i
------------------------------\n";
    foreach my $kk (keys %$record)
    {print "$kk=$record{$kk}\n";
    }
}
```

**deleteRecord**

```perl
#!/usr/bin/perl -w

use SOAP::Lite ( +trace => all, maptype => {} );
use SOAP::Lite;
```
sub SOAP::Transport::HTTP::Client::get_basic_credentials { return 'itil' => 'itil'; }

my $soap = SOAP::Lite->proxy('http://localhost:8080/glide/incident.do?SOAP');

my $method = SOAP::Data->name('deleteRecord')->attr({xmlns => 'http://www.service-now.com/'});

# delete incident by sys_idmy @params = ( SOAP::Data->name(sys_id =>'46f67787a9fe198101e06dfcf3a78e99'));

my $result = $soap->call($method => @params);

print_fault($result);
print_result($result);

sub print_result { my ($result) = @_; }

if ($result->body && $result->body->{'deleteRecordResponse'}) { my %keyHash = %{$result->body->{'deleteRecordResponse'}};
foreach my $k (keys %keyHash) { print "name=$k   value=$keyHash{$k}\n"; } }

sub print_fault { my ($result) = @_; }

if ($result->fault) { print "faultcode=".$result->fault->{'faultcode'}."\n"; print "faultstring=".$result->fault->{'faultstring'}."\n"; print "detail=".$result->fault->{'detail'}."\n"; }

---

**Python web services client examples**

Examples demonstrating an integration with a Python web services client.

**Requirements**
The following examples require the installation of the following Python modules:

- **fpconst** [http://pypi.python.org/pypi/fpconst/0.7.2](http://pypi.python.org/pypi/fpconst/0.7.2)
- **PyXML** [http://pyxml.sourceforge.net/topics/](http://pyxml.sourceforge.net/topics/)

**insert**

This is an example of inserting an incident.

```python
#!/usr/bin/python

from SOAPpy import SOAPProxy
import sys
```
def createincident (params_dict):
    
    # instance to send to
    instance = 'demo'
    
    # username/password
    username = 'itil'
    password = 'itil'
    
    # proxy - NOTE: ALWAYS use https://INSTANCE.service-now.com, not
    # https://www.service-now.com/INSTANCE for web services URL from now on!
    proxy = 'https://%s:%s@%s.service-now.com/incident.do?SOAP' % (username, password, instance)
    namespace = 'http://www.service-now.com/
    server = SOAPProxy (proxy, namespace)
    
    # uncomment these for LOTS of debugging output
    #server.config.dumpHeadersIn = 1
    #server.config.dumpHeadersOut = 1 #server.config.dumpSOAPOut = 1 #server.config.dumpSOAPIn = 1
    
    response = server.insert (impact = int (params_dict[ 'impact' ]), urgency = int (params_dict ['urgency'])), priority = int (params_dict ['priority'])),
    category =params_dict ['category'], location =params_dict ['location'], caller_id =params_dict ['user'], assignment_group =params_dict ['assignment_group'],
    assigned_to =params_dict ['assigned_to'], short_description =params_dict ['short_description'], comments =params_dict ['comments'])
    
    return response

values = { 'impact': 1, 'urgency': 1, 'priority': 1, 'category': 'High',
    'location': 'San Diego', 'user': 'fred.luddy@yourcompany.com', 'assignment_group':
    'Technical Support', 'assigned_to': 'David Loo', 'short_description': 'An incident created using python, SOAPpy, and web services.', 'comments': 'This a test making an incident with python. Isn\'t life wonderful?'}

new_incident_sysid =createincident (values)

print "Returned sysid: "+ repr (new_incident_sysid)
**getKeys**
This is an example of executing getKeys on the demo instance using basic authentication.

```python
#!/bin/env python

# use the SOAPpy module from SOAPpy import SOAPProxy

username, password, instance = 'admin', 'admin', 'demo'
proxy, namespace = 'https://username:password@www.service-now.com/'+instance+
'/incident.do?SOAP', 'http://www.service-now.com/

server = SOAPProxy(proxy, namespace)
response = server.getKeys(category = 'Network')

print response.sys_id.split(',')
```

**getRecords**
In this example, we get an incident, querying for category == "Network" (with basic authentication).

```python
#!/bin/env python

# use the SOAPpy module from SOAPpy import SOAPProxy

username, password, instance = 'admin', 'admin', 'demo'
proxy, namespace = 'https://username:password@www.service-now.com/'+instance+
'/incident.do?SOAP', 'http://www.service-now.com/

server = SOAPProxy(proxy, namespace)
response = server.getRecords(category = 'Network')

for record in response:
    for item in record:
        print item
```

**get**
In this example, we get an incident record by `sys_id` (with basic authentication).

```python
#!/bin/env python

# use the SOAPpy module from SOAPpy import SOAPProxy

username, password, instance = 'admin', 'admin', 'demo'
```

server = SOAPProxy(proxy,namespace)
response = server.get(sys_id = '9c573169c611228700193229fff72400')

for each in response:
    print each

---

Advanced
This is an example of advanced Python script that reads a log file for a keyword invalid spi and creates an ECC Queue record where the payload is set to an alert of XML format.

#!/bin/env python

# kevin.pickard@service-now.com 2008.07.03 initial creation

from SOAPpy import SOAPProxy
from xml.dom.minidom import getDOMImplementation
import sys, os, socket, pickle, re

# instance to send to
instance = 'demo'

# username/pass
username = 'admin'
password = 'admin'

# log file to watch
syslogfile = '/var/log/cisco.log.ksp'

# state file
statefile = '/tmp/syslog_ecc.state-test'

# ECC queue values
soapagent = 'SOAPpy'
cectopic = 'PIX Error: '
cecname = 'Invalid SPI: '
cecsource = 'Syslog'

# regex string to match
matchstring = 'invalid spi'
try:
state = open(statefile, 'r')
lastbyte = pickle.load(state)
state.close() except:
lastbyte = 0

#print 'DEBUG: lastbyte = '+'str(lastbyte)

try:
log = open(syslogfile, 'ro') except:
errortopic = 'Script Error'
errorname = 'Unable to open log file '+syslogfile+'.
errorpayload = 'This message was generated due to an error condition encountered in a script. The name of the script is '+os.path.basename(sys.argv[0])+ ' on server '+socket.gethostname()+ '.

proxy = 'https://'+username+':'+password+'@'+instance+'.service-now.com/ecc_queue.do?SOAP'
namespace = 'http://www.service-now.com/'
server = SOAPProxy(proxy, namespace)
server.config.dumpSOAPOut = 1
server.config.dumpSOAPIn = 1
response = server.insert(agent=soapagent, topic=errortopic, name=errorname, source=sys.argv[0], payload=errorpayload)

sys.exit(1)

if lastbyte != 0:
try:
log.seek(lastbyte) except IOError:
pass

loglines = log.readlines()

lastbyte = log.tell()

log.close()

state = open(statefile, 'w') pickle.dump(lastbyte, state)
state.close()
matchedlines. append (line )

# print 'DEBUG: len->loglines = '+str(len(loglines)) # print 'DEBUG: lastbyte ='
# print '+str(lastbyte) # print 'DEBUG: matchedlines = '+str(matchedlines)

if len (matchedlines ) == 0:
    sys. exit ( 0 )

proxy  = 'https://'+username+ ':'+password+ '@'+instance+'.service-now.com/ecc_queue.do?SOAP'
namespace  = 'http://www.service-now.com/'

server  = SOAPProxy (proxy , namespace ) #server.config.dumpSOAPOut = 1
#server.config.dumpSOAPIn = 1

entriestosend = {} for line  in matchedlines:
    device =line. split () [ 3 ]
    sourceip =line. split () [- 1 ]
    entriestosend [sourceip ] = [device , line ]

for key ,value  in entriestosend. iteritems ( ):
    #impl=getDOMImplementation() #newdoc = impl.createDocument(None, "log_line", None) #top_element = newdoc.documentElement #text = newdoc.createTextNode(value[1])
    #top_element.appendChild(text)

response  = server. insert (agent =soapagent , topic =ecctopic+value [ 0 ] , name =eccname+key , source =eccsource , payload =value [ 1 ] )

---

**Web services C Sharp .NET end to end tutorial**

Examples demonstrating how to use .NET to consume a ServiceNow web service.

This tutorial will show you how to configure ServiceNow correctly to receive a web service request from your .NET client, as well as how to consume our web services using C# .NET.

**Configure C sharp with .NET**

Configure web services within to receive web service requests from a .NET client..
Procedure

1. To configure web services within ServiceNow, access the **System Properties > Web Services** module.

   This module displays the system properties that are specific to web services within your instance. For security reasons, you will want to make sure that you require basic authorization for incoming SOAP requests. This ensures that only authenticated users will be able to make any web services calls, whether it be via web service import sets or inserting/deleting/querying via direct web services.

   ![Web Services](image)

   Please edit your changes and press Save

   **Customization Properties for Web Services**

   - **Require basic authorization for incoming RSS requests**
     - [ ] Yes | No

   - **Require basic authorization for incoming SOAP requests**
     - [ ] Yes | No

2. This next step is very important if you are using .NET as a client to connect to ServiceNow. You must set the **elementFormDefault** property to false.

   This property defines how the WSDLs are qualified. Of course, if you do not consume our WSDL and just create the XML manually, then this property is irrelevant.

   ![Element Form Default](image)

   This property sets the elementFormDefault attribute of the embedded XML schema to the value of unqualified, if set to true. This attribute indicates whether or not locally declared elements must be qualified by the target namespace in an instance document. If the value of this attribute is 'qualified', then locally declared elements must be qualified by the target namespace. For compatibility with clients generated from WSDL (.NET Web Reference, Axle2 stub, webMethods, etc.), set this value to false. This value defaults to true.

   [ ] Yes | No

**Call a web service in visual studio .NET**

Call a web service using Visual Studio 2008.

In this example, we will be using Visual Studio 2008. First, create a new Windows Form Application for this example.
On the resulting form, we created a richTextBox (which we named 'richTextBoxResult') and a button (named buttonResult).
**Use a service reference in a C Sharp integration**

Use a wizard to add a service reference for a C Sharp integration.

Go to the **Solutions Explorer** and select **Service References > Add Service Reference**. A wizard will appear asking for an address. Use: https://<instance name>.service-now.com/incident.do?WSDL. Accept the defaults for the rest of the wizard.

Open the app.config file and change the Security mode to "Transport" and the clientCredentialType and proxyCredentialType to "Basic"

```xml
  <security mode="Transport">
    <transport clientCredentialType="Basic" proxyCredentialType="Basic">
      <realm=""></realm>
      <extendedProtectionPolicy policy Enforcement="Never" />
    </transport>
    <message clientCredentialType="UserName" algorithmSuite="Default" />
  </security>
```

**Use a web reference in a C Sharp integration**

Use a wizard to add a web reference for a C Sharp integration.

Go to the **Solutions Explorer** and select **Service References > Add Service Reference**. A wizard will appear. At the bottom of the form, there is an **Advanced** button. Click on it and click on the **Add Web Reference** button at the bottom of the new wizard page. This will start the **Web Reference** wizard. For the URL, use: https://<instance name>.service-now.com/incident.do?WSDL and name the web reference, ‘WebReference1’. Accept the defaults for the rest of the wizard.

**C Sharp integration source code**

After defining the source code, insert it.

Now we are ready to insert the code. Double-click on the **Send Web Service** button on your form to open the backend code to the form that has been created. Here is the code to insert a record into the demo instance and to read the response.

```csharp
using System;
using System.Collections.Generic;
using System.ComponentModel;
using System.Data;
using System.Drawing;
using System.Linq;
```
using System.Text;
using System.Windows.Forms;

namespace ExampleWebServiceForWiki
{
    public partial class FormMain : Form
    {
        public FormMain()
        {
            InitializeComponent();
        }

        private void buttonSend_Click(object sender, EventArgs e)
        {
            /* SERVICE REFERENCE-SPECIFIC CODE */
            ServiceReference1.ServiceNowSoapClient soapClient = new ServiceReference1.ServiceNowSoapClient();
            soapClient.ClientCredentials.UserName.UserName = "itil";
            soapClient.ClientCredentials.UserName.Password = "itil";

            ServiceReference1.insert insert = new ExampleWebServiceForWiki.ServiceReference1.insert();
            ServiceReference1.insertResponse response = new ExampleWebServiceForWiki.ServiceReference1.insertResponse();
            // END OF SERVICE REFERENCE CODE */

            // WEB REFERENCE-SPECIFIC CODE
            soapClient.Credentials = cred;

            WebReference1.insert insert = new WebReference1.insert();
            WebReference1.insertResponse response = new WebReference1.insertResponse();
            // END OF WEB REFERENCE CODE

            insert.category = "Category";
            insert.comments = "Comments";
            insert.short_description = "My short description";

            try
            {
                response = soapClient.insert(insert);
            }

C Sharp integration results

If you have followed the tutorial correctly, you should receive the result whether you used a Service Reference or a Web Reference.

Dot net tutorial results

Troubleshoot a null response in a C Sharp integration

Receiving a null response from ServiceNow's web service.

If you are receiving a "null" response from your web service in your client code, then you may have missed the step in this tutorial for setting the elementFormDefault setting to "False".

Remember to recompile your code against the WSDL after you have changed this setting and saved it.
Retrieve a large number of records using SOAP

By default, a single SOAP request can retrieve a maximum of 250 records.

SOAP relies on Extensible Markup Language (XML) as its message format, and usually relies on other Application Layer protocols (most notably Remote Procedure Call (RPC) and HTTP) for message negotiation and transmission. SOAP can form the foundation layer of a web services protocol stack, providing a basic messaging framework upon which web services can be built.

Because of the verbose XML format, SOAP can be considerably slower than other transport methods. Therefore, sending a large amount of data via SOAP is inefficient and is discouraged. Because of this, ServiceNow has imposed a hard-limit of 250 records that can be retrieved at any time in a single query. You may find that this limit poses some technological challenges for your integration design.

SOAP strategies

Retrieve the information that you need and make your integration more efficient.

Use filters to limit the number of results

One way to make your web service calls fit within the 250 record limit is to think about the design of your integrating application.

For example, let's assume that we are making an incident form in C# to show a user the incidents that are assigned to him.

Problematic query approach

The C# application makes a soap call to retrieve all of the incidents within ServiceNow. The application would then store the results locally in memory. When the user decides to view the incidents that are assigned to him, the application loops the internal array and displays the incidents that are assigned to the user.

A better query approach

The C# application makes a soap call to retrieve all of the incidents within ServiceNow that are assigned to the logged-in user. The results are stored locally in memory. When the user decides to view the incidents that are assigned to him, the application shows all the results to the user.
A performance-optimized query approach

The C# application makes no SOAP call initially. When a logged-in user decides to view the incidents that are assigned to him, the application presents him with the choice of viewing active, closed, etc. It gives him the ability to filter the results that he wants to see before the SOAP call is even made. Then, the user is only presented with the results that he wished to view.

Use a local data store to pull data from

If a large amount of data needs to be queried often, and the data does not need to be real-time, perform a sync of the ServiceNow table that you're interested in with your integrating application's data store.

Data push

• Using a scheduled job, ServiceNow can generate a csv/xml from a report and have it emailed to a specific location. The receiver might have a trigger to take the email attachment, parse it, and populate an internal table from which the application can communicate when the data is needed.
• Using a schedule job, ServiceNow can generate a csv/xml from a report and FTP it to an public FTP/FTPS location. The integrating product would consume this csv file on a regular basis and populate an internal table from which the application can communicate when the data is needed.

Note: Currently, the platform does not provide a method for extracting very large amounts of data and sending the output to an FTP server. However, a customization to perform that function is described at here. The customization was developed for use in specific ServiceNow instances, and is not supported by ServiceNow Customer support. The method is provided as-is and should be tested thoroughly before implementation. Post all questions and comments regarding this customization to our community forum.

Data pull

Using a cron job, a machine internal to your network can make a wget call to pull csv/xml data from any table within ServiceNow. The integrating product would consume this csv/xml file on a regular basis and populate an internal table from which the application can communicate when the data is needed. Examples of the wget command that would be used:
• wget --user=itil --password=itil --no-check-certificate https://<instance name>.service-now.com/incident_list.do?CSV

• wget --user=itil --password=itil --no-check-certificate https://<instance name>.service-now.com/incident_list.do?XML

**Use Java/C#/PHP code to fetch the XML data using basic authentication**

If a local data store is not an option, another way to get the data is to call the CSV/XML processor directly and then parse the results.

Use the resulting data in a similar manner as you would a direct SOAP call. An example of this in PHP:

```php
<?php
//This example is in PHP

$user = "itil";
$pass = "itil";
$userPass = $user.':'.$pass;

$ch = curl_init();
curl_setopt($ch, CURLOPT_URL, 'https://<instance name>.service-now.com/incident_list.do?CSV');
curl_setopt($ch, CURLOPT_HEADER, 0);
curl_setopt($ch, CURLOPT_RETURNTRANSFER, 1);
curl_setopt($ch, CURLOPT_FOLLOWLOCATION, true);
curl_setopt($ch, CURLOPT_HTTPAUTH, CURLAUTH_BASIC);
curl_setopt($ch, CURLOPT_USERPWD, $userPass);

$data = curl_exec($ch);
$info = curl_getinfo($ch);

if ($output === false) {
    $output = "No cURL data returned for $addr [". $info['http_code']. "]";
    if (curl_error($ch))
        $output .= "\n". curl_error($ch);
    print $output;
} else{
    echo $data;
}
```
Exporting and converting records into complex data types

Use URL parameters to export table records and convert them into complex data types, such as JSON, XML, PDF, CSV, and XLS.

Exporting records as complex data types

You can use an HTTP GET request to retrieve records from a table and put them in a specified format. For example, use the PDF parameter in a GET request to export records from a table as PDF files; use the XLS parameter to export records from a table as XLS files. For example, to retrieve a list of incident records as XLS files, issue an HTTP GET using the following URL: https://instance_name.service-now.com/incident.do?XLS. The file returned is incident.xls. incident.do is basically a GET that returns a list of the records from the incident table. The XLS parameter converts those records into XLS files.

The general syntax is: https://<serviceNow-instance-name>/<table-name>.do?<Data-type-parameter>

URL parameters

The following table shows URL parameters you can use in GET requests, filters you can use to filter out unwanted table records in the return, and an indicator of whether you can POST the data type directly to a table. The parameter becomes the extension of the returned file, for example, using the XLS parameter returns a file in the form <table-name>.xls.

<table>
<thead>
<tr>
<th>Data type</th>
<th>Parameter</th>
<th>Valid filters</th>
<th>Directly POST to table?</th>
</tr>
</thead>
<tbody>
<tr>
<td>CSV</td>
<td>CSV</td>
<td>sysparm_query, sysparm_view</td>
<td>Y</td>
</tr>
<tr>
<td>Excel</td>
<td>XLS, EXCEL, XLSX</td>
<td>sysparm_query, sysparm_view</td>
<td>Y</td>
</tr>
<tr>
<td>JSON</td>
<td>JSONv2</td>
<td>Various. See JSON data retrieval API.</td>
<td>Y</td>
</tr>
<tr>
<td>PDF</td>
<td>PDF</td>
<td>sysparm_query, sysparm_view</td>
<td>N</td>
</tr>
<tr>
<td>RSS</td>
<td>RSS</td>
<td>sysparm_query, sysparm_view and more.</td>
<td>N</td>
</tr>
</tbody>
</table>
For more information about retrieving and converting table records into the JSON file format, see JSONv2 Web Service.

For more information about retrieving and converting table records into the RSS file format, see RSS feed generator.

**Converting records to PDFs**

For PDF export, there is a distinction between targeting a table and targeting its list. To generate a PDF of a list of records, suffix the target with _list. To target a single record, you must specify the `sys_id` parameter to identify the record for which you are generating the PDF.

**Filters**

All URL parameters work with filters that enable you to export a subset of table records. For example, `sysparm_query=active=true` in a GET request exports only active records. The following example exports only active incident records in an Excel format: https://instance_name.service-now.com/incident.do?EXCEL&sysparm_query=active=true.

The general syntax is: https://<serviceNow-instance-name>/<table_list>.do?<Data-type-parameter>&<filter>

Filters include:

- `sysparm_query`—Filters the data using the encoded query before exporting files, for example, `sysparm_query=active=true` exports only active records.
- `sysparm_view`—Specify the name of a list view to control which fields are returned. For example, to return the ESS view, use `sysparm_view=ess`.
- `useUnloadFormat`—Indicates that the XML format returned is an unload format. The unload format is the same format you get when, from a list in the UI, you select Export > XML > ... You can import unload-formatted XML files back into the tables. To enable the unload format from a URL, use the `useUnloadFormat=true` URL parameter, for example, https://instance_name.service-now.com/incident.do?XML&useUnloadFormat=true.
Example GET queries

<table>
<thead>
<tr>
<th>Data type</th>
<th>Example query</th>
</tr>
</thead>
<tbody>
<tr>
<td>CSV</td>
<td><a href="https://instance_name.service-now.com/incident.do?CSV&amp;sysparm_query=active=true">https://instance_name.service-now.com/incident.do?CSV&amp;sysparm_query=active=true</a></td>
</tr>
<tr>
<td>Excel</td>
<td><a href="https://instance_name.service-now.com/incident.do?XLS&amp;sysparm_query=active=true">https://instance_name.service-now.com/incident.do?XLS&amp;sysparm_query=active=true</a></td>
</tr>
<tr>
<td>PDF</td>
<td><a href="https://instance_name.service-now.com/incident.do?PDF&amp;sysparm_view=ess">https://instance_name.service-now.com/incident.do?PDF&amp;sysparm_view=ess</a></td>
</tr>
<tr>
<td>RSS</td>
<td><a href="https://instance_name.service-now.com/incident.do?RSS&amp;sysparm_view=ess">https://instance_name.service-now.com/incident.do?RSS&amp;sysparm_view=ess</a></td>
</tr>
<tr>
<td>XML</td>
<td><a href="https://instance_name.service-now.com/incident.do?XML&amp;sysparm_query=active=true">https://instance_name.service-now.com/incident.do?XML&amp;sysparm_query=active=true</a></td>
</tr>
</tbody>
</table>

Returned files

GET queries return records from a table in the format specified in the request. For example, a query that uses the XLS parameter returns a table record in a file with the .xls extension.

The Content-Disposition header in the response displays the file name and extension of the returned file. The file name is based on the table you export from, such as incident.xls, incident.pdf, or incident.xml.

Exporting data into tables

You can POST the following data types directly into tables:

- CSV
- Excel
- JSON

The file headers must match the field columns in the targeted table. For more information, see Post CSV or Excel files directly to an import set.

JSONv2 Web Service

The ability to describe sets of data in JSON format is a natural extension to the JavaScript language.
ServiceNow supports a web service interface that operates on the JSON object as the data input and output format.

The JSONv2 web service is provided by a platform-level processor similar to the services for SOAP, WSDL, CSV, Excel, and XML. Like those services, the JSON web service is triggered by a standalone JSONv2 URL parameter. For example:

```
https://<instance name>.service-now.com/mytable.do?JSONv2
```

Having the JSON object available as a data format for web services means that you can create (insert), update, and query any data in the system using the JSON object format, and get results in the JSON object format.

**Security**

Like all other HTTP-based web services available on the platform, the JSONv2 web service is required to authenticate using basic authentication by default. The user ID that is used for authentication is subjected to access control in the same way as an interactive user.

**Related information**

- SOAP web services security
- JSON object format

**JSON object format**

The JSON object is built in two structures.

- A collection of name/value pairs. In various languages, this is realized as an object, record, struct, dictionary, hash table, keyed list, or associative array.
- An ordered list of values. In most languages, this is realized as an array, vector, list, or sequence.

In its simplest form, a JSON object is just a comma delimited set of name/value pairs. For example:

```
{"name one":"value one","name two":"value two"}
```

The following is a sample of a single record array of incidents in JSON:

```
{"records":
[["closed_by":null,
  "__status": "success",
  "category":"inquiry",
  "escalation":0,
  "state":1,
  "location":null,
  "reassignment_count":0,
  "time_worked":null],
```

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
The following is a record array of incident responses with an error.

```json
{
  "records": [
    {
      "__error": {
        "message": "Invalid Insert into: incident",
        "reason": "Data Policy Exception:  Short description is mandatory ",
      },
      "__status": "failure",
      "active": "true",
      "activity_due": "",
      "approval": "not requested",
      "approval_history": "",
      "approval_set": "",
      "assigned_to": "",
      "assignment_group": "d625dceca0a8016700a222a0f7900d06",
      "business_duration": "",
      "business_stc": ""
    }
  ]
}
```
JSON response status

JSONv2 requests may return one of several response statuses.

**JSON Success Response**

Each JSON success response includes a record array containing the records retrieved by the given action. Each JSON object contains one or more metadata elements, prefixed with __, regarding the status for the action on each record, as illustrated in the previous examples. The JSON success responses use the following syntax:

```
__status

"__status": "<value>"
```

where <value> is success or failure.
**JSON Failure Response**
When the _status element returns failure, the _error element is added to identify the error and reason.

```
"_error": { "message": "<error value>", "reason": "<reason value> "}
```

where `<error value>` is the error message text and `<reason value>` is the reason the error was triggered.

The JSON error response contains only the error and reason elements. Generally, this indicates that the whole JSON operation failed and no records can be processed.

For example:

```
{"_error":"Cannot update with empty sysparm_query","reason":null}
```

**Setting the number of rows returned**
The following system property controls how many rows JSON returns with each query.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>glide.processor.json.row_limit</code></td>
<td>Specify the maximum number of rows a JSON query returns.</td>
</tr>
<tr>
<td></td>
<td>• Type: integer</td>
</tr>
<tr>
<td></td>
<td>• Default value: 10,000</td>
</tr>
<tr>
<td></td>
<td>• Location: Add to the System Properties [sys_properties] table</td>
</tr>
</tbody>
</table>

**Requiring basic authentication for incoming JSONv2 requests**
The following system property controls whether basic authentication is required for incoming JSONv2 requests.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>glide.basicauth.required.jsonv2</code></td>
<td>Enables (true) or disables (false) requiring basic authentication for incoming JSONv2 requests.</td>
</tr>
</tbody>
</table>
Requiring Basic Authentication for Incoming JSONv2 Requests (continued)

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Type: true</td>
</tr>
<tr>
<td></td>
<td>• Default value: true</td>
</tr>
<tr>
<td></td>
<td>• Location: Add to the System Properties [sys_properties] table</td>
</tr>
</tbody>
</table>

Note: To learn more about this property, see Basic auth: JSONv2 requests in Instance Security Hardening Settings.

Action parameters

Action parameters are separate and different from data parameters because they specify the action to take when the JSON object parameter is part of an HTTP GET or POST request.

The parameters can also be specified as a field in the supplied JSON object. They have the effect of triggering an action in the case of sysparm_action, or filtering the results of an update or query in the case of sysparm_query.

sysparm_action

The following are the valid values for sysparm_action and the corresponding action triggered by the API.

<table>
<thead>
<tr>
<th>Method Summary</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getKeys</td>
<td>Query the targeted table using an encoded query string and return a comma delimited list of sys_id values.</td>
</tr>
<tr>
<td>getRecords</td>
<td>Query the targeted table using an encoded query string and return all matching records and their fields.</td>
</tr>
<tr>
<td>get</td>
<td>Query a single record from the targeted table by specifying the sys_id in the sysparm_sys_id URL parameter, and return the record and its fields.</td>
</tr>
</tbody>
</table>
Data Modification

<table>
<thead>
<tr>
<th>Method Summary</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>insert</td>
<td>Create one or more new records for the table targeted in the URL.</td>
</tr>
<tr>
<td>insertMultiple</td>
<td>Create multiple new records for the table targeted in the URL.</td>
</tr>
<tr>
<td>update</td>
<td>Update existing records in the targeted table in the URL, filtered by an encoded query string.</td>
</tr>
<tr>
<td>deleteRecord</td>
<td>Delete a record from the table targeted in the URL by specifying its sys_id in the sysparm_sys_id URL parameter.</td>
</tr>
<tr>
<td>deleteMultiple</td>
<td>Delete multiple records from the table targeted in the URL, filtered by an encoded query string.</td>
</tr>
</tbody>
</table>

**sysparm_query**

Specify an encoded query string to be used in get, getRecords, update or deleteMultiple sysparm_action value.

**sysparm_view**

Specify a form view to customize the return values for get and getRecords function calls. When using a view, the query returns only the fields defined in the view, including referenced values. If there is no view name, or if the view name is not valid, then the query returns all field names that are marked active in the dictionary.

**sysparm_sys_id**

Specify a target sys_id during a get or delete function call (sysparm_action value).

**sysparm_record_count**

Specify an integer value to limit the number of records retrieved for this request. Note that this value is capped by the glide.processor.json.row_limit system property.

**displayvalue**

Get the display value of a reference field, if any are in the record. For example, the Incident record can have an assigned_to field that is a reference to a user record. Instead of sending the sys_id of the user record, the user name is sent.

The displayvalue parameter can have three values: true, false, or all.
• **true**: All the references fields show the display value instead of `sys_id`.

• **false** (default): All reference fields show `sys_ids`.

• **all**: The display value and the `sys_id` are shown. For example, the `assignedto` field in the Incident record is sent back as `assigned_to:1234556, dv_assigned_to:Fred Luddy`.

**displayvariables**

Set this boolean value to **true** during a get or getRecords function call to retrieve all variables attached to this record.

**JSON Data Retrieval API**

Query for data by issuing an HTTPS GET request to the instance.

By default, a GET request is interpreted as a get function if a `sysparm_sys_id` parameter is present. Otherwise, it is interpreted as a getRecords function. You can also specify a URL parameter `sysparm_action=get`. Query responses are always encapsulated by a records hash of records, where each individual record's values are themselves hashed by field name.

**Return Display Value for Reference Variables**

When you are getting a record from a get or getRecords function, all the fields associated with that record are returned. The fields are often reference fields that contain a `sys_id` for another table. The base system behavior is to return the `sys_id` value for those fields. To have the display value for the field returned, use one of these options:

• Add the property `glide.json.return_displayValue` to the system properties, and every JSON request will return a display value for a reference field.

• Add the parameter `displayvalue=true` to the JSON request URL and JSON requests with that parameter will return a display value instead of the `sys_id` for a reference field. The JSON URL would look like this:

```
https://<instance_name>.service-now.com/incident.do?JSON&sysparm_action=getRecords&sysparm_query=active=true^category=hardware&displayvalue=true
```

• Add the parameter `displayvalue=all` to the JSON request URL and JSON requests with that parameter return a display value and the `sys_id` for a reference field. The response element name for the display value field will be prefixed with `dv_`, for example `dv_caller_id`.
Get variables

Use the displayvariables query parameter to return an array of variables associated with a Service Catalog item record. To get variables, add the parameter displayvariables=true to the JSON request URL. For example, here is a URL to retrieve a record in JSON format that includes Service Catalog variables:

Here is the example response that displays a multi-row variable set from the record:

```json
{
  "records": [
    {
      ...
      "variables": [
        {
          "display_value": [
            {
              "quantity": "1",
              "color": "Black",
              "device_type": "Apple iPhone 8",
              "storage": "64GB"
            },
            {
              "quantity": "1",
              "color": "Black",
              "device_type": "Apple iPhone 8",
              "storage": "64GB"
            }
          ],
          "columns_meta": [
            {
              "name": "device_type",
              "label": "Device Type",
              "id": "da7d3f3241411300964ff05369414eca",
              "type": 5,
              "order": 0
            },
            {
              "name": "storage",
              "label": "Storage",
              "id": "691e337241411300964ff05369414e31"
            }
          ]
        }
      ]
    }
  ]
}
```
"type": 5,
"order": "1"
},
{
  "name": "color",
  "label": "Color",
  "id": "e89fb7724141300964ff05369414e74",
  "type": 5,
  "order": "2"
},
{
  "name": "quantity",
  "label": "Quantity",
  "id": "2d5f73724141300964ff05369414eaf",
  "type": 5,
  "order": "3"
}
],
"max_rows": 50,
"name": "mobile_devices_set",
"id": "e84d3f324141300964ff05369414e3e",
"type": "one_to_many",
"value": [
  {
    "quantity": "1",
    "color": "black",
    "device_type": "iphone8",
    "storage": "64GB"
  },
  {
    "quantity": "1",
    "color": "black",
    "device_type": "iphone8",
    "storage": "64GB"
  }
],
"row_count": 2
},
{
  "question_text": "Department",
  "name": "department",
  "type": 8,
  "value": "Development",
  "order": 100
The keys in the response are defined as follows:

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>display_value</td>
<td>Multi-row variable set question display value. Only returned with multi-row variable sets.</td>
</tr>
<tr>
<td>columns_meta</td>
<td>Array of multi-row variable set metadata, such as the sys_id and name of the field. Only returned when the variable contains multiple fields.</td>
</tr>
<tr>
<td>max_rows</td>
<td>Maximum rows allowed in the multi-row variable set. Only returned with multi-row variable sets.</td>
</tr>
<tr>
<td>name</td>
<td>Question name.</td>
</tr>
</tbody>
</table>
### Key Description

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>Sys_id of the multi-row variable set. Only returned with multi-row variable sets.</td>
</tr>
<tr>
<td>type</td>
<td>Type of question.</td>
</tr>
<tr>
<td>value</td>
<td>Question value.</td>
</tr>
<tr>
<td>row_count</td>
<td>Current number of rows in the multi-row variable set. Only returned with multi-row variable sets.</td>
</tr>
<tr>
<td>question_text</td>
<td>Question label. Only returned with single-row variable sets.</td>
</tr>
<tr>
<td>order</td>
<td>Order of the question.</td>
</tr>
</tbody>
</table>

### Control the order of records

You can control the order that records appear in the JSON response. To set an order, use the **ORDERBY** or **ORDERBYDESC** clauses in the URL encoded query. For example,

```
sysparm_query=active=true^ORDERBYnumber^ORDERBYDESCcategory
```

filters all active records and orders the results in ascending order by number first, and then in descending order by category. For more information, see Encoded query strings.

### getKeys

Get the **sys_id** of multiple records by specifying an encoded query string in the **sysparm_query** parameter.

```
https://<instance name>.service-now.com/incident.do?JSONv2&sysparm_action=getKeys&sysparm_query=active=true^ORDERBYnumber^ORDERBYDESCcategory
```

### get

Get a record directly by specifying the **sys_id** in a **sysparm_sys_id** parameter.

```
https://<instance name>.service-now.com/incident.do?JSONv2&sysparm_sys_id=9d385017c611228701d22104cc95c371
```

Optionally, you may also specify the **sysparm_action** parameter:

```
https://<instance name>.service-now.com/incident.do?JSONv2&sysparm_action=get&sysparm_sys_id=9d385017c611228701d22104cc95c371
```
getRecords
Get all records by specifying an encoded query string in the `sysparm_query` parameter.

```plaintext
https://<instance name>.service-now.com/incident.do?JSONv2&sysparm_action=getRecords&sysparm_query=active=true^category=hardware
```

JSON Data Modification API
Modify data using the JSON web service by sending an HTTPS POST request to the instance.

The HTTP POST must contain a `sysparm_action` parameter to indicate the type of action to be performed, with the incoming JSON object post in the body.

⚠️ Note: The content-type of the POST should be application/json. It cannot be application/x-www-form-urlencoded or multipart/form-data.

insert
Create a new record in ServiceNow. The JSON object has to be POSTed as the body (content-type is usually application/json, although not enforced). The response from the record creation is a JSON object of the incident that was created.

For example, posting the following JSON object:

```plaintext
{"short_description":"this is a test","priority":"1"}
```

to the following URL:

```plaintext
https://your_instance.service-now.com/incident.do?JSONv2&sysparm_action=insert
```
creates an incident.

Optionally, you may also specify the `sysparm_action` in the JSON object. The parameter inside the JSON object takes precedence over the URL parameter. For example:

```plaintext
{"sysparm_action":"insert","short_description":"this is a test","priority":"1"}
```

insertMultiple
To create multiple new records in ServiceNow, the input JSON object for the `insert` function must be an array. The response from the record creation is a JSON object of the incidents that were created. For example, the following JSON object:
posted to one the following URLs:

https://<instance name>.service-now.com/incident.do?JSONv2&sysparm_action=insert
https://<instance name>.service-now.com/incident.do?JSONv2&sysparm_action=insertMultiple

creates two incidents. Note the fields described as an array value for the **records** field.

**update**

Update a record or a list of records filtered by an encoded query string specified by the sysparm_query URL parameter. The JSON object has to be posted as the body (content-type is usually application/json, although not enforced). The response from the record creation is an array of JSON objects representing the records that were updated.

For example, posting the following JSON object:

```json
{ "short_description":"this was updated with python", "priority": "3", "impact":"1" }```

to the following URL:

https://instance_name.service-now.com/incident.do?JSONv2&sysparm_query=priority=3&sysparm_action=update

updates all incidents with priority 3, and sets the values specified by the JSON object.

**deleteRecord**

Delete a single record from the targeted table, identified by a sysparm_sys_id parameter. The parameter may be encoded in the input JSON object or given as a URL parameter.

For example, posting:

```json
{"sysparm_sys_id":"fd4001f80a0a0b380032ffa2b749927b"}"
```

to the following URL:

http://instance_name.service-now.com/incident.do?JSONv2&sysparm_action=deleteRecord

deletes the incident record identified by the sys_id fd4001f80a0a0b380032ffa2b749927b.
**deleteMultiple**

Delete multiple records from the targeted table, filtered by an encoded query string specified in the `sysparm_query` URL parameter. The filter may also be encoded in the input JSON object.

For example, posting:

```json
{"sysparm_query":"short_description=this was updated with python"}
```

to the following URL:

http://instance_name.service-now.com/incident.do?JSONv2&sysparm_action=deleteMultiple

deletes all incident records where the `short_description` field contains the value "this was updated with python".

**RSS web service**

RSS (Rich Site Summary) is a format for delivering web-based information that changes regularly.

**RSS feed generator**

ServiceNow supports the dynamic generation of RSS feeds.

Much like our Web Services implementation, the retrieval of an RSS feed representation of information is simply done by specifying an RSS parameter at the end of the URL to a table list. For example, the following will return a list of all incidents in RSS 2.0 format:

**Adding a Query**

To associate a query to the list so that a filtered list is returned, use the `sysparm_query` parameter. For example, the following will return a list of all incidents where the priority field is 1 (Critical):

```text
https://<instance name>.service-now.com/incident.do?sysparm_query=priority=1&RSS
```

If you have a multi part query then you would separate the parts with the `^` character. For example to get all priority 1 incidents with a category of software you would:

```text
https://<instance name>.service-now.com/incident.do?sysparm_query=priority=1^category=software&RSS
```

If you want to query on a field that is a reference to another file then you need to use javascript to resolve the reference to the other file. For example, the `assigned_to` field in incident is a reference to a user record. If you wanted to find all the incidents assigned to "ITIL User" then you would do the following:
Note: You can in most cases simply append "&RSS" to a URL that you generate in the U.I. or that of your favorite module. The easiest way to get the URL is to simply click the last breadcrumb from the list view. After appending "&RSS" then you can use this URL in your RSS feed reader.

Get Bread URL

Limiting results with a view

The description element in the returned RSS xml is constructed using the view as specified in the URL, when no view is specified, the default no-name view is used.

To change this format, specify the `sysparm_view` parameter on the URL. For example, the following request will return the incidents list. However the result will be restricted to only the fields available in the ess view:

https://<instance name>.service-now.com/incident.do?sysparm_query=priority=1&sysparm_view=ess&RSS

Additionally, the RSS item title can be modified using the `sysparm_title_view` URL parameter. When specified, the item title will be constructed using the fields specified in the view. For example:

Formatting results

The description element in the returned RSS xml can be formatted by setting the URL parameter `sysparm_format=true` and specifying the format string in the property `glide.rss.description_format`.

© 2021 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
By default, when the URL parameter is present, the description element will be formatted to contain the field label and value using the following format string:

```
<b>{1}</b>: {2}<br/>
```

- `{0}` - field name
- `{1}` - field label
- `{2}` - field value

This default format string can be overridden using the property `glide.rss.description_format`. An example of the formatted RSS feed can be seen in the following screen capture from Firefox:

**RSS Format**

**Problem (All)**

<table>
<thead>
<tr>
<th>Problem (All)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>PRB00001</strong></td>
</tr>
<tr>
<td>Sun, Aug 10, 2008 3:39 PM</td>
</tr>

</tr>
<tr>
<td><strong>Short description</strong>: Windows xp SP2 causing errors in Enterprise</td>
</tr>
<tr>
<td><strong>Problem state</strong>: Pending Change</td>
</tr>
<tr>
<td><strong>RFC</strong>: CHG00003</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>PRB00008</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Sun, Aug 10, 2008 3:40 PM</td>
</tr>
<tr>
<td><strong>Number</strong>: PRB00008</td>
</tr>
<tr>
<td><strong>Escalation</strong>: Normal</td>
</tr>
<tr>
<td><strong>Short description</strong>: Hang when trying to print VISIO document</td>
</tr>
<tr>
<td><strong>Problem state</strong>: Open</td>
</tr>
<tr>
<td><strong>RFC</strong>:</td>
</tr>
</tbody>
</table>

**RSS basic authentication**

To enforce basic authentication on each request for an RSS feed, set the property `glide.basicauth.required.rss` to `true`.

RSS request would have to contain the Authorization header as specified in the Authentication protocol. Because the request is non-interactive, we always require the `Authorization` header during a request.

⚠️ **Note**: If you plan to disable RSS basic authentication, make sure that tables in the platform have the right ACL entries to protect from unauthorized access.
To specify basic authentication on the URL, put the username and password pair separated by a colon in front of the server name before an @ character. For example, to submit the demo credentials for the ITIL user, use the following URL.

```
https://itil:itil@<instance name>.service-now.com/incident.do?RSS
```

Some older browsers, such as Microsoft IE 7 do not support direct URL authentication. If the site uses basic authentication, Internet Explorer automatically prompts users for a user name and a password. In some cases, users can click the Remember my password box in the prompt to save their credentials for later visits to that site.

- RSS request authorization

**RSS title override**

You may optionally override the automatically generated title of the RSS feed by added the `sysparm_title` parameter to the request URL.

For example, you can specify the title **Priority One Incidents** using the following request URL.

```
```

This will produce results as follows:
RSS Out

RSS feed reader

Create a scrolling RSS feed reader using a UI page.

You must create a feed parser using an RSS API, such as the Google Feed API. Developer's guide: http://code.google.com/apis/ajaxfeeds/documentation/API: http://code.google.com/apis/ajaxfeeds/documentation/reference.html

Scrollable areas

A scrollable area is a div where contents scroll from the bottom up over time.

You can scroll any HTML content, and anything inside the scroller is operational HTML with functioning links and images.

To make a scrollable areas, wrap the scrolling content inside of a scrollable_area tag, likely in a UI Page:

```html
<g:scrollable_area height="100px">
  <g:evaluate var="jvar_temp" expression="var kb = new GlideRecord('kb_knowledge');"/>
  <g:inline template="kb_section.xml"/>
</g:scrollable_area>
```

The system will then create a 100 pixel high div and the contents will automatically scroll from bottom to top. If you have a 1000 pixel high block of text, for example, you'll see the top 100 pixels and then pixels 2-101, then 3-102, etc. Once it reaches the top it'll wrap back around to the bottom.
This sample code will create a scroller with a list of priority 1 incidents.

```xml
<?xml version="1.0" encoding="utf-8" ?>
<j:jelly trim="false" xmlns:j="jelly:core" xmlns:g="glide" xmlns:j2="null" xmlns:g2="null">
  <g2:evaluate var="jvar_inc">
    var inc = new GlideRecord('incident');
    inc.addActiveQuery();
    inc.addQuery('priority',1);
    inc.query();
  </g2:evaluate>

  <g2:scrollable_area height="100px">
    <table border="0" cellspacing="2" cellpadding="0" width="100%">
      <j2:while test="$[inc.next()]">
        <j2:set var="jvar_inc_link" value="incident.do?sys_id=$[inc.sys_id]"/>
        <j2:set var="jvar_inc_list_link" value="incident_list.do?sysparm_query=active=true"/>
        <tr>
          <td>
            <a href="${jvar_inc_link}">
              <IMG SRC="images/services.png" style="padding-right:10px"></IMG>
            </a>
            <a href="${jvar_inc_link}" style="padding-right:10px; color:blue">${inc.number}</a>
          </td>
          <td>${inc.short_description}</td>
        </tr>
      </j2:while>
    </table>
    <tr>
      <td align="center" colspan="2"><a href="${jvar_inc_list_link}" style="color:blue">View all active incidents</a></td>
    </tr>
  </g2:scrollable_area>
</j:jelly>
```

Add scrolling elements in forms

You can add scrolling areas to forms as well as UI pages.

**Procedure**

1. Create a UI Macro with the script.
2. Create a Formatter to reference the script.
Priority 1 incidents example

This example scrolling element demonstrates how to create a UI macro to a scrolling list of priority 1 incidents.

Use the following example code:

```xml
<?xml version="1.0" encoding="utf-8" ?>
<j:jelly trim="false" xmlns:j="jelly:core" xmlns:g="glide" xmlns:j2="null" xmlns:g2="null">
    <g2:evaluate var="jvar_inc">
        var inc = new GlideRecord('incident');
        inc.addActiveQuery();
        inc.addQuery('priority',1);
        inc.query();
    </g2:evaluate>

    <div style="background-color:DDDDDD; padding-left:10px; line-height:19px; border:2px white solid" width="100%" nowrap="true">
        Priority 1 Incidents:
        <input id="make_spacing_ok" style="visibility:hidden;width:0px:" title=""/>
    </div>

    <g2:scrollable_area height="100px" width="100%">
        <j2:while test="$[inc.next()]">
            <j2:set var="jvar_inc_link" value="incident.do?sys_id=$[inc.sys_id]"/>
            <j2:set var="jvar_inc_list_link" value="incident_list.do?sysparm_query=active=true"/>
            <span style="line-height: 10px; padding-left:10px">
                <a href="$[jvar_inc_link]">
                    <img src="images/services.png" style="padding-right:10px"></img>
                </a>
                <a href="$[jvar_inc_link]" style="padding-right:10px; color:blue">$[inc.number]</a>
            </span>
            $[inc.short_description]
            <br style="line-height:5px"/>
        </j2:while>
    </g2:scrollable_area>
</j:jelly>
```
Navigate to **System UI > Formatters** and create a Formatter that refers to the UI Macro above.

**Add a scrolling news panel to your homepage**
Display knowledge article content in a scrolling news panel.

**Before you begin**
Create knowledge content to display in the news panel.

**Procedure**
1. Navigate to a homepage.
2. Click **Add Content** to get a list of possible content types.
3. Click **Scrollers** in the leftmost box of the add content dialog.
4. Click the news scroller.
5. Click **Add** to add it on your page.

![News scroller example](image)

**News in the scroller**
The news scroller gets its news list by going to the Knowledge Base and querying the short descriptions of any items there with a topic of "News".

To add news, go to the Knowledge Base and add new entries with a topic of "News".

**Style Control**
If you want to make a headline standout in the news scroller, use HTML tags on the short description. For example, enter `<b>My Bold Test</b>` and **My Bold Test** will appear in the scroller.

ℹ️ **Note:** The property `glide.ui.escape_text` must be `false` to use HTML formatting.
Scrolling News Panel Notes and Limitations

Scrollable news panels offer a way for you to display high impact news items on your users home pages in an eye catching scrolling news display.

- Scrolling is currently always from the bottom to the top.
- Scrolling is 1 pixel a at a time every 100 ms.
- You can have as many scrollable areas on a screen as you want (they get system generated unique names).
- Works in Internet Explorer and Firefox.
- If the object you are scrolling is shorter than the scrollable area, it still scrolls.
- If you mouse over a scrollable area, it stops scrolling (so you can click something without chasing it as it scrolls).

RSS feed reader example

An example of how to set up an RSS feed reader using an RSS feed.
For an example RSS feed reader, refer to the Now Community.

REST & SOAP API analytics

REST & SOAP API analytics allow you to track and analyze web service API usage.

Use analytics to help answer questions such as
- Which APIs are used most?
- Which API versions are being used? Can I deprecate older versions?
- Which API methods are being used?
- What resources are being accessed?
- Who is using each API and resource?

The instance tracks analytics for all inbound web services, including platform web services such as the REST Table API or the SOAP API, and custom web services such as scripted REST APIs and scripted SOAP web services. Analytics are aggregated by each resource and HTTP action combination.

Outbound web services, such as REST Messages, are not tracked.

Collect analytics for an API

Select which APIs to collect analytics for and select if requestor information should be collected for each API.
Before you begin

Note: API analytics is not available for certain APIs used for internal platform functionality, such as the UI and Mobile app APIs.

Role required: api_analytics_read or admin

About this task

When a new API is added, an inclusion list record is created automatically. You can modify or create new inclusion list records to manually configure which APIs and requestor information are logged.

Procedure

Navigate to System Web Services > Inclusion List and create a new record.

API Transactions Stats Inclusion Lists fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API name</td>
<td>For REST APIs, enter the API name. This name should contain only the namespace and ID of the API. Do not include any request parameters in the API name. For example, for the Table API endpoints api/now/table/incident and api/now/table/problem, the namespace and ID are now/table. SOAP APIs do not support separate logging configurations for different APIs. You can configure logging for all SOAP APIs by modifying the SOAP APIs inclusion list record.</td>
</tr>
<tr>
<td>Collect API stats</td>
<td>Select this check box to track analytics for the specified API.</td>
</tr>
<tr>
<td>Collect API requestor stats</td>
<td>Select this check box to track which users make requests to this API. This option is available only if Collect API stats is selected.</td>
</tr>
</tbody>
</table>

REST & SOAP API analytics dashboards

You can view API analytics for the entire instance or for specific APIs using the included dashboards.

REST & SOAP API Analytics includes dashboards that present the overall analytics, analytics per API, and analytics per requesting user.
To access API Analytics dashboards, navigate to System Web Services and select Usage Overview, Usage by API, or Usage by Requestor. Users with the api_analytics_read or admin roles can view these dashboards.

Note: The Usage by Requestor dashboard uses the Responsive Canvas feature available with Istanbul. For the best experience on upgraded instances, you may need to enable responsive dashboards.

The following dashboards are available:

### Available API analytics dashboards

<table>
<thead>
<tr>
<th>Dashboard</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Usage Overview</td>
<td>Provides general usage statistics for all REST and SOAP APIs.</td>
</tr>
<tr>
<td>Usage by Web API</td>
<td>Provides detailed usage statistics for each API.</td>
</tr>
<tr>
<td>Usage by Requestor</td>
<td>Provides detailed usage statistics for each requesting user.</td>
</tr>
<tr>
<td></td>
<td>You can additionally filter by API to view detailed stats for a specific user and API combination. If the selected user has not made requests to the selected API, no data is shown for that combination.</td>
</tr>
</tbody>
</table>

Note: To view API stats for all users, do not clear the user breakdown selection. Instead, use the Usage by Web API dashboard.

You can access API analytics from the REST API Explorer. When exploring an API, click the context menu icon (⋮) then select API analytics to view analytics for that specific API.

For custom web services, such as scripted REST APIs or scripted SOAP web services, you can access analytics for the API by clicking the API analytics related link on the scripted REST Service or scripted Web Service forms.

When you directly access the analytics for an API, if there are no analytics for that specific API, the analytics for all APIs appears.
Related information

Use the REST API Explorer

REST and SOAP API analytics collection and cleanup

API analytics uses scheduled jobs to collect and clean up analytics data. The instance tracks all web service transactions for APIs on the inclusion list and maintains a daily history, aggregated by resource and HTTP action combination. Requester information is aggregated per requester, resource, and HTTP action combination and tracked up to the daily limit defined by the property `com.glide.api.stats.daily_limit`.

Refer to the following table to determine which requests are logged.

<table>
<thead>
<tr>
<th>Whitelist API name</th>
<th>Example resource</th>
<th>Response code</th>
<th>Description</th>
<th>Logged</th>
</tr>
</thead>
<tbody>
<tr>
<td>now/table</td>
<td>/api/now/table/incident</td>
<td>Any except 401</td>
<td>Valid resource and table</td>
<td>Yes</td>
</tr>
<tr>
<td>now/table</td>
<td>/api/now/table/invalidResource</td>
<td>400</td>
<td>Valid resource but an invalid table</td>
<td>Yes</td>
</tr>
<tr>
<td>now/table</td>
<td>/api/now/table/incident</td>
<td>403</td>
<td>Requesting user has insufficient privileges</td>
<td>Yes</td>
</tr>
<tr>
<td>now/table</td>
<td>/api/now/table/incident</td>
<td>401</td>
<td>Requesting user is not authenticated</td>
<td>No</td>
</tr>
<tr>
<td>myApp/myScriptedApi</td>
<td>myApp/myScriptedApi/myResource</td>
<td>Any except 401</td>
<td>Valid resource</td>
<td>Yes</td>
</tr>
<tr>
<td>myApp/invalidApiName</td>
<td>• myApp/invalidApiName • myApp/invalidApiName/myResource</td>
<td>400</td>
<td>Invalid API, even with a matching inclusion list entry</td>
<td>No</td>
</tr>
</tbody>
</table>

On the 2nd of each month, the API Monthly Stats scheduled job calculates the monthly total for each resource and HTTP action combination. Each day the API Monthly Requestor Stats scheduled job calculates the monthly total for each
resource, requester, and HTTP action combination based on daily scores older than 2 days.

Daily statistics are maintained for 33 days. Monthly totals are maintained for 13 months. Table cleaners for the sys_api_stats, sys_api_stats_requestor, and sys_api_stats_requestor_monthly tables remove analytics records older than these limits.

**REST & SOAP API analytics naming**

The **API Name** used when tracking API analytics is determined by the type of API being described, such as a REST API or a Scripted SOAP service.

<table>
<thead>
<tr>
<th>API type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REST</td>
<td>The API namespace and the first part of the URI following the namespace is used as the API name. For example, for the Table API endpoints api/now/table/incident and api/now/table/problem, the namespace and ID are now/table.</td>
</tr>
<tr>
<td>Direct SOAP (table does not extend Import Set Row table)</td>
<td>If the direct SOAP request accesses a table, Direct SOAP is used as the API name.</td>
</tr>
<tr>
<td>SOAP import (table extends Import Set Row table)</td>
<td>Import Set SOAP is used as the API name.</td>
</tr>
<tr>
<td>Scripted SOAP Services</td>
<td>The SOAP request endpoint page is used as the API name, such as my_service.do.</td>
</tr>
</tbody>
</table>

**API analytics properties**

Certain properties control the behavior of API analytics.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.glide.api.stats.enabled</td>
<td>When true, enables the collection of API usage statistics. When false, no analytics are collected even for domains on the inclusion list.</td>
</tr>
<tr>
<td><strong>Property</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>--------------</td>
<td>----------------</td>
</tr>
<tr>
<td>com.glide.api.stats.max_bytes_nursery_size</td>
<td>The maximum amount of memory, in bytes, used to store transaction data before it is written to the log. Transaction data is written to the log regularly based on the value of <code>com.glide.api.stats.persist_interval</code>. If a large volume of transactions exceeds this memory limit before the log is written, some transactions may not be logged. The event <code>api.stats.cache.size.reached</code> is fired if this limit is reached. This property value must be between 1 and 3 megabytes.</td>
</tr>
<tr>
<td>com.glide.api.stats.persist_interval</td>
<td>The frequency, in seconds, for writing transactions stored in memory to the log. This property value must be between 30 and 120 seconds.</td>
</tr>
<tr>
<td>com.glide.api.stats.daily_limit</td>
<td>The daily limit of requestor stats records per instance node. As soon as the value is reached, data is no longer aggregated and</td>
</tr>
</tbody>
</table>
Outbound REST web service

ServiceNow outbound REST functionality allows you to retrieve, create, update, or delete data on a web services server that supports the REST architecture.

A REST message can be sent by a REST workflow activity or by using the RESTMessageV2 script API. You can run REST messages from a MID Server which allows the message to communicate with REST providers on an internal network.

ServiceNow REST functionality is flexible enough to accommodate many web service APIs. Be sure you are familiar with your web service and the parameters it accepts before attempting to define a REST message in ServiceNow.

REST message elements

An outbound REST message is composed of several elements, such as the endpoint and HTTP methods.

A REST message contains the following elements:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api.stats.requestor.daily.limit.reached</td>
<td>stored for that day. The event is fired if this limit is reached.</td>
</tr>
<tr>
<td></td>
<td>• Type: integer</td>
</tr>
<tr>
<td></td>
<td>• Default value: 20000</td>
</tr>
<tr>
<td></td>
<td>• Location: Add to the System Properties [sys_properties] table</td>
</tr>
<tr>
<td>glide.api.stats.debug</td>
<td>When true, enables debug logging for API stats.</td>
</tr>
<tr>
<td></td>
<td>• Type: true</td>
</tr>
<tr>
<td></td>
<td>• Default value: false</td>
</tr>
<tr>
<td></td>
<td>• Location: Add to the System Properties [sys_properties] table</td>
</tr>
</tbody>
</table>
### Elements

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Endpoint</td>
<td>The endpoint is the URL of the data to be retrieved, updated, or deleted. Every REST message must specify an endpoint.</td>
</tr>
<tr>
<td>Headers</td>
<td>HTTP headers in REST messages contain information about the request, such as the desired response format. A REST message may specify any number of headers.</td>
</tr>
<tr>
<td>Authentication</td>
<td>Authentication settings include which type of authentication to use, such as basic auth or OAuth, as well as the credentials to use.</td>
</tr>
<tr>
<td>settings</td>
<td>HTTP methods, such as GET, POST, or DELETE interact with the data at the endpoint.</td>
</tr>
<tr>
<td>HTTP methods</td>
<td>You can optionally override the parent REST message configuration in each HTTP method such as by specifying a different endpoint, authentication credentials, or headers.</td>
</tr>
<tr>
<td></td>
<td>HTTP methods that send content, such as POST, include a message body detailing this content.</td>
</tr>
<tr>
<td></td>
<td>A REST message may specify multiple HTTP methods. When sending a REST message, such as through a workflow activity or script, you must specify which HTTP method to use.</td>
</tr>
</tbody>
</table>

### Create a REST message

You can send requests to a REST web service endpoint by creating a REST message record.

#### Before you begin

Role required: web_service_admin

#### Procedure

1. Navigate to **System Web Services > REST Message**.
2. Click **New**.
3. Complete the following fields:
### REST Message form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a descriptive name for this message.</td>
</tr>
<tr>
<td>Endpoint</td>
<td>Enter the endpoint that this REST message is sent to. The endpoint value may include variables using the format <code>${variable}</code>.</td>
</tr>
<tr>
<td>Authentication type</td>
<td>Select the type of authentication to use, if any, and the profile record that contains the user credentials.</td>
</tr>
<tr>
<td></td>
<td>Outbound REST supports basic authentication and OAuth 2.0. Outbound REST supports mutual authentication with basic authentication only.</td>
</tr>
<tr>
<td></td>
<td>Authentication configured here is inherited by the associated HTTP methods. You can configure authentication for each method which overrides any authentication setting at the message level.</td>
</tr>
<tr>
<td>HTTP Headers</td>
<td>Double-click a row in the HTTP Headers embedded list to define the header Name and Value. The web service provider determines which headers are supported or required.</td>
</tr>
</tbody>
</table>

4. Click **Submit**.

After creating the REST message, a GET HTTP method is created automatically using the values from the REST message record.

### What to do next
Create or edit HTTP methods and run a request.

### Define a REST message HTTP method

Define an HTTP method such as GET or POST to send a request to a web service provider.

**Before you begin**
Role required: web_service_admin

**About this task**
When you create a REST message record, several default HTTP methods are automatically created using settings inherited from the REST message record, such as the **Endpoint**. Subsequent changes to the REST message record are not
applied to the HTTP methods automatically. You can create additional HTTP methods or modify the default HTTP methods to implement new behavior.

**Procedure**

1. Navigate to **System Web Services > Outbound > REST Message**.
2. Select a REST message you want to define an HTTP method for.
3. In the **HTTP Methods** related list, click **New**.
4. Select the **HTTP method** you want to use, such as GET or POST.
5. Enter the **Endpoint** this HTTP method should access.
   The endpoint value may include variables using the format `${variable}`.
6. Right-click the form header and select **Save**.

**What to do next**

After creating the HTTP method, you can override the security settings from the parent REST message, configure HTTP headers, add variables, or test the method. For PUT, POST, and PATCH methods you can define a message body.

**Testing REST message HTTP methods**

After configuring an HTTP method for an outbound REST message, you can test it to ensure that the request is valid and the response returns as expected.

To test an HTTP method, click the **Test** related link on the HTTP Method form.

Each test run displays the response status, such as 200 for a successful GET request, the full endpoint URL, any parameters passed in the request, and the response body.

**Note:** Fields on the Test Runs form are for information only; changes to these fields do not apply to the REST message or HTTP method. Do not modify these values when testing different REST message configurations. Instead, update the REST message or HTTP method, then run a new test.

If the HTTP method includes variables, the **Test value** for each variable in the **Variable Substitutions** related list is used when testing the method.

Completed test runs for an HTTP method appear in the **Test Runs** related list. If there was an error during the request, the **Error Code** and **Error Message** fields appear.
Define a REST message HTTP header

Define an HTTP header for a REST message or HTTP method to send that header with REST requests.

Before you begin
Role required: web_service_admin

About this task
You can specify an HTTP header for a REST message, or for an HTTP method. Headers defined for a REST message apply to all HTTP methods for that REST message. If you specify the same header for both a REST message and a child HTTP method, the value defined for the HTTP method overrides the value from the parent REST message.

Procedure
1. Navigate to System Web Services > REST Message.
2. Select a REST message.
3. Optional: To specify a header for an HTTP method instead of the REST message, in the HTTP Method related list, select an HTTP method.
4. Select the HTTP Request tab.
5. In the HTTP Headers embedded list, click Insert a new row.
6. Enter the name of the header, such as Content-Type or Accept. Supported headers depend on the REST web service provider you want to connect to. Refer to the documentation for your web service provider to identify which headers are valid or required.
7. Click on the Value field for the new row and enter the value you want to assign this header.
   You can use a variable in the format `${variable}` instead of a static value. You can assign a value to the variable when sending a REST request.
8. Click Update.

Sending outbound REST messages through a MID Server

You can configure a REST message HTTP method to be sent through a MID Server.

By using a MID Server, the request can reach an endpoint that is behind a firewall or within a private network.
To configure an HTTP method to use a MID Server, select a MID Server in the **Use MID Server** field on the HTTP Method form. The instance must have an active MID Server to use this functionality.

**Using special characters in URIs**

A REST function URI or function variable may use special characters, such as pipe (|) characters.

When using these characters in a REST message, use URL encoding to escape these characters. For example, to use a parameter value of `user|title`, enter `user%7Ctitle`. Entering special characters directly may cause the REST message to fail and display the response *Invalid uri <URI>: Invalid query*.

**Outbound REST authentication**

Outbound REST messages support multiple types of authentication. Different web service providers may require a specific type of authentication. Outbound REST supports the following authentication formats.

- Basic authentication using a username and password
- OAuth 2.0 using an OAuth provider and profile
- Mutual authentication using protocol profiles

**Overriding REST authentication**

You can define authentication for a REST message, or individually for each HTTP method. HTTP methods inherit authentication from their parent REST message record when the HTTP method **Authentication type** is **Inherit from parent**, which is the default value.

You can disable authentication for a specific HTTP method by setting the **Authentication type** field to **No authentication**, or specify authentication that is different from the parent REST message by selecting basic auth or OAuth.

**Authentication requirements**

Outbound REST supports mutual authentication only when using basic authentication. Mutual authentication is not available with OAuth 2.0.

OAuth 2.0 can be used only with messages that are not configured to use a MID Server. You cannot send OAuth 2.0 authenticated messages through a MID Server.

When scripting new REST messages configured with authentication you must use the RESTMessageV2 API. The legacy RESTMessage APIs do not support current authentication formats.
Configure a REST message with basic auth

You can configure an outbound REST message to provide basic authentication credentials with each request.

**Before you begin**
Role required: web_service_admin
Before starting this procedure, ensure there is a REST Message record that you want to configure to use basic auth.

ℹ️ **Note:** Ensure any scripts that call this REST message use the RESTMessageV2 API. The RESTMessageV2 API is required to send authenticated REST messages via scripts.

**Procedure**

1. Navigate to **System Web Services > Outbound > REST Message**.
2. Select a REST message record.
3. In the **Authentication type** field, select **Basic**.

ℹ️ **Note:** The Basic (Simple) choice appears on REST message records configured to use basic authentication prior to the Geneva release. This choice is intended for compatibility with older REST messages and should not be used for REST messages created in the Geneva release or later.

4. In the **Basic auth profile** field, select the basic authentication profile that contains the credentials you want to send.
5. Click **Submit**.

**What to do next**
Test the REST message to ensure you receive the expected response. You can optionally specify different authentication settings for each HTTP method related to this REST message, overriding the parent REST message settings.

**Create a basic auth profile**
Create a basic auth profile to specify basic authentication credentials for one or more REST messages.

**Before you begin**
Role required: web_service_admin
Procedure

1. Navigate to **System Web Services > REST Message**.
2. Select a REST message record.
3. In the **Authentication type** field, select **Basic**.
4. In the **Basic auth profile** field, click the reference lookup icon.
5. Click **New**.
6. Enter a descriptive **Name** for the profile.
7. Enter the **Username** and **Password** you want to send as basic authentication credentials.
8. Click **Submit**.

**What to do next**
Configure a REST message to use this basic auth profile.

**Configure a REST message with OAuth**

You can configure an outbound REST message to send OAuth credentials with the request.

**Before you begin**
Role required: web_service_admin and oauth_admin
Before starting this procedure, ensure:

- There is a REST Message record that you want to configure to use OAuth.
- There is an OAuth provider set up in the OAuth application registry with the OAuth client information to use.
- The OAuth provider has an associated OAuth 2.0 profile.
- The REST message HTTP Methods are not configured to use a MID Server.

⚠ **Note:** Ensure any scripts that call this REST message use the RESTMessageV2 API. The RESTMessageV2 API is required to send authenticated REST messages via scripts.

Procedure

1. Navigate to **System Web Services > Outbound > REST Message**.
2. Select a REST message record.
3. In the **Authentication type** field, select **OAuth 2.0**.
4. In the **OAuth profile** field, select the OAuth 2.0 profile that specifies the credentials you want to send.

5. Right-click the form header and select **Save**.
   An info message appears at the top of the form indicating that you must request a new OAuth token.

6. Click the **Get OAuth Token** related link.
   Depending on your OAuth provider, a separate window from your provider may appear asking for confirmation before providing a token. Complete any steps required by the provider to obtain the token.

**What to do next**
Test the REST message to ensure you receive the expected response. You can optionally specify different authentication settings for each HTTP method related to this REST message, overriding the parent REST message settings.

**Use a third-party OAuth provider**
Each client application must register with the instance to participate in OAuth authorization.

**Before you begin**
Role required: admin

**About this task**

*Note:* ServiceNow only supports third-party OAuth providers to authorize requests from ServiceNow to third-party APIs.

For example, you might want to integrate with a third-party Calendar service which requires OAuth 2.0 access tokens to read a user's scheduled events and create events. Configure the Calendar service as a third-party OAuth provider. This configuration allows you to get an access token from the Calendar service and then use the token to make requests against the service from ServiceNow.

**Procedure**

1. Navigate to **System OAuth > Application Registry** and then click **New**.
2. On the interceptor page, click **Connect to a third party OAuth Provider** and then fill in the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique name that identifies the application to access.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Client ID</td>
<td>The unique ID of the application. The instance uses the client ID when requesting an access token. You must get the client ID from the authorization server.</td>
</tr>
<tr>
<td>Client Secret</td>
<td>[Required] The shared secret string that the instance and the application use to authorize communications with one another. If you do not enter the correct client secret, tokens are not issued.</td>
</tr>
<tr>
<td>OAuth API Script</td>
<td>This option enables you to reference an amended OAuthUtil script include. Copy and rename the default OAuthUtil script include file, and then amend this version for specific requests and responses to match your 3rd party OAuth provider. The amended script name must have the prefix OAuth. See OAuthUtil to add the required body parameter in the proper method.</td>
</tr>
<tr>
<td>Logo URL</td>
<td>The URL that contains an image to use as the application logo.</td>
</tr>
<tr>
<td>Default Grant Type</td>
<td>The type of grant:</td>
</tr>
<tr>
<td></td>
<td>• Authorization code: The code that is granted to the client to obtain an access token, which is then used to obtain access to the resource. If you select this option, then you need an authorization URL (the URL of the authorization server).</td>
</tr>
<tr>
<td></td>
<td>• Resource owner password credentials: The user name and password of the user that is trying to obtain access to the resource.</td>
</tr>
<tr>
<td></td>
<td>• Client Credentials: The client ID and client secret, which are both used to get the access token. This method does not provide refresh tokens.</td>
</tr>
<tr>
<td></td>
<td>• JWT Bearer: An authorization server validates a JWT token which enables identity and security information to be shared across security domains.</td>
</tr>
<tr>
<td>Refresh Token Lifespan</td>
<td>The refresh token lifespan in seconds.</td>
</tr>
<tr>
<td>Accessible from</td>
<td>The application scope that this registry is accessible from.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Active</td>
<td>A check box that indicates that the application registry is active.</td>
</tr>
<tr>
<td>Authorization URL</td>
<td>If you are using the authorization code grant type, the URL of the endpoint to authorize the user. If you are accessing another ServiceNow instance, append /oauth_auth.do to the URL.</td>
</tr>
<tr>
<td>Token URL</td>
<td>The location of the token endpoint that the instance uses to retrieve and refresh tokens. If you are accessing another ServiceNow instance, append /oauth_token.do to the URL.</td>
</tr>
<tr>
<td>Redirect URL</td>
<td>The application endpoint that receives the authorization code. Leave the field empty to have the instance auto-generate the URL. If you are accessing another ServiceNow instance, append /oauth_redirect.do to the URL.</td>
</tr>
<tr>
<td>Token Revocation URL</td>
<td>The location of the endpoint that the instance uses to revoke the token. If you are accessing another instance, append /oauth_revoke.do to the URL.</td>
</tr>
<tr>
<td>Comments</td>
<td>Additional information to associate with the application.</td>
</tr>
<tr>
<td>Embedded lists</td>
<td></td>
</tr>
<tr>
<td>OAuth Entity Profiles</td>
<td>The profiles that are associated with the OAuth provider. The profile includes the grant type. Click the profile name to go to the OAuth Entity Profile form.</td>
</tr>
<tr>
<td>OAuth Entity Scopes</td>
<td>The entity scopes associated with the OAuth provider. The scope identifies the services the application has access to. Click the scope name to go to the OAuth Entity Scope form.</td>
</tr>
</tbody>
</table>

3. Click **Submit**. The record is saved in the Application Registries [oauth_entity] table.

   The system creates a record in the Application Registries [oauth_entity] table of type **OAuth Provider**. The instance also auto-generates a default profile using the specified grant type, but without any scopes.

**What to do next**

You can create additional profiles, each with scopes.

**OAuth profiles and scopes**

In the OAuth provider scenario, profiles and scopes specify the grant type, authorization type, and level of access.
In the OAuth provider scenario, the OAuth profile refers to a combination of a grant type and at least one scope. The scope specifies the access that the user has to the protected resource, such as read or write. You can create a profile for each third-party provider and obtain the specific set of scopes from the provider. See Specify an OAuth profile and Specify an OAuth scope for more information. The instance also uses OAuth profiles when a REST call specifies OAuth 2.0 authentication. The instance auto-creates a default profile for each third-party provider record that you create. There can be only one default profile.

Specify the following parameters, which are saved in the OAuth Requestor Profile [OAuth_requestor_profile] table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oauth_requestor</td>
<td>The sys_id of the object, which can be a user record or an email account.</td>
</tr>
<tr>
<td>oauth_requestor_context</td>
<td>Descriptor that provides context for the OAuth requestor. As a good practice, use the name of the table where the oauth_requestor object is saved.</td>
</tr>
<tr>
<td>oauth_provider_profile</td>
<td>The sys_id of the OAuth profile record that is the default (see Specify an OAuth profile).</td>
</tr>
</tbody>
</table>

When the user attempts to authenticate, the provider accesses the OAuth Requestor Profile table to look for the user. If the user is found, the authentication is successful. If not, the provider accesses the default profile to determine the grant type and how to proceed with the authentication.

Specify an OAuth profile

An OAuth profile includes the grant type that the third-party OAuth provider needs to obtain access to the restricted resource.

Before you begin
Role required: admin
About this task

Procedure
1. Open a third-party OAuth provider record.
2. In the OAuth Entity Profiles embedded list, click **Insert a new row** and then enter a name for the profile.
3. Right-click the Application Registry form header and select **Save**. The system creates the profile record.
4. Click the name of the profile you created and then fill in the form fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a descriptive name.</td>
</tr>
<tr>
<td>OAuth provider</td>
<td>Verify the provider that is associated with the profile.</td>
</tr>
<tr>
<td>Grant type</td>
<td>Select the grant type:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Authorization code</strong>: The code that is granted to the client to obtain an access token, which is then used to obtain access to the resource. If you select this option, then you need an authorization URL (the URL of the authorization server).</td>
</tr>
<tr>
<td></td>
<td>• <strong>Resource owner password credentials</strong>: The user name and password of the user that is trying to obtain access to the resource.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>• Client Credentials</td>
<td>The client ID and client secret, which are both used to get the access token. This method does not provide refresh tokens.</td>
</tr>
<tr>
<td>• JWT Bearer</td>
<td>An authorization server validates a JWT token which enables identity and security information to be shared across security domains.</td>
</tr>
<tr>
<td>Is default</td>
<td>Select this option to make the profile the default option for the associated provider.</td>
</tr>
<tr>
<td>5. Click Update.</td>
<td></td>
</tr>
</tbody>
</table>

Specify an OAuth scope

Specify the OAuth scopes that you get from the provider. Scopes can be any level of access specified by the provider, such as read, write, or any string, including a URL.

Before you begin
Role required: admin

Procedure
1. Open a third-party OAuth provider record.
2. Open a profile associated with the provider.
3. In the OAuth Entity Profile Scopes embedded list, click Insert a new row and then enter a Name for the profile.
4. Right-click the OAuth Entity Profile form header and select Save. The profile record is created.
5. Click the name of the scope that you created and then fill in the form fields.
OAuth Entity Scope form fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a descriptive name.</td>
</tr>
<tr>
<td>OAuth provider</td>
<td>Verify the provider associated with this scope.</td>
</tr>
<tr>
<td>OAuth scope</td>
<td>The scope that you are granted by the provider. Typical scopes are read and write. Scopes can be any string that the provider specifies.</td>
</tr>
</tbody>
</table>

6. Click **Update**.

Outbound REST with OAuth 2.0 profile tutorial - integrating with Google Contacts API

This tutorial explains how to use an OAuth 2.0 profile to authenticate an outbound REST message with Google to retrieve contact information.

The procedures detailed in this tutorial require the oauth_admin and web_service_admin roles. Ensure you have both of these roles before starting this tutorial.

OAuth 2.0 tutorial - configure the Google service as an OAuth provider

Use the Google Developer Console to set up an OAuth 2.0 provider.

**Before you begin**

Role required: None

This procedure is performed within the Google Developer Console. You must have a Google account to access this console.

**About this task**

Configure the Google service in order to obtain a client ID and client secret, and specify your ServiceNow instance URL as the OAuth redirect URL.
Note: This information describes the state of the Google Developer Console and Contacts API as of July 22, 2015. Changes made after that date may not be included in this document.

Procedure

2. Log in using your Google credentials.
3. Click Select a project.
4. Click Create a project.
5. Enter a Project name.
6. Click Create.  
   After Google creates the project, the project dashboard appears.
7. Navigate to APIs & auth > APIs.
8. Select the Contacts API.
9. Click Enable API.
10. Navigate to APIs & auth > Credentials.
11. Click Create new Client ID.
12. Ensure the Web application radio button is selected and click Configure consent screen.
13. Enter a descriptive Product name.  
   This name appears when you authorize the OAuth token in your instance.
14. Click Save.
15. In the Create Client ID window, add the OAuth redirect URI for your instance to the Authorized redirect URIs field.  
   This URI follows the format https://<instance>.service-now.com/oauth_redirect.do
16. Click Create Client ID.  
   The client ID information appears.
17. Record the Client ID and Client secret values.  
   You will need these values to configure the Google service as an OAuth provider in your instance.

OAuth 2.0 tutorial - create an OAuth provider and profile

Set up the Google service as an OAuth provider in ServiceNow by entering your client information, Google API URLs, and configuring the OAuth profile.
Before you begin
Role required: oauth_admin
You must have configured the Google service as an OAuth provider and recorded your Client ID and Client Secret values.

Procedure
1. Navigate to System OAuth > Application Registry.
2. Click New.
3. Select Connect to a third party OAuth Provider.
4. Enter a Name for the OAuth provider. For this example, use Google.
5. Enter the Client ID and Client Secret that you obtained from Google.
7. In the Authorization URL field, enter https://accounts.google.com/o/oauth2/
   auth.
9. In the Redirect URL field, enter https://<instance>.service-now.com/
   oauth_redirect.do.
   This URL must match the redirect URL provided to Google.
10. In the Token Revocation URL field, enter https://accounts.google.com/o/oauth2/
    revoke.
11. Right-click the form header and select Save.
    A new OAuth Entity Profile record is created.
12. In the OAuth Entity Scopes embedded list, add a new row with the Name and
13. Right-click the form header and select Save.
14. In the OAuth Entity Profiles embedded list, select the automatically-created
    profile.
15. In the OAuth Entity Profile Scopes embedded list, add a new row and select
    the Google contacts API read-only scope.
16. Click Update.

OAuth 2.0 tutorial - create a REST message
Create a REST message and associated HTTP method to contact the Google service using the OAuth 2.0 profile.
Before you begin
Role required: web_service_admin and oauth_admin
You must have configured an OAuth provider and profile using the Google API information and your OAuth credentials.

Procedure
1. Navigate to System Web Services > REST Message.
2. Click New.
3. Enter a descriptive Name.
4. In the Endpoint field, enter https://www.google.com/m8/feeds/contacts/default/full.
   By using default instead of a specific username, the Google API uses the OAuth credentials to determine which account to get information from.
5. In the Authentication tab, set the Authentication type to OAuth 2.0.
6. In the OAuth profile field, select the Google contacts OAuth profile.
7. Right-click the form header and select Save.
8. Click the Get OAuth Token related link to request an authorization token from Google using the configured client ID and secret.
9. In the Request for Permission window that appears, click Accept to grant access to your Google contacts.
   The token acquired is not directly accessible in your instance.
10. In the HTTP Methods related list, select the GET method.
11. Leave the HTTP method Authentication type as -- None -- to use the OAuth profile from the parent REST message record.
12. On the HTTP Request tab, add a new row to the HTTP Headers related list with a Name of GData - Version and a Value of 3.0.
13. Right-click the form header and select Save.
14. Click the Test related link.
   The test result should display an HTTP Status of 200, and the result of the contacts API call.

Outbound REST mutual authentication
Mutual authentication causes the web service provider and consumer to authenticate with each other before communicating.
ServiceNow supports mutual authentication for outbound web services. Mutual authentication is not available for inbound web services or for outbound web services that use a MID Server.

**Related information**
- Outbound web services mutual authentication

### Variable substitution in outbound REST messages

You can use variables when creating outbound REST messages and assign values to those variables when performing a request.

Variables are allowed in the **Endpoint** URL, HTTP Header and HTTP Query Parameter **Value** fields, and the **Content** field for POST and PUT methods.

The syntax for variables is `${variable_name}`. The REST message substitutes this variable with the parameter values provided when the method runs. For example, if the REST message **Endpoint** is `http://myserver.mycompany.com/offices/${id}`, a parameter named `id` must exist and contain a value that can be used when the method runs.

You can assign a value to variables when running the request using the RESTMessageV2 API `setStringParameter` and `setStringParameterNoEscape` methods.

When testing an HTTP method that includes variables, the **Test value** for each variable in the **Variable Substitutions** related list is used.

### Generate REST message variables

You can automatically populate the list of variable substitutions, based on variables defined in several REST message HTTP method fields.

**Before you begin**

Role required: web_service_admin

Before starting this procedure, create a REST Message record with at least one HTTP method that uses variables.

**Procedure**

1. Navigate to **System Web Services** > **REST Message**.
2. Select a REST Message record.
3. Select a method from the **HTTP Methods** related list.
4. Click the **Auto-generate variables** related link.
The **Variable Substitutions** related list is automatically populated for any variables defined in the HTTP Method **Endpoint** field and the **HTTP Headers** and **HTTP Query Parameters** embedded lists. For POST and PUT messages, variables defined in the **Content** field are also used.

**What to do next**
You can use the REST Message workflow activity to send the message, or click **Preview Script Usage** to get a sample script. The sample script includes a `setStringParameter` call for each defined variable substitution that allows you to assign a value to the variable in your script.

**Scripting outbound REST**
You can send outbound REST requests from any place in the Now Platform where scripting is allowed.

For example, you can return data from a REST endpoint using a business rule when an event is triggered. Create a script from scratch or let the REST message preview feature create the script based on content and parameters you provide in the method record.

For detailed API information about the server-side RESTMessageV2 and RESTResponseV2 APIs, see the API documentation on developer.servicenow.com.

**Generate a REST message script preview**
You can generate an example script to send a REST message based on content and parameters you provide in the method record.

**Before you begin**
Role required: web_service_admin or admin

**About this task**
Generate an example script and use it as a starting point when scripting outbound REST messages.

**Procedure**
1. Navigate to **System Web Services > REST Message**.
2. Select a REST message record.
3. In the **HTTP Methods** related list, select an HTTP method record.
4. Ensure the HTTP method is configured as needed, including any variables.
5. Save the record.
6. In the Variable Substitutions related list, assign a value to each variable.

7. Under Related Links, click Preview script usage.
   The instance displays the script that the REST message generated for this method.

8. Copy this script and modify it as needed to use elsewhere in the instance.

What to do next
Refer to the RESTMessageV2 and RESTResponseV2 APIs for more information on available scripting methods. Outbound REST scripting examples are also available.

Direct RESTMessageV2 example
You can send an outbound REST message directly to the endpoint.

In this example, the script sends a REST message requesting a stock quote and waits for a response. If there is no response from the web service provider, or if the specified REST message record is unavailable, the script throws an error, handled in this example by the try-catch block.

```javascript
var requestBody;
var responseBody;
var status;
var sm;
try{
    var r = new sn_ws.RESTMessageV2('Yahoo Finance', 'get');
    //override authentication profile
    //authentication type = 'basic' / 'oauth2'
    //r.setAuthentication(authentication type, profile name);
    var response = r.execute();
    var responseBody = response.getBody();
    var httpStatus = response.getStatusCode();
}
catch(ex) {
    var message = ex.getMessage();
}
```
RESTMessageV2 MID server example

You can send an outbound REST message through a MID Server.

By sending the message through a MID Server, you can access endpoints that are behind a firewall or within a private network. All REST messages sent through a MID Server are asynchronous.

```
var requestBody;
var responseBody;
var status;
var sm;
try{
    sm = new sn_ws.RESTMessageV2("Yahoo Finance", "get"); // Might throw exception if message
doesn't exist or not visible due to scope.
    sm.setBasicAuth("admin","admin");
    sm.setStringParameter("symbol","NOW");
    sm.setStringParameterNoEscape("xml_data","<data>test</data>");
    sm.setHttpTimeout(10000); //In milliseconds. Wait at most 10 seconds for response from
http request.
    response = sm.execute(); //Might throw exception if http connection timed out or some issue
with sending request itself because of encryption/decryption of password.
    responseBody = response.haveError() ? response.getError Message() : response.getBody();
    status = response.getStatusCode();
} catch(ex) {
    responseBody = ex.getMessage();
    status = '500';
} finally {
    requestBody = sm ? sm.getRequestBody():null;
}
    gs.info("Request Body: " + requestBody);
    gs.info("Response: " + responseBody);
    gs.info("HTTP Status: " + status);
```
response.waitForResponse(60); // In seconds. Wait at most 60 seconds to get response from ECC Queue/Mid Server // Might throw exception timing out waiting for response in ECC queue.

responseBody = response.haveError() ? response.getErrorMessage() : response.getBody();
status = response.getStatusCode();
} catch(ex) {
  responseBody = ex.getMessage();
  status = '500';
} finally {
  requestBody = sm ? sm.getRequestBody():null;
}
gs.info("Request Body: " + requestBody);
gs.info("Response: " + responseBody);
gs.info("HTTP Status: " + status);

Note: This example uses waitForResponse to pause for a response, and then details how the response is handled. However, when using executeAsync, consider processing the response body in a separate business rule to take advantage of the asynchronous call rather than using waitForResponse.

Recordless RESTMessageV2 example

You can use the RESTMessageV2() constructor with no parameters to define a REST message entirely in the script.

When using this constructor you must provide an endpoint and HTTP method. In this example, the script creates an empty REST message and sets the values needed to insert an incident record.

```javascript
var restMessage = new sn_ws.RESTMessageV2();
restMessage.setBasicAuth("admin", "admin");
restMessage.setHttpMethod("post");
restMessage.setEndpoint("http://<instance>.service-now.com/api/now/table/incident");
restMessage.setRequestBody("{"short_description" : "Test incident"}");
var response = restMessage.execute();
```

Outbound SOAP web service

The SOAP Message module can be used to develop, prototype, and save outbound SOAP messages that can be reused in business rules and scripts.

You can use outbound SOAP messages in scripts using the SOAPMessageV2 API and the SOAPResponseV2 API. Examples detailing how to script outbound SOAP are available.
Outbound SOAP video tutorial
The following video tutorial demonstrates how to configure outbound SOAP web service messages to consume third-party web services from an instance.

Outbound SOAP video tutorial

SOAP message
Information needed to send SOAP requests is stored in SOAP message records. Each record specifies an endpoint for the request, the required format of the request as a web services description language (WSDL) file, authentication information, and a list of functions that can run against the endpoint.

Create a SOAP message
Create a SOAP message to define the remote endpoint, WSDL, and authentication settings.

Before you begin
Role required: web_service_admin

Procedure
1. Navigate to System Web Services > SOAP Message.
2. Click New.
3. Enter a Name to identify the SOAP message.
4. Specify a WSDL using one of these options:
   - To download and use an online WSDL source, select the Download WSDL check box and enter the URL for the WSDL in the WSDL field.
   - To enter the WSDL directly, clear the Download WSDL check box, and then copy and paste the WSDL XML into the WSDL XML field.
5. If the endpoint is protected by basic authentication, select the Use basic auth check box and enter the credentials.
6. If the endpoint requires mutual authentication, select the Enable mutual authentication check box and select a Protocol profile to use for mutual authentication.
7. Click Submit.
This image shows an example of a SOAP message that connects to a demo instance of ServiceNow.

**SOAP message functions**

After you create a SOAP message record, you can click **Generate sample SOAP messages** to populate the SOAP Message Functions related list.

The instance creates these functions by reading the supplied WSDL definition.
The SOAP action, SOAP endpoint, and Envelope fields should be populated automatically based on the WSDL definition. The Envelope defines the message to send to the endpoint. In this example, the Envelope values have this format:

```xml
<!-- optional --><short_description xsi:type="xsd:string">String</short_description>
```

To submit a specific value, enter the value directly in the appropriate XML tag. In this example, to set the Short description for a record, enter:

```xml
<short_description xsi:type="xsd:string">This is the short description</short_description>
```
Variable substitution in outbound SOAP

To use variable substitution, use the format `${<variable_name>}` instead of defining a specific value.

```xml
<short_description xsi:type="xsd:string">${short_desc}</short_description>
```

To test variable substitution after you have modified the SOAP envelope with the variables, define values for the variables in the SOAP Message Parameters related list. For example, click New and enter the following information:

**Soap message parameters**

| Name  | Value          | SOAP Function | soap message parameters
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>short_desc</td>
<td>this is the short description</td>
<td>insert</td>
<td><img src="image" alt="Soap message parameters" /></td>
</tr>
</tbody>
</table>

**Test the SOAP message**

Test a SOAP message to validate the configuration before using the message in an integration.

To test the SOAP message, click the Test related link. You are redirected to a test result form as shown below.

**Soap message test**

![Soap message test](image)
You can see the original SOAP request message, the resulting HTTP status code, and the SOAP response in this screen. You can also click the Rerun test related link to resubmit the SOAP request.

ℹ️ Note: A test SOAP message will time out after 60 seconds if a response is not received.

**Send a SOAP message through a MID server**

When creating SOAP message functions, you can configure the function to be sent through a MID Server.

There must be a running MID Server associated with your instance to use this functionality. All SOAP messages sent through a MID Server are performed asynchronously.

By specifying a MID Server, all SOAP requests that use this SOAP message are sent through that MID Server. You can override the selected MID Server by using the `setMIDServer(mid server)` API call in a script.

**Create a SOAP message from a WSDL that references an external XSD file**

Create a SOAP message from a WSDL and external XSD file.

**Before you begin**

Role required: `web_service_admin`
About this task
This task includes example WSDL and XSD files for a weather forecast SOAP message. Your WSDL and XSD file will vary.

Procedure
1. Navigate to System Web Services > SOAP Message and create a new record.
2. Clear the Download WSDL check box.
3. Paste the content of the WSDL into the WSDL XML field.
4. Save the record.
5. In the SOAP Message Imports related list, click New.
6. Paste the content of the XSD file into the External Document field.
7. Set the Schema Location field to db://<name of the referenced XSD file>.xsd. Specifying the schema location allows the instance to know the location of the referenced XSD file.
8. Click Submit.
9. Click Generate sample SOAP messages.

Example: Example WSDL and XSD files

```xml
<?xml version="1.0" encoding="utf-8"?>
 xmlns:soapenc="http://schemas.xmlsoap.org/soap/encoding/"
 xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
 xmlns:s="http://www.w3.org/2001/XMLSchema"
 xmlns:soap12="http://schemas.xmlsoap.org/wsdl/soap12/"
 xmlns:http="http://schemas.xmlsoap.org/wsdl/http/"
targetNamespace="http://www.webservicex.net"
 xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/">  
 <wsdl:documentation xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/">Get one week weather forecast for valid zip code or Place name in USA</wsdl:documentation>
 <wsdl:types>

Connectivity details

For the ServiceNow-initiated SOAP requests to successfully communicate with the web service provider inside a remote network, the ServiceNow instance must have HTTP or HTTPS access to the SOAP endpoint at the provider.

Like any integration, such as LDAP, web services, or JDBC, the SOAP endpoint may reside behind a firewall that is blocking inbound communication from the instance. If this is the case, you need to make network changes to allow this connectivity into your network. You can either modify the firewall and ACL rules to allow the instance IP address, configure the SOAP message to use a MID Server, or implement a VPN tunnel to allow the instance communication into your network.

Note: A common misconception is that because asynchronous SOAP requests are routed through the ECC queue, they are always sent through a MID Server. This is not the case. Asynchronous SOAP requests only use a MID Server when configured to do so.
Outbound SOAP security

You can authenticate outbound SOAP messages using several different security protocols.

The security protocol you should use depends on the requirements of the web service provider. Mutual authentication is supported for outbound web services.

Related information

Outbound web services mutual authentication

Enable basic authentication for outbound SOAP

If the endpoint requires a user name and password, you can provide credentials using basic authentication.

Procedure

1. Navigate to System Web Services > Outbound > SOAP Message.
2. Select a SOAP message record.
3. In the SOAP Message Functions related list, select a function.
4. Select Use basic auth.
5. Enter a user name in the Basic auth user ID field.
6. Enter the password for that user in Basic auth user password.
7. Click Update.

Enable WS-Security for outbound SOAP

You can sign outbound SOAP messages using username and password or a key store and trusted server certificate saved on the instance.

Before you begin

Role required: admin

Procedure

1. Navigate to System Web Services > Outbound > SOAP Message.
2. Select a SOAP message record.
3. In the SOAP Message Functions related list, select a function.
4. In the WS-Security type field select the type of credentials to use, such as Username or X.509.
Some web service providers may require you to submit both types of credential.

5. In the **WS-Security x.509 profile** or **WS-Security Username profile** field, select the profile that contains the credentials you want to use. If the record was configured with x.509 security prior to the Helsinki release, you can migrate the security settings to a WS-Security x.509 profile record by clicking the **Migrate to X509 Security Profile** button. When you click this button, security configuration field values (**Key store**, **Certificate**, **Key store alias**, and **Password**) are migrated to a new WS-Security x.509 profile record and that record is referenced from the SOAP message function. If an x.509 profile record already exists with matching values, that record is referenced.

⚠️ **Note:** Existing SOAP message functions that use the legacy security configuration will still work, however new records can use only an x.509 profile record for x.509 security.

6. Click **Update**. Credentials from the selected profile are sent as part of the SOAP message header.

Related information

Create a new WS-Security profile

Configure SOAP with a proxy

Certain properties provide support for SOAP requests to use a web proxy server.

### SOAP properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.http.proxy_host</td>
<td>The proxy server hostname or IP address</td>
<td>proxy.company.com, 192.168.34.54</td>
</tr>
<tr>
<td>glide.http.proxy_port</td>
<td>The port number for the proxy server</td>
<td>8080, 9100</td>
</tr>
<tr>
<td>glide.http.proxy_username</td>
<td>If the proxy server is authenticating using user name and password, enter a value for this property</td>
<td>proxyuser</td>
</tr>
<tr>
<td>glide.http.proxy_password</td>
<td>If the proxy server is authenticating using user</td>
<td>password</td>
</tr>
</tbody>
</table>
### SOAP properties (continued)

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>name and password</td>
<td>enter a value for this property</td>
<td></td>
</tr>
</tbody>
</table>

### Scripting outbound SOAP

You can send outbound SOAP requests from any place in the Now Platform where scripting is allowed.

For detailed API information about the server-side SOAPMessageV2 and SOAPResponseV2 APIs, see the API documentation on developer.servicenow.com.

### Preview a SOAP message script

Generate a sample script to send the SOAP message.

After you have developed and tested the SOAP message, click the **Preview script usage** related link in the SOAP Message Function form. The dialog box displays an example of how you can invoke the SOAP message from a script.

You can manipulate the resulting XML response body with `XMLDocument` or with `gs.getXMLText` and `gs.getXMLNodeList`.

### Direct SOAPMessageV2 example

You can send an outbound SOAP message directly to the endpoint.

In this example, the script sends a SOAP message requesting a stock quote and waits for a response. If there is no response from the web service provider, or if the specified SOAP message record is unavailable, the script throws an error, handled in this example by the try-catch block.

```javascript
var requestBody;
var responseBody;
var status;
var sm;
try{
    sm = new sn_ws.SOAPMessageV2("StockQuote", "GetQuote"); // Might throw exception if
    message doesn't exist or not visible due to scope
    sm.setBasicAuth("admin","admin");
    sm.setStringParameter("symbol", "NOW");
    sm.setStringParameterNoEscape("xml_data","<data>test</data>");
```
Asynchronous SOAPMessageV2 example

You can send an outbound SOAP message asynchronously.

When you send an asynchronous message the instance does not wait for a response before proceeding. You must handle waiting for a response within your code.
You can send an outbound SOAP message through a MID Server.

By sending the message through a MID Server, you can access endpoints that are behind a firewall or within a private network. All SOAP messages sent through a MID Server are asynchronous.

```javascript
var requestBody;
var responseBody;
var status;
var sm;
try{
    sm = new sn_ws.SOAPMessageV2("StockQuote", "GetQuote");  // Might throw exception if message doesn't exist or not visible due to scope
    sm.setBasicAuth("admin","admin");
    sm.setStringParameter("symbol", "NOW");
    sm.setStringParameterNoEscape("xml_data","<data>test</data>");
    sm.setMIDServer('mid_server_name');
    response = sm.execute(); // Might throw exception if http connection timed out or some issue with sending request itself because of encryption/decryption of password and stuff
    response.waitForResponse(60); // In Seconds, Wait at most 60 seconds to get response from ECC Queue/Mid Server // Might throw exception timing out waiting for response in ECC queue
    responseBody = response.haveError() ? response.getErrorMessage() : response.getBody();
    status = response.getStatusCode();
} catch(ex) {
    responseBody = ex.getMessage();
    status = '500';
} finally {
    requestBody = sm ? sm.getRequestBody():null;
}
gs.info("Request Body: " + requestBody);
gs.info("Response: " + responseBody);
gs.info("HTTP Status: " + status);
```
Recordless SOAPMessageV2 example

You can use the SOAPMessageV2() constructor with no parameters to define a SOAP message entirely in the script.

When using this constructor you must provide an endpoint and SOAP action. In this example, the script creates an empty SOAP message and sets the values needed to insert an incident record.

```javascript
var s = new sn_ws.SOAPMessageV2(); //create an empty SOAP message
s.setBasicAuth('admin','admin');
s.setSOAPAction('http://www.service-now.com/incident/insert'); //set the SOAP action to perform
s.setEndpoint('http://<instance>.service-now.com/incident.do?SOAP'); //set the web service provider endpoint
s.setRequestBody('<soapenv:Envelope
    xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
    xmlns:inc="http://www.service-now.com/incident"><soapenv:Header/>
    <soapenv:Body><inc:insert>
        <short_description>Test Dynamic SOAP</short_description>
    </inc:insert></soapenv:Body></soapenv:Envelope>');
var response = s.execute();
var xmldoc = new XMLDocument(response.getBody());
var incident_sysid = xmldoc.getNodeText('//sys_id');
```

Outbound web services mutual authentication

Mutual authentication establishes trust by exchanging Secure Sockets Layer (SSL) certificates.

Before connecting to a server, the client requests an SSL certificate. The server responds by requesting that the client send its own certificate. Both respond by validating the certificates of the other and sending acknowledgments before initiating an HTTPS connection. Mutual authentication is not available for inbound requests or for outbound web service calls through a MID Server.

As an administrator, you can enable mutual authentication by defining a protocol profile for connections that require mutual authentication. Protocol profiles allow you to associate a specific certificate record with a protocol, such as HTTPS.

For example, you can create a protocol profile called `mauth` with a certificate for mutual authentication. You can then make an HTTPS web service request...
by calling `mauth://<external-endpoint.com>` when the end point requires mutual authentication.

⚠️ **Note:** This feature enables mutual authentication only on outbound HTTPS connections, such as SOAP, REST, or direct HTTPS calls. ServiceNow does not support mutual authentication for inbound requests or for outbound requests sent through a MID Server.

## Create a protocol profile

You can create a custom HTTPS protocol profile to specify the credentials and certificates used for outbound web services. For example, you can create a custom HTTPS protocol profile to enable mutual authentication.

### Before you begin

- **Role required:** admin
- **Upload a certificate** to authenticate the client certificate of the instance.
- **Upload a trusted server certificate** to authenticate the server certificate of the web service provider.

### About this task

Mutual authentication causes the web service provider and consumer to authenticate with each other before communicating. You must configure a REST or SOAP message to support mutual authentication.

- **Outbound REST:** Create a REST message using basic authentication. Mutual authentication is not available with OAuth 2.0.
- **Outbound SOAP:** Create a SOAP message using mutual authentication.

⚠️ **Note:** Mutual authentication is not available when making outbound web service calls through a MID Server.

### Procedure

1. Navigate to **System Security > Protocol Profiles**.
2. Click **New**.
3. Fill in the fields on the form, as appropriate.
Name of form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Protocol</td>
<td>Enter a unique name to identify this HTTPS protocol, such as <code>mauth</code>. The protocol name allows you to differentiate between normal HTTPS connections and HTTPS connections that use this protocol profile. The name you enter becomes the protocol name in the URL. For example, <code>mauth://endpoint.service.com</code></td>
</tr>
<tr>
<td>Note:</td>
<td>You cannot create a custom protocol whose name matches as an existing protocol name such as HTTPS.</td>
</tr>
<tr>
<td>Default port</td>
<td>Enter the port number for connections that use this protocol.</td>
</tr>
<tr>
<td>Check box</td>
<td>Select the client certificate the protocol uses to authenticate itself with the web service provider. The certificate must have a Value of Java Key Store or PKCS12 Key Store.</td>
</tr>
</tbody>
</table>

**Enable mutual authentication**

You can configure a SOAP or REST message for mutual authentication using a protocol profile

**Before you begin**

Role required: web_service_admin or admin

**Procedure**

1. Navigate to System Web Services > SOAP Message or System Web Services > REST Message.
2. Select a message record.
3. Select the Use mutual authentication check box.
4. In the Protocol profile field, select a protocol profile configured for mutual authentication.
5. Click Update.

**Outbound web services logging**

Log requests and responses for outbound web services such as REST and SOAP.

Outbound request logging allows you to better understand what 3rd-party services your instance accesses and the volume of outbound requests.
Additionally, logging can provide valuable information when debugging outbound integrations.

Outbound web services logging tracks outbound REST and SOAP requests, as well as outbound requests made using the GlideHTTPRequest and GlideHTTPClient APIs.

To view outbound web service logs, navigate to System Logs > Outbound HTTP Requests.

All log information is read only.

**Configure outbound logging**

You can configure outbound request logging to log basic, elevated, or all HTTP request and response information for specific domains.

To configure the log level for a REST method or SOAP message function, navigate to the record you want to configure and click the **Set log level** related link, then select a log level for the current record.

To modify the log level for multiple outbound requests, navigate to System Web Services > HTTP Log Levels and change the log levels using the list. All outbound requests that have been configured with a specific log level are listed.

You can override the log level for all outbound requests using the properties `glide.outbound_http_log.override` and `glide.outbound_http_log.override.level`. Use these properties only for a limited time when troubleshooting.

You can set the log level in a script using the `setLogLevel()` function from the SOAPMessageV2 and RESTMessageV2 APIs. For more information about using these APIs, refer to the API documentation.

**Related information**

- RESTMessageV2 - `setLogLevel()`
- SOAPMessageV2 - `setLogLevel()`

**Outbound request log levels**

Certain elements are logged based on the configured log level.

**Logged elements**

The following elements from the request and response are logged depending on the configured log level.
Logged elements by level

<table>

Outbound request logging exclusion domain requirements

When you exclude outbound request logging for a domain, the value you enter in the Domain field must meet certain requirements.

**Requirements**
The value you enter in the Domain field must meet the following requirements.

- Begins with `HTTP://` or `HTTPS://`.
- Is a domain pattern or IP address.
- Ends with alphanumeric characters preceded by a period, such as `.com`.
- Includes at most a single wildcard character immediately following the scheme and hierarchical portion of the domain pattern.

**Wildcard**
You can use a single wildcard character (`*`) in the domain pattern. Use this wildcard immediately following the scheme and hierarchical portion of the domain pattern, such as `http://*.domain.com` to include all subdomains. The wildcard must immediately follow the scheme and hierarchical portion of the domain pattern. If you use an IP address instead of domain pattern, you must enter the full IP address without a wildcard.

**Note:** You cannot use multiple wildcards, or specify a wildcard without a domain pattern. Values such as `*` or `*.*` are not supported.

**Domain matching**
When evaluating the Origin header in a request, ServiceNow prioritizes rules that match the domain pattern exactly. If no exact match is found, the next closest match is used.

For example, if there are rules for the domain patterns `http://*.blog.mysite.com` and `http://*.mysite.com`, a request from `http://alice.blog.mysite.com` will match the `http://*.blog.mysite.com` pattern.

**Examples of valid and invalid domains**

<table>
<thead>
<tr>
<th>Valid domain</th>
<th>Invalid domain</th>
</tr>
</thead>
<tbody>
<tr>
<td>http://*.ms.net</td>
<td>https://*com</td>
</tr>
<tr>
<td>https://*.ms.com</td>
<td>http://*.com</td>
</tr>
</tbody>
</table>
Examples (continued)

<table>
<thead>
<tr>
<th>Valid domain</th>
<th>Invalid domain</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://192.168.1.1">http://192.168.1.1</a></td>
<td>http://*.168.1.126</td>
</tr>
<tr>
<td>http://*.service-now.com</td>
<td><a href="http://blog.*.service-now.com">http://blog.*.service-now.com</a></td>
</tr>
<tr>
<td>http://*.com</td>
<td>http://*com</td>
</tr>
</tbody>
</table>

**Outbound request logging exclusion**

You can exclude domains to allow only basic-level logging on those domains.

To exclude a domain, navigate to **System Web Services > Outbound HTTP Log Domain Exclusion List** and create a new record. You must have the **web_service_admin** role to exclude domains.

**Outbound web service logging properties**

These properties allow you to control the behavior of outbound web service request logging.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.outbound_http.db.log</td>
<td>By default, log information is written to a log file and to the instance database. Set this property to false to disable database logging.</td>
</tr>
<tr>
<td></td>
<td>• Type: true</td>
</tr>
<tr>
<td></td>
<td>• Default value: true</td>
</tr>
<tr>
<td></td>
<td>• Location: Add to the System Property [sys_properties] table</td>
</tr>
<tr>
<td>glide.outbound_http.text.content_types</td>
<td>A comma-separated list of content types. The body of requests or responses with one of these content types is logged. By default, the content types text/*, application/json, and application/xml are always logged. Use this property to add additional content types.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>glide.outbound_http.content.max_limit</td>
<td>The maximum number of characters logged from a request or response body. The first characters of the body, up to this limit, are logged. This property has a maximum possible value of 1000.</td>
</tr>
<tr>
<td>glide.outbound_http_log.override</td>
<td>When this property is set to true, the property <code>glide.outbound_http_log.override.level</code> determines the log level for all requests and responses. This log level overrides any other log level settings. Only use this property for a limited time when troubleshooting.</td>
</tr>
<tr>
<td>glide.outbound_http_log.override.level</td>
<td>The log level to use for all requests and responses when <code>glide.outbound_http_log.override</code> is true. Valid values are <code>basic</code>, <code>elevated</code>, and <code>all</code>.</td>
</tr>
</tbody>
</table>

Server Name Indication for outbound web services

Outbound HTTP requests, including outbound SOAP, REST, and GlideHTTPClient requests support Server Name Indication.

Server Name Indication (SNI) is a TLS extension that enables service providers to serve multiple host names from a single IP address. With SNI support, outbound web service requests specify the hostname to connect to as part of the TLS handshake. This information allows the server to present the correct certificate to the client.

SNI support is provided for outbound requests sent directly from an instance, as well as outbound requests sent through a MID Server. The hostname is automatically included in the HTTP request when SNI is enabled, it is not necessary to configure the request for SNI support.

For example, when SNI support is enabled, a REST message sent to the endpoint https://myhost.com/some/path will include the domain myhost.com in the TLS SNI extension.

Configure Server Name Indication

Server Name Indication support is disabled by default for all outbound HTTP requests.

To enable or disable SNI support for outbound HTTP requests sent directly from the instance, set the system property `glide.outbound.tls_sni.enabled` to true or false (default).

To enable or disable SNI support for outbound HTTP requests sent through a MID Server, create the property `glide.outbound.tls_sni.enabled` on the MID Server with a value of true or false (default), then restart the MID Server.

⚠️ Note: After you change the property, wait at least 30 seconds before testing a request to ensure that a cached connection is not reused.

HTTP Client Connection Management

Outbound HTTP(S) connections from a base system instance or inbound connections from MID Servers, the ODBC driver, and other clients are maintained and reused where possible.

Connection pooling is used to keep track of HTTP(S) client connections to determine if they are alive and available for reuse.

ServiceNow HTTP client code means:
• Any application or script which makes outbound HTTP(S) requests from a base system instance.
• ServiceNow code in the MID Server or the ODBC driver which makes HTTP(S) requests to one or more base system instances.

⚠️ Note: This discussion does not apply to browser-to-instance communication. No changes have been made with respect to the management of HTTP(S) connections for browser-based communication with ServiceNow. This discussion also does not apply to customer-developed Web Services clients making requests to ServiceNow.

What Should the Customer Do?

Users should monitor performance, such as the decreased time for loading Discovery data and improved ODBC driver performance. For systems with an unusually large amount of simultaneous outbound HTTP(S) activity, such as numerous third-party integrations or high-volume automated activities which generate HTTP(S) requests from the base system instance to other places, review the `max_connections` and `max_connections_per_host` properties to ensure that the settings are sufficient. This enhancement has no impact on end-user connections from browsers and no impact on connections from customer-developed Web Services client applications.

HTTP Connection Management Properties

Connection pooling is controlled by three properties.

The default values for these properties are appropriate for most customers. The Glide properties are dynamic, meaning that changes to these properties will take effect immediately. No outage or restart is required to update the values.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.http.connection_mgr.max_connections</td>
<td>Controls the total number of permitted HTTP(S) connections outbound from the base system instance. This is an instance-wide value.</td>
<td>20</td>
</tr>
<tr>
<td>glide.http.connection_mgr.max_connections_per_host</td>
<td>Controls how many of the <code>glide.http.connection_mgr.max_connections</code> can communicate in</td>

<td>glide.http.use_connection_mgr</td>
<td>Switches connection pooling on and off. To disable the new behavior (not recommended) set glide.http.use_connection_mgr to false.</td>
<td>true</td>
</tr>
</tbody>
</table>

**ODBC driver**

The ServiceNow open database connectivity (ODBC) driver provides read-only access to the database associated with your ServiceNow instance.
The ODBC driver is compliant to version 3.52 of the Microsoft ODBC core API conformance. The ServiceNow ODBC driver uses ServiceNow web services support for a query-only interface. The ODBC driver supports only select statements or read-only functions and does not modify your instance data. Because the ODBC driver uses the web services interface, platform-wide access control (ACL) is enforced and data security is in place.

⚠️ **Note:**
The ODBC driver has these limitations:

- The ODBC driver supports only select statements or read-only functions, and does not modify your instance data.
- There is no supported way to use the ODBC driver with a Java client application or with a Java JDBC-ODBC bridge.
- There is a hard-coded limit of 512 characters when accessing views through ODBC. Because of this limitation, a maximum of 11 table sys_ids can be included in an ODBC view query. Anything over 11 tables results in an error.

⚠️ **Note:** Versions of the ODBC driver older than 1.0.7.3 are no longer supported.

### Getting started with ODBC

Before installing the ODBC driver, view the video on this page, create an ODBC user account, assign the odbc role, and define an ACL rule for the odbc role.

A ServiceNow user with the admin role can perform these procedures.

Watch this seven-minute video for an overview of installing, configuring and testing the ServiceNow ODBC driver, which provides read-only access to the database associated with your ServiceNow instance. This video explains the ODBC prerequisites and demonstrates how to install, configure, and test the ServiceNow ODBC driver, which provides read-only access to the database associated with your ServiceNow instance.

Before downloading and installing the ODBC driver, review the requirements to ensure that your configuration is compatible.

### Create an ODBC user account and assign the odbc role

The ODBC driver communicates with your ServiceNow instance as a specific user. Create an ODBC user account and assign the odbc role to enable the user to communicate via ODBC.
Before you begin
Role required: admin

About this task
The odbc role contains various additional roles, including the soap_query role required to make ODBC requests and the itil role required to access core tables such as the incident table. You can modify the odbc role to allow access to other tables as needed by adding additional child roles.

Procedure
1. Navigate to User Administration > Users.
2. Click New.
3. In the User ID field, enter odbc.user.
4. Enter a Password for this user.
5. From the form context menu, select Save.
6. In the Roles related list, click Edit.
7. Use the slushbucket to add the odbc role, and then click Save.
8. Click Submit.

What to do next
In a separate browser session, confirm that the odbc.user is able to log in to your ServiceNow instance.

Define an ACL rule for the odbc role
Define an ACL rule for the odbc role to provide read access to the incident table. You can create other ACL rules for the odbc role to provide read access to other tables.

Before you begin
Role required: admin

Procedure
1. Elevate the session permissions to security_admin so you can create ACL rules.
3. Click New.
4. From the Operation choice list, select read.
5. From the Name choice list, select Incident [incident].
Leave the second **Name** choice list as **None**.

6. From the form context menu, select **Save**.

7. In the **Requires role** related list, click **Edit**.

8. Use the slushbucket to add the ODBC role, and then click **Save**.

9. Click **Submit**.

### Installing the ODBC driver

Review setup requirements, download the ODBC driver installer, and install the ODBC driver to a computer.

You can install the ServiceNow ODBC driver on Microsoft Windows computers. To install the ODBC driver, set up an ODBC user in your ServiceNow instance, then download and install the ODBC driver. If you already have the ODBC driver installed, you can upgrade to the newest version.

### ODBC driver installation requirements and supported software

Install the ServiceNow ODBC driver on Microsoft Windows computers.

### Installation requirements

Before installing the ODBC driver, ensure that your configuration meets these requirements.

<table>
<thead>
<tr>
<th>Category</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active user</td>
<td>The user record on the instance used to perform the queries.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>The account used to connect to the instance via the ODBC driver must be defined on the instance. Accounts using single sign-on are not supported by the ODBC driver.</td>
</tr>
<tr>
<td>The soap_query role</td>
<td>The user you use to query the database must have the soap_query role if the instance uses the glide.soap.strict_security high security setting.</td>
</tr>
<tr>
<td><strong>Warning:</strong></td>
<td>Do not enable WS-Security for all SOAP requests by setting the glide.soap.require_ws_security system property. It is incompatible with the ODBC driver. Enabling this setting blocks both ODBC driver and MID Server connections. Instead, use basic authentication.</td>
</tr>
</tbody>
</table>
## Installation requirements (continued)

<table>
<thead>
<tr>
<th>Category</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target Table ACLs</td>
<td>The user you use to query the database must have read access for the tables that you want to query. For example, a user with the itil role can read task tables, such as Incident.</td>
</tr>
<tr>
<td>Target Table Web Service Access</td>
<td>The table you want to query must allow web service interaction. You can enable web service interaction using the application access settings.</td>
</tr>
<tr>
<td>Java Runtime Environment (JRE)</td>
<td>JRE must be enabled on your instance.</td>
</tr>
<tr>
<td>Operating System</td>
<td>The ServiceNow ODBC driver supports installation on the following operating systems:</td>
</tr>
<tr>
<td></td>
<td>• Windows XP</td>
</tr>
<tr>
<td></td>
<td>• Windows Server 2003</td>
</tr>
<tr>
<td></td>
<td>• Windows Server 2008</td>

For more information, see Application access settings.

### Supported software

The following table lists the operating systems and reporting applications compatible with each version of the ODBC driver.

#### Supported software

<table>
<thead>
<tr>
<th>Driver Version</th>
<th>Operating System</th>
<th>Microsoft Excel</th>
<th>Microsoft SQL Server</th>
<th>Crystal Reports</th>
<th>Tableau</th>
<th>Informatica</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.0.13 and later</td>
<td>Windows XP SP2</td>
<td>2007, 2010</td>
<td>2008</td>
<td>2008</td>
<td>8.1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Windows 7</td>
<td></td>
<td></td>
<td>2013</td>
<td>8.3</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Windows 8.x</td>
<td></td>
<td></td>
<td></td>
<td>9.0</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Windows 10</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Windows Server 2003</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Windows Server 2008</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Windows Server 2008 R2</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The ODBC driver provides only basic support for Informatica. Use the ODBC driver with Informatica only for simple operations. Thoroughly test integrations with Informatica before using them in a production environment.

Download and install the ODBC driver

Download the ODBC driver from the ServiceNow Knowledge Base and install the driver for the first time.

Before you begin

You must have administrator-level access for the Windows computer onto which you want to install the ODBC driver.

About this task

If this is the first time the driver is installed, the installer is in first-time installation mode and prompts for the driver to be installed. Install only one version of the ODBC driver on a computer. If the ODBC driver was previously installed, the installer is in upgrade mode and prompts for removal of the previous driver first.

Note: Versions of the ODBC driver older than 1.0.7.3 are no longer supported.
Procedure

1. To download the latest ODBC drivers, click the following links:
   - 1.0.14_01 (32 bit) download
   - 1.0.14_01 (64 bit) download

2. Download the ODBC driver version compatible with your computer’s operating system and the application you are using to query the database. The ODBC driver is available as 32-bit or 64-bit. Most applications require the 32-bit ODBC driver even if the operating system is 64-bit.

3. Right-click the executable and select Run as Administrator to launch the installer. The ODBC Driver Setup Wizard appears.

4. Click Next.

5. Read and accept the End User License Agreement.

6. The installer prompts for the Installation Directory. Select the target directory for installing the ServiceNow ODBC driver. The default directory is C:\Program Files\Service-now\ODBC.

7. The installer prompts for the Service Name. Enter a name to identify the service (for example, ServiceNow_ODBC) and press Next.

8. The installer prompts for the Java Virtual Machine Location.
• Browse to and select the directory where the jvm.dll file is located (usually C:\Program Files\Java\jre<version>\bin\server).

• If you do not want to enter the JRE location at the time of the installation, click **Next**.
  On the popup window, click **Yes** to enter the JRE location now, or click **No** to enter the JRE location later.

**Important:** You must specify the JRE location before the ODBC driver will work. After the installation, you can access the Management console as an administrator and navigate to **Services > <Service_Name> > Service Settings > IP Parameters** and enter the JRE location in the **ServiceJVMLocation** property.

**Tip:** For the configuration of a Java service, ServiceNow strongly recommends using the server jvm.dll file from the Java Development Kit (JDK).

9. The installer prompts for the **ODBC Data Source** details. Specify the following parameters, which are required to create an ODBC data source that can be used to create a DSN.

• **Data Source Name**: A short name to identify this data source.

• **Description**: A short description of the driver. The driver's version number is appended to the end of this value.

• **Service Name**: Enter the same **Service Name** entered at step 7.

• **Service Data Source**: The name that can be selected in the **Service Data Source** field of the ODBC Administrator. Usually the default values are appropriate.
10. Select the **Program Folder** to create links for the driver. This is the program folder that appears under the **Start** menu.
The installation creates the following links in the menu.

- **Interactive SQL (ODBC):** An interactive SQL command window for directly testing SQL statements.
- **Management Console:** A Microsoft MMC snap-in for configuring default properties for the ODBC driver.
- **ODBC Administrator:** A Microsoft ODBC Administrator program.

The driver code is copied to the target folder.

A progress bar appears.

11. When prompted, click **Finish** to complete the installation.
Upgrade the ODBC driver

If you have previously installed an older version of the ODBC driver, run the installer to uninstall the previous version, and then run the installer again to upgrade.

About this task
To check the build date and time of the ODBC driver, use CheckVersion located in the Service-Now\ODBC\ip\tools folder. This is an executable Windows host script that reports the build date and time of the current ODBC driver. Use it to assist ServiceNow Technical Support to determine which build of the ODBC driver is running. If the CheckVersion tool is absent, the ODBC driver is out of date; upgrade to the current version. To check the version of an older ODBC driver, see the previous version information.

Note: The ODBC installation also has a Service-Now\ODBC\tools folder, which is not the correct path for the CheckVersion tool.

Procedure
1. Right-click the executable and select Run as Administrator.

2. Click OK when prompted to uninstall the current driver, which is required for the upgrade.

   A list appears, displaying the existing ODBC DSN names that you have previously created. You have the option to delete them.

3. Select Yes to remove all previous DSNs or No to keep them for use with the upgraded driver.

   An ODBC DSN is a connection handle to use the ODBC driver in an application. For more information from Microsoft, see Administer ODBC data sources.
4. After removing the previous ODBC driver, double-click the executable again to run the installer. Then, follow the steps in Download and install the ODBC driver.

If you encounter errors when uninstalling the ODBC driver, see the Troubleshooting uninstalling ODBC driver knowledge article.

What to do next
After installing the ODBC driver, configure it to connect to your ServiceNow instance.

Install an ODBC driver patch
Use ServiceNow patches to install incremental ODBC fixes that occur between major ODBC releases.

Before you begin
Incremental ODBC patches contain only fixes to the ODBC driver and do not include fixes for third-party products such as Progress SDK. Third-party product fixes are included only in major ODBC release updates.
You must have administrator-level access for the Windows computer onto which you want to install the ODBC driver patch.
Before applying a new ODBC patch:
• Ensure that you have the Java Runtime Environment (JRE) already installed in your instance.
• Close any applications currently using the ODBC driver.

Procedure
1. Download and unzip the ODBC patch zip file from KB0540707 in the ServiceNow Knowledge Base.
2. Extract the zip files into a folder named odbc-patch.
3. From the Start menu, right-click Command Prompt and select Run as administrator.
4. In the Command Prompt window, cd to the odbc-patch folder created in step 2, type update.bat, and press Enter.
5. The installer prompts for the installation directory of the ODBC driver. The default installation location is C:\Program Files\ServiceNow\ODBC.
   • If the ODBC driver is installed in C:\Program Files\ServiceNow\ODBC, enter y and press Enter.
   • If the ODBC driver is not installed in C:\Program Files\ServiceNow\ODBC, enter the complete path to the ODBC installation directory and press Enter.
The installer validates the installation location. If the location specified is not valid, the installer prompts for the correct location of the installed ODBC driver.

Once you enter a valid installation location, the installer checks for the installed version and compares it with the version of the patch.

   • If the currently-installed version is the latest version, the installer aborts the installation process and displays the following message:

     The version you are trying to install is same as the existing version. Installation aborted.

   • If the currently-installed version is the same as the patch version, the installer aborts the installation process and displays the following message:

     The current installed version is the most recent version. Installation aborted.

   • If the patch version is the latest version, the installer continues with the patch installation. Once the installation is complete, you receive the following confirmation message:

     Patch is successfully installed.
Configuring the ODBC driver

After installing the ODBC driver, configure it to connect to your ServiceNow instance and to communicate through a proxy server, if applicable, and set properties to control ODBC behavior.

Configure the ODBC driver

Configure the ODBC driver to connect to your ServiceNow instance.

Before you begin

You must have administrator-level access for the Windows computer on which you want to configure the ODBC driver.

About this task

After the driver is installed, configure it for your instance. The driver is preconfigured to connect to https://demoodbc.service-now.com using the DSN ServiceNow. There are two ways to configure connectivity for the driver.

- Configure the global default used by all newly created DSNs.
- Configure each new DSN with its own connection.

Procedure

1. In Windows, navigate to Start > Programs > ServiceNow ODBC Management Console.
2. Expand the Console Root tree to: ServiceNow ODBC Manager\Manager \<installation location>\Services\ServiceNow_ODBC\Data Source Settings \ServiceNow\IP Parameters.
3. Double-click the DataSourceIPProperties attribute.
4. Change the Value to the URL of your instance, such as https://<instance>.service-now.com.
   If integrating the ODBC driver with Edge Encryption, change the Value to the URL of your encryption proxy. See Integrate Edge Encryption with the ODBC driver for more information.
5. Click OK.

Configure the global DSN default

Configure the global default used by all newly created DSNs.
Before you begin
You must have administrator-level access for the Windows computer on which you want to configure the global DSN default.

About this task
A default DSN is preloaded with the ODBC driver installation ServiceNow data source. This preloaded DSN connects using the default connection URL, which is set to https://demo.service-now.com. To change the global default for the instance URL, do the following.

Procedure
1. In Windows, navigate to Start > Programs > ServiceNow ODBC > Management Console.
2. Expand the Console Root tree using the following path:
   OpenAccess SDK 6.0 Manager\<installation location>\Services\ServiceNow_ODBC\Data Source Settings\ServiceNow\IP Parameters
3. Double-click the DataSourceIPProperties attribute for the ServiceNow data source setting to open the Properties dialog box.
4. Change the value to the URL of your instance, using the following format, and then click OK:
Create a new DSN

Use the ODBC driver and the ServiceNow data source to create an unlimited number of DSNs configured to connect with different instance URLs.

Before you begin
You must have administrator-level access for the Windows computer on which you want to create a new DSN.

About this task
Select the target instance for your ODBC connection by DSN name. As an option during installation or upgrade, you can elect to keep the DSNs when you uninstall.
Instead of creating a new DSN, you can Specify a connection string to connect with different instance URLs.
Procedure

1. In Windows, navigate to Start > Programs > Service-now ODBC > ODBC Administrator.

2. To create a system DSN, select the System DSN tab, and then click Add.
3. Select ServiceNow **ODBC driver 32-bit** from the list, and then click **Finish**.

4. Configure the driver and its connection URL by specifying the `url=` parameter value in the **Custom Properties** field. For example:
   
   `url=https://myinstance.service-now.com`

5. Click **OK**.

**Results**

You can now use the new driver.

**Specify a connection string**

You can specify a connection string instead of defining a DSN.

**Before you begin**

You must have administrator-level access for the Windows computer on which you want to specify a connection string.

**About this task**

This is an alternative method of connecting with different instance URLs. See also **Create a new DSN**.

A connection string must follow this format:

```
Driver=ServiceNow ODBC driver 32-bit;ServiceName=ServiceNow_ODBC;UID=youruser;PWD=yourpassword;ServerDataSource=ServiceNow;CustomProperties=url=https://<instance>.service-now.com
```
The driver name varies depending on whether you use the 32-bit or 64-bit version of the ODBC driver. To determine your driver name, do the following.

**Procedure**

1. In Windows, navigate to **Start > Programs > Service-now ODBC > ODBC Administrator**.
2. Select the **System DSN** tab.
3. Note the value in the **Driver** column for the ServiceNow data source.

**Configure the logging level of the ODBC driver**

Change the logging level of the ODBC driver.

**Before you begin**

You must have administrator-level access for the Windows computer on which you want to configure the logging level.

**Procedure**

1. In Windows, navigate to **Start > Programs > ServiceNow ODBC > Management Console**.
2. [ODBC version 1.0.8] Within the management console, navigate to  
   `<your_installation_directory> > Services > ServiceNow_ODBC > Service Settings > IP Parameters`.  
3. [ODBC version 1.0.8] Change the value of the **ServiceJVMOptions** attribute to the desired logging level.
4. Within the management console, navigate to `<your_installation_directory> > Services > ServiceNow_ODBC > Service Settings > Logging.

5. Change the value of the `ServiceDebugLogLevel` by selecting all available check boxes.
6. In Windows, navigate to **Start > Programs > ServiceNow ODBC > ODBC Administrator**.

7. In the ODBC Administrator, select the **Tracing** tab.

8. Navigate to the path in the **Log File Path** field and delete the old log file, if it exists.

9. Click **Start Tracing Now**.

10. Enable SOAP debugging for your ServiceNow instance.

**Related information**

- Enable debug logging
- Debug incoming SOAP envelope

**Configure the ODBC driver for large data sets**

You can set two ODBC driver properties to deal with errors you receive when using queries that return large amounts of data.
Before you begin
You must have administrator-level access for the Windows computer on which you want to configure the ODBC driver for large data sets.

About this task
These properties are set using the ODBC Management Console available on Windows operating systems. For more information, see ODBC management console properties.

Procedure
1. In Windows, navigate to Start > Programs > ServiceNow ODBC > Management Console.
2. Navigate to Data Source Settings > ServiceNow > IP Parameters.
3. Set the Timeout property to be more than the glide.soap.request_processing_timeout.odbc value.
4. Navigate to Services > Service Settings > SQL Engine Parameters.
5. Increase the ServiceSQLDiskCacheMaxSize property.
   Typically, when running a query that returns 50,000 rows, the default value of 200 must be increased.

Configure ODBC to use proxy servers
The ODBC driver can be configured to route its HTTP SOAP requests via an HTTP proxy server.

Before you begin
You must have administrator-level access for the Windows computer on which you want to configure ODBC to use proxy servers.

About this task
Setting up a proxy server gives you the option to control access to the ServiceNow instance from the proxy server, and potentially allows a network configuration that can monitor usage statistics. However, because the proxy server intercepts the ODBC driver's requests to your ServiceNow instance, it will degrade the performance of the driver.

Note: This feature is recommended for use with ODBC driver builds dated 7/15/2011 or later.

To enable the use of proxy servers, the custom properties for proxy server settings must be defined first for the data source. After that, these properties can be overridden by specific ODBC DSNs.
Procedure

1. In Windows, navigate to **Start > Programs > ServiceNow ODBC > Management Console**.

2. Expand the Console Root tree to: **ServiceNow ODBC Manager\Manager \<installation location>\Services\ServiceNow_ODBC\Data Source Settings \ServiceNow\IP Parameters**.

3. Double-click the **DataSourceIpCustomProperties** attribute.

4. Set the following custom properties to configure the ODBC proxy server.

   **Configure ODBC to use proxy servers**

<table>
<thead>
<tr>
<th>Property name</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>proxy_host</td>
<td>The proxy server host name or IP address.</td>
<td>proxy.company.com</td>
</tr>
<tr>
<td>proxy_port</td>
<td>The proxy server port number.</td>

### Setting ODBC properties

The following properties customize connectivity and optimize the query behavior of the ODBC driver.

### ODBC administrator properties

These properties are specified in the ODBC Data Source Administrator for the DSN or in the **Custom Properties** field of the login dialog box.

### ODBC administrator properties

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>BatchSize</td>
<td>During fetching of results from the instance, this batch size configures the number of records to fetch for every request. Typically, the default is an optimal number for normal sized rows. If an error occurs during fetching of records that indicates this value should be lowered, you can modify it to optimize memory usage versus performance.</td>
<td>2000</td>
</tr>
<tr>
<td>url</td>
<td>This is the ServiceNow instance URL or endpoint. It should indicate the URL to the ServiceNow instance you want to connect to.</td>
<td><a href="https://demo.service-now.com">https://demo.service-now.com</a></td>
</tr>
<tr>
<td>EnablePassThrough</td>
<td>During processing of aggregate functions, enabling pass through mode allows directly calling Aggregate Web Service for optimized and speedy response. Whenever possible, this mode should be left enabled.</td>
<td>true</td>
</tr>
<tr>
<td>Property Name</td>
<td>Description</td>
<td>Default</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------</td>
<td>---------</td>
</tr>
<tr>
<td>debug</td>
<td>By default, debugging messages are not produced. Set <code>debug</code> to <code>true</code> when you operate the ODBC driver from the ISQL console window to write all HTTP-related network communication traffic to the console window. When using this option, set <code>gzip</code> to <code>false</code> so that data is not compressed. Otherwise, the data is unreadable.</td>
<td><code>false</code></td>
</tr>
<tr>
<td>gzip</td>
<td>By default, data sent over the network is compressed. Set <code>gzip</code> to <code>false</code> when using the <code>debug</code> parameter to write network communication to the ISQL console so that data is not compressed.</td>
<td><code>true</code></td>
</tr>
<tr>
<td>timeout</td>
<td>Specifies the socket inactivity timeout value in seconds.</td>
<td><code>175</code></td>
</tr>
<tr>
<td>retries</td>
<td>Number of times to retry the failing request in the event of a socket timeout error.</td>
<td><code>0</code></td>
</tr>
<tr>
<td>mode</td>
<td>The query mode used to parse complex where clauses. You can configure the ODBC driver query mode to use either AND or OR operators. While the OR operator provides the greatest compatibility with complex queries, the AND operator is usually more efficient and results in fewer database operations.</td>
<td><code>or</code></td>
</tr>
<tr>
<td>EnableDBSchema</td>
<td>The ODBC driver issues a database schema request to retrieve table names from the instance. This functionality is enabled by default so reporting applications such as Microsoft Excel can display a list</td>
<td><code>true</code></td>
</tr>
</tbody>
</table>
### ODBC administrator properties (continued)

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>of tables to query from. Disabling this property may improve the performance of the first query sent from a reporting application, especially if the instance has a large number of tables.</td>
<td></td>
</tr>
<tr>
<td>ExtendedSchemaCache</td>
<td>The ODBC driver caches the database schema for each connection. When a new connection is created, the driver clears the database cache and queries the database schema from the instance again. This behavior is beneficial when connecting to different data source, or when modifying the table schema. When querying a single data source with a consistent schema, enable this property to avoid sending unnecessary schema requests, including when <code>EnableDBSchema</code> is <code>true</code>.</td>
<td>false</td>
</tr>
<tr>
<td>LegacyDurationTimeZone</td>
<td>The ODBC driver returns timer and duration field values in the UTC timezone by default, starting with the 1.0.10 version. When this property is <code>true</code>, the ODBC driver returns timer and duration field values using the display value, as shown in the UI. This property can be used to preserve compatibility with legacy integrations that depend on the display value. See KB0583982 for details about this behavior.</td>
<td>false</td>
</tr>
</tbody>
</table>

If you need to use more than one of these properties in your connection, concatenate the settings with a semicolon (;) delimiter. For example, the
following string sets the URL to a specific instance and changes the batch size to 200 records.

`url=https://demo1234.service-now.com;BatchSize=200`

**ODBC management console properties**
You can access these properties from the ODBC Management Console available in the Windows Start menu at *ServiceNow ODBC > Management Console*.

<table>
<thead>
<tr>
<th>Property name</th>

<td>The maximum number of rows returned by a database view.</td>
<td>10000</td>
</tr>
</tbody>
</table>
Test the ODBC driver

After configuring the ODBC driver, test that the driver can connect to the base instance as the ODBC user and can query data from a target table.

Before you begin
You must have administrator-level access for the Windows computer on which you want to test the ODBC driver.

About this task
To test the connection, run the ODBC Administrator program.

Procedure
1. In Windows, navigate to Start > Programs > ServiceNow ODBC > ODBC Administrator.
   The ServiceNow ODBC data source is installed as a system data source.
2. Select the System DSN tab, and then select the ServiceNow data source.
3. Click Configure.

4. Click Test Connect in the ODBC driver Setup dialog box.
5. Enter the login credentials.

These are the usual ServiceNow base system login credentials for the ODBC user you created.
6. Click **OK** to log in to the data source.

7. Click **OK** again when the success message appears.

**Related information**

Configure the ODBC driver

**Enable debug logging**

If you experience unexpected behavior when using the ODBC driver, you can enable debug logging and generate debug logs to help identify the issue.

**About this task**

Debug logs can be useful when submitting an incident with Customer Service and Support.

When you enable debug logging, note the version and bitness (32 bit or 64 bit) of the installed ODBC driver, the Windows operating system, and the client application you are using with the ODBC driver.

To generate debug logs, follow these steps.
Procedure

1. Close all active applications that may use the ODBC driver.
2. Navigate to one of these paths, based on your operating system.
   - For Windows 7: C:\Users\<user_name>\AppData\Local\ServiceNow\odbc\logging
   - For Windows XP and earlier: C:\Program Files\ServiceNow\ODBC\%LOCALAPPDATA\ServiceNow\odbc\logging
3. Delete any existing log data to ensure that you log only relevant information.
4. Run a query that produces the unexpected behavior, then immediately close the application and review the log files.

Related information

Configure the logging level of the ODBC driver

Test a query

To verify that the user has the appropriate permissions to send requests to the instance using ODBC, run a query using Interactive SQL.

About this task

For testing, use a query that returns exactly one record, such as a query using the **Number** value of a record.

Procedure

1. In the base system instance, navigate to **Incident > All**.
2. Record the **Number** of an incident record.
3. On the computer where the ODBC driver is installed, navigate to **Start > Programs > ServiceNow ODBC > Interactive SQL**.
4. Enter connect "odbc.user"**"password"@ServiceNow and press Enter.
5. Enter the following text, substituting the incident number you recorded.
   ```sql
   select short_description from incident where number='<incident number>';
   ```
6. Press Enter.

Results

The instance should respond with the short description of the incident record.

ODBC troubleshooting

Review these troubleshooting resources to resolve issues with the ODBC driver.
For troubleshooting information, see the Knowledge Base articles troubleshooting ODBC driver issues and troubleshooting common ODBC error messages.

**Related information**
- Getting started with ODBC
- Create an ODBC user account and assign the odbc role
- Define an ACL rule for the odbc role
- Configure the ODBC driver
- Test the ODBC driver

**ODBC behavior**
After testing the ODBC driver you can use it to query your instance database from a variety of client applications.

**ODBC aggregate functions**
The ODBC driver attempts to download data and apply aggregate functions locally. The ODBC driver supports the following aggregate functions.

- COUNT
- SUM
- MIN
- MAX
- AVG

Activate the Aggregate Web Service plugin to improve the performance of aggregate queries through the ODBC driver.

**ODBC date and time values**
The instance and the machine on which the ODBC driver is installed may use two different time zones. Date and time values returned by the ODBC driver are in the local time zone of the application using the driver, not the ServiceNow instance time zone.

Ensure that you query in accurate time zones for both the instance and the machine that hosts the ODBC driver. GlideRecord performs filtering based on the instance time zone, and the ODBC client is filtered based on the Windows time zone.
For example, an instance is in Central Standard Time (CST), and the ODBC driver is installed on a machine that is in Pacific Standard Time (PST). An incident is created on the instance at 2014-05-20 10:00:00, and the time that the incident was created is displayed in the UI as 10:00:00 for users in both time zones. However, in order to successfully query this incident by creation date and time, a user on the machine in PST must query 2014-05-20 08:00:00 instead of 2014-05-20 10:00:00.

Duration and timer type fields are returned using the UTC timezone, starting with ODBC version 1.0.10. See KB0583982 for details about this change.

**ODBC display values**

Some examples of how to use and work with ODBC display values are shown below.

- **Display values in Choice and Reference columns:**

  When querying a column of type Choice, Reference, Duration, or Timer, an additional column with the prefix `dv_` is available that contains the display value. For example, you can select `dv_caller_id` to return the `sys_user.name` display value of the reference field from an incident record without making another request to the sys_user table.

  ```sql
  ISQL> select number, dv_caller_id, caller_id from incident;
  number  dv_caller_id  caller_id
  INC00000009  Rick Berzle  5137153cc611227c000b0d1bdcd00d006
  INC00000010  Fred Luddy  5137153cc611227c000b0d1bdcd00d006
  INC00000011  Don Goodliffe 9e31b2d1d0611227d000b0d1bdcd00d006
  INC00000012  Don Goodliffe 9e31b2d1d0611227d000b0d1bdcd00d006
  INC00000013  Joe Employee 681c1c960a8016400b98a06818d57c7
  INC00000014  Bow Ruggeri f2982d2d2c611227d0105c6be7f1548c8
  INC00000015  Fred Luddy  5137153cc611227c000b0d1bdcd00d006
  INC00000016  Bow Ruggeri f2982d2d2c611227d0105c6be7f1548c8
  INC00000017  Joe Employee 681c1c960a8016400b98a06818d57c7
  INC00000018  Taylor Uveland 46b3a1e3d0a9e1f9810005f2994799b8f8
  INC00000019  Fred Luddy  5137153cc611227c000b0d1bdcd00d006
  ```

- **Display values in filter conditions:**

  Display values can also be used in a filter condition. The ODBC driver optimizes the query condition and processes the filter on the server, for example, querying on the display value of `sys_user` for the `caller_id` field of an incident by using the `dv_caller_id` field name.

  ```sql
  ISQL> select number, dv_caller_id, caller_id from incident where dv_caller_id = 'Fred Luddy';
  number  dv_caller_id  caller_id
  INC00000010  Fred Luddy  5137153cc611227c000b0d1bdcd00d006
  ```

- **Display values in aggregate queries:**

© 2021 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
Aggregate queries can also take advantage of display values if you specify them in the group by or where clause, for example, grouping on the `caller_id` field of an incident, as well as specifying a filter for it. The query is optimized by passing through to the server.

**Display values in aggregate queries**

![SQL Query Example]

```sql
SELECT COUNT(*) AS dv_caller_id FROM incident WHERE dv_caller_id IS NOT NULL GROUP BY dv_caller_id;
```

**Querying table and column names**

You can get a list of accessible tables and columns based on the read ACLs for the querying user.

- The following query will return the names of all tables for which the querying user has read access:

  ```sql
  SELECT * FROM oa_tables;
  ```

- After you know the name of the table you want to query, you can query the names of all columns for which the user has read access. The querying user must have read access for both the table and the columns.

  ```sql
  SELECT * FROM oa_columns WHERE table_name = 'table_name';
  ```

**Note:** The `oa_tables` and `oa_columns` tables are internal ODBC tables. These tables are accessible only via the ODBC driver.

**Increase the field length in SQL queries**

The ODBC driver limits the field length in SQL queries to the maximum length defined by the ServiceNow dictionary entry. You can increase the maximum field length to avoid truncating data.

**Before you begin**

Role required: admin
About this task
If the data coming from the ODBC source exceeds the field size of the dictionary entry, ServiceNow truncates the query output to fit the field size. If your data is truncated, you can do the following.

Procedure
1. Increase the maximum length in the dictionary entry for the field in question.
2. Reconnect the ODBC driver to pick up the change.

Note: By default, the ODBC driver uses the VARCHAR data type to store query string output. When strings become very large (roughly 16000 characters), the ODBC driver uses the LONGVARCHAR data type instead. It is important to keep in mind, however, that the LONGVARCHAR data type has a more limited set of SQL commands that can be executed on it. For example, it does not support queries using scalar data.

Related information
Modify dictionary entries
Use Interactive SQL with ODBC

ODBC and client applications
See the following pages for examples of how to use the ODBC driver to create data sources from other applications.

Use Interactive SQL with ODBC
Run the Interactive SQL application for quick verification of connectivity and to test query results without using a full application.

Procedure
1. In Windows, navigate to Start > Programs > ServiceNow ODBC > Interactive SQL (ODBC).
2. Enter the following command to connect to the base instance. Select the appropriate user credentials in the format: ID*password@DSNName. The password cannot contain special characters.

CONNECT odbcuser*password@ServiceNow
3. Issue a `SELECT` SQL command, such as:

```sql
SELECT NUMBER, short_description FROM incident;
```

Make sure to include the semicolon at the end of your query statement. You will be presented with a `Cont>` prompt otherwise.

Specify the maximum number of rows returned

By default, ServiceNow only returns 100 rows of data with each iSQL query. If you need to return more rows of data, set the `maxrows` parameter for the iSQL session.

To return all rows set `maxrows` to zero:

```
maxrows 0
```

To return more than 100 rows set `maxrows` to a higher value. For example, to return 500 rows:

```
maxrows 500
```
Note: If running the Interactive SQL console from a shortcut, you must modify the shortcut Target to include the `-maxrows` parameter with the desired value.

SQL support
The ODBC driver embeds a third party SQL/ODBC engine from DataDirect, a division of Progress Software.

See the DataDirect SQL Reference for information on proper SQL syntax.

Note: The ServiceNow ODBC driver only supports `SELECT` statements. The driver ignores other SQL statements such as `CREATE` and `ALTER`.

ODBC driver in SQL Server
Use the ServiceNow ODBC driver in SQL Server as a Linked Server.
Using the ODBC driver in SQL Server as a Linked Server allows SQL Server to query tables from a ServiceNow instance directly via the ODBC driver. Only use the procedures described with SQL Server 2008 and 2012. Other versions of SQL Server may cause unexpected behavior. If you encounter unexpected behavior, refer to the troubleshooting linked server Knowledge Base article.

**Required Permissions**
Additional information on the required permissions for SQL Server Linked Servers can be found on the MSDN blog.

⚠️ **Note:** Review this information if you encounter permission errors with SQL Server.

**ODBC SQL Server video tutorials**
Watch video tutorials about configuring and troubleshooting the ODBC driver with a SQL Linked Server.

**Configuring Microsoft SQL Linked Server with the ODBC driver**
Configuring Microsoft SQL Linked Server with the ODBC driver

**Troubleshooting Microsoft SQL Linked Server permissions**
Troubleshooting Microsoft SQL Linked Server permissions

**Configure SQL Server**
The following example configuration was performed on SQL Server 2008, installed on Windows Server 2008.

**Before you begin**
The ODBC driver must be installed on the same computer on which SQL Server is installed.

**Procedure**
1. Right-click the SQL Server Management Studio application and select Run as Administrator.
2. Log in to the database to which you want to link.
3. Right-click Server Objects > Linked Servers.
4. Click New Linked Server.
5. Enter the following values in the dialog.
   - Linked server: SERVICENOW. This is the name of the Linked Server.
   - Provider: Microsoft OLE DB Provider for ODBC drivers
• Product name: ServiceNow. This is an identifier. Enter any value that is appropriate.

• Data source: ServiceNow. This is the name of your DSN.

6. Select **Security** from the Select a page list, and then enter the following security values:

a. For a login connection, select **Be made using this security context**.

b. Enter the user name and password for connecting to the ServiceNow instance.

c. Click **OK**.
7. Navigate to Server Objects > Linked Server > Providers and double-click Microsoft OLE DB Provider for ODBC drivers.

8. Select the following options.

- Nested Queries
- Level zero only
- Support 'Like' operator

**Tip:**

ServiceNow recommends running the third-party provider in the out-of-process mode setting (AllowInProcess=FALSE). If you run the provider in-process (within the same process as SQL Server), then any issues with the provider can affect the SQL Server process, which in turn could result in crashing SQL server.
9. Test your connection by selecting the newly created linked server SERVICENOW and selecting **Test connection**.
10. Execute the following query in a query builder window to retrieve some results.

```sql
SELECT * FROM OPENQUERY (SERVICENOW, 'select Cast(sys_mod_count as Decimal(38,0)), number, short_description from incident') 
```

### What to do next

**Number Precision Errors**

You may encounter precision errors querying for decimal or number field values using the `OPENQUERY` syntax with the ODBC driver. In this case, use the `Cast` syntax to convert the precision. For example:

```sql
SELECT * FROM OPENQUERY (SERVICENOW, 'select Cast(sys_mod_count as Decimal(38,0)), number, short_description from incident')
```

### SQL Server Connection String

To use the ODBC driver directly in SQL Server 2008, specify the connection string in the following format.

```
Dsn=ServiceNow;uid=username;pwd=password
```

**Note:** The latest SQL Server 2008 patches are required for the ability to specify a connection string in the user interface, via the SQL import wizard.

### Using sp_addlinkedserver

The following example creates a linked server named "ServiceNow ODBC" that uses the Microsoft OLE DB Provider for ODBC (MSDASQL) and the data_source parameter.
EXEC sp_addlinkedserver
    @server = N 'ServiceNow ODBC' ,
    @srvproduct = N '' ,
    @provider = N 'MSDASQL' ,
    @datasrc = N 'ServiceNow';
GO

After creating the linked server, you must update its properties to specify the login credentials.

**Use the ODBC driver in Excel**

After installing the ODBC driver and its associated DSN, use it in Excel as a data source provider.

**Procedure**

1. In Excel open the **Data** tab.
2. Under **From Other Sources** open **From Microsoft Query**.
3. Select **ServiceNow** as your database (the default DSN name).
4. Clear the **Use the Query Wizard to create/edit queries** check box.
5. Supply the ServiceNow user name and password.

6. Select a table from the ServiceNow instance and click Add.
7. Close the dialog box.

8. Select the table columns from which the Query Builder will retrieve data. Use the list above the table, or type the names directly into the columns, and then press Enter.

9. To retrieve the data and create the Excel record, click the Return Data icon or select File > Return Data to Microsoft Office Excel.
The requested data is brought into Excel.

Use the ODBC driver in Crystal Reports

After installing the ODBC driver and its associated DSN, use it in Crystal Reports as
da data source provider.

About this task

>Note: Crystal Reports includes the configuration file CRConfig.xml that
contains the JVM minimum heap size (Xms) and maximum heap size (Xmx)
values. When configuring the ODBC driver with Crystal Reports, ensure that
the ODBC driver uses the same minimum and maximum JVM heap size
as Crystal Reports. If these values do not match, update the ODBC driver
design settings, not the Crystal Reports settings.
Procedure

2. Create a new connection using the ServiceNow DSN.
3. Select a table from the list of available tables.

4. Select the available fields from the selected table.
5. Click **Finish** to render the report.

Domain separation and ODBC driver

This is an overview of domain separation and ODBC drivers. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

**Support level: Basic**

- There is business logic to ensure data goes into the proper domain for the application’s service provider use cases.
- In the application, the user interface, cache keys, reporting, rollups, aggregations, and so on, all consider domain at run time.
- The owner of the instance needs to be able to set up the application to function normally across multiple tenants.

**Use case:** As a service provider when I use chat to respond to a tenant-customer’s message, the client must be able to see my response.

**Related information**

Domain separation for service providers
Domain separation and Web Services

Domain separation is supported in Web Services. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

Support level: Standard*

The support level is Standard but has some exceptions or special conditions.

- Includes Basic level
- Business logic: The service provider (SP) creates or modifies processes per customer. The use cases reflect proper use of the application by multiple SP customers in a single instance.
- The instance owner must be able to configure minimum viable product (MVP) business logic and data parameters. This configuration is done per tenant, as expected for the specific application.

Sample use case: An admin must be able to make comments required when a record closes for one tenant, but not for another.

For more information on support levels, see Application support for domain separation.
