Now Platform App Engine

The Now Platform® App Engine provides a single mobile and web application development platform to build business applications and extend existing apps that power your digital transformation.

Build with no code or pro code

- ServiceNow Studio
- Automated Test Framework
- Web Services
- Scripts

Build or extend apps to accelerate your business

With the Now Platform capabilities as your foundation, developers of all levels can reduce time to market and speed up delivery. You get full-stack development power with an application structure that is set up in the base system.

View and download the full infocard for a highlight of Now Platform App Engine features.

Build new apps fast

Turn business processes into digital workflows to deliver faster, smarter experiences. Build new apps with no-code development tools.
### Extend your ServiceNow apps

Extend apps using a shared code set. You can build business apps from scratch or extend base system ServiceNow applications—all on one platform.

### Turn anyone into a developer

From no-code to pro-code, enable anyone to innovate with a full stack of developer tools. Develop faster with application templates and reusable components.

### Integrate everything

Quickly connect your systems and apps. The Now Platform provides a rich set of APIs and tools for integrating with virtually any service or third-party app.

## Build new apps fast

Use base system solutions like Guided Application Creator to quickly build an app to automate a manual process. Get straight to work using standard tools and technologies, such as JavaScript and Angular, or use a no-code or low-code solution to get started quickly. The Now Platform comes with intuitive graphical tools that make app design easy even if you’ve never built an app before. And when you’re ready to grow the power of your custom apps even further, it’s easy to add new business logic with the ServiceNow development framework.

© 2021 ServiceNow, Inc. All rights reserved. ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
Extend your ServiceNow apps

Custom apps enable you to extend the services you offer. For example, when using ServiceNow HR, instead of using email to handle time-off requests, build an easy-to-access and easy-to-use custom application on the Now Platform UI to capture this information as an extension of your ServiceNow HR solution.

Turn anyone into a developer

If your organization has pent-up demand for custom applications across business teams, you can delegate certain capabilities to business stakeholders and analysts and work together to build apps that meet specific business needs.
Building your custom applications on the Now Platform centralizes activities and data on a single system of record, which helps to break down data silos and unlock insights across the enterprise.

**Integrate everything**

![REST API Explorer](image)

When your project does require the full power of coding for more complex workflow designs, integrations, or user experiences, use Now Platform to get straight to work. Write custom code using standard tools such as JavaScript and Angular, all within an integrated development environment. The Now Platform APIs, integration tools, and analytics capabilities help you address business problems faster by integrating valuable resources inside and outside the enterprise.

**Get started**

- Access developer trainings, connect with the developer community, and explore a personal developer instance through the ServiceNow® Developer Site.
- Sign up for the ServiceNow Application Development Fundamentals course to learn to design, build, test, and deploy an application.
- Connect, collaborate, and get answers on the Now Community by visiting the Developer forum.
Applications and features

- App Engine Studio
- Automated Test Framework (ATF)
- Custom components
- Delegated development
- Guided Application Creator
- JavaScript API reference
- REST API reference
- Scripts
- ServiceNow application repository
- ServiceNow Extensions for Visual Studio Code
- ServiceNow Studio
- Service Creator
- System update sets
- Team Development
- UI Builder
- Web services
- Developer guides

Creating applications

Develop an application in the Now Platform that can help your organization store information and manage business processes.

Basic application development process

<table>
<thead>
<tr>
<th>Process</th>
<th>Description</th>
<th>Recommended tools</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Define business requirements.</td>
<td>Create business requirements and track their progress. Your requirements should answer questions such as:</td>
<td>- Project Portfolio Suite</td>
</tr>
<tr>
<td></td>
<td>• What does the application need to do?</td>
<td>- Visual Task Boards</td>
</tr>
<tr>
<td></td>
<td>• Who will use it?</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• How will you know if it works?</td>
<td></td>
</tr>
<tr>
<td>Process</td>
<td>Description</td>
<td>Recommended tools</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
<td>-------------------</td>
</tr>
</tbody>
</table>
| 2. Define the data model. | Identify what information the application needs to track.  
- What information needs to be captured as a record?  
- What references are there between records?  
- Are there any existing tables you can extend? | ServiceNow Studio |
| 3. Build the application. | Create application and configuration records.  
1. Create a custom application record and set the application scope.  
2. Create an application data table to store application-specific data.  
3. Design the user interface, such as how it appears in the Now Platform, an application workspace, or the ServiceNow mobile app.  
4. Set application access settings to permit or restrict other applications from accessing application data.  
5. Add business logic and automation to meet your business requirements.  
Support multiple developers working on the application.  
- Push the application to other instances in the team development environment.  
- Link the application to a Git repository to save and manage multiple versions. | Guided Application Creator  
ServiceNow Studio  
Flow Designer  
Team Development |
Basic application development process (continued)

<table>
<thead>
<tr>
<th>Process</th>
<th>Description</th>
<th>Recommended tools</th>
</tr>
</thead>
</table>
| 4. Test the application.     | Verify the application meets your business requirements. Your testing should cover:  
• Record operations such as create, read, update, and delete.  
• User interface elements such as views and UI policies.  
• Runtime operations such as business rules and event script actions. | • Project Portfolio Suite  
• Visual Task Boards                                                                 |  
| Share the application.       | Share the completed application with others.  
• Publish the application to the ServiceNow application repository to share it with other instances assigned to the same company.  
• Publish the application to the ServiceNow Store to share it with everyone.  
• Publish the application as an Update Set to comply with a change management or backup policy. | • ServiceNow application repository  
• System update sets  
• ServiceNow Studio                                                                 |  

For more information, see Application sharing.

Watch this 11-minute video to learn more about defining business requirements for an app on the Now Platform. Sets the use case scenario for the Builder video series and answers questions to define business requirements for an app on the Now Platform.

Watch this seven-minute video to learn about steps that are irreversible in the app-building process. Explains steps that are irreversible in the app-building process, so that you can make informed decisions that will facilitate maintenance of your app going forward.

Parts of an application

Applications consist of several types of files and records that collectively deliver a service.
Custom application record

The custom application record defines and identifies an application and all its associated artifacts.

It is similar to a system dictionary record for a table or column in that it stores the most current configuration of an application. The system automatically creates a custom application record during the application creation process. Application developers can use this record to perform the following tasks.

- Change the application name
- Change the application version
- View the scope the system uses to identify application files and configuration records
- Enable scoped administration
- Manage design and runtime access to the application
  - Select what JavaScript standards the application supports
  - Select how the system tracks runtime API operations
  - Permit or restrict access to tables from other applications
• Monitor or enforce subscriptions
• Select the default menu in which to display application modules
• Set the user role required to access the application
• Add or update a logo
• View all application files
• View resources from other applications on which the application depends
• View the run-time resource to which the application has been granted access
• View the design-time resources to which the application has been granted access

**Application versions**

Each installed application has a version as defined by its application developer in the custom application record.

The system uses this version information to determine whether there are updates available from the ServiceNow application repository or ServiceNow Store.

**Application scope**

Application scoping protects applications by identifying and restricting access to application files and data.

Administrators can specify what parts of an application are accessible to other applications from:

• The Custom application record
• Each application Table record

For example, suppose that you create a conference room booking application in its own application scope. By default, the application can access and change its own tables and business logic but other applications can't unless you give them explicit permission. The application scope ensures:

• The conference room booking application does not interrupt core business services.
• Other applications do not interfere with its normal functioning.

By default, all custom applications have a private scope that uniquely identifies them and their associated artifacts with a namespace identifier. The application scope prevents naming conflicts and allows the contextual development
environment to determine what changes, if any, are permitted. Application developers specify an application scope when they create an application.

**Tip:** Global apps can alter data that you don’t intend to alter. You should leverage scoped apps to create new tables, and consider transitioning old ones to scoped apps. This allows you to split responsibilities with Delegated Development. To learn more about delegated development, see Delegated development and deployment.

Selecting the **Can Edit Application in Studio** option does not affect any custom or global applications in development on an instance. If you are the owner and choose to publish the application, you can restrict the development of customizations in Studio of. If you set **Can Edit Application in Studio** to false and then publish it, those who download the application to their own instances won’t be able to edit the application in Studio. But they will have access to **Source Control** features inside of Studio.

**Related information**

Runtime access to applications tables

**Global scope**

The global scope is a special application scope that identifies applications developed prior to application scoping, or applications intended to be accessible to all other global applications.

Applications in the global scope do not append a unique namespace identifier to the application name. Global applications can have naming conflicts and data collisions when developers create multiple global applications with the same name.

Since all global applications are in the same scope, they bypass scope protections. Global applications allow other global applications access to their tables to
• Read records
• Run API requests
• Create configuration records

Typically, only applications provided by ServiceNow are in the global scope, however any custom applications created before application scope was implemented are also in the global scope.

Applications in the global scope are eligible for upload to the application repository, but not to the ServiceNow Store.

Related information
- Publish an application to the application repository
- Publish an application to the ServiceNow Store

Namespace identifier
The system adds a namespace identifier to the front of application artifacts such as tables, scripts, and configuration records.

The identifier cannot be changed or removed from application artifacts to ensure that they are always associated to the proper application and that they have a unique name.

The system generates a namespace identifier from the following information:

<table>
<thead>
<tr>
<th>Elements used to generate a namespace identifier</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Element</strong></td>
</tr>
<tr>
<td>The prefix characters for a scoped application.</td>
</tr>
<tr>
<td>The instance customer prefix</td>
</tr>
<tr>
<td>(glide.appcreator.company.code)</td>
</tr>
<tr>
<td>The application ID</td>
</tr>
</tbody>
</table>
Elements used to generate a namespace identifier (continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Requirements</th>
<th>Sample Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>x_&lt;glide.appctreator.company.code&gt;_.</td>
<td>Application developers set this ID when they create the application. The system uses the application name by default.</td>
<td></td>
</tr>
</tbody>
</table>

The example values generate a namespace identifier of x_acme_book_rooms.

Namespace identifier examples

The following examples illustrate generating namespace identifiers for applications, tables, and fields.

Example namespace identifiers

<table>
<thead>
<tr>
<th>Action</th>
<th>Element generated</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Generate a namespace identifier for a private scope application called Book Rooms.</td>
<td>x_acme_book_rooms</td>
<td>This is a combination of the vendor prefix and application ID.</td>
</tr>
<tr>
<td>2. Generate a namespace identifier for a global scope application called Marketing Events.</td>
<td>None</td>
<td>The system does not generate namespace prefixes for global applications.</td>
</tr>
<tr>
<td>3. Add the conference rooms table</td>
<td>x_acme_book_rooms_conference_rooms</td>
<td>This table is in the Book Rooms scope and begins with the namespace identifier.</td>
</tr>
</tbody>
</table>

### Example namespace identifiers (continued)

<table>
<thead>
<tr>
<th>Action</th>
<th>Element generated</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>to the Book Rooms application.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>4. Add a Marketing Event table to a global</td>
<td>u_marketing_event</td>
<td>Custom tables in the global scope always use the u_ namespace identifier.</td>
</tr>
<tr>
<td>application.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>5. Select Book Rooms in the application picker</td>
<td>capacity</td>
<td>The field is in the same scope as the table so it does not have its own namespace identifier.</td>
</tr>
<tr>
<td>and add the <strong>Capacity</strong> field on the Conference</td>
<td></td>
<td>However, to dot-walk to the field in a script, you would use the full path including the</td>
</tr>
<tr>
<td>Rooms table.</td>
<td></td>
<td>table namespace identifier: x_acme_book_rooms_conference_rooms.capacity.</td>
</tr>
<tr>
<td>6. Select Book Rooms in the application picker</td>
<td>x_acme_book_rooms_theme</td>
<td>The field is in a different scope from the table so it is prefixed with the namespace id:</td>
</tr>
<tr>
<td>and add the <strong>Theme</strong> field to the Marketing Event</td>
<td></td>
<td>x_acme_book_rooms. To dot-walk to the field in a script, you would use full path including the</td>
</tr>
<tr>
<td>table.</td>
<td></td>
<td>field namespace identifier: u_marketing_event.x_acme_book_rooms_theme.</td>
</tr>
<tr>
<td>7. Select Marketing Events in the application</td>
<td>u_theme</td>
<td>Custom fields in the global scope use the u_ prefix. To dot-walk to the field in a script,</td>
</tr>
<tr>
<td>picker and</td>
<td></td>
<td>you would use u_marketing_event.u_theme.</td>
</tr>
</tbody>
</table>

**Note:** This example assumes that the Marketing Event table allows other application scopes to add fields. For more information, see Application Access Settings.
Example namespace identifiers (continued)

<table>
<thead>
<tr>
<th>Action</th>
<th>Element generated</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>add the <strong>Theme</strong> field to the Marketing Event table.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Application tables

Application developers create tables and their associated lists and forms for users to add and update records.

An application owns its tables and determines whether other applications can access resources from them. For example, the Book Rooms application can store conference room data in the Conference Rooms [x_acme_book_rooms_conference_rooms] table and permit other applications to read this data.

The system uses standard access controls to manage user access to application data. During application creation, developers can specify an application-specific user role for these access controls. They can also use application access settings to manage runtime and design time access to application tables.

⚠️ **Note:** Certain Now Platform subscriptions include custom table allotments. You can create custom tables for any purpose, up to the allotment limit in the subscription. To learn more about how your usage administrator allocates the custom tables you create to subscriptions, see Allocating your custom tables to a subscription allotment.

### Related information

- Application access settings

### User interface elements

By default, the system creates a list and form view for each table.

Application developers can configure the layout of these views to provide a basic user interface. In addition, they can also create supporting menus, modules, or UI pages to access these list and form views.

Alternatively, developers can create their own custom user interface with Service Portal or the Content Management System.
Related information

Content Management System

**Application user roles**

Application developers can create application-specific user roles to control access to application data.

Application developers can create an end-user role for the primary users of a custom application. The system automatically restricts access to application data by:

- Standard record operations on application tables are restricted to the application user role or the admin role.
  - Create
  - Read
  - Write
  - Delete
- The application menu is restricted to the application user role or the admin role.
- All application modules are restricted to the application user role or the admin role.

Application developers can create additional user roles to support the application but must manually create any associated access controls or role requirements.

**Web services integrations**

Application developers can create web services integrations to application tables.

By default, the system allows other applications to access application tables using web services integrations. Application developers can allow or restrict web services access from the table application access settings.

**Dependencies for custom applications**

Every custom application record includes a related list identifying its dependencies on other applications.
Administrators can review this list to determine whether an application poses any risk to existing processes or data. Application developers can use this list to ensure that their applications have the proper access to other applications.

Sample application dependencies

<table>
<thead>
<tr>
<th>Application Files (21)</th>
<th>Dependencies (1)</th>
<th>Cross scope privileges</th>
<th>Design Access</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dependencies</td>
<td>New</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Sample application dependencies

Application files

Application files are configuration records that allow developers to extend application functionality.

Application developers create application files when they add configuration records for application logic such as business rules, workflows, and script includes. Scoped applications do not own these tables, but they do own the records (files) within these tables. For example, adding a business rule to check for available rooms from the Conference Room table adds an application file to the Business Rule [sys_script] table. Application developers can view the complete list of application files from the custom application record.

The Application File [sys_metadata] table is the parent table for all tables that contain configuration records. It provides a series of standard fields that define the attributes for a configuration record. Tables that contain configuration records extend the Application File table. For example, the Business Rule [sys_script] table extends the Application File table.

Developers do not create application file records directly from the Application File table. Instead, they create or modify configuration records, and the system creates or modifies the associated application file record. Most configuration record tables do not display a reference field or related list for the Application File table. By default, only Applications [sys_scope] and Tables [sys_db_object] have a reference to the Application File table.

The system also tracks application file records in Update Sets. Whenever you change an application file record or its related configuration record, the system adds a corresponding record in the Customer Updates [sys_update_xml] table. The system uses a single update record, ensuring that a configuration record and its application file are kept in sync when transferring applications between
instances. To avoid collision, users are warned when they edit an application file that has been previously edited in another Update Set.

Administrators can:

- View file properties for configuration records.
- Protect application files from changes during upgrades.
- View parent-child relationships between configuration records.

Related information

Add an application file to an application

View file properties

Administrators can view the application file properties of a single record.

Procedure

1. Navigate to the form view of the configuration record. For example, navigate to System Definition > Business Rules and select a business rule for the Incident table.
2. Right-click the form header and select Show File Properties.

The Application File table provides the standard fields that define the attributes for the configuration record.

3. To return to the configuration record view, click the Show Related Record related link.
4. Navigate between a customer update record, the file properties view, and the configuration record view.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Show Related Record related link</td>
<td>Navigate to the configuration record</td>
</tr>
<tr>
<td>Show Parent Record related link</td>
<td>Navigate to the parent record of the current configuration record.</td>
</tr>
<tr>
<td>Descendants related link</td>
<td>View child configuration records, such as a field label translation.</td>
</tr>
</tbody>
</table>

**Application File form**

Use the Application File form to view relationships between applications and configuration records.
# Application File form fields

<table>
<thead>
<tr>
<th>Field</th>

</tr>
</thead>
<tbody>
<tr>
<td>Display name</td>
<td>Display name for the configuration record.</td>
</tr>
<tr>
<td>Update name</td>
<td>Unique identifier for the configuration record. This value is used to identify versions and updates of the record.</td>
</tr>
<tr>
<td>Class</td>
<td>Table that contains the configuration record.</td>
</tr>
<tr>
<td>Application</td>
<td>Application that contains the configuration record.</td>
</tr>
<tr>
<td>Protection policy</td>
<td>Policy that determines if the configuration record is protected from changes. See Protected Application Files.</td>
</tr>
<tr>
<td>Created</td>
<td>Creation date of the configuration record.</td>
</tr>
<tr>
<td>Created by</td>
<td>User who created the configuration record.</td>
</tr>
<tr>
<td>Updated</td>
<td>Last update date for the configuration record.</td>
</tr>
<tr>
<td>Updated by</td>
<td>User who last updated the configuration record.</td>
</tr>
<tr>
<td>Related Record</td>
<td>Version records for the related configuration record. A version record is created every time a user changes the related record. Use this list to compare versions of the configuration record or to revert to a previous version. See Versions.</td>
</tr>
<tr>
<td>Versions</td>
<td></td>
</tr>
<tr>
<td>Related Record</td>
<td>Local update records for the related configuration record. An update record is created for the most recent change to the related record in a given Update Set. See Update Sets.</td>
</tr>
<tr>
<td>Updates</td>
<td></td>
</tr>
</tbody>
</table>

⚠️ Note: You may find it useful to manually add an **Owned By** (owned_by) field to this form. It indicates, for each application, who in IT owns the application and is responsible for maintaining information about it. The Data Certification function uses this field to send certification tasks every quarter, or at any time interval that is configured. You can assign certification tasks to other users, but using this field limits configuration effort. To learn more about adding a field to a form, and about Data Certification, see [Using the form designer](#) and [Data Certification](#).

### Application file protection policy

A read-only protection policy prevents anyone from modifying an application file or its related record.
Some application code shipped with the ServiceNow system requires special protection. Only a ServiceNow employee can alter the protection policy and then modify the application file or its related record. A ServiceNow employee cannot edit protected files without changing the policy designation first.

To prevent customizations from being overwritten by system upgrades, the upgrade process automatically skips changes to customer-updated records. If you modify an application file or related record that is later designated as Read-only in an upgrade, the application file maintains the default protection policy of Write. You keep the existing modifications and can continue modifying the records.

⚠️ **Note:** Reverting a customized file to its baseline state causes the record to inherit the new protection policy as well. For example, a record going from a Write protection policy to a Read-only protection policy.

### Relationships between configuration records

The Application File Types table defines parent-child relationships between configuration records.

The system uses this structure to keep configuration records that normally belong together in the same application.

⚠️ **Note:** Do not modify the Application File Types table as it provides system functionality.

For example, consider the parent-child relationships for a UI policy.

- The UI policy is a child of the application table.
- UI policy actions are children of the UI policy.
- UI policy actions have a parent UI policy and a grandparent application table.
- The UI policy actions and the UI policy are all descendants of the application table.
Fix scripts

A fix script is server-side JavaScript code that you run after an application is installed or upgraded.

Include fix scripts to make changes that are necessary for the data integrity or product stability of an application.

Administrators can create, manage, and run fix scripts. Users with the script_fix_admin role can create and manage fix scripts but cannot run fix scripts.

Note: An annotation with the following message shows up when you open an existing fix script or create a new fix script.

Any customizations you make to the fix script will apply only when you manually run the script. Instance upgrades use the out of box fix script.

Create a fix script

Create fix scripts to ensure the system installs or updates an application properly.

Before you begin
Role required: script_fix_admin or admin
About this task
Use fix scripts to add, update, and delete data, including rules, scripts, and property settings.

Procedure
1. Navigate to **System Definition > Fix Scripts**.
2. Click **New**.
3. Define the fix script by completing the fields on the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a unique, descriptive name for the fix script.</td>
</tr>
<tr>
<td>Unloadable</td>
<td>Select the check box to create Customer Update [sys_update_xml] records when the fix script runs. Clear the check box to run upgrades without creating these records (default). Fix script tests enforce the Unloadable option.</td>
</tr>
<tr>
<td>Before</td>
<td>Select the check box to run the fix script before installing or upgrading the application. Clear the check box to run the fix script after (default).</td>
</tr>
<tr>
<td>Description</td>
<td>Enter a description of the fix script.</td>
</tr>
<tr>
<td>Script</td>
<td>Enter the code for the fix script.</td>
</tr>
</tbody>
</table>

4. Click **Submit**.
5. Test the fix script and make any necessary changes.

Test a fix script
Test your fix scripts to ensure they install or update applications as expected.

Before you begin
Role required: admin

About this task
Fix scripts add, update, and delete data, including rules, scripts, and property settings.

ℹ️ Note: Do not test fix scripts on production instances.
Procedure

1. Open the fix script record.
2. Review the code design to ensure that it can run more than once on the same system without causing damage. For example, you may write a fix script that adds a role to a property by default. Design the script so that it can run multiple times on the same system without overwriting the existing data, even if it is not necessary to run the script again after the initial installation.
3. Click the Run Fix Script related link.
   Tests enforce the Unloadable option.
4. Confirm how to run the script.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Proceed in Background</td>
<td>Use this option for long-running scripts, or if you do not know the expected execution time.</td>
</tr>
<tr>
<td>Proceed</td>
<td>Use this option to run the script immediately and display the results in a confirmation window.</td>
</tr>
</tbody>
</table>

5. Review the results from the Progress Workers related list, and make any necessary changes. To manually stop a running fix script:
   a. From the Progress Workers related list, select a worker in the Running State.
   b. Select the Cancel job related link.
Run fix scripts

After you transfer an application to another instance, you must manually run any necessary fix scripts.

Before you begin
Role required: admin

About this task
To run a fix script:

Procedure
1. Navigate to System Definition > Fix Scripts.
2. Edit the filter to search for your application name. For example, Application | is | Book Rooms).
3. Open the fix script record.
4. Click Run Fix Script.

Fulfillment tables

To enable a production instance to enforce entitled usage of your ServiceNow Store App, you configure the tables where only record owners or subscribed app users can make updates.

For any table that you, the developer, create or extend to support a custom application, you can specify that the table is a fulfillment table. In a fulfillment table, only a subscribed fulfiller user can perform a fulfiller action (typically, create/update/delete a not-own record).

In contrast, for a table that is not a fulfillment table, any user—e ven a user who is not subscribed—can act as a requester. The intent is to allow the usage admin to enable subscription enforcement on any production instance that implements the application.

Ownership of records in a fulfillment table

To enable the system to identify a fulfiller action, you define how to determine ownership of any record in the table. The developer of the application specifies the set of conditions that determine whether a user owns the record. For example, UserA owns a record in a task table if UserA opened the record or another resource opened the record on behalf of UserA.

For task-extended tables, time cards, and apps that require a subscription, the system sets the table as a fulfillment table by default and auto-assigns the ownership condition. For tables that you create to support your app,
you can mark the table as a fulfillment table and can specify the ownership condition (for example, use the filter `opened_by[[is][currentUser] OR [caller_id][is][currentUser]`).

System default conditions for ownership

<table>
<thead>
<tr>
<th>Action</th>
<th>Ownership condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>task extension</td>
<td>opened_by (read-only)</td>
</tr>
<tr>
<td>catalog request</td>
<td>requested_for (read-only)</td>
</tr>
<tr>
<td>other tables in apps that require a subscription</td>
<td>sys_created_by (read-only)</td>
</tr>
<tr>
<td>tables created by developer for app that requires a subscription</td>
<td>Specified by developer</td>
</tr>
</tbody>
</table>

Specify that a table is a fulfillment table

You configure a table as a fulfillment table to enable the system to prevent updates by users who are not subscribed to the app. For ServiceNow Store apps, you configure a table as a fulfillment table to enforce that fulfillment usage complies with your subscription use policy.

Before you begin
Role required: usage_admin, admin

Procedure

1. While working on a table, open the Subscription Management related list.
2. Select Fulfillment table.
3. Specify how the system determines ownership of records in the table so that both end users who own a record and subscribed fulfiller users can update the record: Specify the Ownership condition. For example, set the filter as `[opened_by][is][currentUser] OR [caller_id][is][currentUser]`.

Contextual development environment

The platform is a contextual development environment that displays the currently selected application, identifies the scope of every application artifact, and prevents any changes that violate the access settings for an application.
Application developers can use the contextual development environment to:

- Determine the application context
- View and select applications
- Enforce application version standards
- Enforce application resource throttling
- Enforce script protection policies

**Application context**

When application developers create new records, the system automatically assigns the records to the currently selected application in the application picker.

When application developers attempt to change existing records, the platform checks whether the currently selected application matches the scope of the application artifact. If they match, the application developer can save changes to the artifact. If they differ, the system makes the following changes to the user interface:

- Makes all the fields on the current record read-only.
- Displays a warning message that the application artifact belongs to another scope.

**Application access settings**

Application access settings determine whether one application can access resources from another application.

Application access settings are similar to access controls (ACLs) in that they allow you to restrict access to certain resources, but instead of restricting tables and records from users they restrict applications resources from other applications. There are several ways to set cross-scope access.

<table>
<thead>
<tr>
<th>Setting type</th>
<th>Use</th>
<th>Description</th>
<th>Access setting location</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application design and runtime</td>
<td>Your application or application script requires access to a</td>
<td>Application designers can configure the following application access settings for the entire application.</td>
<td>Access determined by the cross-scope privilege record owned</td>
</tr>
<tr>

<tr>
<td><strong>cross-scope resource.</strong></td>
<td></td>
<td>• Specify whether cross-scope tables can be selected during design-time activities. • Specify when scripts can run on cross-scope resources. • Specify what JavaScript standard the application supports.</td>
<td>by the calling application.</td>
</tr>
<tr>
<td><strong>Table design and runtime settings</strong></td>
<td>A cross-scope application or web service requires access to perform CRUD operations on a table.</td>
<td>Application developers can also configure application access settings for individual tables. • Specify whether the table is available to other application scopes. • Specify what runtime operations from other application scopes the table supports. • Specify whether the table can be selected during design-time activities. • Specify whether the table can be accessed from web services.</td>
<td>Access determined by settings on the target table.</td>
</tr>
<tr>
<td><strong>Restricted caller access privilege settings</strong></td>
<td>A cross-scope application or script requires access to your application or application resource.</td>
<td>Admin users can configure the following application access settings for an entire application scope or application resource. • Specify whether a cross-scope script can access your application scope or an application resource.</td>
<td>Access determined by the restricted caller access record owned by the target application.</td>
</tr>
</tbody>
</table>
### Setting type

<table>
<thead>
<tr>
<th>Use</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Track cross-scope requests for access to application resources.</td>
</tr>
<tr>
<td></td>
<td>• Approve or deny cross-scope requests to access application resources.</td>
</tr>
<tr>
<td>Access setting location</td>
<td></td>
</tr>
</tbody>
</table>

### Application design and runtime settings

The application design and runtime settings determine whether an application can access cross-scope resources.

### Design and Runtime fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JavaScript Mode</td>
<td>The application’s supported JavaScript standard. Select <strong>ES5 Standards Mode</strong> to support features in ECMAScript 5th edition. Select <strong>Compatibility Mode</strong> to support earlier ECMAScript editions.</td>
</tr>
<tr>
<td>Runtime Access Tracking</td>
<td>The application’s handling of script access requests to resources in other applications. Select <strong>None</strong> to authorize all access requests to cross-scope resources without logging them. Select <strong>Tracking</strong> to log and authorize all access requests to cross-scope resources. Select <strong>Enforcing</strong> to log access requests to cross-scope resources but require an administrator to authorize each request.</td>
</tr>
<tr>
<td>Restrict Table Choices</td>
<td>The availability of cross-scope tables when designing the application. Clear the option to allow the application to see tables from other application scopes. Select the option to restrict design choices to only tables in the same application.</td>
</tr>
</tbody>
</table>

### Runtime access tracking

Runtime access tracking allows administrators to manage script access to application resources by creating a list of script operations and targets that the system authorizes to run.

Runtime access tracking provides the following options:
## Runtime access tracking options

<table>
<thead>
<tr>
<th>Option</th>
<th>Tracking done</th>
<th>Authorization done</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>The system does not track runtime access requests.</td>
<td>The system does not require authorization to run access requests.</td>
<td>Application scripts can access resources from other applications as long as the table-level access settings allow it.</td>
</tr>
<tr>
<td>Tracking</td>
<td>During development, the system creates a Cross-Scope Privilege record for each runtime access request. After installation, the system no longer tracks new runtime access requests.</td>
<td>The system sets the status of the Cross-Scope Privilege record to <strong>Allowed</strong>.</td>
<td>The system runs the tracked operation as long as the table-level access settings allow it.</td>
</tr>
<tr>
<td>Enforcing</td>
<td>During development, the system creates a Cross-Scope Privilege record for each runtime access request. After installation, the system no longer tracks new runtime access requests.</td>
<td>The system sets the status of the Cross-Scope Privilege record to <strong>Requested</strong>.</td>
<td>The system blocks the tracked operation from running until an Administrator manually changes the status to <strong>Allowed</strong> and the table-level access settings allow it.</td>
</tr>
</tbody>
</table>

During development, application designers must run all of an application’s script logic to ensure the system tracks and authorizes the access requests to other applications.
Cross-scope privilege record

Runtime access tracking uses cross-scope privilege records to determine which script operations and targets the system allows to run.

The system creates cross-scope privilege records when:

• Runtime access tracking is set to **Tracking** or **Enforcing**.
• A script attempts to access another application.

Each cross-scope privilege record contains the following information.

**Cross-scope privilege fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source Scope</td>
<td>The application requesting runtime access to another application's resources.</td>
</tr>
<tr>
<td>Target Scope</td>
<td>The application whose resources are being requested.</td>
</tr>
<tr>
<td>Target Name</td>
<td>The name of the table, script include, or script object being requested.</td>
</tr>
<tr>
<td>Target Type</td>
<td>The type of request: table, script include, or script object.</td>
</tr>
<tr>
<td>Operation</td>
<td>The operation the script performs on the target. The target type determines the available operations. Tables support the read, write, create, and delete operations. Script includes and script objects only support the execute API operation.</td>
</tr>
<tr>
<td>Status</td>
<td>The authorization for this record: requested, allowed, or denied</td>
</tr>
</tbody>
</table>

Administrators can manually create cross-scope privilege records for application developers in advance to communicate which cross-scope resources they expect developers to access. For example, administrators could create these cross-scope privilege records to permit application developers access to resources from Incident Management.

**Sample cross-scope privilege records**

<table>
<thead>
<tr>
<th>Source Scope</th>
<th>Target Scope</th>
<th>Target Name</th>
<th>Operation</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>My App</td>
<td>Global</td>
<td>incident</td>
<td>Read</td>
<td>Allowed</td>
</tr>
<tr>
<td>My App</td>
<td>Global</td>
<td>incident</td>
<td>Write</td>
<td>Allowed</td>
</tr>
</tbody>
</table>
Sample cross-scope privilege records (continued)

<table>
<thead>
<tr>
<th>Source Scope</th>
<th>Target Scope</th>
<th>Target Name</th>
<th>Operation</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>My App</td>
<td>Global</td>
<td>ScopedGlideRecord</td>
<td>Execute API</td>
<td>Allowed</td>
</tr>
</tbody>
</table>

During testing, application developers should run all of their application scripting logic to ensure the system creates any necessary cross-scope privilege records. After application publication, the system only allows runtime requests to run that have a valid cross-scope privilege record.

**Note:** Table privilege granting is limited to, at most, the permissions set on the table object (sys_db_object) record. For example, granting a scope privilege to delete for table incident would not be allowed if the table object for incident did not allow Can delete scopes.

Application design access record

Administrators use application design access records to specify which other applications are available to developers during application creation.

When administrators restrict an application’s table choices, they can then create application design access records to grant developers access to the tables of selected applications.

Each application design access record contains the following information.

**Application design access fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source Scope</td>
<td>The application requesting design access to another application’s tables.</td>
</tr>
<tr>
<td>Target Package</td>
<td>The application whose tables will be available for design time access.</td>
</tr>
<tr>
<td>Application</td>
<td>The application to which this record belongs.</td>
</tr>
</tbody>
</table>

Application design access records allow administrators to have complete control of the resources available to application developers. When creating configuration records, application developers can only select tables from another application if there is an application design access record granting them access to the application. For example, administrators could create the following application design access records to grant developers access to tables from Incident Management and Problem Management.
Sample application design access records

<table>
<thead>
<tr>
<th>Source Scope</th>
<th>Target Package</th>
</tr>
</thead>
<tbody>
<tr>
<td>My App</td>
<td>Incident</td>
</tr>
<tr>
<td>My App</td>
<td>Problem Management</td>
</tr>
</tbody>
</table>

After developers create configuration records to other applications, the system displays these applications as dependencies.

**Table design and runtime settings**

The Application access fields determine whether a table is accessible to other applications during design-time or run-time operations.

**Application access fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Can read</td>
<td>Select the check box to allow script objects from other application scopes to read records stored in this table. This option offers runtime protection. For example, a script in another application can query data on this table. You must first select read access to grant any other API record operation.</td>
</tr>
<tr>
<td>Can write</td>
<td>Select the check box to allow script objects from other application scopes to modify records stored in this table. This option offers runtime protection. For example, a script in another application can modify a field value on this table. This option is available only when the Can read check box is selected. Clear the check box to prevent script objects from other application scopes from modifying data stored in this table.</td>
</tr>
<tr>
<td>Can create</td>
<td>Select the check box to allow script objects from other application scopes to create records in this table. This option offers runtime protection. For example, a script in another application can insert a new record in this table. This option is available only when the Can read check box is selected. Clear the check box to prevent script objects from other application scopes from creating records in this table.</td>
</tr>
<tr>
<td>Can delete</td>
<td>Select the check box to allow script objects from other application scopes to delete records from this table. This option offers runtime protection. For example, a script in another application can remove</td>
</tr>
</tbody>
</table>
Application access fields (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>a record from this table</td>
<td>This option is available only when the <strong>Can read</strong> check box is selected. Clear the check box to prevent script objects from other application scopes from deleting records from this table.</td>
</tr>
<tr>
<td>Allow access to this table</td>
<td>Select the check box to allow users to make inbound web service queries to this table. This option offers both design-time and runtime protection. The user performing the query must have the correct permissions to access this table, even when this check box is selected. Clear the check box to prevent users from making web service queries to this table.</td>
</tr>
<tr>
<td>via web services</td>
<td></td>
</tr>
</tbody>
</table>

Runtime access to applications tables

Runtime access determines if an API or web service call can run against an application table.

Access permissions can be set for the following access points.

Runtime access points

<table>
<thead>
<tr>
<th>Access points</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Script API</td>
<td>Any supported object or method call from the scoped system API such as a GlideRecord call.</td>
</tr>
<tr>
<td>Web services</td>
<td>Any supported web service call such as a REST, JSON, or SOAP web service.</td>
</tr>
</tbody>
</table>

The system does not prevent you from creating API or web service calls to the application tables, rather it determines if the API or web service call is allowed to run against the application table. API or web service calls that violate the access permissions for an application table produce an error. For example, making a web service call to a protected application table produces a 403 Forbidden HTTP error.

Default runtime access permissions

The default runtime access permissions apply to new application data tables.
By default, new application tables only allow read access from other application scopes.

### Default runtime access

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accessible from</td>
<td>All application scopes</td>
</tr>
<tr>
<td>Can read</td>
<td>Enabled</td>
</tr>
<tr>
<td>Can create</td>
<td>Disabled</td>
</tr>
<tr>
<td>Can update</td>
<td>Disabled</td>
</tr>
<tr>
<td>Can delete</td>
<td>Disabled</td>
</tr>
<tr>
<td>Allow access to this table via web services</td>
<td>Enabled</td>
</tr>
</tbody>
</table>

### Application access permissions for a table record

**Procedure**

1. Navigate to **System Applications > Applications**.
2. Click the button for the application type you want to edit.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Developed</td>
<td>displays applications created on this instance.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>Downloaded</td>
<td>displays applications downloaded on this instance.</td>
</tr>
</tbody>
</table>

3. Click the application name or the **Edit** button for the application you want to work on.

4. From the **Tables** related list, select the table whose access permission you want to set.

5. From the **Application Access** section, set the runtime access permissions.

6. Click **Update**.

**Example denying all runtime access to a table**

You can prevent script API and web service calls from other application scopes. Typically, this is to prevent any other application from creating or modifying data in the table. Denying access requires setting the following value in the table record.

<table>
<thead>
<tr>
<th>Denying all runtime access</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Field</strong></td>
</tr>
<tr>
<td>Accessible from</td>
</tr>
<tr>
<td>Can read</td>
</tr>
<tr>
<td>Can create</td>
</tr>
<tr>
<td>Can update</td>
</tr>
<tr>
<td>Can delete</td>
</tr>
<tr>
<td>Allow access to this table via web services</td>
</tr>
</tbody>
</table>
Limiting runtime access to this application scope only

The following diagram illustrates the effect of denying other application scopes access to application tables from script API and web service calls.

Deny all runtime access permissions to application tables

Example granting all runtime access to a table
You can permit some or all runtime script API and web service calls from other application scopes.
Granting access requires setting the following values in the table record.
Granting all runtime access

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accessible from</td>
<td>All application scopes</td>
</tr>
<tr>
<td>Can read</td>
<td>Enabled</td>
</tr>
<tr>
<td>Can create</td>
<td>Enabled</td>
</tr>
<tr>
<td>Can update</td>
<td>Enabled</td>
</tr>
<tr>
<td>Can delete</td>
<td>Enabled</td>
</tr>
<tr>
<td>Allow access to this table via web services</td>
<td>Enabled</td>
</tr>
</tbody>
</table>

Granting other application scopes all runtime access permissions

The following diagram illustrates the effect of granting access to application tables from API calls and web services in other application scopes.
Granted access to application tables

As the application developer, you can grant or deny other applications the permission to create configuration records, also known as application files, that extend the functionality of an application.

The permission applies to any platform feature that extends the functionality of an application data table such as:

- Business rules
- UI actions
- Client scripts

These access permissions protect the application data table at design-time. The system prevents you from creating configuration records by hiding the application data table as an option in the **Table** field. For example, a protected application table does not appear as an option when you create configuration records such as UI actions and client scripts.

Even when permission is granted to create configuration records, some configuration records have additional restrictions to protect application data from unwanted changes from other application scopes.
Default design access permissions

By default, new application tables prevent other application scopes from creating configuration records on application data tables. This prevents any other applications from changing the functionality of a table.

Default design-time access

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accessible from</td>
<td>All application scopes</td>
</tr>
<tr>
<td>Can read</td>
<td>Enabled</td>
</tr>
<tr>
<td>Can create</td>
<td>Disabled</td>
</tr>
<tr>
<td>Can update</td>
<td>Disabled</td>
</tr>
<tr>
<td>Can delete</td>
<td>Disabled</td>
</tr>
<tr>
<td>Allow access to this table via web services</td>
<td>Enabled</td>
</tr>
<tr>
<td>Allow configuration</td>
<td>Disabled</td>
</tr>
</tbody>
</table>

Default access permissions to configuration records

Set design-time access to application tables

Set these access permissions to protect application tables at design-time.

About this task

To set runtime access permissions:
Procedure

1. Navigate to **System Applications > My Company Applications**.
2. Click the button for the application type you want to edit.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Developed</td>
<td>displays applications created on this instance.</td>
</tr>
<tr>
<td>Downloaded</td>
<td>displays applications downloaded on this instance.</td>
</tr>
</tbody>
</table>

3. Click the application name or the **Edit** button for the application you want to work on.
4. From the Tables related list, select the table whose access permission you want to set.
5. From the Application Access section, set the design-time access permissions.
6. Click **Update**.

Related information
- Example denying all design access to a table
- Example allowing configuration records for a table

**Example denying all design access to a table**

You can prevent other application scopes from creating configuration records on application data tables.

Typically, this is to prevent any other applications from changing the functionality of a table. Denying access requires setting the following value in the table record.

Denying all design-time access

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accessible from</td>
<td>This application scope only</td>
</tr>
<tr>
<td>Can read</td>
<td>Disabled</td>
</tr>
<tr>
<td>Can create</td>
<td>Disabled</td>
</tr>
<tr>
<td>Can update</td>
<td>Disabled</td>
</tr>
</tbody>
</table>
Denying all design-time access (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Can delete</td>
<td>Disabled</td>
</tr>
<tr>
<td>Allow access to this table via web services</td>
<td>Disabled</td>
</tr>
<tr>
<td>Allow configuration</td>
<td>Disabled</td>
</tr>
</tbody>
</table>

Limiting design-time access to this application scope only

The following diagram illustrates the effect of denying other application scopes the ability to create configuration records.

Example allowing configuration records for a table

You can permit other application scopes to create configuration records on application data tables.
You can grant access to the following configuration records with these settings.

### Granting access to configuration records

<table>
<thead>
<tr>
<th>Configuration record</th>
<th>Setting required to grant access</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access controls</td>
<td>• Accessible from set to All application scopes</td>
</tr>
<tr>
<td></td>
<td>• Can read is selected</td>
</tr>
<tr>
<td>Business rules</td>
<td></td>
</tr>
<tr>
<td>Client scripts</td>
<td>• Accessible from set to All application scopes</td>
</tr>
<tr>
<td>Dictionary entry (new field only)</td>
<td>• Can read is selected</td>
</tr>
<tr>
<td>UI actions</td>
<td>• Allow configuration is selected</td>
</tr>
</tbody>
</table>

### Granting other application scopes design access permission

The following diagram illustrates the effect of granting other application scopes the ability to create configuration records.
Granting access to configuration records

Restricted caller access privilege settings

By using restricted caller access privilege settings, you can define cross-scope access to an application, application resource (such as an access control role, a business rule, a UI action, or a script include), or event. You can even use these settings to allow or deny requests for access. Restricted caller access [sys_restricted_caller_access] records track cross-scope applications or scripts that request access to an application, application resource, or event in the Now Platform.

Restricted caller access privilege settings overview

The Now Platform creates sys_restricted_caller_access records when one of these actions occurs:

- Caller access is set to **Caller Restriction** or **Caller Tracking**.
- A cross-scope script attempts to access an application resource or event.

**Note:** A system scope to target scope is an example of a cross-scope.

By using these records, you can do these tasks:

- Track cross-scope requests for access to an application resource.
- Approve or deny any cross-scope requests for access to application resources or events. For example, you can create a Restricted Caller Access record to allow access for all scope-to-scope requests.

For more information, see: Requested RCA feature
Restricted caller access privilege setting combinations
You can define various combinations of privilege settings for restricted caller access and specify whether access is allowed or restricted for each relationship. This process ensures that your application has the privileges to access the correct scope and not one you don’t want to access. You can define various combinations of the following settings:

Scope
All application resources in a selected source or target scope. To learn more about application scopes, see Application scope.

Source
A specific application resource in a selected source scope.

Target
A specific application resource in a selected target scope.

These restricted caller access privilege settings combinations include, but are not limited to following combinations:

- Scope-to-scope
- Scope-to-target
- Source-to-scope
- Source-to-target

Note: For more information about these access setting combinations and to learn how to create each combination, see Set the application scope, application resource, and event access.

Activating application restricted caller access
You can activate application restricted caller access through one of the following methods:

- Activate the Scoped Application Restricted Caller Access plugin (com.glide.scope.access.restricted_caller).
- Request the HR Service Delivery or Security Incident Response applications. By default, restricted caller access is active in these applications.

For more information, see: Activate RCA.

Activate application restricted caller access
You can activate the Scoped Application Restricted Caller Access plugin (com.glide.scope.access.restricted_caller) if you have the admin role.
Before you begin
Role required: admin

Procedure

1. Navigate to System Applications > All Available Applications > All.

2. Find the plugin using the filter criteria and search bar.

   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel. For more information, see Request a plugin.

3. Click Install, and then in the Activate Plugin dialog box, click Activate.

   Note: When domain separation and delegated admin are enabled in an instance, the administrative user must be in the global domain. Otherwise, the following error appears: Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.

Related information

List of plugins (madrid)

Define cross-scope access to an application resource
Track cross-scope requests for access to an application resource and approve or deny requests.

Before you begin
If you enable application administration for the target application, only application administrators of the target application can set access to an application. If application administration is not enabled, an admin user can set access to an application.
Role required: admin or application admin

Note: To learn about application-specific administrator roles and delegated development, see Access control rules in application administration apps and Delegated development and deployment.

Procedure

1. To define access to an application resource, navigate to the application resource record. Available application resources include the following:
   - Table
   - Script Include
2. Set the **Accessible from** field to **All application scopes**. If set to **This application scope only**, no other application scopes can access the resource.

3. Select the appropriate access level in the **Caller Access** field.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>Cross-scope calls to the resource are approved or denied based on the value of the <strong>Accessible from</strong> field.</td>
</tr>
<tr>
<td>Caller Restriction</td>
<td>Calls to the resource must be manually approved. Access requests are tracked in the Restricted Caller Access table with a status of Requested.</td>
</tr>
<tr>
<td>Caller Tracking</td>
<td>Calls to the resource are automatically approved. Calls are tracked in the Restricted Caller Access table with a status of Allowed.</td>
</tr>
</tbody>
</table>

4. Allow or deny an access request from a calling application. If a cross-scope application attempts to access a resource set to Caller Restriction, a record is created in the Restricted Caller Access table with a Requested status. An admin user or application administrator must allow or deny the request.

If a calling resource changes (such as when a business rule’s script changes), the restricted caller access record status changes to Invalidated. An admin user or application administrator must update the status to Allowed or Denied.

a. In the application record, navigate to the **Restricted Caller Access Privileges** tab.

b. In the **Status** column, set the value from **Requested** to **Allowed** or **Denied**. Once a calling script is allowed, all subsequent calls are allowed.

**Set the application scope, application resource, and event access**

Create a record in the Restricted Caller Access Privileges [sys_restricted_caller_access] table to set cross-scope resource access requests. Approve or deny requests from a source scope or source scope application resources to a target scope or to target scope application resources.

**Before you begin**

If you enable application administration for the target application, only application administrators of the target application can set access to an application. If application administration is not enabled, an admin user can set access to an application.
Role required: application admin or admin

ℹ️ Note: To learn about application-specific administrator roles and delegated development, see and .

About this task
You can set the following restricted caller access privilege settings combinations:
• Scope-to-Scope
• Scope-to-Target
• Source-to-Scope
• Source-to-Target

ℹ️ Note: In the Rome release, we have enforced that an RCA privilege record must be present in the target application to grant access to a resource. This means that the target scope must match the application scope.

Procedure
1. Navigate to System Applications > Application Restricted Caller Access.
2. On the form, fill in the fields.

Restricted Caller Access fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operation</td>
<td>Operation on the target resource.</td>
</tr>
<tr>
<td>Source</td>
<td>Record of the calling script.</td>
</tr>
<tr>
<td>Source Scope</td>
<td>Scope of the calling application.</td>
</tr>
<tr>
<td>Source Table</td>
<td>Table that contains the Source record.</td>
</tr>
<tr>
<td>Source Type</td>
<td>Type of record that is calling the application resource:</td>
</tr>
<tr>
<td></td>
<td>• ACL</td>
</tr>
<tr>
<td></td>
<td>• Business Rule</td>
</tr>
<tr>
<td></td>
<td>• Document Title</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>• GlideScopedEvaluator</td>
<td></td>
</tr>
<tr>
<td>• Inbound Email Script</td>
<td></td>
</tr>
<tr>
<td>• Orchestration RunScript Activity</td>
<td></td>
</tr>
<tr>
<td>• Service Portal Widget</td>
<td></td>
</tr>
<tr>
<td>• Scheduled Script</td>
<td></td>
</tr>
<tr>
<td>• Scope</td>
<td></td>
</tr>
<tr>
<td>• Script Include</td>
<td></td>
</tr>
<tr>

<td></td>
</tr>
</tbody>
</table>

**Note:** If a calling resource changes, the restricted caller access record status changes to **Invalidated**. If you enable application administration, only application administrators of the target application can update the status of a request.

<table>
<thead>
<tr>
<th>Target</th>
<th>Record of the requested resource.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Target Scope</td>
<td>Scope of the requested resource.</td>
</tr>
<tr>
<td>Target Table</td>
<td>Table that contains the Target record.</td>
</tr>
<tr>
<td>Target Type</td>
<td>Type of requested resource.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| Event         | • **Note:** An event is a special type of target for restricted caller access. By selecting an event in a target scope, you give a source application permission to queue an event that is registered as part of a target application. However, if you set the caller access on the event registry to None, it prevents cross-scope access calls to an event. This setting combination is a one-to-one relationship. To learn more about events, and their function, see Events.  
  
  • **Note:** If you set caller access to None on the event registry, the cross-scope access calls to an event are denied.  
  
  • Scope  
  • Table  
  • Script Include  
  
  For example, to allow access to an entire application, select **Scope**. |

**Note:** Refer to the following sections for instructions on defining each type of restricted caller access privilege setting combination.

**Scope-to-scope settings**

Allow or deny access of all application resources in a source scope to all application resources in a target scope. This setting combination is a many-to-many relationship.

Enter the following field settings for Scope-to-Scope restricted caller access.
<table>
<thead>
<tr>
<th>Field</th>
<th>Entries</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source Scope</td>
<td>Scope of the calling application that contains the source application resources.</td>
</tr>
<tr>
<td>Source Type</td>
<td>Type of record calling the application resource. To allow access from an entire application, select Scope.</td>
</tr>
<tr>
<td>Status</td>
<td>Status of the access request. Select Allowed to allow access, or select Denied to restrict access for this source-target resource relationship.</td>
</tr>
<tr>
<td>Target Scope</td>
<td>Scope of the requested resource that contains the target application resources that the source application resource requests access to.</td>
</tr>
<tr>
<td>Target Type</td>
<td>Type of requested resource. Select Scope to include all application resources in the target scope.</td>
</tr>
</tbody>
</table>

**Scope-to-target settings**

Allow or deny access of all application resources in a source scope to a specific application resource (business rule, table, script include, or event) in a target scope.

This setting combination is a many-to-one relationship. For example, you can specify that all application resources in source Scope A can access a script include in target Scope B.

Enter the following field settings for Scope-to-Target restricted caller access.

<table>
<thead>
<tr>
<th>Field</th>
<th>Entries</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source Scope</td>
<td>Scope of the calling application that contains the source application resources.</td>
</tr>
<tr>
<td>Field</td>
<td>Entries</td>
</tr>
<tr>
<td>-------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Source Type</td>
<td>Type of record calling the application resource. Select <strong>Scope</strong> to include all application resources in the source scope.</td>
</tr>
<tr>
<td>Status</td>
<td>Status of the access request. Select <strong>Allowed</strong> to allow access, or select <strong>Denied</strong> to restrict access for this source-target resource relationship.</td>
</tr>
<tr>
<td>Target Scope</td>
<td>Scope of the requested resource that contains the target application resources that the source application resource requests access to.</td>
</tr>
<tr>
<td>Target Type</td>
<td>Type of requested resource. Select the specific application resource (for example, business rule, script include, UI page, event) the source application resource requests access to.</td>
</tr>
<tr>
<td>Operation</td>
<td>Type of operation (for example, Read, Write) in the target application resource the source application resource requests access to.</td>
</tr>
</tbody>
</table>

**Source-to-scope settings**

Allow or deny access of a specific application resource in a source scope to all application resources in a target scope.

This setting combination is a one-to-many relationship. For example, you can specify that a particular business rule in source Scope A can access all application resources in target Scope B.

Enter the following field settings for Source-to-Scope restricted caller access.
<table>
<thead>
<tr>
<th>Field</th>
<th>Entries</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source Scope</td>
<td>Scope of the calling application that contains the source application resource requesting access to the target scope application resource.</td>
</tr>
<tr>
<td>Source Type</td>
<td>Type of record calling the application resource. Select the specific application resource (for example, business rule or script include) requesting access to the specified target scope application resource.</td>
</tr>
<tr>
<td>Status</td>
<td>Status of the access request. Select <strong>Allowed</strong> to allow access, or select <strong>Denied</strong> to restrict access for this source-target resource relationship.</td>
</tr>
<tr>
<td>Target Scope</td>
<td>Scope of the requested resource that contains the target application resources that the source application resource requests access to.</td>
</tr>
<tr>
<td>Target Type</td>
<td>Type of requested resource. Select <strong>Target</strong> to include all application resources in the selected target scope.</td>
</tr>
<tr>
<td>Operation</td>
<td>Type of operation (for example, Read, Write) in the target application resource the source application resource requests access to.</td>
</tr>
</tbody>
</table>

**Source-to-target settings**

Allow or deny access of a specific application resource in a source scope to a specific application resource in a target scope.

This setting combination is a one-to-one relationship. For example, you can specify that a specific business rule in source Scope A can access a specific application resource, such as a business rule, table, script include or event, in a target scope.
Enter the following field settings for Source-to-Target restricted caller access.

<table>
<thead>
<tr>
<th>Field</th>
<th>Entries</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source Scope</td>
<td>Scope of the calling application that contains the source application resources.</td>
</tr>
<tr>
<td>Source Type</td>
<td>Type of record calling the application resource. Select the specific application resource (for example, business rule, script include, or UI page) requesting access to the specified target scope application resource.</td>
</tr>
<tr>
<td>Status</td>
<td>Status of the access request. Select <strong>Allowed</strong> to allow access, or select <strong>Denied</strong> to restrict access for this source-target resource relationship.</td>
</tr>
<tr>
<td>Target Scope</td>
<td>Scope of the requested resource that contains the target application resources that the source application resource requests access to.</td>
</tr>
<tr>
<td>Target Type</td>
<td>Type of requested resource. Select the specific application resource (for example, business rule, Script Include, event) the source application resource requests access to.</td>
</tr>
</tbody>
</table>

**Requested restricted caller access (RCA)**

You can use a requested RCA to grant store apps access to protected resources in the Now Platform without the need to wait for the next family release. If you have the system admin or application admin role, you can review requested RCAs and approve and deny them.
RCAs are classified into two categories:

- Real RCA: sys_scope==target_scope
- Requested RCA: sys_scope!=target_scope

For example: A real RCA record is where the application scope and target scope match. A requested RCA is a record that is still awaiting approval for access to the target scope.

When you install an application, your scheduled jobs generate RCA records with the status of Requested in the target application for each requested RCA record that is packaged in the source application.

Note: The jobs are generated once Upgrade Summary has run.

Example of how a store app accesses a table

Let's say that a store app called HR Integrations Framework wants to access an HR Core Case table. The table is in the business rule called Find Case in the Integration Service table.

To request access, the HR Integrations Framework app requires that an RCA privilege is packaged in its own scope as follows:

- sys_scope = HR Integrations Framework
- target = HR Core Case
- status = Allowed
- target_scope = Human Resource: Core
- source = Find Case

App development example for developers

When you are developing an application, real RCAs are generated with the status of Requested when the target has a caller restriction. If the target has caller tracking, the status becomes Allowed. The developer can review and finalize all the real RCA records that are required for the application to work. For example, those RCAs with a status of Allowed.

A developer can click the Generate RCA Privileges in Current App in the related links to generate requested RCAs that are packaged in the current application. Requested RCAs are synchronized with real RCAs, which means that if a real RCA is updated or deleted, a requested RCA is updated or deleted too.

Now, the HR Integration Framework application can be packaged and installed on a customer instance.
**App installation example for administrators**

When you are installing an app on a customer’s instance, real RCAs are generated in the target application. A real RCA would have the Human Resource: Core with a status of Requested. This process is done asynchronously in a scheduled job, where some lag time can occur.

To notify the target app admin about an RCA’s pending review, messages have been added to application pages. An example is as follows:

---

**Store App backward compatibility**

If a store app is compatible and can be installed on an instance that is pre-Rome, then you must package the RCA records in their own scope with the status of Allowed.

ℹ️ **Note:** This process ensures that the store app works on all versions.

When upgrading to Rome, you can configure a one-time fix script to move RCAs in the source scope to the target scope. In Rome, if the target app already has the necessary RCA records, no RCA records are generated for the RCAs that are packaged by the source app.

---

**Application list**

The applications list allows application developers to view and select applications.

Application developers can use the applications list to open a custom application record. If the contextual development environment detects that you are editing an application artifact in another application scope, it displays a warning message you can use to switch to another application.

Administrators have the following options from the applications list.
### Sample list of applications

#### Application list options

<table>
<thead>
<tr>
<th>Tab name</th>

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
The application list displays the following information.

### Applications list

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Developed</td>
<td>Display applications created on this instance.</td>
</tr>
<tr>
<td>Downloaded</td>
<td>Display applications downloaded on this instance.</td>
</tr>
<tr>
<td>Updates</td>
<td>Display available updates for downloaded applications on this instance.</td>
</tr>
</tbody>
</table>

### Application picker

The application picker allows application developers to view and select the application where their changes apply.

The application picker is available from the system menu under the gear icon in the banner frame.

### Lists and forms in scoped applications

The current application context determines what customization and form design options are available when working with lists and forms in scoped applications.

The user interface uses visual indicators to identify a list or form in the same or different application scope.
Available layout and design actions

The system allows the following layout and design actions when working on lists or forms in custom applications.

<table>
<thead>
<tr>
<th>Action</th>
<th>Access granted</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a list view</td>
<td>Always allowed</td>
<td>This action is always available to users with access to customization.</td>
</tr>
<tr>
<td>Create a form view</td>
<td>Always allowed</td>
<td>This action is always available to users with access to customization.</td>
</tr>
<tr>
<td>Create a form section</td>
<td>Always allowed</td>
<td>This action is always available to users with access to customization.</td>
</tr>
<tr>
<td>Select fields to display in a view</td>
<td>Only allowed for sections in the view that match the current scope.</td>
<td>This restriction is independent of a user's role. Administrators cannot bypass this restriction.</td>
</tr>
<tr>
<td>Change the order of sections in a view</td>
<td>Only allowed for views that match the current scope.</td>
<td>This restriction is independent of a user's role. Administrators cannot bypass this restriction.</td>
</tr>
<tr>
<td>Select fields to display in a section</td>
<td>Only allowed for sections that match the current scope.</td>
<td>This restriction is independent of a user's role. Administrators cannot bypass this restriction.</td>
</tr>
<tr>
<td>Add or remove section columns</td>
<td>Only allowed for sections that match the current scope.</td>
<td>This restriction is independent of a user's role. Administrators cannot bypass this restriction.</td>
</tr>
<tr>
<td>Delete a form section</td>
<td>Only allowed for sections that match the current scope.</td>
<td>This restriction is independent of a user's role. Administrators cannot bypass this restriction.</td>
</tr>
<tr>
<td>Create new fields</td>
<td>Only allowed for sections that match the current scope and</td>
<td>This restriction is independent of a user's role. Administrators cannot bypass this restriction.</td>
</tr>
</tbody>
</table>
Available layout and design actions (continued)

<table>
<thead>
<tr>
<th>Action</th>
<th>Access granted</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>when the <strong>Allow configuration</strong> option is enabled.</td>
<td>role. Administrators cannot bypass this restriction.</td>
</tr>
</tbody>
</table>

Form design visual indicators

The UI displays the following visual indicators when designing forms in custom applications.

You can only edit views and sections when you are in the same application scope as the form. Editable sections display:

- Section headings with a solid color background.
- A solid line around the section.
- A control to set the number of columns.
- A **Delete this section** button.
- Grip icons beside section headings.
- Grip icons beside fields.

Views and sections in another application scope display as read only. Read-only sections have:

- Section headings with a gray background.
- A gray line around the section.
- No control to set the number of columns.
• No **Delete this section** button.
• No grip icons beside section headings.
• No grip icons beside fields.

**Visual indicators of read-only sections**

![Visual indicators of read-only sections](image)

**Default form design permissions**

By default, new application data tables have the following form design permissions.

<table>
<thead>
<tr>
<th>Default form design permissions</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Form design action</strong></td>
<td><strong>Permission setting</strong></td>
</tr>
<tr>
<td>Create new sections in tables</td>
<td>Allowed</td>
</tr>
<tr>
<td>belonging to another application scope</td>
<td></td>
</tr>
<tr>
<td>Create new fields in sections</td>
<td>By default, denied. Requires application designer to set <strong>Allow configuration</strong> for application table.</td>
</tr>
<tr>
<td>belonging to the same application scope</td>
<td></td>
</tr>
<tr>
<td>Add or remove fields from</td>
<td>Allowed</td>
</tr>
<tr>
<td>sections belonging to the same application scope</td>
<td></td>
</tr>
<tr>
<td>Change the order of fields in sections belonging to the same application scope</td>
<td>Allowed</td>
</tr>
</tbody>
</table>

### Default form design permissions (continued)

<table>
<thead>
<tr>
<th>Form design action</th>
<th>Permission setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change the order of sections belonging to the same application scope</td>
<td>Allowed</td>
</tr>
<tr>
<td>Add or remove fields from sections belonging to another application scope</td>
<td>Denied</td>
</tr>
<tr>
<td>Change the order of fields in sections belonging to another application scope</td>
<td>Denied</td>
</tr>
<tr>
<td>Change the order of sections belonging to another application scope</td>
<td>Denied</td>
</tr>
<tr>
<td>Create new fields in sections belonging to another application scope</td>
<td>Denied</td>
</tr>
</tbody>
</table>

### Layout visual indicators

The UI displays the following visual indicators when configuring the layout of a custom application’s list or form.

You can only edit fields, views, and sections when you are in the same application scope as the form. Editable sections display:

- Field selections with a white background.
- Buttons to add or remove fields.
- Save button with a blue background.
- Editable fields in the **Create new field** section.
Views and sections in another application scope display as read only. Read-only sections have:

- A warning message about the currently selected application scope and the scope of the form.
- Field selections with a gray background.
- No buttons to add or remove fields.
- Save button with a gray background.
- Read only fields in the Create new field section.
Visual indicators of read-only sections

The 'Conference Rooms' section is in the Book Rooms application, but Marketing Events is selected in your application picker. To edit this form:

- Create a new Marketing Events section
- Select an existing Marketing Events section
- Switch to Book Rooms to edit this section

Lists and forms in scoped applications
Form design visual indicators

Contextual development edit messages

The platform displays a message whenever a user attempts to edit an application artifact belonging to a different application.

Application context edit message

This message can be used to:
• Open the application to which the current configuration record belongs.
• Open the application of the currently selected application in the application picker.
• Temporarily switch to the application to which the current configuration record belongs and edit it.

ℹ️ **Note:** The system returns you to the current application context after you save or cancel out of the record.

The system also displays a message when a user attempts to configure a list or form layout while working from another application scope.

**Application context edit message for form layout or design**

The message provides a list of valid options:

• Edit the current section by temporarily switching to the application that owns it.
• Create a new section in the current application context.
• Create a new view in the current application context.

ℹ️ **Note:** The system returns you to the current application context after you save or cancel out of the record.

**Script protection policy**

Application developers can set a protection policy for script includes published as part of a custom application. The policy determines whether someone can view or edit the script include after the application is installed on their instance.

Application developers have these options to protect their custom application script includes:

<table>
<thead>
<tr>
<th>Protection policy</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>Allows anyone who installs your published application to view and modify this script include on their instance.</td>
</tr>
</tbody>
</table>
### Script include protection policy Options (continued)

<table>
<thead>
<tr>
<th>Protection policy</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select</td>
<td>Select this option to allow other application developers to customize your script include.</td>
</tr>
<tr>
<td>Read-only</td>
<td>Allows anyone who installs your published application to view this script include on their instance. Select this option to allow other application developers to see your script logic, but not to change it.</td>
</tr>
<tr>
<td>Protected</td>
<td>Prevents anyone who installs your published application to modify this script included on their instance. Select this option to prevent other application developers from changing your intellectual property.</td>
</tr>
</tbody>
</table>

### Application administration

Protect sensitive application data by using application administration to restrict how users acquire application-specific roles.

### Functions of application administration

Use application administration to:

- Prevent unauthorized users from accessing sensitive data such as financial records or personally identifiable information.
- Restrict who can assign application-specific roles such as the administrator and designated developers for the application.
- Prevent users with the system-level admin role from:
  - Assigning themselves a protected application role.
  - Assigning themselves to a group containing a protected application role.
  - Bypassing existing access controls to a protected application by creating access controls.
  - Changing the password of users who have a protected application role.
  - Impersonating a user who has a protected application role, unless the developer or administrator also has that role.
  - Inheriting a protected application role.
  - Overriding existing access controls to a protected application.
  - Running scripts that access protected application records.
Roles in application administration
You can make any role an application-specific administrator by selecting the Application Administrator check box in Role Configuration. To learn more, see Restrict access to an application. By convention, create the following roles:

### Application administration roles

<table>
<thead>
<tr>
<th>Role name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application-specific admin</td>
<td>Users with this role can assign other users to an application-specific role for that application. For example, you can create a role named my_application.admin. It should include the name of the restricted application, with a suffix of &quot;admin&quot; to indicate that it is the admin role for the application.</td>
</tr>
<tr>
<td>Application-specific developer</td>
<td>Users with this role can access the restricted application. For example, you can create a role named my_application.developer. It should include the name of the restricted application, with a suffix of &quot;developer&quot; to indicate that it is the developer role for the application. The developer role needs both application administrator and delegated development permissions to modify the application files. To learn more, see Delegated development and deployment and Delegate development and deployment permissions to personnel.</td>
</tr>
</tbody>
</table>

**Application-specific admin role**
The application-specific admin role enables a user to access a specific application, but does not grant the user any other admin rights. Assign the system-level admin role to a user before that user can do these tasks:

- Configure form and list layouts.
- Change application tables and fields.
- Assign the application-specific admin role to new users.
If you do not want a user with the application-specific admin role to have the system-level admin role:

- Do not assign the system-level admin role to the user. Assign only the application-specific admin role.
- Have the user assign themselves the application-specific developer role.

As an application-specific developer, the user can perform a subset of administrative tasks without having the system-level admin role.

⚠️ **Note:** Assign the application-specific admin role to more than one user. Then if a user with the application-specific admin role leaves the company, you are not prevented from changing the application.

### Enabling application administration and assigning application-specific roles

You can enable application administration for an application from the application record and restrict the assignment of application-specific roles from the user role record.

⚠️ **Note:** Enable application administration and assign application-specific roles after completing development of the application, but before adding application records. This practice protects sensitive data in the application records from access by unauthorized users.

The target instance must have at least one authorized user with the application-specific admin role.

- If you enable application administration for an application but do not assign the application-specific roles, no user can access the application.
- If you assign only one application-specific role, you cannot delete that role.

A warning appears if you enable application administration for an application, but no users have the application-specific admin role required to assign roles for the application. The warning reminds you to assign the application-specific roles for administrators and developers of the application.

Set the `[scoped_app_name].min_admin_account` property to require that more than one user must have the application-specific admin role. Assigning the application-specific admin role to multiple users reduces the risk of getting locked out of the scoped application. The `[scoped_app_name].min_admin_account` property has the following limitations:
If you specify an invalid value for the property, the default requirement for assigning at least one application-specific admin is enforced.

If you specify a valid value for the property, you can’t delete any application-specific admins unless you exceed the specified value. For example, if you specify a value of two and you have three application-specific admins, you can delete only one of those roles.

You can specify a value higher than the actual number of assigned application-specific admins. However, you can’t delete any application-specific admins until you exceed the specified value. For example, if you specify a value of six, but have only three application-specific admins, you can’t delete any of those roles.

For procedures, see Restrict access to an application.

Deploying applications with application administration

You must have the system-level admin role in both your developer and production instances to deploy an application protected by application administration. The process is outlined in the following steps.

1. Develop the application on a development instance.
2. Create the application-specific admin role.
3. Grant the application-specific admin role to all system-level admin users.
4. Update the application record to enable application administration and restrict access to the application.
5. Publish the application to the application repository.
6. From a production instance, install the application from the application repository.
7. As a system-level admin on the production instance, grant the application-specific admin role to the appropriate users.
8. Remove the application-specific admin role from all users with the system-level admin role.

For procedures to enable application administration and restrict the assignment of application-specific roles, see Restrict access to an application.

Training

The ServiceNow® Developer Site has training for Securing Applications.

Delegated development and deployment

Restrict access to an application

Restrict management of an application and access to that application to prevent unauthorized users from assigning administrative rights to the application or accessing sensitive information in the application records.

Before you begin

- Records required:
  - Role record to designate a role as the application-specific admin role
  - User record to assign an application-specific admin role to a user
  - Application record to enable application administration for a specific application
- Role required: admin

If an application-specific admin role does not already exist, create it before beginning this procedure. For example, you can create a role named my_application.admin that includes the name of the restricted application with the suffix "admin" to indicate that it is the admin role for the application.

Procedure

1. Navigate to System Security > Users and Groups > Roles or User Administration > Roles.
2. Open the role record for the application-specific admin role.
3. Configure the form to add the Application Administrator field.
   
   Note: The Application Administrator check box replaces the Assignable by field. By default, when you upgrade from a Jakarta or earlier release to a Kingston or later release, any role that was in the Assignable by field is defined as the application-specific admin role, and the Application Administrator check box is selected.

4. In the role record, select the Application Administrator check box, and then click Update.
6. Open the user record for the admin user.
7. On the Roles tab, add the application-specific role.
Only users with the application-specific admin role can enable application administration for an application.

**Note:** Assign the application-specific admin role to more than one user. Then, if a user with the application-specific admin role leaves the company, you are not prevented from performing changes to the application.

8. Click **Update**.

9. Log out and then log in with the application-specific admin role.

10. Navigate to **System Applications > Applications**.

11. Select the application for which you want to enable application administration.

12. In the application record, select **Application administration**.

13. Click **Update**.
   The system validates that the following requirements have been met:

   - The application has an application-specific admin role (there is at least one role with **Application Administrator** selected).
   - The current user has the application-specific admin role.

   If the validation passes, the system updates the application record. Otherwise, the system displays this error message and does not update the application record:

   Application Administration uses the 'Application Administrator' role to define what users are application administrators. None of the roles defined by this application have 'Application Administrator' enabled.

14. **Optional:** From the Related Links, you can optionally select one of the following options:

<table>
<thead>
<tr>
<th>Related Link</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Manage Developers</td>
<td>Modal that enables the application-specific admin to manage these tasks:</td>
</tr>
<tr>
<td></td>
<td>• Designate developers for the application.</td>
</tr>
<tr>
<td></td>
<td>• Make themselves a delegated developer. After the application-specific</td>
</tr>
<tr>
<td></td>
<td>admin becomes a delegated developer, the application-specific admin can</td>
</tr>
<tr>
<td></td>
<td>perform a subset of administration tasks without having the system-level</td>
</tr>
<tr>
<td></td>

<td></td>
</tr>
<tr>
<td>Modal that creates a Contained Role [sys_user_role_contains] record for the system-level admin role. This adds the application-specific admin role as a contained role of the system-level admin role.</td>
<td></td>
</tr>
</tbody>
</table>

Note: When you publish the application with this record, users with the application-specific admin role can access the application after installing it.

Access control rules in application administration apps

By default, when application administration is enabled for a scoped application, ACL rules for the scoped application are applied. If no ACL rules for the scoped application are found, global ACL rules can apply.

This behavior applies to configuration records created in tables that extend the Application File [sys_metadata] table only. You can also change the default behavior.

When no access control (ACL) rules for an application administration app are defined, global ACL rules can apply to the configuration records of the application administration apps. See Application files for more information.

To allow a table in an application administration app to inherit global ACL rules, check that the system property is true and add the table to the Application Administration ACL Inheritances table [sys_scoped_admin_acl_inheritance].

- glide.security.scoped_administration.honor_global_acl system property: If no scoped ACL rules are defined, application administration apps can inherit global ACL rules. By default, this property is enabled for new and upgraded instances.

- Application Administration ACL Inheritances [sys_scoped_admin_acl_inheritance] table: If no ACL rules for the application administration app are found, tables added to this list inherit global ACL rules. Only the administrator for the application administration app can add, remove, read the records owned by the application administration app in this configuration table.
Configure a table in an application administration app to inherit global ACL rules

To avoid duplicating global access control rules (ACLs) in your applications, you can configure application file tables in application administration apps to inherit global ACLs when no ACL rules for the scoped application are found.

**Before you begin**
Role required: admin role for the application

**Procedure**

1. Enter `sys_scoped_admin_acl_inheritance.list` in the navigation filter.

2. Click **New**.

3. In the **Table** field, select an application file table (a table that extends the Application File [sys_metadata] table) from the application administration app.
   Only the administrator for the application administration app can add/remove/read records owned by the application administration app in this configuration table.

4. Click **Submit**.
   If no ACL rules from the application administration app are found, tables added to this list inherit global ACL rules.

**Access enforcement for ServiceNow Store apps**

All production instances monitor and generate reports on usage patterns for ServiceNow Store apps. When subscription enforcement is enabled, users who are not subscribed to the app are blocked from performing fulfiller actions in the app.

**Overview**

The following actions are required to enable a production instance to enforce entitled usage of your ServiceNow Store App:

1. The usage admin at your organization uses the Subscription Management application to allocate fulfiller users to the subscription.

2. You decide on the enforcement mode, either:
• Monitor and report usage with no enforcement (default)

• In addition to monitoring and reporting usage, enforce that all usage must be by subscribed fulfiller users.

3. To enforce usage only by subscribed users, you configure the tables where only record owners or subscribed fulfiller users can make updates as fulfillment tables.

Creation restrictions across application scopes

The system restricts the creation of some configuration records when the current application scope does not match the application scope of the configuration record's target table.

Configuration record creation restrictions prevent one application from making unwanted changes to another application's data tables. These restrictions only apply when you create a configuration record whose target table belongs to another application. Configuration records that belong to the same application scope do not have these restrictions.

The system always enforces the following creation restrictions when a developer adds a configuration record belonging to another application scope.

<table>
<thead>
<tr>
<th>Configuration record type</th>
<th>Creation restrictions when target table is in another application scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access controls</td>
<td>• You can only create field-level access controls with a role-based requirement.</td>
</tr>
<tr>
<td></td>
<td>• You cannot create table-level access controls for a table in another application scope.</td>
</tr>
<tr>
<td></td>
<td>• You cannot create field-level access controls that apply to all fields.</td>
</tr>
<tr>
<td></td>
<td>• You cannot create access controls that use conditions.</td>
</tr>
<tr>
<td></td>
<td>• You cannot create access controls that use a script-based condition.</td>
</tr>
</tbody>
</table>
### Configuration record creation restrictions (continued)

</tbody>
</table>

Delegated development and deployment

Delegated development allows designated users without a system admin role to develop or deploy applications on the Now Platform.

If you have the application-specific admin role or the system-level admin role, you can delegate application development to designated developers at the application level.

Delegated deployment tasks

You can also delegate deployment tasks (application publishing, first-time installation, or update) to developers or non-admin users, such as Change Management personnel. You delegate deployment tasks to specific users at the application level, or through assignment of specific user roles at the instance level.

<table>
<thead>
<tr>
<th>Assignment Method</th>
<th>Applies to</th>
<th>Available options</th>
</tr>
</thead>
<tbody>
<tr>
<td>Setting deployment permissions in Manage Developers.</td>
<td>Specific applications</td>
<td>Publishing and upgrades of specific applications. Publishing options include the application repository, ServiceNow Store, and update sets.</td>
</tr>
<tr>
<td>See Delegate development and deployment permissions to personnel</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Assignment of deployment user roles to specific persons.</td>
<td>Local non-production instance (for example, Development or QA)</td>
<td>First-time installations and upgrades of all applications that contain the same company as the current instance. For example, applications for ABC Company and XYZ</td>
</tr>
</tbody>
</table>
### Application-specific permissions

Developer and deployment permissions are application-specific. For example, a developer who has permission to access all file types for one application does not necessarily have any developer permissions for another application. Administrators must set developer (and optionally deployment) permissions for each application. Administrators must be familiar with application files and the system table structure to set developer permissions. For example, a developer expected to create advanced business rules needs both the **All File Types** and **Allow Scripting** developer permissions.

**Important:** If Application administration is enabled, only an application administrator for the target application can delegate developers for an application. Application administrators do not have system admin privileges. To enable a delegated developer to perform the functions granted in the developer permissions, the delegated developer must also be given the application administrator role.

Setting each permission grants one or more system-managed delegated development roles, allowing system admins to retain control over the system. System admins no longer have to elevate developers (or users who deploy applications) to the system admin role to enable them to develop or deploy applications.

### Developer and deployment permissions example

As a system administrator, you want to assign Abel Tuter certain developer and deployment permissions for a specific application in your Development instance. For more details on developer and deployment permissions, see Delegate development and deployment permissions to personnel.

Delegate development and deployment permissions to personnel

A system administrator can assign a non-administrator user or group as a developer or deployment resource for a specific application. You can set permissions that designate what specific actions the assigned user can perform in the current instance.

Before you begin

- Role required: admin or application administrator

  If Application administration is enabled, only an application administrator of the target application can delegate developers to an application. If application administration is not enabled, an admin user can delegate developers.

- Records required:
  - Application
  - User
  - Group
Procedure

1. Navigate to **System Applications > My Company Applications**.

2. Click the name of the application to which you want to add developers. The system opens the application record.

3. Click **Manage Developers**.
   The system displays the Developer Permissions window.

4. Select the type of developer (or user without system admin roles) you want to assign.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Developers</td>
<td>To add individual users as developers or deployers.</td>
</tr>
<tr>
<td>Groups</td>
<td>To add all members of a group as developers or deployers.</td>
</tr>
</tbody>
</table>

5. In **Developer Name** or **Group Name**, enter the name of the user or group you want to grant developer or deployment permissions.

6. Select specific developer and deployment permissions for the application. For details, see Developer and deployment permissions.

7. Click **Save**.
   The system assigns the designated developer and deployment permissions for the application.

Developer and deployment permissions

Using Manage Developers, administrators can assign one or more developer and deployment permissions to a group or user for a specific application. These permissions designate the specific actions the assigned user can perform for the application.

For example, you might grant permissions that enable a user to upgrade the application, publish to the application repository and ServiceNow Store, but prevent publishing to an update set.

Developer permissions

<table>
<thead>
<tr>
<th>Permission</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delete Application</td>
<td>Grants the assigned developer within a scoped app rights to delete the application.</td>
</tr>
<tr>
<td>Permission</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Source Control</td>
<td>Grants the assigned developer full access source control.</td>
</tr>
<tr>
<td>All File Types</td>
<td>Grants the assigned developer access to all application file types, including some not granted by the other options. This permission is equivalent to granting the user the admin role but with some limitations. Specifically, it provides access to all file types that are configured in your application per the Manage Developers task in the Application Creator. For an example of such file types, see the permissions example in Delegated development and deployment.</td>
</tr>
<tr>
<td>Integrations</td>
<td>Grants the assigned developer access to web service APIs, REST APIs, and data sources.</td>
</tr>
<tr>
<td>Reporting</td>
<td>Grants the assigned developer access to reports and scheduled reports.</td>
</tr>
<tr>
<td>Mobile Studio</td>
<td>Grants the assigned developer access to Mobile Studio.</td>
</tr>
<tr>
<td>UI Builder</td>
<td>Grants the assigned developer access to UI Builder to create pages for experiences.</td>
</tr>
<tr>
<td>Workflow</td>
<td>Grants the assigned developer access to the Workflow Editor and Activity Creator.</td>
</tr>
<tr>
<td>Service Catalog</td>
<td>Grants the assigned developer access to catalog related file types such as catalog items, record producers, and variables.</td>
</tr>
<tr>
<td>Flow Designer</td>
<td>Grants the assigned developer access to the Flow Designer design environment to create flows and actions. Script action steps require the Allow Scripting permission.</td>
</tr>
<tr>
<td>Service Portal</td>
<td>Grants the assigned developer access to Service Portal editors and tools.</td>

<td>Grants the assigned developer the ability to invite and manage users and groups. This permission allows the delegated developer to further invite and manage other developers to the application.</td>
</tr>
<tr>
<td>Invite Collaborators</td>
<td>Grants the assigned developer the ability to invite users and groups. This permission allows the delegated developer to further invite other developers to the application.</td>
</tr>
</tbody>
</table>

**Deployment permissions**

<table>
<thead>
<tr>
<th>Permission</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Upgrade App</td>
<td>Grants a user with an assigned delegated developer role permission to upgrade the associated application after it has been installed in the current instance.</td>
</tr>
<tr>
<td>Publish To Update Set</td>
<td>Grants a user with an assigned delegated developer role permission to publish the associated application to an update set in the current instance.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Users with this permission cannot also have the <strong>Manage Update Set</strong> permission.</td>
</tr>
<tr>
<td>Publish To App Store</td>
<td>Grants a user with an assigned delegated developer role permission to publish associated application to the ServiceNow Store in the current instance.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> The <strong>Upgrade App</strong>, <strong>Publish To App Repo</strong>, and <strong>Publish To App Store</strong> permissions display by default. The <strong>Publish To Update Set</strong> permission only displays if manually enabled by a system administrator. For more details, see Display or hide update set deployment permissions.</td>
</tr>
<tr>
<td>Manage Update Set</td>
<td>Grants a user with an assigned delegated developer role permission to manage local and retrieved update sets. This permission allows users to create, update, and delete local update sets as well as preview, resolve conflicts, and commit retrieved update sets.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Users with this permission cannot also have the <strong>Publish To Update Set</strong> permission.</td>
</tr>
<tr>
<td>Permission</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Publish To App Repo</td>
<td>Grants a user with an assigned delegated developer role permission to publish the associated application to the application repository in the current instance.</td>
</tr>
<tr>
<td>Submit for Deployment</td>
<td>Grants a user with assigned delegated developer role permission to Submit the associated application for review and deployment.</td>
</tr>
</tbody>
</table>

⚠️ **Note:** The update set deployment permissions are hidden by default and require a system administrator to enable them with system properties. See Display or hide update set deployment permissions for more information.

⚠️ **Note:** The Submit for Deployment, Manage Collaborators, and Invite Collaborators delegated development permission sets are only available with the Developer Collaborator feature. They will not be shown in Manage Developers.

### Remove a developer

Removing a user as a developer prevents the user from developing, changing, or deploying the application in the current instance.

**Before you begin**

Role required: admin or application administrator

If Application administration is enabled, only an application administrator of the target application can delegate developers to an application. If application administration is not enabled, an admin user can delegate developers.

**Procedure**

1. Navigate to **System Applications > Applications**.
2. Click the application name of the application from which you are removing developers.
   - The system opens the application record.
3. Click **Manage Developers**.
   - The system displays the Developer Permissions window.
4. Point to the developer you want to remove.
   - The system displays a minus icon next to the developer name.
5. Click the minus icon next to the developer name. The system removes the developer and any associated application roles.

**Display or hide update set deployment permissions**

Display or hide deployment permissions for update sets from the Manage Developers dialog.

**Before you begin**

Role required: admin

**About this task**

System properties control the visibility of the Publish To Update Set and Manage Update Sets permissions. By default, both deployment permissions for update sets are hidden.

**Procedure**

1. In the Navigation filter, enter `sys_properties.list`

   The entire list of properties in the System Properties [sys_properties] table appears.

   **Tip:** For details on how to add and enable system properties, see Add a system property.

2. Enable or disable specific deployment permissions by adding or updating the following system properties.

**Deployment permissions**

<table>
<thead>
<tr>
<th>System property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.snc.dd.manage_update_set_enabled</td>
<td>Enables or disables display of the Manage Update Set permission.</td>
</tr>
<tr>
<td>System property</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>com.snc.dd.publish_to_app_repo_enabled</td>
<td>Enables or disables display of the <strong>Publish To App Repo</strong> permission. The default value for this system property is <strong>true</strong>. To disable display of this permission, set this value to <strong>false</strong>.</td>
</tr>
<tr>
<td>com.snc.dd.publish_to_app_store_enabled</td>
<td>Enables or disables display of the <strong>Publish To App Store</strong> permission. The default value for this system property is <strong>true</strong>. To disable display of this permission, set this value to <strong>false</strong>.</td>
</tr>
<tr>
<td>com.snc.dd.publish_to_update_set_enabled</td>
<td>Enables or disables display of the <strong>Publish To Update Set</strong> permission. The default value for this system property is <strong>false</strong> by default, which disables display of this permission. To enable the display of this permission, set this value to <strong>true</strong>.</td>
</tr>
<tr>
<td>com.snc.dd.upgrade_app_enabled</td>
<td>Enables or disables display of the <strong>Upgrade App</strong> permission. The default value for this system property is <strong>true</strong>. To disable display of this permission, set this value to <strong>false</strong>.</td>
</tr>
</tbody>
</table>
Instance-specific deployment user roles

Assign roles that enable non-admin users install or upgrade all applications in specific instances. You delegate these tasks by manually assigning specific user roles per instance.

For example, you can assign user roles to Change Management personnel that allow them to perform application installations in non-production (development or QA) instances.

**Important:** Give careful thought to whom, and in what instances you assign installation and upgrade user roles. You may only want to assign these roles to non-system administrators in non-production instances (for example, Developer or QA), but decline to do so in production instances. Given the potential impact of installing and upgrading applications, you may want to leave the responsibility for installations and upgrades in production instances to a system administrator.

Add deployment user roles

A system administrator can assign user roles to specific personnel that allow them to perform first application installations only, or install and upgrade applications in a local instance.

**Before you begin**

Role required: admin

**Procedure**

1. Navigate to User Administration > Users and then open a user record.

   ![Note](#) For details on how to assign a role to a user, refer to Assign a user role.

2. In the Roles related list, click Edit.

3. In the Collection list, select the desired deployment roles, and then click Add.

**Delegated deployment roles**

<table>
<thead>
<tr>
<th>User Role</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sn_appclient.app_client_company_installer</td>
<td>Allows a designated person to perform first-time installations of applications displayed on the Application Client page that contain the same company as the current instance. A user with this role cannot install</td>
</tr>
<tr>
<td>User Role</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td></td>
<td>an application for another company. For example, applications for ABC Company and XYZ Company display on the Application Client page. A user with this role can only install XYZ Company applications when logged in to a XYZ Company instance. The user cannot install applications for ABC Company.</td>
</tr>
<tr>
<td>sn_appclient.app_client_user</td>
<td>Allows a designated person to install and upgrade all applications displayed on the Application Client page.</td>
</tr>
</tbody>
</table>

4. Click **Save**.

**System-managed developer and deployment roles**

Although system admins can still manually assign and remove the user roles, they are encouraged to let the system manage the following delegated developer roles.
<table>
<thead>
<tr>
<th>Role</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>delegated_developer</td>
<td>User has one or more developer permissions.</td>
</tr>
<tr>
<td>Roles that start with an sn_dd prefix (for example,</td>
<td>User has an application-specific development permission. The role name indicates an application scope to which it applies. For example, after a user with a <code>sn_appclient.app_client_company_installer</code> role installs a company application, the system automatically grants a <code>sn_dd_&lt;app_name&gt;_upgrade_app</code> delegated deployment role. This role allows the user to upgrade the application when future updates are published on the Application Client page.</td>
</tr>
<tr>
<td>glide.security.add_admin_contained_roles_to_system</td>
<td>Default Value: true if the property is true, then all the roles, directly or indirectly contained by the admin role, are added to the system user, including the scoped-admin roles. <strong>Note:</strong> Setting the property to false results in the old behavior, where the system user has the admin role, but not any of the scoped-admin roles contained by the admin role. <img src="https://via.placeholder.com/15" alt="important" /> <strong>Example:</strong> The admin role contains the <code>sn_templated_snip.template_snippet_admin</code> role Old behavior: The system user does not have the <code>sn_templated_snip.template_snippet_admin</code> role. New behavior: The system user has the <code>sn_templated_snip.template_snippet_admin</code> role and other scoped roles that it contains.</td>
</tr>
</tbody>
</table>
Note: Users with delegated developer roles cannot add or remove the system admin role.

Assign source control permissions
Ability to assign full access to source control for a particular scope to a delegated developer. The Source Control menu is only visible if you have the correct permissions for the application that you are working in.

Before you begin
Role required: admin

Procedure
2. Open an application for which you want to assign delegated developer permissions.
3. As a System Admin, click File > Manager Developers.
4. Choose a developer to apply delegated developer permissions.
5. Toggle on Source Control, and then click Save.
6. The delegated developer can now access the Source Control menu options. For more information on source control options, see Available source control operations.

**Assign delete permissions**

Ability to assign the ability to delete an application to a delegated developer.

**Before you begin**

Role required: admin

**Procedure**

2. Open an application for which you want to assign delegated developer permissions.
3. As a System Admin, click File > Manager Developers.
4. Choose a developer to apply delegated developer permissions.
5. Toggle on Delete Application, and then click Save.
6. The delegated developer can now delete the application. For more information on deleting an application, see Delete an application.

Domain separation and Delegated Development

Domain separation is unsupported in the Delegated Development feature. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

Support level: No support

- The domain field may exist on data tables but there is no business logic to manage the data.
- This level is not considered domain-separated.

For more information on support levels, see Application support for domain separation.
How domain separation works with Delegated Development

Delegated Development is not a full application but rather, a feature in the Custom Business Applications suite, meaning it works alongside other features, including domain separation. Delegated development can be used in a domain environment only by the instance owner’s developers.

Related information

Domain separation for service providers

Application collaboration

With application collaboration, you can manage the permissions for the collaborators who develop a platform application. If you have the admin role, you can manage delegated development permissions to designated developers at the application level.

Collaboration descriptors

You can use the predefined collaboration descriptors that are standard with activation, or create a custom collaboration descriptor. By using a collaboration descriptor, you can assign, manage, and monitor delegated development permissions.

<table>
<thead>
<tr>
<th>Descriptors</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Owner</td>
<td>Owner of the application that manages other collaborators and can delete the application.</td>
</tr>
<tr>
<td>Editor</td>
<td>Standard descriptor to invite collaborators.</td>
</tr>
<tr>
<td>Custom</td>
<td>Non-standard (custom) descriptor created by the user.</td>
</tr>
</tbody>
</table>

Development permissions

By setting permissions, you can retain control over the system. You assign permissions to developers (or users who deploy applications) so that they can develop or deploy applications.
Development permissions

<table>
<thead>
<tr>
<th>Permissions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application Management</td>
<td>Capabilities to delete the application and version source control access.</td>
</tr>
<tr>
<td>File type Access</td>
<td>File types that the user has access to.</td>
</tr>
<tr>
<td>Security / Entitlement</td>
<td>Capabilities to manage application security.</td>
</tr>
<tr>
<td>Programming Tools</td>
<td>Capabilities for script fields access.</td>
</tr>
<tr>
<td>Deployment</td>
<td>Deployment capabilities.</td>
</tr>
</tbody>
</table>

Application collaboration users

You can assign a collaboration descriptor for an individual by creating an app collaboration user. The user can only be assigned one collaboration descriptor for any application.

Application collaboration groups

You can assign a collaboration descriptor for a group of users by creating an app collaboration group. The group can only be assigned one collaboration descriptor for any application.

Install the app collaboration application

Install the app collaboration application so that you can view the collaboration feature in the UI.

Before you begin

Download the app collaboration application so that you can view the collaboration feature.
Role required: admin

Procedure

1. Navigate to **System Applications > All Available Applications > All**.

2. Click the search icon (🔍) in the middle of the screen to search for the application collaboration application.

3. Click **Install**.
Note: If app collaboration is already installed, the Install button is inactive.

4. Click Activate.

Results
The app collaboration feature is active.

Note: After you install and activate the app collaboration plugin, all delegated developers will receive custom collaboration descriptors based on their current permissions and applications. The base system table provides standard Owner and Editor collaboration descriptors which are used in the collaboration feature.

Note: If you install this plugin without App Engine Studio (AES) for an application, you should manage the delegated development permissions with this plugin or use the old Manage Developers screen to manage the permissions. Do not use both the plugin and the Manage Developers screen to manage the delegated development permissions.

Note: To use the old Manage Developers screen, select your application and select Manage Developers in the related links on the form.

Create collaboration descriptors to assign permissions
Create descriptors in the collaboration application so that you can assign permissions to users or groups.

Before you begin
Role required: admin

About this task
Use the predefined collaboration descriptors that are standard with activation, or create a custom collaboration descriptor. Collaboration descriptors enable you to assign, manage, and monitor delegated development permissions for each application or uniformly across multiple applications. You can assign each collaborator with one collaboration descriptor for an application. However, users can have multiple collaboration descriptors simultaneously if they belong to groups where collaboration descriptors have been assigned.

Procedure
1. Navigate to App Engine > Collaboration > Descriptors.
2. Click New.
The collaboration descriptor form appears.

3. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name for the descriptor.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the descriptor that includes permissions capabilities.</td>
</tr>
<tr>
<td></td>
<td>Examples are as follows:</td>
</tr>
<tr>
<td></td>
<td>• Owner</td>
</tr>
<tr>
<td></td>
<td>• Editor</td>
</tr>
<tr>
<td>Application</td>
<td>Scope of the collaboration descriptor. An example is the application the descriptor will be used for.</td>
</tr>
<tr>
<td>Standard</td>
<td>Option for inviting other collaborators with this role.</td>
</tr>
</tbody>
</table>

4. Click Submit.

Add permissions to collaboration descriptors

Add permissions to collaboration descriptors to manage your user's capabilities, such as the ability to delete the application or manage collaborators.

Before you begin
Role required: admin

Procedure
1. Navigate to App Engine > Collaboration > Descriptors.
2. To modify the permissions, select a collaboration descriptor from the related list.
3. To view the permission's options, click Edit... in the related list.
4. To add or remove permissions to the descriptor, click the arrows.
5. Click Save and Update.
Assign collaboration descriptors to users
Assign collaboration descriptors to your users for a specific application so that you can define specific permissions for these users.

Before you begin
Role required: admin

Procedure
1. In the related list, click Application collaboration users.
2. Click New.
3. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Collaboration Application</td>
<td>Application that the user works on.</td>
</tr>
<tr>
<td>Collaboration User</td>
<td>User that works on the application.</td>
</tr>
<tr>
<td>Collaboration Descriptor</td>
<td>Descriptor for the user on this application.</td>
</tr>
</tbody>
</table>

4. Click Submit.

Assign collaboration descriptors to groups
Assign collaboration descriptors to user groups for a specific application so that you can define specific permissions for these user groups.

Before you begin
Role required: admin

Procedure
1. In the related list, click Application collaboration groups.
2. Click New.
3. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Collaboration Application</td>
<td>Application that the group will work on.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>Collaboration Group</td>
<td>Name of the collaboration group.</td>
</tr>
<tr>
<td>Collaboration Descriptor</td>
<td>Descriptor for the group on this application.</td>
</tr>
</tbody>
</table>

4. Click **Submit**.

**Application Management**

The system offers several ways to manage applications. You must have the admin role to perform these procedures.

**Application management actions**

<table>
<thead>
<tr>
<th>Action</th>

<tr>
<td>Remove an application</td>
<td>• Deactivate &lt;br&gt;• Delete &lt;br&gt;• Uninstall</td>
<td>Retire an obsolete or legacy application.</td>
</tr>
<tr>
<td>Move application files from one global application to another</td>
<td>None</td>
<td>Edit a legacy application.</td>
</tr>
</tbody>
</table>

Indicators are color coded to indicate if it is an error, warning, or info message.
- An indicator in red color, indicates that it is an error or warning message. This requires you to perform a relevant action.
- An indicator in green color, indicates that it is an info message.

### Opt in to the ServiceNow Store products

Opt in to the required product available on ServiceNow Store by navigating to the ServiceNow Products module.

**Before you begin**
Role required: admin

**Procedure**

1. **Navigate to** System Applications > All Available Applications > ServiceNow Products.  
   ServiceNow products that are available on ServiceNow Store are displayed. The products are organized based on the product family they are part of.

2. To opt in to the ServiceNow products:
   - a. On the tile of the required product, click Opt-in.
   - b. Enter your Now Support credentials.
c. Click Opt-in. A confirmation message is displayed and the Opted-in label is displayed on the product tile.

d. To view the applications that are part of the product, click the product tile. All applications that are part of the product are displayed in the Licensed and Not Licensed tabs.

Note:
- If the application is already available (that is, installed or available for update) in your ServiceNow instance, click Manage Application to navigate to the application page and install, uninstall, or repair the application.
- If the application isn’t available in your ServiceNow instance, click View Detail to navigate to the application listing page, view the application details and dependencies, and navigate to ServiceNow Store.

3. To opt in to the ServiceNow product family:

a. Click Product Family Opt-in.

b. Enter your Now Support credentials.

c. Click Opt-in. You have opted in to all product in the required family.

Manage entitlements from ServiceNow instance
Manage entitlement of applications and products from your ServiceNow instance.

Before you begin
Role required: admin

Entitle an application from ServiceNow instance
Manage entitlement of applications from your ServiceNow instance.

Before you begin
Purchase the application on ServiceNow Store.
Procedure

1. Navigate to System Applications > All Available Applications > All.

2. From the filter options, select the Instance not entitled indicator. All the purchased unentitled apps are displayed.

3. Click the menu icon (⊕) on the application tile, and click Entitle this instance.

4. In the Application entitlement dialog box, click OK.

Results
Application entitlement is provided to your ServiceNow instance.

What to do next
Install the application if it is compatible with the version of ServiceNow instance.

Entitle a product from ServiceNow instance
Manage entitlement of products from your ServiceNow instance.

Before you begin
Purchase the product on ServiceNow Store and opt in from your ServiceNow instance.

Procedure

1. Navigate to System Applications > All Available Applications > All.

2. From the filter options, select the Product not entitled indicator. All the purchased unentitled products are displayed.

3. Click the menu icon (⊕) on the product tile, and click Entitle this instance.
4. In the Application entitlement dialog box, click **OK**.

**Results**
Product entitlement is provided to your ServiceNow instance.

**What to do next**
*Install* the product if it is compatible with the version of ServiceNow instance.

**Skipped records that occur during application installation**

Some records may be skipped when you make local updates to global or scoped applications. Skipped records can occur either when you modify the metadata records in the instance to which you're deploying or when you apply an update set. Depending on the deployment model you use and the state of applicable properties, you may risk "skipped records," which are generated in the sys_upgrade_history_log. Learn what to expect on your instance when you upgrade an application using various different methods.

**General use cases**
Under most circumstances, these general use cases occur during application installation:

<table>
<thead>
<tr>
<th>Deployment type</th>
<th>Application type</th>
<th>Expected outcome</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source Control</td>
<td>Scoped</td>
<td>No skips, application loads from Source Control. If local update xml exists, you are prompted to stash those changes.</td>
</tr>
<tr>
<td>Source Control</td>
<td>Global</td>
<td>No skips, application loads from Source Control. If local update xml exists, you are prompted to stash those changes.</td>
</tr>
<tr>
<td>Deployment type</td>
<td>Application type</td>
<td>Expected outcome</td>
</tr>
<tr>
<td>-------------------------</td>
<td>--------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>xml exists, you are</td>
<td></td>
<td>prompted to stash those changes.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>App Repository</td>
<td>Scoped</td>
<td>Skipped records are generated and customizations preserved.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>App Repository</td>
<td>Global</td>
<td>Application changes applied and skipped records are generated only when a superior claim is found. Refer to Claim Outcomes to Review related list for more details.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Store</td>
<td>Scoped</td>
<td>Skipped records are generated, customization changes applied.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Source Control</td>
<td>Customization</td>
<td>No skips, customization loads from Source Control. If local update xml exists, you are prompted to stash those changes.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>App Repository</td>
<td>Customization</td>
<td>No skipped records are generated, customization changes applied.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Store/App Repository</td>
<td>Scoped and</td>
<td>No skipped records are generated unless the customization updates the base application record. In this case, a log entry of a skipped update for the base application is created.</td>
</tr>
<tr>
<td></td>
<td>Customization</td>
<td></td>
</tr>
</tbody>
</table>
Author Elective Updates

It's important to understand the purpose of the **author_elective_update** folder.

When ServiceNow packages your application for the repository or for committing to Source Control, additional elements (which might have been previously ignored), are unloaded to the **author_elective_update** folder. (These deleted elements are often referred to simply as "deletes.") When your application is installed on your own instance, the deleted files are automatically loaded from the **author_elective_update** folder.

For example, if you changed the schema of your application by deleting a table or a column, those files are tracked in the folder but are not applied by default. There are specific rules that apply to author elective updates that you can change, based on the properties you can set. This folder contains metadata deleted files, including schema changes, and choice set unloads that you can apply or ignore. Whether you apply or ignore them, and whether corresponding skipped records are generated, depends on the state of the following properties and processing flow:

<table>
<thead>
<tr>
<th>Property name</th>
<th>Behavior</th>
<th>Default</th>
<th>Used in Source Control</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.glide.apps.include_only_sys_choice</td>
<td>Loads only deleted elements and updates to sys_choice fields from author_elective_update</td>
<td>False</td>
<td>No</td>
</tr>
<tr>
<td>com.glide.apps.include_my_schema</td>
<td>Loads only deleted elements to schema files from author_elective_update. Applies to customer application installations and not third-party apps.</td>
<td>False</td>
<td>No</td>
</tr>
<tr>
<td>com.glide.apps.force_skips</td>
<td>Creates skipped records for all of author_elective_update</td>
<td>False</td>
<td>No</td>
</tr>
<tr>
<td>Property name</td>
<td>Behavior</td>
<td>Default</td>
<td>Used in Source Control</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------</td>
<td>------------------</td>
<td>------------------------</td>
</tr>
<tr>
<td>com.glide.apps.include_my_deletes</td>
<td>Process author_elective_update</td>
<td>False</td>
<td>Yes</td>
</tr>
<tr>
<td>com.glide.apps.include_global_deletes</td>
<td>Process author_elective_update for global applications</td>
<td>False</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Note:**

When there is no property for `com.glide.apps.include_my_schema`, it defaults to False. However, since the Orlando release, new instances have a default entry in the table to set it as True.
Claims

Claims apply to global applications and application-customizations. In global applications, claims allow the system to choose a record deterministically should the same file be included in multiple applications. If you see a superior claim, an upgrade history log for the skipped record is created to identify a conflicting claim status. See Claim Outcomes to Review related list for details.

Accessing unpurchased recommended apps on ServiceNow Store

Administrators can access the list of unpurchased ServiceNow Store apps, view recommended apps, and view details of the required app without navigating to the ServiceNow Store.

To access the list of unpurchased ServiceNow Store apps, navigate to System Applications > All Available Applications > Available To Obtain From Store. The recommended apps, have the Recommended indicator on the application tile. You can also use the filter options available under Additional Filters to populate the required apps. The filter options include:

<table>
<thead>
<tr>
<th>Filter option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Free Trial</td>
<td>App is available for a free trial.</td>
</tr>
<tr>
<td>Service Graph Connector</td>
<td>App type is Service Graph Connector.</td>
</tr>
<tr>
<td>Purchase In Process</td>
<td>Request to purchase the app is in process and the app has not been purchased on ServiceNow Store yet.</td>
</tr>
<tr>
<td>Rejected Request</td>
<td>Request for app trial or purchase is rejected.</td>
</tr>
<tr>
<td>Request in Progress</td>
<td>Request for app trial or purchase has been initiated and response from the vendor is awaited.</td>
</tr>
</tbody>
</table>

• To view the app details that are available on ServiceNow Store, click View Details.

• To purchase or try the required app, on the app details page, click:
  ◦ Get for free apps.
  ◦ Buy for paid apps.
- **Request App** for free or paid apps that require approval from vendor to purchase the app.
- **Request Trial** for free or paid apps that require approval from vendor to try the app.
- **Try** before procuring the application directly from the application manager. You will be redirected to the ServiceNow Store from where you can purchase the app.

**Request and install free application trial**

Request and install a free application trial of an application before procuring the application directly from your ServiceNow instance, without navigating to ServiceNow Store.

**Before you begin**
Role required: admin

**Procedure**

1. **Optional:** Obtain approval from the vendor to try the application.
   - **Note:** Some applications require vendor approval to try the application.
     - a. Navigate to **System Application > All Available Applications > Available To Obtain From Store**.
     - b. Search for the required application and click the application record.
     - c. Click **Request Trial**.
     - d. Enter your Now Support credentials.
     - e. Click **Sign in**.
       A confirmation message is displayed that the trial request is sent to the vendor. Once the vendor approves the request, you will be notified through an email.

2. Navigate to **System Application > All Available Applications > Available To Obtain From Store**.
   - **Note:** If the application requires vendor approval, perform these steps after you have been notified through email that your request is approved.

3. Search for the required application and click the application record.
4. Click **Try**.
5. In the pop-up window, review information in these tabs and click **Continue**.
• Usage Analytics and Contact
• Platform Licenses
• Terms and Conditions

Note: Select the I read and accept terms of use above check box.
You can download the terms and conditions documents.
In the Confirmation tab, a confirmation message is displayed that the application can be installed.

An application trial is available for 30 days. A green indicator indicates the trial expiration date. After the trial period has expired, a red indicator is displayed to indicate that the trial period has expired.

6. Click Go to install.

Request a free or paid application
Request a free or paid application that requires approval from the vendor to purchase the application directly from the ServiceNow instance, without navigating to ServiceNow Store.

Before you begin
Role required: admin

Procedure
1. Navigate to System Application > All Available Applications > Available To Obtain From Store.
2. Search for the required application and click the application record.
3. Click Request App.
   A confirmation message is displayed that the request is sent to vendor. Once the vendor approves the request, you will be notified through an email.

Get a free application
Get a free application from your ServiceNow instance, without navigating to the ServiceNow Store.

Before you begin
Role required: admin
Procedure
1. Navigate to System Application > All Available Applications > Available To Obtain From Store.
2. Search for the required application and click the application record.
3. Click Get.
4. In the pop-up window, review information in these tabs and click Continue:
   • Usage Analytics and Contact
   • Platform Licenses
   • Terms and Conditions

   Note: Select the I read and accept terms of use above check box.
   You can download the terms and conditions documents.
   In the Confirmation tab, a confirmation message is displayed that the application can be installed.
5. Click Go to install.

Buy a paid application
Request a quote and buy a paid application from your ServiceNow instance, without navigating to the ServiceNow Store.

Before you begin
Role required: admin

Procedure
1. Navigate to System Application > All Available Applications > Available To Obtain From Store.
2. Search for the required application and click the application record.
3. Click Buy.
4. In the pop-up window, review information in these tabs and click Continue:
   • Usage Analytics and Contact
   • Platform Licenses
Terms and Conditions

Note: If Payment Type is Purchase Order, a quote with the displayed payment details is requested. You can cancel or resent quote.

- Review the payment and tax details.
- Select the I read and accept terms of use above check box.

You can download the terms and conditions documents.

- In the Confirmation tab, a confirmation message is displayed that the quote request is sent. An email notification is sent when the request is processed.

- When you close the pop-up window, these buttons are displayed in the application page:
  - Resend Quote
  - Cancel Quote
  - Purchase with PO

5. Optional: If you want to resend quote, click Resend Quote.

6. Optional: If you want to cancel the quote:
   - Click the Cancel Quote button.
   - Provide cancellation reason.
   - Click Cancel Quote.

7. Click Purchase with PO to purchase the application.

- If applicable, select the I authorize ServiceNow to invoice my company without having received a Purchase Order, and I represent that I have authority to represent my company to provide such authorization check box.

- Else, enter PO Number and choose file for Upload PO Document.

8. Click Place an Order.

   An email notification is sent when the PO request is reviewed and approved. Then, you can install the application.

Complete the offline application purchase transaction

Complete the application purchase transaction from your ServiceNow instance after purchasing the application offline, without navigating to the ServiceNow Store.

Before you begin
Role required: admin
Procedure

1. Navigate to System Application > All Available Applications > All.

2. Search for the required application and click the application record and click Install.

   Note: Option to install the application is available after the application is purchased offline. Also, the indicator Click install to complete purchase is displayed in the application tile.

3. Enter your Now Support credentials.

4. Click Sign in.

5. Select the I read and accept terms of use above check box.

   You can download the terms and conditions documents.

6. Click Continue.

   Application is purchased and is ready to be installed.

   Note: If the application isn't compatible with the version of your ServiceNow instance, an error message is displayed informing you the same.

7. Click Install.

Schedule installation

Schedule the installation of a plugin, application, or product at the required time from your ServiceNow instance. You can simultaneously schedule multiple installations.

Before you begin
Role required: admin

Procedure

1. Navigate to System Definition > Plugins.

2. Search for the required plugin, application, or product.

3. Click the schedule installation icon ( ).

   Note:
   - If the app is blocked from installation, the installation and schedule installation icons are disabled.
   - You can't schedule the installation of an in-development plugin.
4. Specify the time at which you want to schedule the installation.

![Schedule Installation dialog box](image)

5. Click **Next**.

   **Note:** If another installation is scheduled at the same time, a message is displayed that the installation can't be scheduled at the mentioned time and auto-populates the next available slot.

![Schedule Installation dialog box with notification message](image)

6. In the Schedule Activation window, choose the option to reschedule if the scheduled installation doesn't complete. That is, the admin can choose to retry the installation once or exit the installation.
The installation is scheduled and a confirmation message is displayed.

**What to do next**

Click the schedule summary icon (📅) to view the installation status and schedule calendar.
• To view the status of the installation, click **View Status**.
  ◦ If the installation is successful, the details of the plugin, application, or product are displayed.
  ◦ If the installation fails, the reason for the failure is displayed along with other details.

• To reschedule or delete the scheduled installation, click **Reschedule** or **Delete** in the app tile.

Note: If you have scheduled the installation of a product, all apps in the product will also be scheduled for installation. However, you can't modify or delete the schedule of an individual app. You can only modify or delete the schedule of the product.

• To view the schedule of installations, click **Full schedule**. A calendar displays the details of the scheduled installations.

**Install or update all applications in a ServiceNow product**

Install or update all applications that are part of a ServiceNow product from your ServiceNow instance at a time.

**Before you begin**
Role required: admin

**Procedure**

1. Navigate to **System Applications > All Available Applications > All**.
2. Select the **ServiceNow Products** option in the **Listing type** filter options.
   The list of the ServiceNow products in displayed.
3. Search for the required ServiceNow product and open the record.
   Use the **Licensed** and **Not Licensed** tabs to view details about applications in the product.
4. Click **Install/Update All**.
Note: By default, application of the latest version is installed. If you want to install the application of another version, select the required version and select the application check box.

5. Optional: Select the Load demo data check box to load demo data for all the applications displayed in the Install pop-up window.

6. Click Install.

- If there are any errors or conflicts, the details are displayed in the Install pop-up window. To proceed with installation, you must address the errors and resolve the conflicts.
- If there are no errors or conflicts, the applications are installed or updated, and a confirmation message is displayed.

7. Optional: While installation is in progress, you can have application installed in the background by clicking Continue in background. After refreshing the page, this message is displayed: Product installation in progress, click here to view details. Click the link to see the installation progress.

Results
A confirmation message is displayed if all the applications are installed. Otherwise, the number of successful and unsuccessful installations are displayed.

Install multiple applications in a batch
The Batch Installation feature helps you install multiple applications, plugins, or application-customizations together, instead of having to install them serially one at a time. You can access this feature either from the Continuous Integration and Continuous Delivery (CI/CD) APIs via three new endpoints, or via the CI/CD Spoke on IntegrationHub using Flow Designer subflows and actions.

Overview
When managing many types of applications, it can be a challenge to have separate pipelines for each application and to wait for them to serially deploy to the same environment. With the Batch Installation feature, you can install several applications together by bundling them into a single JSON manifest file. These applications include scoped or global applications, plugins, and application-customizations.

A batch can contain any combination of the following types:
• A ServiceNow plugin
• Application: Scoped applications in the ServiceNow Store that your company doesn’t own, scoped or global applications in the Application Repository owned by your company, and your application-customizations for Store applications stored in the Application Repository.

Batch installation methods
For details on installing applications in a batch via the REST API see Continuous Integration/Continuous Delivery (CI/CD) API.

For details on installing applications in a batch with the Flow Designer application, see Continuous Integration and Continuous Delivery (CICD) Spoke.

Install a ServiceNow Store application
Install an application that you purchased from the ServiceNow Store to make it available on your instance.

Before you begin
• Purchase an application from the ServiceNow Store.
• Ensure that the application and all of its associated ServiceNow Store applications have valid ServiceNow entitlements. For more information, see Get entitlement for a ServiceNow product or application.

Role required: admin, sn_appclient.app_client_company_installer (can only install applications that match the instance company), or sn_appclient.app_client_user

About this task
Applications that you purchase from the ServiceNow Store are added to the Application Manager automatically. You must install the application from the Application Manager to activate it in an instance.

To install an application that you published to the ServiceNow application repository, follow the steps in Install an application from the application repository instead.

Procedure
1. Navigate to System Applications > All Available Applications > All.
2. Find the application using the filter criteria and search bar.
You can search for the application by its name or ID. If you cannot find an application, you may have to request it from the ServiceNow Store.

Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store. For cumulative release notes information for all released apps, see the ServiceNow Store version history release notes.

3. Click **Install**.

4. In the Application installation dialog box, review the application dependencies.

   If dependent plugins and applications will be installed, are currently installed, or need to be installed, they appear in this dialog box. If there are any plugins or applications that need to be installed, you must install them before you can install the ServiceNow Store application.

5. **Optional:** If demo data is available and you want to install it, click **Load demo data.**

   (Optional) Demo data comprises sample records that describe application features for common use cases. Load demo data when you first install the application on a development or test instance.

   **Important:** If you don't load the demo data during installation, it's unavailable to load later.

6. Click **Install**.

7. **Optional:** Click **Go to Subscription Management** to map the installed application to a subscription.

**Related information**

- Install customizations from an application repository
- System-managed developer and deployment roles

**Install an update to a ServiceNow Store application**

Install an update to an application that you purchased from the ServiceNow Store.

**Before you begin**

Role required: admin
Procedure

1. Navigate to System Applications > All Available Applications > All.
2. Find the application with the filter criteria and search bar.
   If they are available, you can select customized versions to be installed.
3. Next to the application listing, select the version to install.
4. Click Update.

⚠️ Note: When customers upgrade to this new version of your application, the Deletes in your author_elective_update folder will be written as Skips in the Upgrade History entry for this application upgrade. Your users can browse the Skip list, and apply the changes on a case-by-case basis. Your customers have the option of setting com.glide.apps.include_my_deletes to false, which will skip writing Skip records as well.

Related information

- Developer and deployment permissions
- System-managed developer and deployment roles

View the upgrade history of a ServiceNow Store application

View the upgrade history of an application that you purchased and installed from the ServiceNow Store.

Before you begin

Role required: admin, sn_appclient.app_client_company_installer (can only install applications that match the instance company), sn_appclient.app_client_user, unified_plugin_read_only

Procedure

1. Navigate to System Applications > All Available Applications > All.
2. Find the application using the filter criteria and search bar.
3. Click the menu icon () on the application tile, and then click **View upgrade history**.

*i Note:* When customers upgrade to this new version of your application, the Deletes in your author_elective_update folder will be written as Skips in the Upgrade History entry for this application upgrade. Your users can browse the Skip list, and apply the changes on a case-by-case basis. Your customers have the option of setting `com.glide.apps.include_my_deletes` to false, which will skip writing Skip records as well.

**Select an application from the application picker**

Use the application picker to select the application to which any new records and updates apply.

**About this task**

Application developers must select an application as their current scope context. Any new records become part of this application. The Now Platform also uses the current application scope to determine if the developer can view or make changes to records in other scope contexts.

**Procedure**

1. Click the gear icon from the banner frame.
2. From **Application**, select the application scope where you want to save changes.
Repair a ServiceNow application

Repair a ServiceNow application by reinstalling it.

Before you begin
Role required: admin

Procedure
1. Navigate to System Applications > All Available Applications > All.
2. From the filter options, select the Installed indicator. All the installed apps are displayed.
3. Click the menu icon ( ) on the application tile, and click Repair.
4. In the Activate Plugin dialog box, click Repair.

Results
The application and its dependencies are reinstalled.

Note:
- When repairing an application with a customization, the customization is repaired as well, unless it’s linked to a source control repository.
- It is assumed the complete set of customizations for an application is within the application customization. When repairing, installing, or upgrading the underlying application or plugin that has an associated app customization, changes made outside of that application customization are overwritten.

With a repair, all the files with sys_update_xml records are added to the remote update set. The remote update set is named with the format: "Repair/Upgrade app <app scope name> at <timestamp>".

Preserve unpublished applications during a system clone

Application developers must manually save a copy of each application currently in development prior to cloning over their development instance.

Before you begin
- Role required: admin
- Write access to the application record
- A source control repository
About this task
The cloning process does not preserve version differences for applications in development. Instead, the system clone only copies the application version installed on the source instance onto the target instance. If the target instance had a development version of the same application, the application will be editable after the clone, but it will be at whatever version was installed on the source instance. If the application was missing from the source instance, the cloning process deletes the application from the target instance.

Procedure
1. Use one of these actions to preserve the application on the clone target instance.

<table>
<thead>
<tr>
<th>Application version state</th>
<th>Action to take</th>
</tr>
</thead>
<tbody>
<tr>
<td>The application version on the clone target instance is different than the source instance version.</td>
<td>Export each application from the clone target instance. Choices include:</td>
</tr>
<tr>
<td>The application is only available on the clone target instance.</td>
<td>• (Recommended) Link each application to a source control repository.</td>
</tr>
<tr>
<td>The application version on the clone target instance is the same as the source instance.</td>
<td>None. The system clone process will copy this application version onto the target instance during the clone.</td>
</tr>
</tbody>
</table>

2. Request a system clone of the source instance over the target instance.

Example
For example, clone your production instance over your development instance.

3. After the clone process finishes, log in to the clone target instance.

4. If you saved each application to a source control repository, use one of these actions to retrieve them from the source control repository.
5. If you saved each application to an update set, use one of these actions to retrieve them from the update set.

**Retrieve applications from a source control repository**

<table>
<thead>
<tr>
<th>Application installation state</th>
<th>Action to take on clone target</th>
</tr>
</thead>
<tbody>
<tr>
<td>The application was previously installed on the source instance.</td>
<td>Apply remote changes from source control repository.</td>
</tr>
<tr>
<td>The application was never installed on the source instance.</td>
<td>Import the application from source control repository.</td>
</tr>
</tbody>
</table>

**Retrieve applications from an update set**

<table>
<thead>
<tr>
<th>Application installation state</th>
<th>Action to take on clone target</th>
</tr>
</thead>
</table>
| The application was previously installed on the source instance. | a. Delete the application version cloned from the source instance.  
  b. Load the update set containing the current application version. |
| The application was never installed on the source instance. | Load the update set containing the current application version. |

**Results**

The applications previously in development are available for further development on the clone target instance.

**Example: Preserve the Marketing Events application**

Suppose your company previously created version 1.0 of a custom application called Marketing Events. You have already published version 1.0 of the Marketing Events application to the application repository and installed it on your production instance.

Over time, users have submitted enhancement requests for the application, and you decide to develop version 2.0 of the Marketing Events application on a non-production instance to address these requests. As development nears completion, you want to update your non-production instance to the latest copy of production for some comprehensive testing.

Since you previously used a source control integration to develop version 1.0 of the Marketing Events application, you have already linked the Marketing Events application to a source control repository. You commit version 2.0 of the Marketing Events application to the source control repository.
You schedule a clone of the production instance over the development instance. After completion, you log in to the development instance and see that it has version 1.0 of the Marketing Events application, because that was the version installed on the source instance.

Since the application was already installed on the source instance, you apply remote changes from the source control repository to receive the latest application version. The development instance now has version 2.0 of the Marketing Events application available for further development and testing.

**Opt out of the ServiceNow Store products**

Opt out of the required product available on ServiceNow Store by navigating to the ServiceNow Products module.

**Before you begin**

- Opted in product
- Role required: admin

**Procedure**

1. Navigate to **System Applications > All Available Applications > ServiceNow Products**. ServiceNow products that are available on ServiceNow Store are displayed. The products are organized based on the product family they are part of.

2. To opt out of the ServiceNow products:
   
   a. Click the required product tile.
   b. Click **Opt-out**.
   c. Enter your Now Support credentials.
   d. Click **Opt-out**.

**Application sharing**

Administrators can share applications that are complete and are ready for use on other instances.

Application developers can share applications using one of the following methods.
### Application sharing methods

<table>
<thead>
<tr>
<th>Sharing method</th>
<th>Makes available to</th>
<th>Typical use case</th>
</tr>
</thead>
<tbody>
<tr>
<td>Publish to the application repository</td>
<td>All instances assigned to the same company</td>
<td>Transfer an application to a test or production environment.</td>
</tr>
<tr>
<td>Publish to the ServiceNow Store</td>
<td>All ServiceNow customers</td>
<td>Share or sell applications to other companies.</td>
</tr>
<tr>
<td>Publish to an Update Set</td>
<td>Any instance with access to the Update Set file</td>
<td>Save a version of an application for compliance or backup reasons.</td>
</tr>
<tr>
<td>Push to team development instances</td>
<td>Other instances in the team development environment</td>
<td>Push developer changes to the parent instance.</td>
</tr>
</tbody>
</table>

**Note:**

“Tracking schema”: Deleting a table or a column in a scoped application is enabled by default for freshly zbooted instances. This is done by having the system property `com.glide.apps.include_my_schema` set to “true”.

For upgraded instances, if you have no custom applications installed or in development, “tracking schema deletes” is enabled by default. Otherwise the property is set to “false” so that customers get the same experience for schema deletes in their applications as in previous releases before Paris. To learn more see the New York and Scoped Applications New Features article on the ServiceNow Community site.

### Custom licensing for ISV applications

For applications that you are sharing, you can create a definition to track usage metrics on your application. For more information, see Custom licensing for ISV applications.

### Publish an application to the application repository

Publish a custom application to the application repository so that it can be installed on other instances in your organization.

**Before you begin**

To allow a developer to publish an application to the application repository, delegate the Publish to App Repo permission to the developer. For more
Delegate development and deployment permissions to personnel.

Role required: admin, or delegated_developer with Publish To App Repo permission enabled

**Procedure**

1. Navigate to **System Applications > My Company Applications**.
2. Open the In Development tab.
3. Open the application record that you want to publish to the application repository.
4. Click the **Publish to My Application Repository** related link.
5. Click **Submit**.

**What to do next**

Install the application on company instances so that your organization can start using it. For more information, see Install an application from the application repository.

By default, after you publish an application to the application repository, all your company instances are entitled to the application automatically. To limit which company instances are entitled to the application, access the application repository by going to [https://apprepo.service-now.com](https://apprepo.service-now.com), and then change the entitlement type for the application.
Note:
The Can Edit Application in Studio property defaults to true for new applications, but you can set it false before publishing.

In Studio, when an application customization has the Can Edit Application in Studio property set to false, the user sees this warning:

For more information, see Manage application entitlements from the application repository and Access ServiceNow Studio.

Publish an application to the ServiceNow Store

Publishing an application to the ServiceNow Store makes it available to everyone.

Before you begin
To publish an application to the ServiceNow Store:

• Create an application within a private application scope.
• Join the Technology Partner Program.
• Have the application certified.

Note: Applications in the global scope cannot be published to the ServiceNow Store.

Role required: admin, or delegated_developer with Publish To App Store permission enabled
About this task
After you have met the prerequisites, you can publish the application to the ServiceNow Store

ℹ️ Note:
The Can Edit Application in Studio property defaults to true for new applications, but you can set it false before publishing.

In Studio, when an application customization has the Can Edit Application in Studio property set to false, the user sees this warning:

Procedure
1. Navigate to System Applications > Applications.
2. Click the In Development tab.
3. Open the application record you want to publish to the ServiceNow Store.
4. Click the Publish to Store related link.
5. Optional: Fill in the fields, as appropriate (see table).
6. Enter your HI credentials.

7. Click **Submit**.
   The system uploads the current version of the application to the ServiceNow Store allowing other users to download it.

**Related information**
Delegate development and deployment permissions to personnel

**Create application files to include sample data**
Include sample records from an application data table when sharing a custom application.

**About this task**
The system can export selected records as application files that are included as part of the application update set when you share it. Including application files in an update set is not intended for the export and import of large numbers of
records between instances. If you are trying to move data between instances, see Import from another instance instead.

The application data only includes the version of the records that existed when the records were shared. The system does not update this snapshot of the application data when the records change. Application designers can include data on a table by table basis.

Procedure

1. Navigate to the list for an application data table.
2. Filter the list to display the records you want to include.
3. Perform the appropriate action for the list version.

<table>
<thead>
<tr>
<th>Version</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>List v2</td>
<td>Open any column context menu and select Create Application Files.</td>
</tr>
<tr>
<td>List v3</td>
<td>Open the list title menu and select Create Application Files.</td>
</tr>
</tbody>
</table>

4. For Load When, select when the application record includes application data.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>New Install and Upgrades</td>
<td>Includes application data whenever the application is installed or upgraded.</td>
</tr>
<tr>
<td>New Install</td>
<td>Includes application data only when the application is installed.</td>
</tr>
<tr>
<td>New Install with Demo Data</td>
<td>Includes application data only when the application is installed with demo data.</td>
</tr>
</tbody>
</table>

5. Click OK.
The system adds the records to the application files related list.
6. Repeat steps 1–5 for each application data table you want to include.

Publish an application to an Update Set

Publishing an application creates an update set containing the current version of all application configuration records.

Before you begin
Role required: Role required: admin, or delegated_developer with Publish To Update Set permission enabled

About this task
You can use this update set as a backup file for auditing purposes or to transfer the application to another instance.

Procedure
1. Navigate to **System Applications** > **My Company’s Applications**.
2. Click the **In Development** tab.
3. Open the application record you want to create an update set for.
4. Click the **Publish to Update Set** related link.
5. Optional: Fill in the fields, as appropriate (see table).
Publish to Update Set

Publishing an application lets you transfer it to another ServiceNow instance.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application name</td>
<td>[Read-only] Displays the name of the application that you are publishing.</td>
</tr>
<tr>
<td>Version</td>
<td>(Optional) Enter version information to append to the Update Set name in dot-notation such as 1.2.3. The platform saves the information you enter here in the application Version field. The Update Set has the name &lt;Application name&gt; - &lt;Version&gt;. If you leave this field blank, the initial Update Set has the name &lt;Application name&gt; and subsequent Update Sets have the name &lt;Application name&gt; - &lt;Sequential number&gt;.</td>
</tr>
<tr>
<td>Description</td>
<td>Enter a description for the Update Set. By default, this field contains the short description of the application.</td>
</tr>
<tr>
<td>Include data</td>
<td>(Optional) Select the check box to include a limited number of data records from each table in the application. Use this feature to package sample data with your applications.</td>
</tr>
</tbody>
</table>
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Warning:</strong></td>
<td>Using this feature to migrate large quantities of data records between instances can cause performance issues, as it is not intended for this purpose. To migrate data, use an instance-to-instance import. You can adjust the maximum number of data records to include with an application.</td>
</tr>
<tr>
<td></td>
<td>See Import sets.</td>
</tr>
</tbody>
</table>

| Note: | |
|-------| |
| • If your sample data includes tables with record numbering, the current counter value is also transferred. When the update set is applied on another instance, the counter is set to the larger of the sample data or the target instance counter. |
| • For translated fields, only records in English are transferred. |

6. Click **Publish**. 
A new update set is created and the latest update of each application file in the application is copied into it. The update set is marked as complete.

7. Transfer the update set to another instance according to your test process.
   • Retrieve the update set from the source instance.
   • Save the update set as an XML file.

8. Run any fix scripts that are included in the application.

### Related information

- Retrieve an update set
- Save an update set as a local XML file
- Run fix scripts
- Delegate development and deployment permissions to personnel

### Custom licensing for ISV applications

Monitor the usage of ISV applications with Subscription Management. Create a definition for your store application with the metadata you want collected. After publishing the application with the definition to the store, Usage Analytics runs and aggregates your defined metrics.
Overview
Applications that you create with the can be published to the ServiceNow Store. Monitor the usage of your applications with custom licensing.

You can use custom licensing on ISV applications that you publish to the ServiceNow Store if they meet the following criteria:

- The application is licensable.
- The application is not scoped in ServiceNow or Global.
- The application has a capacity subscription model.

Custom licensing functions through the usage analytics (com.glide.usageanalytics) and scoped app author (com.sn_appauthorrr) plugins. These plugins are active by default in the App Engine. Additionally, your instance must be connected to an application repository or application store instance.

Custom license definitions
Custom licensing is achieved by creating a definition. A definition is a set of licensing metrics that you define based on what usage information you want to collect for your application. See Create a definition for your store application.

Create a definition for your store application
Create a definition for your store app to define the licensing metrics you want collected.

Before you begin
Role required: admin or developer

About this task
Create a definition for an application in development or for an application you have already published. However, if you assign a definition to a published application, you will have to re-publish it with the new definition. Additionally, you can only assign one definition to an application.

⚠️ Note: You can only create a definition for capacity subscriptions. See Types of subscriptions.

Procedure
2. Select the application.
3. Under the Subscription Management section, set Subscription Model to Capacity.

4. Select the search icon next to License Definition. The Application License Definitions pop-up loads.

5. Select New.

6. Fill in the Application License Definition record.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the definition.</td>
</tr>
<tr>
<td>Description</td>
<td>Brief summary of the definition.</td>
</tr>
<tr>
<td>Metric Type</td>
<td>Type of collected metric.</td>
</tr>
<tr>
<td>Frequency</td>
<td>How often metrics are collected.</td>
</tr>
<tr>
<td>Performance Validated</td>
<td>Check the box if you have tested the performance of the definition.</td>
</tr>
<tr>
<td>Table</td>
<td>Table used to determine usage.</td>
</tr>
<tr>
<td>Note:</td>
<td>Only lists tables associated with the current application.</td>
</tr>
<tr>
<td>Query</td>
<td>Criteria to use on the table.</td>
</tr>
<tr>
<td>Aggregation</td>
<td>Type of aggregation.</td>
</tr>
<tr>
<td>Note:</td>
<td>Only lists tables associated with the current application.</td>
</tr>
<tr>
<td>Aggregation Column</td>
<td>Table column used for aggregation.</td>
</tr>
<tr>
<td>Note:</td>
<td>Column must be indexed to be aggregated.</td>
</tr>
<tr>
<td>Group By</td>
<td>Columns in the table to group the data by. Max of 3.</td>
</tr>
<tr>
<td>Warning:</td>
<td>Case sensitive.</td>
</tr>
</tbody>
</table>

7. Select Submit. Your new definition appears in the Application License Definitions pop-up.

8. Select the definition to apply it to the application.
What to do next
Create a new version of the application and publish it to the ServiceNow Store. While your application is in review, any changes to the definition may cause subsequent versions of your application to be rejected. Once the application is approved and published to the ServiceNow Store, the definition becomes read-only.

To change the definition of an application already on the ServiceNow Store, you must create a new definition, submit a new version of the application, and go through the review process.

Rolling back and removing applications
As an administrator, you can roll back and remove unwanted applications.

Roll back an application
As an administrator, you can roll back the last installation of a selected application. When you roll back an application, you remove all code, table, and file updates from the initial installation.

Before you begin
- Publish one or more applications to the application repository.
- The selected application must have been installed in the application repository or the application store. See Install a ServiceNow Store application.

Role required: admin

About this task
You can roll back the last installation or upgrade of all applications that are installed from the application store or repository. Rolling back an installation enables you to make needed changes to artifacts associated with an application before you publish and install it again.

Tip: This rollback does not affect the global application record. To remove the global application record, you must instead perform an uninstall of the application. See Uninstall an application.

Procedure
1. Log in to the instance in which you want to roll back the installed application.
3. Click the name or icon of the application that you want to roll back.
4. In the custom application record, click the Rollback related link.

Related information
Uninstall an application

Delete an application
As an administrator, you can delete custom applications that are no longer needed. Typically, you only delete applications that have never been shared with other instances.

Before you begin
• To ensure that you can reinstall the application at a later time, first publish a backup of your application to the ServiceNow application repository, ServiceNow Store, or an update set. See Application sharing.

Role required: admin

About this task
This process ensures that the system can support any published applications. When you delete an application, all the records that are associated with the application, such as tables, business rules, and menus, are also deleted.

Procedure
1. Log in to the instance in which you want to delete the installed application.
2. Navigate to System Applications > Applications.
3. Click the name or icon of the application that you want to delete.
4. In the application record, click Delete.
   A confirmation dialog box appears, indicating if any application files are associated with the application you are deleting.
5. Click the appropriate option.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Show Files</td>
<td>Navigate to a listing of files associated with the application record. Review this listing and determine how to remove the files before deleting the application itself.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>Delete</td>
<td>Delete the selected application.</td>
</tr>
<tr>
<td>Cancel</td>
<td>Cancel deletion of the files associated with the selected application.</td>
</tr>
</tbody>
</table>

6. In the confirmation dialog box, enter delete and click **OK**. Another confirmation dialog box appears, indicating the progress of the deletion. If any remaining metadata files are associated with the application record, the system prevents its deletion until all associated files are removed.

**Results**

Unless the application extends other applications, or files are still associated with the application, the system deletes the application.

**Note:** If an application is linked to Source Control (that is, the Git repository), you must also delete the Git configuration record for an application in the Repository Configurations (sys_repo_config) table. Without deleting this record, the application can’t be re-imported from Source Control on this instance.

**Uninstall an application**

As an administrator, you can uninstall applications that are no longer needed. Typically, you uninstall applications that have been shared with other instances and you want to remove them.

**Before you begin**

**Note:** For global scoped applications, you must first remove the associated files from the application before you delete the application record. These actions help protect the integrity of the instance by preventing the accidental deletion of files in the global scope. See Remove a file from a global application and Move an application file between global applications.

Role required: admin

**About this task**

When you uninstall an application, all application files associated with the application are also removed.
Procedure

1. Log in to the instance on which you want to uninstall an application.
2. Navigate to System Applications > All Available Applications > All.
3. Click the name or icon of the application that you want to uninstall.

   Note: You cannot uninstall applications on the In Development tab, but you can delete them. To learn more about what happens when you perform an application deletion, see Delete an application. You also cannot uninstall ServiceNow-provided system applications.

4. In the custom application record, click the Uninstall related link.
   The following information is displayed in the pop-up window:
   • List of dependent applications.
   • List of in-development applications.
   • Tables and records in the required application.
   • Option to retain the application tables and data.

   Note: If one of the dependent applications is uninstalled after retaining the tables and data, the Uninstalled applications with retained tables list is also displayed. In this case, the Retain tables and data check box is selected by default and can't be cleared.

   Note: When customers upgrade to this new version of your application, the Deletes in your author_elective_update folder will be written as Skips in the Upgrade History entry for this application upgrade. Your users can browse the Skip list, and apply the changes on a case-by-case basis. Your customers have the option of setting com.glide.apps.include_my_deletes to false, which will skip writing Skip records as well.

5. In the Uninstall confirmation dialog box, review the tables and records associated with the application before you uninstall that application.

6. To delete all data associated with this application, clear the Retain tables and data check box. Leave this check box selected to remove only application files.

7. Click OK.

8. In the confirmation dialog box, enter uninstall and click OK.

9. Click Done.
Domain separation and Application Management

Domain separation is unsupported for Application Management. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

Support level: No support
- The domain field may exist on data tables but there is no business logic to manage the data.
- This level is not considered domain-separated.

For more information on support levels, see Application support for domain separation.

Application tools

The platform provides several tools to create, manage, and deploy applications.

App Engine Studio

ServiceNow® App Engine Studio is a development tool for creators of varying skill levels to build applications that meet the immediate needs of your organization.

Overview

Here’s an overview on how you can build apps with App Engine Studio. App Engine Studio Overview

Request apps on the Store

Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store. For cumulative release notes information for all released apps, see the ServiceNow Store version history release notes.

Exploring App Engine Studio

Learn about App Engine Studio features that enable you to expand the development of powerful applications for your organization.

App Engine Studio is a guided, low-code tool for developing rich web applications to store information, automate business processes, and solve business problems. This means that you can delegate development work once assigned to administrators to employees with little to no training. By delegating development to business units in your organization, administrators are freed up to address more strategic, system-wide issues.
Overview

• Empower employees in your organization with a guided, intuitive app development environment.

• Build powerful apps to fit any business need by leveraging a suite of development tools, including UI Builder, Catalog Builder, Mobile Studio, and Flow Designer.

• Application development takes place on a non-production instance, your delegated developers can build applications safely without causing technical issues on your production instance.

• Build apps even faster using app templates for pre-built solutions.

• Control which apps to deploy by reviewing and testing the apps that App Engine Studio users submit for approval.

Key features

App Engine Studio applications are built on the Now Platform so users engage with real-time data.

Development tools

App Engine Studio provides instant access to several tools available in the Now Platform development suite. Developers can use any of the following tools to build applications in App Engine Studio:

**UI Builder**

Edit portal and workspace experiences using a highly configurable UI development tool. For more information on using this tool in App Engine Studio, see Editing an experience in App Engine Studio.

**Catalog Builder**

Edit record producer catalog items in a guided tool for building a Service Catalog. For more information on using this tool in App Engine Studio, see Editing an experience in App Engine Studio.

**Mobile Studio**

Edit mobile experiences. For more information on using this tool in App Engine Studio, see Editing an experience in App Engine Studio.

**Table Builder**
Edit data models in a table format. Table Builder is exclusive to App Engine Studio.

For more information on using this tool in App Engine Studio, see Editing data in App Engine Studio.

**Flow Designer**

Edit flows to automate application processes.

For more information on using this tool in App Engine Studio, see Editing logic and automation in App Engine Studio.

**App Engine Studio user interface**

Learn about the App Engine Studio user interface.

App Engine Studio is a web user interface that lets you build custom applications for your organization. You can build applications using templates which can be customized to fit your organizations needs.

**App Engine Studio home**

The App Engine Studio home page provides easy access to creating apps, viewing your app, quick start actions, and templates.

![App Engine Studio Home Page](image)

**Hi, System**

How do you want to get started?

**Quick start**

- Add a table
- Add an experience
- Add an automated flow
- Browse templates
- Learn the tools

**Templates**

- Emergency Alert Template: Accelerate reporting and communications during an emergency
- Team Contacts App Template: Manage employee contact information
- Performance Review Template: Application automates performance-appraisal process
- Time Off Template: Schedule employee vacations and time-off

Use the top navigation bar to view your apps, access app templates, and find help resources. You can also access the help center by selecting the help icon in the top right.

Users can access the following in App Engine Studio:

- **Create app**— Create an application from scratch.
- **Quick start**— Links to add objects to apps, browse app templates, and learn more about the App Engine Studio tools.
- **My recent apps**— A list of applications you have accessed recently using App Engine Studio.
- **Templates**— A list of templates you can use to create an application with preconfigured data, experience, logic and automation, and security.

**My Apps tab**

View and search the applications you created.

**Templates tab**

Provides a list of available app templates.
Resources tab

View tutorials and helpful resources to get started in App Engine Studio.

App Home

Add data, experience, logic and automation, and security to your app from the app home.
Some objects require access depending on your role. You can request access by selecting **Contact your system administrator** to become a delegated developer. For more information on the delegated developer role, see [Delegated developer role in App Engine Studio](#).

**Application Properties**

View general settings of your application such as the name, description, and logo. You can also open your application in ServiceNow Studio or delete your application.
Repository configuration

View and edit the source control repository settings for your application.

Repository configuration

Edit your integration with your external repository.

Note: Users could go in to make changes to the Home page, but editing all other pages would entail creating a variant/copy. If you edit these pages directly, then they won’t get the latest code in a system upgrade.

Portal

A portal is a site where users inside of your organization can find information, submit requests, and complete business tasks.

The portal that you create in App Engine Studio includes several default pages. You can use these pages as-is or edit them to suit your business needs.

- Article page
- Catalog item page
- Landing page
- Login
- Order success
- Record page (request)
- Record page (task)
- Search page
- Settings page
- Task approved
- Task rejected

Home page
Note: Unlike Service Portal, the portal that you can create in App Engine Studio is built on the Now® Experience UI Framework. You edit the portal by configuring pages and components in UI Builder.

Catalog item
A catalog item is a form that your users can fill in to create requests or tasks. Users can fill out a form to request an item or service.

For example, an employee can fill in a catalog item form to request time-off for a holiday. After submitting the form, a request is created for a manager to approve or reject.

For more information on catalog items, see Service catalog items.

Mobile
A mobile experience allows users to access your application from a ServiceNow native mobile app.

For example, you can enable a time-off requests application for mobile so that managers can approve or reject requests by opening the Now Mobile app on their mobile device.

For more information on the Now Mobile app, see Now Mobile app.

Delegated development in App Engine Studio
Delegated development enables designated users without a system admin role to develop or deploy applications on the Now Platform. This enables administrators and delegated developers to work together to deliver custom applications through App Engine Studio.

Phase I: Development requested
A team in your organization requests an application. For example, a team may request that their IT department build an application to automate task assignments. An administrator receives this request via a catalog request or email.

Phase II: Development delegation
After an administrator reviews a request, they delegate the development work by providing a link to the developer that opens App Engine Studio in your organization’s development environment. The administrator can:
• Send the link directly to a developer via email
• Post the link on a portal page
• Create a catalog item for delegated developers to request App Engine Studio access

Phase III: Building the application
After receiving access to App Engine Studio, the developer can start building an application using a predefined application template or by creating an application from scratch.

After the developer finishes building the application, they submit their application for approval. For more information on developing in App Engine Studio, see Building applications in App Engine Studio.

Phase IV: Administrator review
After the developer submits their application for approval, an administrator receives a deployment request. They log in to your organization's production environment to review the request.

The deployment request contains detailed information about the application. After reviewing the deployment request, the administrator might send feedback to the developer and then deploy the application to your organization's test environment. The administrator then logs into the test environment and inspects the application. Then:

• If the application is ready to publish, the administrator logs into the production environment and accepts the deployment request.
• If the application is not ready to publish, the administrator logs into the production environment and rejects the deployment request. Optionally, they can send feedback to the developer to inform them why the application is not ready.

Phase V: Application revision
If the administrator rejects the application, the developer receives notification. A developer can use the administrator's feedback to improve their application. After addressing application issues, the developer submits the application again to the administrator.

An application may cycle through administrator review and developer revision several times before the application is ready to publish.
Phase VI: Publishing the application

After accepting a deployment request, the administrator publishes the application by deploying it to production.

The application is now available to users through your organization’s production environment. An administrator can then begin on-boarding the team that requested the application. For example, if the developer specified a certain security role for the application, the administrator assigns that role to the relevant users.

Delegated developer role in App Engine Studio

Delegated development allows designated users without a system admin role to develop and/or deploy applications on the Now Platform. The delegated developer role enables an admin to elevate user permissions to a dedicated role with specific access for App Engine Studio.

A delegated developer has more permissions than a user, but less than an admin. The delegated developers each have their own permissions.

An admin may have several delegated developer each with their own set of permissions. For example, you may want a designated developer for developing a time-off request, and another designed developer with separate permissions for creating support tickets.

As a delegated developer, some features of App Engine Studio may be inaccessible, depending on your permissions. Your role’s permissions enable you to access, edit, and add objects. If a feature of App Engine Studio is unavailable to you, contact your system administrator.

For more information about delegated development, see Delegated development and deployment

Instance strategy for App Engine Studio

Learn how to use multiple ServiceNow instances to implement App Engine Studio in your organization.

One of App Engine Studio’s major security features is the pipeline. A pipeline allows you to quickly move an application across development, test, and production environments. Using separate environments ensures that application development doesn’t cause issues in your production instance, and thus interfere with business operations.

To implement App Engine Studio in your organization, you need one production instance and two non-production instances. One non-production instance serves as the development environment, and the other non-production instance serves as the test environment. The production instance is where the application appears after it has been fully built and tested.
If you have more than two non-production instances, you must decide which instances to use as your development and test environments. You may ask the following questions to make this decision:

- Who is developing the application?
- Which instance does your developer already have access to?
- Has the instance reached or almost reached its table limit?
- Is the instance similarly configured to your production instance?

A non-production instance that is similarly configured to your production instance may be the best candidate for your test environment. An administrator can then more accurately find issues that may arise if the application is deployed to production.

We've provided a new pipeline to move apps around an organization’s instance, which provides admins the confidence that they can roll out citizen developer tools to their organization.

Admins will need to establish their company's instance strategy for App Engine Studio. They need to decide whether they want to allow anyone within their company to have access to App Engine Studio to start building. Admins can also choose to give access to a select group of people. Or, they can choose, on a case-by-case basis, who they give access to by setting up a form where individuals can complete information about the app that they are looking to build and then IT decides whether or not to give those individuals access to build that app.

After they have established their instance strategy, they will also need to establish and automate their approval or review process. AES is a product that runs on your sub-prod environment. For an organization with multiple sub-prod environments, they will need to decide which sub-prod environment App Engine Studio will run on. They will then also need to determine what the pipeline is for apps to be promoted from a particular sub-prod instance to their test instance, and then finally to production where the app will be running live.

**Accessing App Engine Studio for the first time**

App Engine Studio enables a frictionless login experience for developers.

An administrator grants access to App Engine Studio by adding users to the App Engine Studio Users group in your organization’s production instance. The user information is then queued up to synchronize with the instance that your organization is using as its development environment. You can track this queue by navigating to **App Engine Studio > Configuration > User Sync Queue**.
After the system successfully adds a user to the development environment, the user receives an email notification. Email recipients use a temporary password to log in to App Engine Studio for the first time. After resetting their password, a user can start building applications in App Engine Studio.
Only users who are added to the App Engine Studio Users group are synchronized. If the sn_app_eng_studio.user role is assigned directly to the user, then the user isn’t synchronized.

If a user is deleted in your production instance, then the user is deactivated in the development environment and removed from the App Engine Studio Users group.

User synchronization depends on the pipeline to correctly identify your production and development environments. For more information on configuring a pipeline, see Create a pipeline.

Alternatively, you may choose to create users in the development instance only. Add these users to the App Engine Studio Users group in the development instance. Each user then receives an email notification that includes a link to log in to App Engine Studio.

**Using guided setup to implement App Engine Studio**

Use App Engine Studio guided setup to step through the initial configuration of App Engine Studio.

App Engine Studio guided setup provides a sequence of tasks that help you configure App Engine Studio on your ServiceNow instance. To open App
Engine Studio guided setup, navigate to **App Engine > App Engine Studio > Configuration > Guided Setup.**

Welcome to App Engine Studio Guided Setup

Getting started

**Introduction**

App Engine Studio is a fast, intuitive, low-code visual development environment that empowers developers to build applications to power the digital enterprise. Guided Setup will help you configure App Engine Studio.

**What you’ll do**

- **Configure environments**
  Decide which instances you will use for development, testing, and production.

- **Review and set up tooling**
  Set up App Engine Studio to easily access our available tools for building apps.

- **Set up user access**
  Configure the admin group and other general settings for App Engine Studio users.

**How to prepare for setup**

Setup is required for each instance you use. Keep this list on-hand and be prepared to do this a few times.

<table>
<thead>
<tr>
<th>Spokes to configure (included with App Engine Studio)</th>
<th>Email address of</th>
<th>URLs and Credentials for</th>
</tr>
</thead>
<tbody>
<tr>
<td>Microsoft 365 Excel</td>
<td>App Engine Studio administrator</td>
<td></td>
</tr>
<tr>
<td>Google Sheets</td>
<td>Production instance</td>
<td></td>
</tr>
<tr>
<td>Jira</td>
<td>Test instance</td>
<td></td>
</tr>
<tr>
<td>Slack</td>
<td>Development instance</td>
<td></td>
</tr>
<tr>
<td>Microsoft Teams</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ServiceNow Core</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Gmail</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Twilio</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Zoom</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Twitter</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The landing page provides information on the different categories, tools, and user access. Select the **Get Started** button in the top, right corner to start your configuration.
The App Engine Studio Guided Setup page provides a list of different categories. Select the **Get Started** button under each category to start configuring App Engine Studio.

For more information on **Guided Setup**, see Using guided setup.

**Set up user access in App Engine Studio**

Configure the admin group and other general settings for App Engine Studio users.

**Before you begin**

Role required: admin

**Procedure**

Navigate to **Application > Module**.

**Install App Engine Studio**

You can install the App Engine Studio application (com.snc.app-engine-studio) if you have the admin role. The application installs related ServiceNow® Store applications and plugins if they are not already installed.
Before you begin

- Ensure that the application and all of its associated ServiceNow Store applications have valid ServiceNow entitlements. For more information, see Get entitlement for a ServiceNow product or application.

Role required: admin

About this task
The following items are installed with App Engine Studio:

- Plugins
- Roles
- Tables

For more information, see Components installed with App Engine Studio.

Procedure

1. Navigate to System Applications > All Available Applications > All.

2. Find the App Engine Studio application (com.snc.app-engine-studio) using the filter criteria and search bar.
   
   You can search for the application by its name or ID. If you cannot find the application, you might have to request it from the ServiceNow Store.

   Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store. For cumulative release notes information for all released apps, see the ServiceNow Store version history release notes.

3. In the Application installation dialog box, review the application dependencies.

   Dependent plugins and applications are listed if they will be installed, are currently installed, or need to be installed. If any plugins or applications need to be installed, you must install them before you can install App Engine Studio.

4. Optional: If demo data is available and you want to install it, click Load demo data.

   (Optional) Demo data comprises sample records that describe application features for common use cases. Load demo data when you first install the application on a development or test instance.

   **Important:** If you don’t load the demo data during installation, it’s unavailable to load later.

5. Click Install.
What to do next
Use App Engine Studio guided setup to step through the initial configuration of App Engine Studio. For more information, see Using guided setup to implement App Engine Studio.

Define environments
Designate which instances to use for development, testing, and deployment.

Before you begin
- Install App Engine Studio
- For each instance that you're using, create a Connection & Credential alias. Ensure that the alias type is Credential, not Connection and Credential. Also, ensure that the credentials are configured in the App Engine Studio scope. For more information on creating a credential alias, see Create a Connection and Credential alias.

Role required: admin

About this task
To set up App Engine Studio, you must define the following environments:

Development
Instance that a developer uses to build applications in App Engine Studio.

Test
Instance that an administrator uses to test applications built in App Engine Studio.

Production
Instance that an administrator uses to deploy applications built in App Engine Studio.

The following steps guide you through defining each environment.

Procedure
1. Navigate to App Engine > App Engine Studio > Configuration > Environment, and then select New.
2. On the form, fill in the fields.
Environment form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the environment. Enter a name that distinguishes the instance as a development, test, or production environment. For example, if you’re defining a development environment, you would include dev in the name.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope of the environment.</td>
</tr>
<tr>
<td>Instance credential</td>
<td>Authentication data related to the instance that you're configuring as an environment. Select a Connection &amp; Credential alias to reference.</td>
</tr>
<tr>
<td>Instance url</td>
<td>Web address of your ServiceNow instance.</td>
</tr>
</tbody>
</table>

3. Select Submit.

4. Repeat the previous steps as you define each remaining environment. For example, if you defined a production environment, repeat the procedure again to define a development environment. Then, repeat the procedure once more to define a test environment.

What to do next
Create a pipeline so that an administrator can quickly move an app from one environment to another. For more information, see Create a pipeline.

Define environments in each instance that you’re using for App Engine Studio. For example, if you defined environments in your production instance, open your development instance and define environments again. Then, do so again in your test instance.

Setting up pipelines
Create a pipeline so that an administrator can quickly move an application from one environment to another.

Set up the administrator contact email
Define the contact email address of the App Engine Studio administrator so that they can receive notifications for deployment requests.

Before you begin
Role required: admin
**Procedure**

1. Navigate to **App Engine > App Engine Studio > Configuration > Properties**.
2. Open the record named **sn_app_eng_studio.aes_admin_contact**.
3. In the **Value** field, enter the email address of the App Engine Studio administrator.
   To enter multiple email addresses, enter a comma-separated list of addresses with no spaces. For example, you would enter multiple addresses as follows: `beth.anglin@example,joe.employee@example.com,abel.tuter@example.com`.
4. Select **Update**.

**Grant access to App Engine Studio**

Let developers in your organization build applications in App Engine Studio by adding them to the App Engine Studio Users group.

**Before you begin**

- Install App Engine Studio
- Define environments
- Create a pipeline

Role required: user_admin or admin

**About this task**

You grant access to App Engine Studio by adding users to the App Engine Studio Users group in your production instance. Each group member is assigned the **sn_app_eng_studio.user** role automatically. Users receive an email notification that includes a link to log in to App Engine Studio.

The user data is synchronized from your production environment to your development environment. User synchronization isn’t supported for non-members who have the **sn_app_eng_studio.user** role. Alternatively, you may choose to create users in the development instance only. Add these users to the App Engine Studio Users group in the development instance.

**Procedure**

1. Log in to your production instance.
2. Navigate to **User Administration > Groups**.
3. Find and open the record named **App Engine Studio Users**.
4. In the Group Members related list, select **Edit**...
5. On the Edit Members page, move each developer from Collection to Group Members List.

6. Select Save.

7. On the group record, select Update.

Results
Users who you add to the App Engine Studio Users group receive an email notification. Email recipients use a temporary password to log in to App Engine Studio for the first time. After resetting their password, a user can start building applications in App Engine Studio.

Note: ServiceNow authentication is not used when App Engine Studio is configured to use single sign-on.

Accessing App Engine Studio for the first time

Building applications in App Engine Studio

Meet the business needs of your organization by building custom applications in App Engine Studio.

Planning your application

Before you begin building, plan your application. Essentially, an application is a digital program that supports user tasks. You may ask the following questions as you plan:

• What are the goals, objectives, and outputs of your application?
• Who uses your application?
• Who has access to what?
• What tasks do people complete with your application?
• Where does the data come from?
• How do people interact with your application?
• What processes must the application support?
Your answers to these questions can help you decide whether to use an application template.

An application template provides predefined content to support a certain use case. For example, the Travel Request template provides application content for submitting and approving employee travel requests.

For a more streamlined development process, you would use the template that most closely fits your application goals. For more information on the available templates, see Template library.

If the available templates don’t fit your application goals, then you would create an application from scratch.

**Building your application**

To build an application in App Engine Studio, add the following content:

**Data**
Information that is stored in your application. For example, employee phone numbers or office locations. You configure application data using tables.

**Experience**
Graphical interface that your users interact with. For example, you can create a portal where users find information, submit requests, or complete business tasks.

**Logic and automation**
Business logic to automate application processes. You define logic and automation using flows. A flow includes a sequence of actions and a trigger. You can use a flow template or create a flow from scratch.

**Security**
Roles and access controls to limit who can use your application.

If you use an application template, the template automatically adds one or more of these items to your application. You can then edit them to tailor to your specific business needs. You can also add more data, experience, logic and automation, or security to an application that you created using a template.

To build an application from scratch, add data, experience, logic and automation, and security to your application and then edit each.

**Submitting your application**

After you’ve finished building your application, you start the process of getting the application published by submitting it for administrator approval.
The administrator reviews the submitted application and checks for potential issues. The administrator then rejects or approves the application.

You can check the status of your submitted application from the application dashboard in App Engine Studio.

"Pending Approval" status

If the administrator rejects the application, then it’s up to you to address the issues that the administrator discovered. You can use administrator feedback to guide you as you improve your application. After you’ve updated your application, re-submit it for administrator review.

After the administrator approves the application, they publish the application and on-board the relevant users.

For more information on submitting your application, see Submit an application for approval.

For more information on the application review process, see Delegated development in App Engine Studio.

Considerations
There are several considerations to keep in mind as you build applications in App Engine Studio:

• You access App Engine Studio by navigating to App Engine Studio or with the following web address: <instance-name>.servicenow.com/now/appenginestudio. If you don’t have a working link, contact your administrator.

• When you navigate back and forth between different applications in App Engine Studio, the application scope changes accordingly.

Intake request process for application development ideas
Application developers can easily submit application ideas through intake request forms. After ideas are submitted, the requests are automatically assigned to a designated group for review and approval.

After a request is approved or denied, an email notification is sent to the requester. If the request was approved, the developer is granted access to App Engine Studio to enable app development.
Benefits

The intake request process provides the following benefits:

• Streamlined process to submit ideas for app development.

• Automatic workflow process sends ideas to specified approvers or approval groups to accept or reject. Notification email messages are automatically sent once an idea is accepted or rejected.

• By exporting requests to a spreadsheet, approvers can easily check for duplicate or previously rejected requests.

Related concepts

• Refine the intake request form by modifying the related Service Catalog items. For more information, see Service catalog items

• Customize the approval flow. For more information, see Flows.

Submit an intake request form

Submit an idea for app development in your organization using an intake request form.

Before you begin

Role required: None

Procedure

1. Navigate to Service Catalog > Catalog.

2. Select Can We Help You?.

3. Select the Apply for Citizen Development catalog item.

4. On the form, fill in the fields.

Citizen Development form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application Name</td>
<td>Name for the application.</td>
</tr>
<tr>
<td>Describe your idea in a few sentences</td>
<td>Brief overview of the app development idea.</td>
</tr>
<tr>
<td>Is your process repeatable?</td>
<td>Option to indicate whether the app development process can be repeated.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>-------------</td>
</tr>
<tr>
<td>Do you have an email or excel based process?</td>
<td>Indicates whether the app development process is based on email or a Microsoft Excel spreadsheet.</td>
</tr>
<tr>
<td>How many users are involved in this?</td>
<td>Number of developers involved in developing or implementing the app development idea.</td>
</tr>
<tr>
<td>Does this involve any sensitive/PII data?</td>
<td>Indicates whether the app development idea requires access to sensitive customer information.</td>
</tr>
<tr>
<td>Do you need data from other departments?</td>
<td>Indicates whether the app developers require data from other departments.</td>
</tr>
<tr>
<td>Who are the users that will have access to the data in this application?</td>
<td>Lists groups or departments that require access to the app.</td>
</tr>
</tbody>
</table>

5. Click **Submit**.

Results
Your intake request is submitted to a designated group for approval. You will receive an email notification after a decision is made.

Review an intake request
After an idea for app development is submitted, review the intake request to approve or reject it.

Before you begin
Role required: admin
Procedure

1. Access the approval request record in one of the following ways.

<table>
<thead>
<tr>
<th>Option</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>ServiceNow instance</td>
<td>a. Navigate to Self-Service &gt; My Approvals.</td>
</tr>
<tr>
<td></td>
<td>b. Select the approval record that you want to review.</td>
</tr>
<tr>
<td></td>
<td>c. View the details by clicking Requested Items.</td>
</tr>
<tr>
<td>Email</td>
<td>Click the link in the Approval Request email you receive.</td>
</tr>
</tbody>
</table>

2. On the approval record, review the intake request and either approve or reject it.

<table>
<thead>
<tr>
<th>Option</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>The request is of value and you think it should be implemented</td>
<td>Click Approve.</td>
</tr>
<tr>
<td>The request is not viable. Possible reasons include:</td>
<td></td>
</tr>
<tr>
<td>• It has already been implemented.</td>
<td></td>
</tr>
<tr>
<td>• It's too difficult to implement.</td>
<td></td>
</tr>
<tr>
<td>• It's a duplicate.</td>
<td></td>
</tr>
<tr>
<td>• It has previously been rejected.</td>
<td></td>
</tr>
</tbody>
</table>

Results
A notification email is sent to the requester indicating the approval decision.

Use an application template
Build an application that uses predefined data, experience, logic and automation, and security.

Procedure

1. From the Template page, select a template.
2. On the template detail page, select Use Template.
3. Enter a name and description for your application.

4. **Optional:** Add a logo by dragging an image or browsing your computer.

5. Select **Continue**.

6. On the summary screen, select **Go to app home**.

7. From the app home, review the data, experience, logic and automation, or security that was created with the template. To tailor the application to your business needs, you can edit these predefined items or add your own. For more information, see the following topics:
   - Editing data in App Engine Studio
   - Adding data in App Engine Studio
   - Editing an experience in App Engine Studio
   - Adding an experience in App Engine Studio
   - Editing logic and automation in App Engine Studio
   - Adding logic and automation in App Engine Studio
   - Editing security in App Engine Studio
   - Adding security in App Engine Studio

**What to do next**

After you've finished building your application, submit the application for approval to get it reviewed and deployed by an administrator. For more information, see **Submit an application for approval**.

**Create an application from scratch for App Engine Studio**

If the available application templates don't fit your application goal, create an empty application to which you can add data, experience, logic and automation, and security.

**Before you begin**

Role required: admin, sn_app_engine_studio.user

**Procedure**

1. From the My Apps page, select **Create app**.

2. Enter a name and description for your application.

3. **Optional:** Add a logo by dragging an image or browsing your computer.

4. Select **Continue**.

5. On the summary screen, select **Go to app home**.
6. From the app home, add data, experience, logic and automation, and security to your app.
For more information, see the following topics:

- Adding data in App Engine Studio
- Adding an experience in App Engine Studio
- Adding logic and automation in App Engine Studio
- Adding security in App Engine Studio

What to do next
After you've finished building your application, submit the application for approval to get it reviewed and deployed by an administrator. For more information, see Submit an application for approval.

Adding data in App Engine Studio
Store information in an application by uploading a spreadsheet, extending a table, or building a custom table.

Data is a key starting point for any new application. Data populates a user interface. People who use your application may provide data, such as their name and phone number, when they fill in a form. Other people may refer to data as they fulfill a request.

In App Engine Studio, you store application data in a table format. Organizing data in a table makes it easier to track. When users update your application data, they create a row or change an existing row on your table.

The data that you use in your application may come from several sources. You may want to use data that you’re already storing in a spreadsheet. Or, you may want to use data that your organization is storing on the Now Platform.

Use any of the following methods to add a data table to your application:

- Upload a spreadsheet that has one sheet
- Upload a spreadsheet that has multiple sheets
- Create a table from an existing table
- Create a table from scratch

Application templates automatically add data to your application. If you use a template to create your application, you can edit the tables that were added or add different tables.
Upload a spreadsheet that has one sheet

Add a table to your application by uploading a Microsoft Excel spreadsheet that has one sheet.

Before you begin
Check that the spreadsheet meets the following requirements:
• Formatted with horizontal columns and a header label for each
• Saved as an XLSX file type
• Has only one sheet

Procedure
1. From the My Apps page, open your application.
2. In your application, next to Data, select the add icon (➕).
3. Select Upload a spreadsheet and then select Continue.
4. Upload your spreadsheet.
   You can drag the spreadsheet file onto App Engine Studio or browse your computer.
5. In the Enter a row number for the table header field, enter the row number in which column headers are located.
   For example, if the headers are in the second row, enter 2.
6. Optional: To upload the information below the column headers in your spreadsheet, select the Import spreadsheet data field.
   To upload only the column headers, leave the field blank.
7. Select Continue to review the data parsed from your spreadsheet.
8. Review the properties for each column header.

<table>
<thead>
<tr>
<th>Column header property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Field Label</td>
<td>Unique label for the column.</td>
</tr>
<tr>
<td>Field name</td>
<td>Database name for the column.</td>
</tr>
<tr>
<td>Type</td>
<td>Type of information that the column contains. For example, to contain plain text in the column, select String. Depending on the type that you select, fill in the additional fields to further define the table column. For</td>
</tr>
<tr>
<td>Column header property</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>example, if you select <strong>String</strong>, define the character limit of the string input. Or, if you select <strong>Choice</strong>, define the choices that users can choose from.</td>
<td></td>
</tr>
<tr>
<td>Character limit</td>
<td>Max length of the strings that can be stored.</td>
</tr>
<tr>
<td>Display</td>
<td>Option to set the column as the display value for the table. A reference field shows the display value of the table to which it is referring. For example, the <strong>Opened by</strong> column of the task table refers to the user table. Because the display value of the user table is the user name, the <strong>Opened by</strong> field shows something like <strong>Beth Anglin</strong> or <strong>Joe Employee</strong>. When you select a display value, choose the table column that would act as an appropriate title for individual records. Only one column can act as the display value for a table.</td>
</tr>
<tr>
<td>Mandatory</td>
<td>Option to require that the column must contain a value before a new record can be saved.</td>
</tr>
</tbody>
</table>

To add another column to your table, select **Add new field**.

To delete a column, select the trash icon (🗑️).

9. Select **Continue** to define table properties.

10. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table label</td>
<td>Unique label to identify the table.</td>
</tr>
<tr>
<td>Table name</td>
<td>Database name for the table. A table name is created automatically after you enter a table label. You can edit the name if needed.</td>
</tr>
<tr>
<td>Make extensible</td>
<td>Option to allow other tables to share data from this table. For more information on table extension, see Table extension and classes.</td>
</tr>
<tr>
<td>Auto number</td>
<td>Option to track table records with a unique number. If you select this option, define the <strong>Prefix</strong>, <strong>Starting number</strong>, and <strong>Number of digits</strong>.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Prefix</td>
<td>Abbreviated name of the table to append to the beginning of the record number. For example, if you are creating a &quot;Laptop&quot; table, then your prefix may be &quot;LPTP&quot; or &quot;LT.&quot;</td>
</tr>
<tr>
<td>Starting number</td>
<td>Number to identify the first record created for your table.</td>
</tr>
<tr>
<td>Number of digits</td>
<td>Maximum number of digits to allow in the record number. This value determines the highest possible record number. For example, if you enter 7, then the highest possible number is 9999999.</td>
</tr>
</tbody>
</table>

11. Select **Continue**, and then select **Done** on the summary screen.
   Alternatively, to view your table, you can select **Edit table** on the summary screen.

**Upload a spreadsheet that has multiple sheets**

If your Microsoft Excel spreadsheet has multiple sheets, you can upload each sheet to add multiple tables to your application.

**Before you begin**

Check that the spreadsheet meets the following requirements:

- Formatted with horizontal columns and a header label for each
- Saved as an XLSX file type
- Has more than one sheet

**Procedure**

1. From the My Apps page, open your application.

2. In your application, next to Data, select the add icon (⊕).

3. Select **Upload a spreadsheet** and then select **Continue**.

4. Upload your spreadsheet and then select **Continue**.
   You can drag the spreadsheet file onto App Engine Studio or browse your computer.

5. From the list of sheets, select a sheet to add as a table to your application.

   a. In the **Enter a row number for the table header** field, enter the row number in which the sheet column headers are located.
      For example, if the headers are in the second row, enter 2.
b. **Optional:** To upload the information below the column headers in the sheet, select the **Import spreadsheet data** field. To upload only the column headers, leave the field blank.

c. Select **Convert to table**.

6. Review the properties for each column header.

<table>
<thead>
<tr>
<th>Column header property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Field Label</td>
<td>Unique label for the column.</td>
</tr>
<tr>
<td>Field name</td>
<td>Database name for the column.</td>
</tr>
<tr>
<td>Type</td>
<td>Type of information that the column contains. For example, to contain plain text in the column, select <strong>String</strong>. Depending on the type that you select, fill in the additional fields to further define the table column. For example, if you select <strong>String</strong>, define the character limit of the string input. Or, if you select <strong>Choice</strong>, define the choices that users can choose from.</td>
</tr>
<tr>
<td>Character limit</td>
<td>Max length of the strings that can be stored.</td>
</tr>
<tr>
<td>Display</td>
<td>Option to set the column as the display value for the table. A reference field shows the display value of the table to which it is referring. When you select a display value, choose the table column that would act as an appropriate title for individual records. Only one column can act as the display value for a table.</td>
</tr>
<tr>
<td>Mandatory</td>
<td>Option to require that the column must contain a value before a new record can be saved.</td>
</tr>
</tbody>
</table>

To add another column to your table, select **Add new field**.

To delete a column, select the trash icon (łuż).
7. Select **Continue** to define table properties.
8. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table label</td>
<td>Unique label to identify the table.</td>
</tr>
<tr>
<td>Table name</td>
<td>Database name for the table. A table name is created automatically after you enter a table label. You can edit the name if needed.</td>
</tr>
<tr>
<td>Make extensible</td>
<td>Option to allow other tables to share data from this table. For more information on table extension, see Table extension and classes.</td>
</tr>
<tr>
<td>Auto number</td>

<tr>
<td>Number of digits</td>
<td>Maximum number of digits to allow in the record number. This value determines the highest possible record number. For example, if you enter 7, then the highest possible number is 9999999.</td>
</tr>
</tbody>
</table>

9. For each sheet that you want to upload, repeat steps 5-8.

10. After you’ve uploaded your sheets, select **Done**.

    Alternatively, to view your tables, you can select **Edit Tables** on the summary screen.

**Create a table from an existing table**

Add a data table to your application by extending a table that you or someone else previously created.

**About this task**

There are several tables that your organization is already using in other applications. For example, your organization may be using the Incident [incident] table for its Incident Management application. You can create a table for your application by extending any of these existing tables.
Table extension means enabling a table to share fields and records with a parent table. You would extend a table if you expect users to fill in similar fields as an existing table. For example, to create a ticketing type of table, you would extend the Task [task] table. The Task table includes fields that are standard for most work tickets, such as **Number** and **Assigned to**.

After extending an existing table, you can further customize the new table by adding more columns.

For more information on extending tables, see **Table extension and classes**.

**Procedure**

1. From the My Apps page, open your application.
2. In your application, next to Data, select the add icon (➕).
3. Select **Create from an existing table**, and then select **Continue**.
4. Select a table to extend, and then select **Continue**.
5. On the form, fill in the fields and then select **Continue**.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table label</td>
<td>Unique label to identify the table.</td>
</tr>
<tr>
<td>Table name</td>
<td>Database name for the table. A table name is created automatically after you enter a table label. You can edit the name if needed.</td>
</tr>
<tr>
<td>Make extensible</td>
<td>Option to allow other tables to share data from this table. For more information on table extension, see <strong>Table extension and classes</strong>.</td>

<td>Abbreviated name of the table to append to the beginning of the record number. For example, if you are creating a &quot;Laptop&quot; table, then your prefix may be &quot;LPTP&quot; or &quot;LT.&quot;</td>
</tr>
<tr>
<td>Starting number</td>
<td>Number to identify the first record created for your table.</td>
</tr>
<tr>
<td>Number of digits</td>
<td>Maximum number of digits to allow in the record number. This value determines the highest possible record number. For example, if you enter 7, then the highest possible number is 9999999.</td>
</tr>
</tbody>
</table>
6. To review the columns that were added to your table, select **Edit table**.

7. In the new tab that opens, review the table columns.
   
   Each table column appears as a row in Table Builder.

   A lock icon (🔒) appears next to columns from the extended table. You can’t modify these columns.

8. Customize your table by adding table columns.

   a. In Table Builder, select **+ Add new field**.

   b. On the blank row, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Column label</td>
<td>Unique label for the column.</td>
</tr>
<tr>
<td>Column name</td>
<td>Database name for the column.</td>
</tr>
<tr>
<td>Type</td>
<td>Type of information that the column contains. For example, to contain plain text in the column, select <strong>String</strong>. Depending on the type that you select, fill in the additional fields to further define the table column. For example, if you select <strong>String</strong>, define the character limit of the string input. Or, if you select <strong>Choice</strong>, define the choices that users can choose from.</td>
</tr>
<tr>
<td>Reference</td>
<td>Table that is associated with the column. This field applies only if the column type is <strong>Reference</strong>.</td>
</tr>
<tr>
<td>Max length</td>
<td>Maximum number of characters that users can enter in the field.</td>
</tr>
<tr>
<td>Default value</td>
<td>Value that populates the field automatically after a new record is created.</td>

When you select a display...</td>
</tr>
</tbody>
</table>
Create a table from scratch

If there are no spreadsheets or existing tables to use for your application, you can create a table that is completely custom.

Procedure

1. From the My Apps page, open your application.
2. In your application, next to Data, select the add icon (+).
3. Select Create from scratch, and then select Continue.
4. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table label</td>
<td>Unique label to identify the table.</td>
</tr>
<tr>
<td>Table name</td>
<td>Database name for the table. A table name is created automatically after you enter a table label. You can edit the name if needed.</td>
</tr>
<tr>
<td>Make extensible</td>
<td>Option to allow other tables to share data from this table. For more information on table extension, see Table extension and classes.</td>
</tr>
<tr>
<td>Auto number</td>
<td>Option to track table records with a unique number. If you select this option, define the Prefix, Starting number, and Number of digits.</td>
</tr>
<tr>
<td>Prefix</td>
<td>Abbreviated name of the table to append to the beginning of the record number. For example, if you are creating a “Laptop” table, then your prefix may be “LPTP” or “LT.”</td>
</tr>
<tr>
<td>Starting number</td>
<td>Number to identify the first record created for your table.</td>
</tr>
<tr>
<td>Number of digits</td>
<td>Maximum number of digits to allow in the record number. This value determines the highest possible</td>
</tr>
</tbody>
</table>
5. To begin building your table, select **Edit table**.

Table Builder opens in a new tab.

Your new table includes several default columns, including **Created** and **Updated**. You can’t delete these default columns.

6. Customize your table by adding table columns.

   a. In Table Builder, select **+ Add new field**.

   b. On the blank row, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Column label</td>
<td>Unique label for the column.</td>
</tr>
<tr>
<td>Column name</td>
<td>Database name for the column.</td>
</tr>
<tr>
<td>Type</td>
<td>Type of information that the column contains. For example, to contain plain text in the column, select <strong>String</strong>. Depending on the type that you select, fill in the additional fields to further define the table column. For example, if you select <strong>String</strong>, define the character limit of the string input. Or, if you select <strong>Choice</strong>, define the choices that users can choose from.</td>
</tr>
<tr>
<td>Reference</td>
<td>Table that is associated with the column. This field applies only if the column type is <strong>Reference</strong>.</td>
</tr>
<tr>
<td>Max length</td>
<td>Maximum number of characters that users can enter in the field.</td>
</tr>
<tr>
<td>Default value</td>
<td>Value that populates the field automatically after a new record is created.</td>
</tr>
<tr>
<td>Display</td>
<td>Option to set the column as the display value for the table. A reference field shows the display value of the table to which it is referring. For example, the <strong>Opened by</strong> column of the task table refers to the user table. Because the display value of the user table is the user name, the <strong>Opened by</strong> field shows something like <strong>Beth</strong>.</td>
</tr>
</tbody>
</table>
Adding an experience in App Engine Studio

Create a portal, workspace, record producer, or mobile experience for users to interact with your app.

Application templates automatically add experiences to your application.

Add a workspace

Give your users a service desk-like experience to manage tickets.

Procedure

1. From the My Apps page, open your application.
2. In your application, next to Experience, select the add icon (+).
3. Select Workspace, and then select Begin.
4. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the workspace. By default, the workspace shares the same name as your application.</td>
</tr>
<tr>
<td></td>
<td><strong>Tip:</strong> Use a name that uniquely identifies the workspace from other experiences. For example, Office art requests workspace.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the workspace.</td>
</tr>
<tr>
<td>URL</td>
<td>Web address of the workspace. By default, the workspace URL is based on the application name.</td>
</tr>
<tr>
<td>Roles</td>
<td>User roles to limit who can access the workspace. To use a custom role for your workspace, you must create one in Security first. For more information, see Adding security in App Engine Studio.</td>
</tr>
</tbody>
</table>

5. Select Continue to define data for your workspace.
6. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary Table</td>
<td>Data table that workspace users view or update.</td>
</tr>
<tr>
<td>Secondary Tables</td>
<td>Additional data tables that workspace users view and update.</td>
</tr>
</tbody>
</table>

7. Select **Continue**, and then select **Done**.

**What to do next**
Customize the workspace to your organization's needs by editing in UI Builder.
For more information, see [Editing data in App Engine Studio](#).

**Add a portal**
Give your users a site where they can find information, create requests, and complete business tasks.

**Procedure**
1. From the My Apps page, open your application.
2. In your application, next to Experience, select the add icon (➕).
3. Select **Portal**, and then select **Begin**.
4. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the portal. By default, the portal shares the same name as your application.</td>
</tr>
<tr>
<td></td>
<td>☛ <strong>Tip:</strong> Use a name that uniquely identifies the portal from other experiences. For example, Office art portal.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the portal.</td>
</tr>
<tr>
<td>URL</td>
<td>Web address of the portal. By default, the workspace URL is based on the application name.</td>
</tr>
<tr>
<td>Roles</td>
<td>User roles to limit who can access the portal. To use a custom role for your portal, you must create one in</td>
</tr>
</tbody>
</table>
5. Select **Continue**, and then select **Done**.

**What to do next**
Customize the portal to your organization's needs by editing in UI Builder. For more information, see **Editing data in App Engine Studio**.

**Add a mobile experience**
Give your users the ability to perform application tasks from their mobile device.

**Procedure**
1. From the My Apps page, open your application.
2. In your application, next to Experience, select the add icon (➕).
3. Select **Mobile**, and then select **Begin**.
4. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the mobile experience. By default, the mobile experience shares the same name as your application.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of your mobile experience.</td>
</tr>
<tr>
<td>Tables</td>
<td>Data tables that mobile users view and update.</td>
</tr>
<tr>
<td>Roles</td>
<td>User roles to limit who can access the mobile experience. To use a custom role for your mobile experience, you must create one in <strong>Security</strong> first. For more information, see <strong>Adding security in App Engine Studio</strong>.</td>
</tr>
<tr>
<td>Available offline</td>
<td>Option to enable mobile users work on data without an internet connection. Updates that users make while offline are synced to the application after they connect to the internet again.</td>
</tr>
</tbody>
</table>

5. Select **Continue**, and then select **Done**.

**What to do next**
Customize the mobile experience to your organization's needs by editing in Mobile Studio. For more information, see **Editing data in App Engine Studio**.
Add a catalog item

Give your users a way to submit a request by filling out a form.

Before you begin

Create a data table that you plan to update using the request form. For more information, see Adding data in App Engine Studio.

Procedure

1. From the My Apps page, open your application.
2. In your application, next to Experience, select the add icon (+).
3. Select Catalog item, and then select Begin.
4. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the catalog item.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the catalog item.</td>
</tr>
</tbody>
</table>

5. Select Edit catalog item to open Catalog Builder.
6. Specify the required information.

Catalog Builder steps

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Details</td>
<td>• Basic info: Item name and short description.</td>
</tr>
<tr>
<td></td>
<td>• Item details: Description of the item.</td>
</tr>
<tr>
<td>Destination</td>
<td>Destination table in which a record producer creates records.</td>
</tr>
<tr>
<td>Location</td>
<td>Catalogs and categories that the item can belong to.</td>
</tr>
<tr>
<td></td>
<td>Note: You can add up to a maximum of 50 catalogs or categories.</td>
</tr>
<tr>
<td>Questions</td>
<td>Question sets (variable sets) or questions for the item. By default, the question sets included in the template are added and cannot be removed. Available question types are restricted to those specified in the template.</td>
</tr>
<tr>
<td>Step</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td></td>
<td>From the <strong>Insert new question</strong> list, you can include additional question sets, questions, deactivated questions, single-column container, two-column container, and line break. For information on creating a question and supported question types, see <em>Create a question for a catalog item in Catalog Builder</em>. You can also add dynamic form behavior for a question. For information on adding dynamic form behavior, see <em>Edit a question in Catalog Builder</em>.</td>
</tr>
</tbody>
</table>

**Note:**
- The questions within a question set cannot be edited. The question sets can be reordered by dragging and dropping them.
- Question sets specified in the template cannot be removed, while the ones added by the user can be removed.
- Removal of question sets simply removes the association with the item and does not delete the question set.
- A single-column question set can be added to a single-column or a two-column container. A two-column question set cannot be added to a container.

<table>
<thead>
<tr>
<th>Settings</th>
<th>Settings to configure the catalog item behavior in Service Portal based on the request method.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access</td>
<td>User criteria to specify users for whom the item is available or not available.</td>
</tr>
<tr>
<td>Review and submit</td>
<td>Review the item and submit it.</td>
</tr>
</tbody>
</table>

To save your changes in each step, select **Save**.

7. To preview a catalog item in Portal or Now Mobile, select **Preview**.

**Note:** When you preview an item, you can interact with it but not submit it.
a. To preview the item in Portal, select Portal for the View within field.

   Note: Portal preview is based on portal URL configured for the catalog builder.

b. To view an item representation in Now Mobile, select Now Mobile for the View within field.

c. To open the preview in a new tab, select Open preview in a new tab.

   Note: When you make any changes to the item and save it, the preview is dynamically refreshed in the opened tab.

8. Select Submit.

Adding logic and automation in App Engine Studio

Replace manual processes with application logic and automation.

In App Engine Studio, you define logic and automation by using flows. A flow is a sequence of actions that run when the flow starts. App Engine Studio provides pre-built flows you can apply to common use cases, or you can create your own custom flows. You can automatically start flows by defining a trigger or manually start flows from an API call. For example, you can create a flow that is triggered when a user fills in a request form. Then, you can define the flow to send a notification to another user who fulfills the request.

Application templates automatically add logic and automation to your application.

To add automation to your application, you can use a flow template or create a flow from scratch.

Use an automation template

Use a pre-built flow to automate application processes.

Procedure

1. From the My Apps page, open your application.

2. In your application, next to automation, select the add icon (➕).

3. From the gallery of automation templates, select a template and then select Begin.
Create an approval for a requested catalog item

This flow template creates an approval flow for a requested item from the Service Catalog. This flow automatically approves any item with a price lower than a specific amount. During configuration, you specify the automatic approval price amount.

4. Complete the wizard for the template that you selected.
5. On the summary screen, select Done.

What to do next
You can edit the flow to tailor it to your specific business needs. For more information on editing flows, see Editing logic and automation in App Engine Studio.

Create a flow from scratch
If an existing automation template doesn't fit your application goal, define custom automation by building a flow from scratch.

Procedure
1. From the My Apps page, open your application.
2. In your application, next to automation, select the add icon (➕).
3. Select Build from scratch.
4. On the form, fill in the fields and then select **Continue**.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name to uniquely identify your flow.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of your flow.</td>
</tr>
<tr>
<td>Protection</td>
<td>Access settings for the flow. You can select one of the following options:</td>
</tr>
<tr>
<td></td>
<td><strong>-- None --</strong></td>
</tr>
<tr>
<td></td>
<td>Option to allow other users to edit the flow.</td>
</tr>
<tr>
<td></td>
<td><strong>Read-only</strong></td>
</tr>
<tr>
<td></td>
<td>Option to allow other users to view the flow but not edit it.</td>
</tr>
</tbody>
</table>
| Run As      | Selection to specify if the flow runs as a system user or the user who initiates the session. If updates should come from the user who triggered the flow, select **User who initiates session**. For example, when you want incident
### Field Description

- **Run with roles**
  - Roles that the flow runs with. This option is available only when **Run As** is set to **User who initiates session**.
  - To use a custom role for your flow, you must create one in **Security** first. For more information, see Adding security in App Engine Studio.

5. On the summary screen, select **Edit this flow** to open Flow Designer.

6. Add a trigger to your flow.

   a. Under the **TRIGGER** section, select **Add a trigger**.

   b. From the Trigger list, select a trigger that will start running your flow.
      - For more information on trigger types, see Flow trigger types.
      - The system displays a set of fields depending on the type of trigger that you’ve selected.

   c. Set up your trigger by filling in the fields.
      - For a record-based trigger, for example, select a table and optionally set field conditions that, when met, will start running your flow.

   d. Click **Done**.
7. To add actions, flows, subflows, or flow logic, click **Select to add an Action, Flow Logic, or Subflow**.

   a. Select an option.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action</td>
<td>Select the desired action. Flow Designer includes a set of Actions available to flows and subflows. Alternatively, a user with the action_designer role can create additional actions to add to flows. The IntegrationHub and spoke plugins install additional actions. To add draft actions from the More Actions menu, set <strong>Show draft actions</strong> to <strong>true</strong>. To view spokes available in the ServiceNow Store, set <strong>Show store spokes</strong> to <strong>true</strong> from the More Actions menu. <strong>Note:</strong> Under <strong>Not Installed Spokes</strong>, the system displays spokes available in the ServiceNow Store based on compatibility with the ServiceNow version and application dependency on Flow Designer.</td>
</tr>
<tr>
<td>Flow Logic</td>
<td>Select an option to specify conditional or repeated operations.</td>
</tr>
<tr>
<td>Subflow</td>
<td>Select a published subflow and define input values. In addition to adding a subflow as a flow action, you can enable the <strong>Show triggered flows</strong> option from the More Actions menu to select an activated flow and define the required inputs. Running a triggered flow ignores its trigger conditions and runs all actions.</td>
</tr>
</tbody>
</table>

To change the order of an action in a flow, drag the handle on the left side of the action to the desired location.

The system displays a set of fields depending on the option selected.

   b. To configure the action, flow logic, or subflow, fill in the fields.

   c. Click **Done**.

   d. Repeat adding actions until complete.
8. Select **Save**.  
Flow Designer saves a draft of the flow, trigger, and actions.

**What to do next**
Test your flow until you're ready to activate it. For more information on testing and editing flows, see [Editing logic and automation in App Engine Studio](#).

ℹ️ **Note:** Only activated flows can be triggered in your application.

**Adding security in App Engine Studio**
Control who can use or edit your application by adding a role.

You add security to your application by defining roles. A role is used to limit and control access to your application. The access that you define for a role is granted to all users who are assigned to the role.

An administrator assigns a role to the appropriate user based on the kind of work that the role permits. For example, to enable a manager to read and approve employee requests, an administrator would assign a role that has access to read and update records from the relevant table. The role may also need access to the portal or workspace where the manager would see the request.

Application templates automatically add security to your application. If you use a template to create your application, you can edit the roles that were added or add different roles.

App Engine Studio includes default roles that you can use for your application. For more information on the default roles, see [Base system roles](#).

Alternatively, you can build custom roles for your application.

After you submit your application, an administrator on-boards the requesting team by assigning the roles that you've defined.

**Build a new role**
Create a custom role for your application.

**Procedure**
1. From the My Apps page, open your application.
2. In your application, next to Security, select the add icon (➕).
3. Select **Build a new role** and then select **Continue**.
4. Enter a name and description for your role, and then select Continue.

Tip: For consistency with existing role names, enter a role name that is all lower-case and uses underscores instead of spaces. For example, for an office art requester role, you would enter office_art_requester.

5. For each table in your application, select one or more access controls for your role.

- **Create**
  Users with the role can create new records on the data table.

- **Read**
  Users with the role can read the data that is stored in the table.

- **Write**
  Users with the role can update existing records in the table.

- **Delete**
  Users with the role can delete table records.
6. Select the **Experience** tab, and then select the experiences that users with the role can access.

7. Select **Continue**, and then select **Done** on the summary screen.

**Use an existing role**

Use a previously created role for your application.

**About this task**

App Engine Studio includes default roles that you can use for your application. For more information on the default roles, see [Base system roles](#).

**Procedure**

1. From the My Apps page, open your application.

2. In your application, next to Security, select the add icon (+).

3. Select **Use an existing role**, and then select **Continue**.

   ![Option to use an existing role](#)

**ADD SECURITY**

**How do you want to add a role to your app?**

- ![Build a new role](#)
- ![Use an existing role](#)

4. Select the search field and then select a role from the list.
5. Select **Edit**.
   A new tab opens to set access controls for the existing role.

6. In the Experience section, select the experiences that users with the role can access.

7. In the Data section, set access controls for each available table.
   
   **Create**
   Users with the role can create new records on the data table.

   **Read**
   Users with the role can read the data that is stored in the table.

   **Write**
   Users with the role can update existing records in the table.

   **Delete**
   Users with the role can delete table records.

8. Select **Save**.

**Editing data in App Engine Studio**

Use Table Builder to edit data in your application.

Table Builder is a tool for editing data tables that you’ve added to your application. You edit a table by editing the columns of the table.

![Table Builder](image-url)
In Table Builder, each table column is represented as a row. For example, "Art title," "Image," and "Available" appear as column headers on the actual table. However, when you edit the columns in Table Builder, they appear as rows.

**Editing columns in Table Builder**

<table>
<thead>
<tr>
<th>Column label</th>
<th>Column name</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Art title</td>
<td>art_title</td>
<td>String</td>
</tr>
<tr>
<td>Image</td>
<td>image</td>
<td>Image</td>
</tr>
<tr>
<td>Available</td>
<td>available</td>
<td>True/False</td>
</tr>
</tbody>
</table>

**Actual table**

<table>
<thead>
<tr>
<th>Art title</th>
<th>Image</th>
<th>Available</th>
</tr>
</thead>
<tbody>
<tr>
<td>Search</td>
<td>Search</td>
<td>Search</td>
</tr>
</tbody>
</table>

As you edit table columns in Table Builder, think of each row as a field on a form. For example, if you change a column label, use a label that describes the data that you expect the user to enter in the form field. Change the column type to support this kind of form entry.
To open Table Builder, open an application in App Engine Studio. From the application home, select the menu icon (⋯) next to a table, and then select Edit.

In Table Builder, you can perform any of the following tasks:

- Edit table properties
- Add a table column
- Delete a table column
- Change a column label
- Change a column name
- Change a column type
- Add a default value to a table column
- Select a column as the table display value
- Preview a table
- Delete a table

**Edit table properties**
Change table properties such as the table label and access controls.

**About this task**
By editing table properties, you can relabel your table, make your table extensible, or add record numbers. You can also set application access settings.

Making a table extensible means allowing new tables to share columns from your table. For example, if you created an “Office location” column in your table, you can allow new tables to use the “Office location” column also. For more information on table extension, see Table extension and classes.

Adding record numbers means automatically creating a tracking number for each new table entry. For example, a new entry to the Travel Requests table would get a record number like TRV1234567. You can use this number to find table records more easily.

Application access settings determine whether script objects from other applications can access the table in your application. You can give these script objects access to read, create, update, or delete records on your table. Alternatively, you can disable access to your table from other applications. For more information on the application access controls, see Table design and runtime settings.
Procedure

1. Select **Properties**.

2. On the dialog box that appears, update the table properties.

<table>
<thead>
<tr>
<th>Option</th>
<th>Procedure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change the table label</td>
<td>In the General information tab, update the <strong>Table label</strong> field.</td>
</tr>
<tr>
<td>Make the table extensible</td>
<td>a. In the General information tab, select <strong>Advanced</strong>.</td>
</tr>
<tr>
<td></td>
<td>b. Select the <strong>Make extensible</strong> check box.</td>
</tr>
<tr>
<td>Add record numbers</td>
<td>a. In the General information tab, select <strong>Advanced</strong>.</td>
</tr>
<tr>
<td></td>
<td>b. Select the <strong>Add record number</strong> check box.</td>
</tr>
<tr>
<td></td>
<td>c. Define the record numbers by updating the Prefix, Starting number, and Number of digits fields.</td>
</tr>
<tr>
<td>Make the table accessible from other applications</td>
<td>a. Open the Access tab.</td>
</tr>
<tr>
<td></td>
<td>b. In the <strong>Accessible From</strong> field, select All Application Scopes.</td>
</tr>
<tr>
<td></td>
<td>c. In the <strong>Application Access Controls</strong> field, set the access controls for the table.</td>
</tr>
<tr>
<td>Disable other tables from accessing the table</td>
<td>a. Open the Access tab.</td>
</tr>
<tr>
<td></td>
<td>b. In the <strong>Accessible From</strong> field, select This Application Scope Only.</td>
</tr>
</tbody>
</table>

3. Select **Save** to close the dialog box.

**Add a table column**

Store more information in a table record by adding a table column.
Procedure
1. Select + Add new field.
2. On the blank row, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Column label</td>
<td>Unique label for the column.</td>
</tr>
<tr>
<td>Column name</td>
<td>Database name for the column.</td>
</tr>
<tr>
<td>Type</td>
<td>Type of information that the column contains. For example, to contain plain text in the column, select String. Depending on the type that you select, fill in the additional fields to further define the table column. For example, if you select String, define the character limit of the string input. Or, if you select Choice, define the choices that users can choose from.</td>
</tr>
<tr>
<td>Reference</td>
<td>Table that is associated with the column. This field applies only if the column type is Reference.</td>
</tr>
<tr>
<td>Max length</td>
<td>Maximum number of characters that users can enter in the field.</td>
</tr>
<tr>
<td>Default value</td>
<td>Value that populates the field automatically after a new record is created.</td>
</tr>
<tr>
<td>Display</td>
<td>Option to set the column as the display value for the table. A reference field shows the display value of the table to which it is referring. For example, the Opened by column of the task table refers to the user table. Because the display value of the user table is the user name, the Opened by field shows something like Beth Anglin or Joe Employee. When you select a display value, choose the table column that would act as an appropriate title for individual records. Only one column can act as the display value for a table.</td>
</tr>
</tbody>
</table>

Results
If you preview the table, you can see the new column added to your table. For more information on previewing a table, see Preview a table.
Delete a table column
Delete a column from your table.

Procedure
Next to the row that represents your table column, select the trash icon (🗑).

Note: Your table includes several default columns, including Created and Updated, that you can’t delete. Also, you can’t delete columns that are extended from another table.

Results
If you preview the table, you can see that the table column is no longer used in the table. For more information on previewing a table, see Preview a table.

Change a column label
Change the label that uniquely identifies a table column.

About this task
A column label is the text that’s visible to your users when they’re reading or updating application data. For example, if you create a form for requesters to fill in, each column label appears as a form field label.

Use a column label that describes the specific information that you expect users to enter. For example, to prompt a user to add comments, you would use the column label Comments instead of Text.

Procedure
From the Column label column, change a column label by updating the text in the corresponding row.

For example, to change the label of the "Office location" column, you would select the cell that says "Office location" and enter a different label.

The column label updates automatically after you select another cell.

Change a column name
Change the database name for the column.

About this task
A column name is the text that an administrator uses to track column data in the database. A column name is created automatically after you enter a column label. In Table Builder, if you change the column label, the column name also changes automatically.
You may choose to change the column name manually if a reviewer finds that the column name was causing issues in testing. Changing the column name allows you to resolve the issue without having to change the text that's visible to users.

**Procedure**

From the **Column name** column, change the column name by updating the text in the corresponding row.

For example, to change the name of the "Office location" column, you would select the cell that says u_office_location and enter a different name.

The column name updates automatically after you select another cell.

**Change a column type**

Change the type of information that is stored in a table column.

**Procedure**

1. From the **Type** column, select a cell and clear the text.
2. From the list, select a column type.

![List of column types](image)

You can search the list by entering new text. For example, to find all the string types, you would enter *string*. 
3. If required, further define the column type. For example, if you select **Choice**, define the choices that users can select from.

![Choice Type Example](image)

The column type updates automatically after you select another cell.

**Add a default value to a table column**

Define the default value to populate a table column automatically after a user creates a record.
Procedure

From the **Default value** column, add a default value of a column by updating the content in the corresponding row.

You define the default value by selecting a cell and then entering the value. The value that you enter depends on the column type. For example, if the column requires a choice, you would select one of the choices that you defined in the **Type** column.

The column name updates automatically after you select another cell.

**Select a column as the table display value**

Select a column value that is displayed in the reference fields of other tables.

**About this task**

A reference field shows the display value of the table to which it is referring. For example, the **Opened by** column of the task table refers to the user table. Because the display value of the user table is the user name, the **Opened by** field shows something like **Beth Anglin** or **Joe Employee**. When you select a display value, choose the table column that would act as an appropriate title for individual records.

Only one column can act as the display value for a table.

**Procedure**

1. From the **Display** column, check that all selections are cleared.
   
   To clear a selection, toggle off the switch.

2. From the **Display** column, select one row to act as the table display value.
   
   To select a row, toggle on the switch.

3. Select **Save**.

**Preview a table**

See what your table looks like after you’ve edited the table columns.
About this task
Each row in Table Builder represents a column from your table. Previewing the table allows you to see what the columns look like in their proper place. You can also test the experience of creating records on your table.

Procedure
1. Select Preview.
2. From the new tab, review the table preview.

Example table preview

<table>
<thead>
<tr>
<th>Requested by</th>
<th>Requested time</th>
<th>Location</th>
<th>Preferred meal</th>
<th>Dietary restrictions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bath Angel</td>
<td>2013-05-08 18:00:00</td>
<td>Luigi's Ristora</td>
<td>Pizza</td>
<td>Vegetarian</td>
</tr>
<tr>
<td>John Smith</td>
<td>2013-05-08 17:00:00</td>
<td>Call by the Sea</td>
<td>Seafood</td>
<td>Some allergies</td>
</tr>
<tr>
<td>Jane Doe</td>
<td>2013-02-23 17:30:00</td>
<td>Men's Texas Style BBQ</td>
<td>Barbecue</td>
<td>None</td>
</tr>
<tr>
<td>Joe Employee</td>
<td>2013-05-01 09:00:00</td>
<td>La Cina</td>
<td>Burritos</td>
<td>Vegan</td>
</tr>
</tbody>
</table>

What to do next
If your table doesn’t work as expected, continue editing in Table Builder. Then, preview the table again.

Delete a table
Delete a table from your application.

Procedure
1. Select the menu icon (・・・), and then select Delete Table.
2. On the dialog box that appears, enter delete and then select Delete.
Results
The table is no longer available in the app dashboard.

Editing an experience in App Engine Studio
Use UI Builder, Catalog Builder, or Mobile Studio to tailor your experience to your business needs.

Edit a workspace
Use UI Builder to edit a workspace experience.

Before you begin
Add a workspace to your application. If you created an application using a template, a workspace may already be added to your application. For more information on adding a custom workspace, see Adding an experience in App Engine Studio.

Procedure
1. From the My Apps page, open your application.
2. Next to a workspace, select the menu icon (≡≡≡) and then select Edit.

3. In UI Builder, edit the workspace by adding or configuring components on each page.
   You can also add more pages to the workspace, if needed.

   Note: The default workspace pages are read-only and can't be edited. To change the content of each page, create a page variant and edit the variant.

Edit a portal
Use UI Builder to edit a portal experience.
Before you begin
Add a portal to your application. If you created an application using a template, a portal may already be added to your application. For more information on adding a custom portal, see Adding an experience in App Engine Studio.

Procedure
1. From the My Apps page, open your application.
2. Next to a portal, select the menu icon (・・・) and then select Edit.

3. In UI Builder, edit the portal by adding or configuring components on each page. You can also add more pages to the portal, if needed.

Note: The default portal pages are read-only and can’t be edited. To change the content of each page, create a page variant and edit the variant.

Edit a mobile experience
Use Mobile Studio to edit a mobile experience.

Before you begin
Add a mobile experience to your application. If you created an application using a template, a mobile experience may already be added to your application. For more information on adding a custom mobile experience, see Adding an experience in App Engine Studio.

Procedure
1. From the My Apps page, open your application.
2. Next to a mobile experience, select the menu icon (・・・) and then select Edit.
3. Edit the mobile experience in Mobile Studio.

### Edit a request form

Use Catalog Builder to edit a request form.

### Before you begin

Add a request form to your application. If you created an application using a template, a request form may already be added to your application. For more information on adding a custom request form, see Adding an experience in App Engine Studio.

### Procedure

1. From the My Apps page, open your application.
2. Next to a catalog item, select the menu icon (≡≡≡) and then select **Edit**.

### Edit a catalog item

3. Edit the request form.
## Catalog Builder steps

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
</table>
| Details | - Basic info: Item name and short description.  
- Item details: Description of the item. |
| Destination | Destination table in which a record producer creates records. |
| Location | Catalogs and categories that the item can belong to.  
**Note:** You can add up to a maximum of 50 catalogs or categories. |
| Questions | Question sets (variable sets) or questions for the item. By default, the question sets included in the template are added and cannot be removed.  
Available question types are restricted to those specified in the template.  
From the **Insert new question** list, you can include additional question sets, questions, deactivated questions, single-column container, two-column container, and line break. For information on creating a question and supported question types, see [Create a question for a catalog item in Catalog Builder](#).  
You can also add dynamic form behavior for a question. For information on adding dynamic form behavior, see [Edit a question in Catalog Builder](#).  
**Note:**  
- The questions within a question set cannot be edited. The question sets can be reordered by dragging and dropping them.  
- Question sets specified in the template cannot be removed, while the ones added by the user can be removed.  
- Removal of question sets simply removes the association with the item and does not delete the question set.  
- A single-column question set can be added to a single-column or a two-column container. A two-column question set cannot be added to a container. |
<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Settings</td>
<td>Settings to configure the catalog item behavior in Service Portal based on the request method.</td>
</tr>
<tr>
<td>Access</td>
<td>User criteria to specify users for whom the item is available or not available.</td>
</tr>
<tr>
<td>Review and submit</td>
<td>Review the item and submit it.</td>
</tr>
</tbody>
</table>

To save your changes in each step, select **Save**.

**Preview an experience**

See what an application experience looks like to your users.

**Before you begin**

Add an experience to your application. For more information, see **Adding an experience in App Engine Studio**.

**Procedure**

1. From the My Apps page, open your application.
2. From the application home, next to an experience, select **Preview**.

3. On the browser tab that opens, review the experience.

**What to do next**

If the experience looks or behaves differently than expected, edit the experience.
Delete an experience

Delete a portal, workspace, mobile experience, or request form that you no longer need.

Procedure

1. From the My Apps page, open your application.
2. Next to an experience, select the menu icon (・・・) and then select Delete.

3. On the dialog box that appears, enter delete and then select Delete.

Editing logic and automation in App Engine Studio

Use Flow Designer to tailor your automation to your business needs.

Edit a flow

Edit an existing flow in Flow Designer.

Before you begin

Add logic and automation to your application. If you created an application using a template, logic and automation may already be added to your application. For more information on adding custom logic and automation, see Adding logic and automation in App Engine Studio.

Procedure

1. From the My Apps page, open your application.
2. Next to a flow, select the menu icon (・・・) and then select Edit.
3. Take the appropriate actions to edit the flow.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change the flow name, description, or roles</td>
<td>In the main header, select Properties, enter the values you want into the appropriate fields, and then select Update.</td>
</tr>
<tr>
<td>To edit the trigger</td>
<td>In your flow, select the trigger description, fill in the fields as desired, and then select Done.</td>
</tr>
<tr>
<td>Note:</td>
<td>Modifying triggers can result in the deletion of referenced action configurations.</td>
</tr>
<tr>
<td>To edit an existing action</td>
<td>In your flow, select the action description, fill in the fields as desired, and then select Done.</td>
</tr>
<tr>
<td>To add a new action</td>
<td>In your flow, select the plus icon in the ACTION section, then proceed as you would for adding an action to a new flow.</td>
</tr>
</tbody>
</table>

4. To save your changes, select Save.

Test a flow
Test a flow to make certain it works the way you expect.

Procedure
1. From the My Apps page, open your application.
2. Next to a flow, select the menu icon (⋮) and then select Edit.
3. In Flow Designer, select Test.
The system displays the Test flow dialog. The contents of the Test flow dialog depend on the type of trigger.

4. If the flow has a record trigger, create or select a record to use for the test. To create a record, select the **Create new record** button.

5. If the flow has a record **Updated** or **Created or Updated** trigger, specify which fields and values changed in the update. To specify a field value change, select the **Create new changed field** button for each field whose value you want to change. Complete the changed field details for each changed field.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Field Name</td>
<td>The field updated by the test.</td>
</tr>
<tr>
<td>Previous Value</td>
<td>The field value prior to the update.</td>
</tr>
<tr>
<td>Current Value</td>
<td>The field value after the update.</td>
</tr>
<tr>
<td>Previous Display Value</td>
<td>The field display value prior to the update.</td>
</tr>
<tr>
<td>Current Display Value</td>
<td>The field display value after the update.</td>
</tr>
</tbody>
</table>

6. Select **Run Test**.

   **Note:** Select the **Run test in background** option to test a flow asynchronously in the background.

   The system tests the flow.

7. Select **Your test has finished running. View the flow execution details**.

   **Note:** This link is created irrespective of your choice for the **Run test in background** option. If you have selected the **Run test in background** option, the execution details are displayed only after the execution is completed asynchronously in the background. Also, the execution details are associated with the flow only after execution is completed.

   The system displays the flow execution details for the test.

**What to do next**

- Review the flow execution details. For more information, see Flow execution details.

**Activate a flow**

Activate a flow to make it available to other users.
About this task
To use a flow in your application, you must activate it.

Procedure
1. From the My Apps page, open your application.
2. Next to a flow, select the menu icon (•••) and then select Edit.

3. In Flow Designer, select Activate.

Delete a flow
Delete a flow that you no longer need.

Procedure
1. From the My Apps page, open your application.
2. Next to a flow, select the menu icon (•••) and then select Delete.

3. On the dialog box that appears, enter delete and then select Delete.

Editing security in App Engine Studio
Edit the application role that you added.

Editing a role entails changing the access settings for the role. You may choose to change access settings for any of the following reasons:
- Expand the access of a role
- Reduce the access of a role
- Define role access for a newly added table or experience

Application templates automatically add security to your application. If you use a template to create your application, you can edit the roles that were added.

**Change access settings for a role**
Control the application permissions for a role.

**Procedure**
1. From the My Apps page, open your application.
2. Next to a role, select the menu icon (･･･) and then select **Edit**.

![](image.png)

A new tab opens to edit the role.
3. In the Experience section, select the experiences that users with the role can access.
4. In the Data section, set the access controls for each available table.
   - **Create**
     Users with the role can create new records on the data table.
   - **Read**
     Users with the role can read the data that is stored in the table.
   - **Write**
     Users with the role can update existing records in the table.
   - **Delete**
     Users with the role can delete table records.
5. Select **Save**.

**Delete a role**
Delete a role that you no longer need.
Procedure

1. From the My Apps page, open your application.
2. Next to a role, select the menu icon (・・・) and then select Delete.

Deleting a role

3. On the dialog box that appears, enter delete and then select Delete.

Using the Collaboration feature

Developers can add additional developers to work on an application using the Collaboration feature. In App Engine Studio, you can add or remove users and groups to be collaborators on an application from the AES dashboard.

Users have varying levels of permissions for actions on the Collaboration feature. At a high level:

<table>
<thead>
<tr>
<th>User</th>
<th>Collaboration permissions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Users with Manage Collaborators delegated development permission to the application</td>
<td>Can:</td>
</tr>
<tr>
<td></td>
<td>• See a list of Collaborators and their descriptors</td>
</tr>
<tr>
<td></td>
<td>• Search for users or groups</td>
</tr>
<tr>
<td></td>
<td>• Select/change user or group’s Collaboration descriptor (but users cannot change customized users or groups and cannot change the owner if there is only one owner)</td>
</tr>
<tr>
<td></td>
<td>• Add collaborators by sending invite</td>
</tr>
<tr>
<td></td>
<td>• Remove users or groups (but users cannot remove customized users or groups and cannot remove the owner if there is only one owner)</td>
</tr>
<tr>
<td></td>
<td>Cannot:</td>
</tr>
<tr>
<td>User</td>
<td>Collaboration permissions</td>
</tr>
<tr>
<td>------</td>
<td>--------------------------</td>
</tr>
</tbody>
</table>
| Users with Invite Collaborators delegated development permission to the application | Can:  
- See a list of Collaborators and their descriptors  
- Search for users or groups  
- Add collaborators by sending invite  
Cannot:  
- Select/change user or group's Collaboration descriptor  
- Remove users or groups  
- Customize a user or group's permissions |
| Users who do not have any Collaborator related roles to the application | Can:  
- See a read-only list of Collaborators and their descriptors  
Cannot:  
- Search for users or groups  
- Select/change user or group's Collaboration descriptor  
- Add collaborators by sending invite  
- Remove users or groups  
- Customize a user or group's permissions |
| Administrators | Can:  
- See a list of Collaborators and their descriptors  
- Show/hide members of a group  
- Search for users or groups  
- Select/change user or group's Collaboration descriptor (includes changing customized users or groups) |
<table>
<thead>
<tr>
<th>User</th>
<th>Collaboration permissions</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>groups and changing the owner even if there is only one owner)</td>
</tr>
<tr>
<td></td>
<td>• Add collaborators by sending invite</td>
</tr>
<tr>
<td></td>
<td>• Remove users or groups (includes removing customized users and groups and removing the owner even if there is only one owner)</td>
</tr>
<tr>
<td></td>
<td>• Customize a user or group’s permissions</td>
</tr>
</tbody>
</table>

When a user or group is added, an collaboration task is generated and an approval flow kicks off. To find all collaboration tasks, navigate to **App Engine > Collaboration > Collaboration Tasks**. The collaboration task provides information on which application a developer is being added to, and what permissions will be granted. Approvers will sometimes need to review these task records before developers can be added to the application.

If you are an admin, you can use flow designer to modify the Collaboration Request flow. The base system Collaboration Request flow handles collaboration requests as follows:

- If the user has AES or delegated developer permissions and is not new to the platform, the collaboration request approval record is auto-approved.
- If the user does not have AES or delegated developer permissions and is new to the platform, approval is required.

See **Flow Designer** for more information.

If you are an admin, you can modify the collaboration descriptors with which developers assign other developers delegated development permissions. The base system table provides Owner and Editor collaboration descriptors. By default, Owners have the manage collaborator delegated development permission set and Editors have the invite collaborator delegated development permission set. See **Application collaboration** for more information.

**Adding a user or group to collaboration**

You can add a user or group to the Collaboration feature.

**Before you begin**

Role required: admin, manage collaborator delegated development role, or invite collaborator delegated development role
Procedure

1. From the AES dashboard, select the Manage Collaborators button.

2. The Collaborate with others modal appears with the users and groups that are collaborators. To add another user or group as a collaborator, enter the user name or group name in the Invite field.

3. You can search for a specific user or group by entering the first few characters in the Invite field. A drop-down list with matching user names and groups displays and you can select the user or group you want to add. If a user or group displays in the drop-down list but cannot be selected, that user or group has already been added as a collaborator and cannot be selected again.

4. Select the collaboration descriptor for the user or group you are adding (users with invite collaborators do not have this ability and will default to the Editor option). Only App Collaboration Descriptors that are defined in the global scope and have the standard option selected display in the list.

5. Select Send.
   One of the following things happens:
• If the user has AES or delegated developer permissions and is new to the platform, the user is listed under the pending requests section and approval is required. Once the request is approved, both the requester and the user will get an email that the user has been added to the application.

![Welcome to the team!](image)

• If the user has AES or delegated developer permissions and is not new to the platform, the collaboration request is auto-approved. Both the requester and the user will get an email that the user has been added to the application.

**Changing collaborator permissions or creating custom descriptions**

You can change the permissions that are currently assigned to a collaborator or create a custom description.

**Before you begin**

Role required: admin or manage collaborator delegated development role
Procedure

1. From the AES dashboard, select the Manage Collaborators button. The Collaborate with others modal appears with the users and groups that are collaborators.

2. For the user or group you want to change, select a different collaborator descriptor from the drop-down list.

   Every application must have at least one owner and customized users and groups are not editable by non-admins.

3. Admin only: Custom collaboration descriptions can only be changed by administrators.
   a. To customize a user or group’s collaboration descriptor in the UI, select Custom Permissions from the drop-down list.
   b. Select or deselect delegated development permissions for the user or group. If the selection matches that of another standard Collaboration descriptor, the system will provide a prompt before proceeding. For details
on each delegated development permission, see Delegate development and deployment permissions to personnel delegated development permission documentation.

4. Select Save.

Removing a user or group from Collaboration

You can remove a user or group from the Collaboration feature.

Before you begin

Note: Every application must have at least one owner. If an application has only one owner, you cannot remove the owner until another owner is assigned first.

Role required: admin or manage collaborator delegated development role
Procedure

1. From the AES dashboard, select the Manage Collaborators button. The Collaborate with others modal appears with a list of the current collaborators.

2. To remove a user or group as a collaborator, select Remove from the drop-down list.

**Collaborate with others**

<table>
<thead>
<tr>
<th>Collaborators</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="mailto:AC@example.com">AC@example.com</a></td>
</tr>
<tr>
<td><a href="mailto:AT@example.com">AT@example.com</a></td>
</tr>
</tbody>
</table>

**Edit application properties**

Rename your app, rewrite the app description, or replace the app image.

**Procedure**

1. From the My Apps page, open your application.

2. From the app home, select the gear icon (⚙).

3. On the dialog box that appears, update the application properties.
   
   - To rename the application, update the Name field.
   
   - To rewrite the application description, update the Description field.
   
   - To replace an image, select Remove image and then add a new image.

4. Select Save.
Submit an application for approval

Start the process of getting your application published by submitting it for administrator review.

Before you begin
Role required: delegated developer with permissions

Procedure
1. From the My Apps page, open your application.
2. From the app home, select Submit.
3. On the dialog box that appears, review the submission details and then select Submit.

What to do next
The administrator reviews the submitted application and checks for potential issues. You can check the status of your application from the application home in App Engine Studio.

"Pending Approval" status

Office art loaner app Pending Approval
Updated: 2021-01-21 18:05:53

After a reviewer begins testing the application, the status changes to In Validation.

"In Validation" status

Office art loaner app In Validation
Updated: 2021-01-22 12:43:58

An administrator may provide you with test accounts for different roles in your application. Log in with each of these accounts to check that the application works as expected.

If the reviewer rejects the application, the status changes to Rejected. You may also receive an email that includes the reviewer’s comments. Use the feedback to improve your application, and then submit the application again.
"Rejected" status

Office art loaner app

Updated: 2021-01-22 12:43:58

If the application passes testing, the administrator publishes the application and the status changes to Published. The administrator on-boards the team that requested the application. For example, if you specified a certain security role for the application, the administrator assigns that role to the relevant users.

"Published" status

Delegated development in App Engine Studio

Publish an application from App Engine Studio when linked to Source Control

You can publish a custom application from App Engine Studio when linked to source control.

Before you begin

Role required: admin

About this task

When you publish an application from App Engine Studio that is linked to source control, there is a different outcome than when you publish via the sys_app or sys_store_app Publish related link.

Procedure

1. From the My Apps page, open your application.

2. From the app home, select Publish.
   App Engine Studio displays the publish app fields.
3. Enter the following field values.

**Provide a version number and release notes**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version</td>
<td>View your current app version and provide a new version number for your application.</td>
</tr>
<tr>
<td>Release notes</td>
<td>Provide a brief description of the changes made to your application.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Publish options</td>
<td>Select if you want the application to be published to your application repository or the ServiceNow Store.</td>
</tr>
</tbody>
</table>

Note: All application developers on the instance share the credential used to link a Git repository to an application.

4. Click **Continue**.

5. The current state of the application is committed to source control, including any untracked or uncommitted changes. The value of the `glide.sourcecontrol.default_commit_mode` property is ignored. This occurs because when the application is published, all the untracked and uncommitted changes are also published. Therefore, the state of the application in the Git repository matches what is published. See the **Commit changes** topic for more information about the `glide.sourcecontrol.default_commit_mode` property.

6. A Source Control tag is created for the new version and the application is published. If needed, the sys_app record is updated with the new store correlation ID.

Remove an application from App Engine Studio

If you have the appropriate permissions, you can remove an application from App Engine Studio.

**Before you begin**
Role required: admin, delegated developer with permissions

**About this task**
Delegated developers can delete applications based on their permissions. To request delete permissions, contact your administrator.

**Procedure**
1. From the My Apps page, open your application.
2. In your application, select the gear icon (⚙).
3. Select **Delete application**.
4. On the dialog box, enter `delete` and then select **Delete**.
Template library

Use an application template to create an application with preconfigured data, experience, automation, and security.

Document Approval template

Build an application to manage the approval of documents in your organization.

A document approval app enables your users to quickly create & use document approval workflows. Document owners & submitters can upload documents needing approvals and check the progress on those approvals. Designated approvers can approve, reject, or return documents with comments.

Admins can use the document approval application to create different workflows for different document types.

The document approval app template is an ideal solution for making your internal workflows for processing documents quickly and efficiently. Document owners/submitters can upload a document needing approval to a portal using simple upload functionality that automatically sends submissions through a unique workflow. Once a document has been received, submitters can follow the progress of their documents while designated users approve, reject, or return their document for edits. Both submitters and approvers use comments to add notes and feedback to the submission, which is stored in the system for future reference. To give this app even more variety, admins can create unlimited workflows that are customized for each document type and user that allows for multiple stages and approvers depending on what the document category requires.

For more information on creating an application using a template, see Use an application template.

Data

The Document Approval app template includes the following tables:

<table>
<thead>
<tr>
<th>Tables</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Table label [name]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Document Approver Table [x_ &lt;company-code&gt;_ &lt;document_approver&gt;]</td>
<td>Tracks document approvers, their comments, and state of a document.</td>
</tr>
</tbody>
</table>
Tables (continued)

<table>
<thead>
<tr>
<th>Table label [name]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Document Approval Category Table [x_ &lt;company-code&gt;_ &lt;document_approval_category&gt;]</td>
<td>Tracks the category of document approval requests.</td>
</tr>
<tr>
<td>Document Approval Table [x_ &lt;company-code&gt;_ &lt;document_approval&gt;]</td>
<td>Tracks the document approval requests.</td>
</tr>
</tbody>
</table>

**Experience**
The Document Approval app template includes the following experiences:

<table>
<thead>
<tr>
<th>Experience</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Document approval mobile experience</td>
<td>Employees and managers can use the mobile app check the status of an approval, approve/reject documents, and view submissions using your organization's iOS or Android app.</td>
</tr>
<tr>
<td>Document approval workspace</td>
<td>Employees can upload documents, check the status of an approval, edit documents, and view their submissions in the workspace. Approvers can view assigned approvals, view previous submissions, and approve/reject submissions.</td>
</tr>
<tr>
<td>Document approver form</td>
<td>Approvers can view assigned approvals and approve/reject submissions.</td>
</tr>
<tr>
<td>Doc approval portal</td>
<td>Approvers can view assigned approvals, view previous submissions, and approve/reject submissions using the doc approval portal.</td>
</tr>
</tbody>
</table>

**Logic and automation**
The Document Approval app template includes the following flows:
Flows

<table>
<thead>
<tr>
<th>Flow name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Document Approval - Master Flow</td>
<td>This flow is executed when a new document approval record is submitted. It then retrieves the flow to be executed from the document category and executes it.</td>
</tr>
<tr>
<td>Single Stage Approval</td>
<td>This flow allows for the user’s manager to be the approver, with basic email notifications being generated on approval, return, or rejection.</td>
</tr>
</tbody>
</table>

Security

The Document Approval app template includes the following user roles:

Roles

<table>
<thead>
<tr>
<th>Role title [name]</th>

</tr>
<tr>
<td>Submitters [x_&lt;company-name&gt;_&lt;document_approval_app&gt;.submitter]</td>
<td>Submitters can create documents, read their own documents, edit their own documents when status is not submitted and delete their own documents. They can also read data from document approval category.</td>
<td>Create, Read (own), Edit (own when status is not submitted), Delete (own)</td>
</tr>
</tbody>
</table>
Emergency Alert template

Build an application to manage communications and track essential resources during an emergency.

An emergency alert app allows your organization to keep employees informed and connected during natural disasters and infectious diseases, such as COVID-19.

You can use the emergency alert template to create command center dashboards and a mobile app to monitor and notify employees about the latest news. Employees can self-report their status, request work-from-home or time off, and receive instructions during an emergency. Managers can assess the impact on their respective teams, approve/reject requests, request for status, and automatically receive instruction on actions to take during any emergency.

For more information on creating an application using a template, see Use an application template.

Data

The Emergency Alert app template includes the following tables:

<table>
<thead>
<tr>
<th>Table label [name]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Self Report Table [x_&lt;company&gt;_my_emergency_alert_app&gt;_status_report]</td>
<td>Track reported emergencies created by employees or managers. For example, the emergency details, status, duration, and affected individuals.</td>
</tr>
<tr>
<td>Work Status Request Task Table [x_&lt;company&gt;_my_emergency_alert_app&gt;_work_status_request_task]</td>
<td>Track the work status request of an emergency. For example, the requestor, the assignee, and the state of the work status.</td>
</tr>
<tr>
<td>Emergency Alert Table [x_&lt;company&gt;_my_emergency_alert_app&gt;_emergency_alert]</td>
<td>Track emergency alerts for your company. For example, the emergency type, who created the alert, and who has read the alerts.</td>
</tr>
<tr>
<td>Status Report Request Table [x_&lt;company&gt;_my_emergency_alert_app&gt;_status_report_requests]</td>
<td>Track the severity of an emergency reported by employees. For example, the status, the color associated with danger levels, and conditions.</td>
</tr>
</tbody>
</table>
Experience
The Emergency Alert app template includes the following experiences:

<table>
<thead>
<tr>
<th>Experience</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Emergency Alert App</td>
<td>Employees and managers can report emergencies, provide status updates, and view/manage time off requests using your organization's iOS or Android app.</td>
</tr>
<tr>
<td>Emergency Alert - Portal</td>
<td>Employees can view reported emergencies, the status of their team, and submit a self-report using the web portal.</td>
</tr>
<tr>
<td>Self Report Form</td>
<td>Employees and managers can use the self report form to report emergencies.</td>
</tr>
<tr>
<td>Emergency Alert - Workspace</td>
<td>Admins can use the workspace to set up and send notifications, view dashboards, and configure list and forms.</td>
</tr>
</tbody>
</table>

Logic and automation
The Emergency Alert app template includes the following flows:

<table>
<thead>
<tr>
<th>Flow name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Employee emergency report request response submitted</td>
<td>Sends a notification when an employee emergency report has been submitted.</td>
</tr>
<tr>
<td>Please report or update status</td>
<td>Sends a notification when a status change has been committed.</td>
</tr>
<tr>
<td>Status request for employees from manager</td>
<td>Sends a notification to employees when a status request is made by their manager.</td>
</tr>
<tr>
<td>Create App Self Reports</td>
<td>Sends a notification when a report request is created or updated.</td>

## Event Registration template

Build an application to manage scheduling, booking, and registration for company events.

An internal event registration app allows your event organizers to publish a list of events to employees and collect attendees in a centralized database. The app helps streamline the event discovery and registration process.

Event organizers can manage events, wait-lists, publish new events, and view registered users’ details. Employees and attendees can view a list of events, view event info, and register to attend in a portal. Event organizers can set the size of the event, and requesters will automatically be added to a wait-list.

For more information on creating an application using a template, see Use an application template.

## Data

The Event Registration app template includes the following tables:

### Tables

<table>
<thead>
<tr>
<th>Table label [name]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Event Table</td>
<td>Track event information such as event name, date of the event, and capacity.</td>
</tr>
<tr>
<td>[x_&lt;company-code&gt;_ &lt;event&gt;]</td>
<td></td>
</tr>
<tr>
<td>Attendee Table</td>
<td>Track event attendee information such as name, status, and date of submission.</td>
</tr>
<tr>
<td>[x_&lt;company-code&gt;_ &lt;attendee&gt;]</td>

Inventory Tracker template

Build an application to track the status of inventory and assets.

An Inventory Tracker app enables your business and teams to easily track what they have, where it is, and who has it. Anytime, anywhere, and on any device. If your company needs to track the stock of items, this app can be used as a stock management tool or inventory tracker at home or in a warehouse.

This app covers three inventory use cases: consumables, loaners, and discontinued. Employees can request items via mobile app or web portal from any warehouse. Inventory managers can set reorder levels and will be automatically notified if an item is low on stock. Discontinued items with outstanding stock can still be requested but will not prompt inventory managers for reorder. Inventory managers can create items manually or by uploading a spreadsheet.

For more information on creating an application using a template, see Use an application template.

Data

The Inventory Tracker app template includes the following tables:
### Tables

<table>
<thead>
<tr>
<th>Table label [name]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inventory Control Table</td>
<td>Track the stock of items used by your business. For example, item name, manufacturer, image, category, and location.</td>
</tr>
<tr>
<td>Inventory Request Table</td>
<td>Track inventory requests submitted by employees. For example, the name and department of the requestor, stock location, count, requested date, and return date.</td>
</tr>
<tr>
<td>Stock Location Table</td>
<td>Track the location of stocked items. For example, name, address, and inventory manager.</td>
</tr>
</tbody>
</table>

### Experience

The Inventory Tracker app template includes the following experiences:

<table>
<thead>
<tr>
<th>Experience</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inventory Tracker App</td>
<td>Employees can view inventory list, see stock quantities, request items, and check the status of their requests using your organization's iOS or Android app.</td>
</tr>
<tr>
<td>Inventory Control Portal</td>
<td>Admins and managers can use the inventory control portal to manage inventory items, view stock quantity, and stock locations.</td>
</tr>
<tr>
<td>Inventory Tracker Portal App Config</td>
<td>Admins and managers can configure the employee request form.</td>
</tr>
<tr>
<td>Inventory request</td>
<td>Employees can use the inventory request form to submit and manage inventory requests.</td>

Performance Review template

Build an application to automate scheduling, notifications, and feedback for performance reviews.

A performance review app automates the process of scheduling annual or quarterly reviews, reviewing employee performance, and providing manager
feedback. The app displays report information by default and lets managers view, update, and request employee performance reviews.

Employees can complete their self-evaluation, monitor the status, and confirm evaluations via a web portal. The app will automatically notify employees and managers to submit their evaluations.

Managers can request an update to the self-evaluations, submit manager-evaluations, confirm evaluations, and monitor the status of their team's submissions via a portal.

The HR/admin role can select an annual, bi-annual, or quarterly review process schedule and edit both the self-evaluation and manager-evaluation templates. HR/admins can monitor the status of all evaluations by department, organization, or manager.

You can improve this template by incorporating the following features:

- Add continuous option as a review process
- Use Playbook to manage review schedules
- Include HR review/escalation process for both self-reviews and manager reviews
- Add peer reviews process
- Add goal setting or OKRs
- Add integration with HR software
- Add skill set assessment metrics
- Add PIP process/individual development plans
- Include compensation info/APR

For more information on creating an application using a template, see Use an application template.

Data
The Performance Review template includes the following tables:

<table>
<thead>
<tr>
<th>Table label [name]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Performance review table</td>
<td>Track the performance evaluations created by employees and managers. For example, the employee name, state of the review,</td>
</tr>
</tbody>
</table>
### Experience

The Performance Review template includes the following experiences:

<table>
<thead>
<tr>
<th>Experience</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mobile app</td>
<td>Employees can access their performance reviews using your organization's iOS or Android app.</td>
</tr>
<tr>
<td>Edit Settings form</td>
<td>Admins can use the Edit Settings form to configure performance reviews. For example, the frequency of a review, which employees are affected, and when the review is due.</td>
</tr>
<tr>
<td>Performance Review Test Workspace</td>
<td>HR/Admin users can use the workspace to configure review schedules, update evaluation templates, and monitor the status of all evaluations.</td>
</tr>
<tr>
<td>Manager Review form</td>
<td>Managers can review and make updates employee performance reviews using the manager review form.</td>
</tr>
<tr>
<td>Self Review form</td>
<td>Employees and managers can submit a self-assessment of their performance using the self review form.</td>
</tr>
<tr>
<td>Workspace form</td>
<td>Employees and managers can complete performance review using the workspace form.</td>
</tr>
<tr>
<td>Employee Portal</td>
<td>Employees can use the portal to submit, update, review, and confirm evaluations.</td>
</tr>
</tbody>
</table>
**Experiences (continued)**

<table>
<thead>
<tr>
<th>Experience</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default view form</td>
<td>Managers and Admins can use the default form view as a template for performance reviews.</td>
</tr>
</tbody>
</table>

**Logic and automation**

The Performance Review app template includes the following flows:

<table>
<thead>
<tr>
<th>Flows</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Flow name</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>Send PR Employee Update Self-Eval email</td>
<td>This flow triggers the PR Employee Update Self-Eval email.</td>
</tr>
<tr>
<td>Send PR Employee Complete Evaluation email</td>
<td>This flow triggers the PR Employee Complete Evaluation email.</td>
</tr>
<tr>
<td>Send PR Employee Manager-Eval submitted</td>
<td>This flow triggers the PR Employee Manager-Evaluation submitted email.</td>
</tr>
<tr>
<td>Send deadline email</td>
<td>Send notifications to employees to submit their reviews by a specific date.</td>
</tr>
<tr>
<td>Main Flow</td>
<td>Main flow which triggers daily. This flow controls when reviews are triggered, email reminders, and end of review period is reached.</td>
</tr>
<tr>
<td>Send reminder emails</td>
<td>Subflow to trigger reminder emails on the date indicated by sys_properties.</td>
</tr>
<tr>
<td>Create records</td>
<td>Subflow to trigger review records on date indicated by sys_properties.</td>
</tr>
<tr>
<td>Set review inactive</td>
<td>Subflow to inactivate reviews on the end date of the review period, specified in sys_properties.</td>
</tr>
<tr>
<td>Send Manager/ADMIN Self Evaluation Submitted email</td>
<td>This flow triggers the PR Admin Self-Evaluation Submitted w/o manager or the PR Manager Self Evaluation Submitted email.</td>
</tr>
</tbody>
</table>
Security
The Performance Review app template includes the following user roles:

<table>
<thead>
<tr>
<th>Role title [name]</th>
<th>Description</th>
<th>Contains roles</th>
</tr>
</thead>
<tbody>
<tr>
<td>Employee [x_&lt;company-name&gt;_ &lt;my performance_review_app&gt;.employee]</td>
<td>Employees can complete/update self-evaluations and confirm evaluations.</td>
<td>Create, Read (own), Update (own, Delete (own)</td>
</tr>
<tr>
<td>Managers [x_&lt;company-name&gt;_ &lt;my performance_review_app&gt;.manager]</td>
<td>Managers can request updates to a self-evaluation, submit manager evaluations, and monitor issues related to evaluation submissions.</td>
<td>Create, Read (my team), Update (my team)</td>
</tr>
<tr>
<td>HR/Admins [x_&lt;company-name&gt;_ &lt;my performance_review_app&gt;.admin]</td>
<td>HR/Admins can schedule reviews (annual, bi-annual, custom, or manual), edit self and manager evaluation templates, and monitor the status of all reviews.</td>
<td>Read (all), Update (all), Delete (all)</td>
</tr>
</tbody>
</table>

Team Contacts template
Build an application to manage contact information for the people in your organization.

A Team Contacts app uses a mobile experience to view employee contact information, tag favorites, and add privacy notes. The app displays report information by default and lets an employee search for employees, view employee profiles, and create a list of favorite employee contacts.

For more information on creating an application using a template, see Use an application template.

Data
The Team Contacts app template includes the following tables:
Tables

<table>
<thead>
<tr>
<th>Table label [name]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Relationship Contact Table [x_&lt;company-code&gt;_&lt;team_contact&gt;_relationship_contact]</td>
<td>Tracks employee contact information. For example, contact names, date created, favorites, and updates.</td>
</tr>
<tr>
<td>Reminder Table [x_&lt;company-code&gt;_&lt;team_contact&gt;_relationship_contact_reminders]</td>
<td>Tracks reminders created by your team. For example, when to send a reminder and the subject of a reminder.</td>
</tr>
<tr>
<td>Relationship Notes Table [x_&lt;company-code&gt;_&lt;team_contact&gt;_relationship_notes]</td>
<td>Tracks the notes that employees create for each other. For example, the employee name, reason for contact, HTML notes, and option to mark the contact as a favorite.</td>
</tr>
</tbody>
</table>

Experience
The Team Contacts app template includes the following experiences:

<table>
<thead>
<tr>
<th>Experience</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mobile</td>
<td>Employees can access an employee directory, and relationship notes using your organization’s iOS or Android app.</td>
</tr>
<tr>
<td>Portal</td>
<td>Employees and managers can view employee profiles, mark favorite contacts, and add relationship notes using a website. The team contacts portal includes a sign-in page, a home page, and a page to add relationship notes.</td>
</tr>
<tr>
<td>Reminder Form</td>
<td>Employees can set reminders using the team contacts form.</td>
</tr>
</tbody>
</table>

Logic and automation
The Team Contacts app template includes the following flows:
Flows

<table>
<thead>
<tr>
<th>Flow name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Notify Contact Reminder</td>
<td>Sends a notification about a reminder that an employee sets up in a relationship note. The notification contains details from the relationship note.</td>
</tr>
</tbody>
</table>

Security

The TeamContacts app template includes the following user roles:

<table>
<thead>
<tr>
<th>Role title [name]</th>
<th>Description</th>
<th>Contains roles</th>
</tr>
</thead>
<tbody>
<tr>
<td>Manager [x_&lt;company-name&gt;_ &lt;app-name&gt;.manager]</td>
<td>Managers can view profile info, add relationship notes, and see their direct reports.</td>
<td>Create, Read (own), Update (own), Delete (own)</td>
</tr>
<tr>
<td>Admin [x_&lt;company-name&gt;_ &lt;app-name&gt;.admin]</td>
<td>Managers can configure the team contacts app and grant access to the app.</td>
<td>Read (all), Update (all), Delete</td>
</tr>
<tr>
<td>Employee [x_&lt;company-name&gt;_ &lt;app-name&gt;.employee]</td>
<td>Employees can view information on their team, search for employees, view employee profiles, and mark favorite contacts.</td>
<td>Create, Read (own), Update (own), Delete (own)</td>
</tr>
</tbody>
</table>

Time Off Requests template

Build an application to schedule employee vacations and time-off.

Streamline the process for employees to request time off through a single mobile or web-based form. Managers are notified via email when a request is submitted. They can use a mobile app or a web-based portal to view historical and pending requests by month or year for an employee or their entire team. This allows the manager to make informed decisions, improve planning for upcoming work, or identify where shifts must be covered. Employees are automatically notified when their requests are approved or rejected and why. If plans change and updates to an approved request are required, the employee
can edit and resubmitted their requests for approval through a mobile or a web-based portal where they can also see their historical requests.

For more information on creating an application using a template, see Use an application template.

Data
The Time Off Request app template includes the following tables:

<table>
<thead>
<tr>
<th>Tables</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Table label [name]</strong></td>
</tr>
<tr>
<td>Time Off Requests Table</td>
</tr>
</tbody>
</table>

Experience
The Time Off Request app template includes the following experiences:

<table>
<thead>
<tr>
<th>Experiences</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Experience</strong></td>
</tr>
<tr>
<td>Mobile app</td>
</tr>
<tr>
<td>Time off request form</td>
</tr>
<tr>
<td>Time off request workspace</td>
</tr>
</tbody>
</table>
Experiences (continued)

<table>
<thead>
<tr>
<th>Experience</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time off request portal</td>
<td>Employees can use the portal to view, edit, review, or cancel their time off requests.</td>
</tr>
<tr>
<td>Time off request record form</td>
<td>Managers can use the record form to view, submit, and approve/deny time off requests.</td>
</tr>
<tr>
<td>Time off request default form</td>
<td>Managers and Admins can use the default form view as a template for time off requests.</td>
</tr>
</tbody>
</table>

Logic and automation
The Time Off Request app template includes the following flows:

<table>
<thead>
<tr>
<th>Flows</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Send notifications</td>
<td>Sends a notification to an employee or manager when a time off request state changes. The notification contains details from the time off request.</td>
</tr>
<tr>
<td>Time Off Request</td>
<td>Employees can draft, request, approve, reject, and cancel time off requests.</td>
</tr>
<tr>
<td>Send comments</td>
<td>Sends a notification to an employee or manager when a comment has been added to a time off request.</td>
</tr>
<tr>
<td>Daily Time Off inactivating records</td>
<td>Time off requests will update the remaining time off until the remaining days is set to 0.</td>
</tr>
</tbody>
</table>

Security
The Time Off Request app template includes the following user roles:
## Roles

<table>
<thead>
<tr>
<th>Role title [name]</th>
<th>Description</th>
<th>Contains roles</th>
</tr>
</thead>
<tbody>
<tr>
<td>Employee [x_&lt;company-name&gt;_ &lt;my_time_off_request_app&gt;.employee]</td>
<td>Employees can submit, view, edit, and cancel time off requests</td>
<td>Create, Read (own), Edit (own), Delete (own)</td>
</tr>
<tr>
<td>Manager [x_&lt;company-name&gt;_ &lt;my_time_off_request_app&gt;.manager]</td>
<td>Managers can submit, view, approve, and deny time off requests</td>
<td>Create, Read (all), Edit (all)</td>
</tr>
<tr>
<td>Admin [x_&lt;company-name&gt;_ &lt;my_time_off_request_app&gt;.admin]</td>
<td>Admins can manage the time off app and view all records</td>
<td>Create, Read (all), Edit (all), Delete (all)</td>
</tr>
</tbody>
</table>

### Getting help in App Engine Studio

Find help for building your application from product documentation, learning tutorials, or community forums.

The App Engine Studio Resources page contains helpful links to assist you as you build your application. For example, for help with editing a portal page, you can access the relevant UI Builder documentation on working with components.

#### Resources page

You can refer to any of the following resources:

**ServiceNow product documentation**

Read product documentation to learn about App Engine Studio concepts. You can also follow step-by-step instructions to get started on specific tasks.

**ServiceNow Developer Site**

Follow tutorials on the Developer Site to build applications for example use cases.

**Now Community**

Browse community forums to find answers from other developers using App Engine Studio. If you can’t find an answer, you can post a question in the Now Platform forum.
Source Control integration in App Engine Studio

Enable application developers to integrate with a Git Source Control repository. Save and manage multiple versions of an application from a non-production instance.

Linking an application to Source Control enables all application developers on a non-production instance to:

- Import applications from a Git repository.
- Pull and apply remote changes from a Git repository.
- Commit all local changes on the instance to a Git repository.
- Create tags to permanently link to a given version of an application.
- Create branches to maintain multiple versions of an application simultaneously.

Integration requirements

To link an application to source control:

- The user must have the admin role.
- The non-production instance must have network access to the Git repository.
- Each application must be within its own Git repository.
- The repository user credentials must grant read and write access.

⚠️ Note: All application developers on the instance share a single set of credentials per repository.

Options available from App Engine Studio

After linking an application to Source Control, application developers can use App Engine Studio to manage the repository. From App Engine Studio, developers can:

- Edit the application repository credentials.
- Commit all local changes on the instance.
- Apply remote changes from the repository.
- Create a branch.
- Switch branches.
- Import an application from a remote repository.

Source Control integration does not support managing applications on a production instance. Instead, you can manage applications on a production
instance using the application repository, an update set, or App Engine Studio. For more information about managing applications on a production instance, see Application sharing.

Options available from a Git repository
The ServiceNow platform offers limited support for modifying linked application files outside of an instance. From Git, developers can:

- Move application files to a different Git directory structure.
- Edit application files outside of App Engine Studio.

The system generates a properties text file called **sn_source_control.properties** at the root level of the repository. To move application files to a different Git directory structure, application developers can set the **path** parameter to specify the subfolder path containing their application files. For example, if you moved your application to the **src/app** subfolder, set the **path** to `path=src/app`.

The system generates a **checksum.txt** file in the Git repository to determine if any application files have been changed outside of App Engine Studio. When the checksum value from the file matches the current checksum value, the integration skips the validation and sanitization process. When the checksum values do not match, the integration validates and sanitizes the application files as part of the Source Control operation. The sanitization process:

- Creates upgrade log entries for each sanitization action taken.
- Removes unsupported folders and files from the repository.
- Aborts all Source Control operations when a system application file fails XML schema validation. For example, if a database dictionary record fails XML schema validation, the system aborts all operations.
- Skips the current Source Control operation when a non-system application file fails XML schema validation.

The Source Control integration sanitizes only content within the application path listed in the **sn_source_control.properties** file. Repository content outside the application path is ignored.

MID Server support
Use an existing MID Server to connect to a Source Control repository, or an application through a MID Server enables access to repositories behind a firewall.
Source control operations in App Engine Studio

The source control integration primarily supports operations from App Engine Studio, but can also support some operations directly from the GIT repository.

### Available source control operations

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
<th>Available from</th>
</tr>
</thead>
<tbody>
<tr>
<td>Import from Source Control</td>
<td>Imports an application from the repository to the local instance.</td>

Import application or application-customization from source control

Import an application or application-customization from a source control repository to continue developing it on this instance.

Before you begin

- Role required: admin
- Verify that the non-production instance has network access to the Git repository.
- Verify that the repository contains a valid application.
- Ensure that users add the email address to their respective Users Table (ServiceNow sys_user) record that they use in their commits to the Git repository.
- Learn more about application-customizations Manage customizations to applications.

About this task

The source control integration does not support importing an application on a production instance. Instead install applications on a production instance from the application repository, an update set, or the App Engine Studio.

Procedure

   App Engine Studio will open in a new tab.
2. Click Import app.
   App Engine Studio displays the Import from source control fields.
3. Enter the following field values.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Network protocol</td>
<td>Https or ssh credential type that enables secure channel data exchange.</td>
</tr>
<tr>
<td>URL</td>
<td>The URL to the Git repository where the application files reside.</td>
</tr>
<tr>
<td>Branch</td>
<td>The repository branch to work on within the application.</td>
</tr>
</tbody>
</table>

**Note:** If the Git repo URL for SSH provided by your Git server does not work, check with your Git server owner or provider for the correct URL. There may be additional specifications such as scheme protocol prefixes, port numbers, and so on, required for your Git repo URL to function.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MID Server Name</td>
<td>Select an existing MID Server to link to a Git repository stored behind your corporate firewall. &lt;br&gt; <strong>Note:</strong> Use a separate MID Server to prevent conflicts with Discovery activities.</td>
</tr>
<tr>
<td>Default email</td>
<td>The committer email address is defined by the sys_user record if available. But if a committer's sys_user record email field is empty, the system generates an alternate email (<a href="mailto:username@instancename.service-now.com">username@instancename.service-now.com</a>). You can also enter a default email address and change it later. To use that default email address in all cases, select the check box.</td>
</tr>
<tr>
<td>Credential</td>
<td>Select the credential for your Git repository. (See Getting started with Credentials.) &lt;br&gt; <strong>Note:</strong> If you select the ssh network protocol, enter a valid credential of the SSH Private Key type. If you select the https protocol, enter a valid credential of the Basic Auth Credentials type.</td>
</tr>
</tbody>
</table>

**Note:** All application developers on the instance share the credential used to link a Git repository to an application.

4. **Click Import app.** <br>The system compares the checksum in the checksum.txt file to current checksum. When the checksum values match, the integration skips validation and imports the application. When the checksum values do not match, the integration first validates and sanitizes the application files before importing them.

5. **Click Select Application.** <br>App Engine Studio displays the application as a new choice in the Switch Applications window.

**What to do next**
- Review the upgrade logs for any sanitization applied to application files during the import.
- Select the imported application to edit it.

Getting started with credentials

Link an application or application-customization to source control

Linking an application or application-customization to source control allows application developers to manage changes from a Git repository.

Before you begin

- Role required: admin
- Learn more about Manage customizations to applications.
- Create a dedicated Git repository for the application. For increased security, enable multi-factor authentication for the Git repository.
- Generate an access token that the source control integration can use instead of a password and multi-factor authentication passkey. Search for personal access token on GitHub or GitLab.
- Restrict permissions on the access token to allow read and write access to the Git repository.
- Verify that the non-production instance has network access to the Git repository.
- Ensure that users add the email address to their respective Users Table (ServiceNow sys_user) records that they use in their commits to the Git repository.
- Learn more:

About this task

The source control integration does not support linking to an application or customization on a production instance. Instead, install applications on a production instance from the application repository, an update set, or the App Engine Studio.

Procedure

1. Open the application you want to link to source control in App Engine Studio.
2. Select Source Control > Link to source control.
   App Engine Studio displays the Link to Source Control dialog box.
3. Enter the connection details for the Git repository.

### Source control connection details

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Network protocol</td>
<td>Https or SSH credential type that enables secure channel data exchange.</td>
</tr>
<tr>
<td>URL</td>
<td>The URL to the Git repository where you want to save application files. For SSH protocol, use command to generate private key ssh-keygen -t rsa -m PEM -b 4096 -C “email@address”.</td>
</tr>
<tr>
<td>Note</td>
<td>If the Git repo URL for SSH provided by your Git server does not work, check with your Git server owner or provider for the correct URL. There may be additional specifications such as scheme protocol prefixes, port numbers, and so on, required for your Git repo URL to function.</td>
</tr>
<tr>
<td>Branch</td>
<td>The repository branch to work on within the application.</td>
</tr>
<tr>
<td>MID Server Name</td>
<td>The name of the existing MID Server to link through.</td>
</tr>
</tbody>
</table>
Field | Description
---|---
| **Note:** Use a separate MID Server to prevent conflicts with Discovery activities.  
Be sure that the MID server user can create files to the sys_attachment table and that the table can accept files of the “bundle” type.  
Linking or an application through a MID Server enables access to repositories behind a firewall.

| Default email | The committer email address is defined by the sys_user record if available. But if a committer's sys_user record email field is empty, the system generates an alternate email (username@instancename.service-now.com). You can also enter a default email address and change it later. To use that default email address in all cases, select the check box.

| Credential | The credential to be used with the selected protocol. See Getting started with Credentials to learn more about creating credentials.  
**Note:** If you select the SSH network protocol, enter a valid credential of the SSH private key type. If you select the https protocol, enter a valid credential of the Basic Auth credentials type.

| Commit Comment | An optional description of the repository or application.

**Note:** All application developers on the instance share a single set of repository credentials.

4. Click **Link to source control**.  
The system validates the connection and user credentials and displays a success message.  
All application developers on the instance can use the linked Git repository to manage changes.

**Related information**

MID Server
Getting started with credentials
Edit a Git repository configuration

You can edit a Git repository to change the network protocol selection, credentials or other field entries.

Before you begin
Role required: admin

Procedure

1. In your App Engine Studio app, select Source control > Edit repository configuration.

2. Choose https or ssh Network protocol and enter the URL address of your repository.
3. Change your credential or MID Server name if you wish.

*i Note:* If you have no MID server name, you can select a new one from the drop-down list. If you choose a new MID server, in the Source Control menu before making any further Source Control operations to avoid errors.

4. Default email field: The committer email address is defined by the sys_user record if available. But if a committer's sys_user record email field is empty, the system generates an alternate email (username@instancename.service-now.com). You can also enter a default email address and change it later. To use that default email address in all cases, select the check box.

5. Click Save.
Pull changes from repository

Application developers can pull changes from a linked Git repository to apply remote changes to the local instance.

Before you begin

- Role required: admin
- Link an application or application-customization to source control

Procedure

1. In your App Engine Studio app, select Source control > Pull from repository.
2. Review your uncommitted files, then select Stash local changes or Discard local changes.
3. Click Pull from repository.

The following operations occur:
• The system fetches the most recent changes from the remote repository.
• The system applies the remote changes to the instance.
• The system identifies any change conflicts requiring resolution.
If there are conflicts, the system displays the Resolve Conflicts window.

Delta loading is enabled by default in sys properties so your data isn't removed. You can disable this feature if you want data automatically deleted.

What to do next
Resolve any change conflicts.

Commit changes
Application developers can commit their changes on the instance to the linked Git repository. You can either select a few changes to commit, or commit all changes on the instance at once.

Before you begin
• Role required: admin
• Link an application or application-customization to source control

Procedure
1. In your App Engine Studio app, select Source control > Commit changes. The system displays the Select files to commit to source control window. The file changes from all the updates sets display. By default, the file changes from the current update set display.
2. Select the file changes you wish to commit.

3. To include untracked changes, select the **Include changes not tracked via the Customer Update [sys_update_xml] table** check box.
   - The default for this check box is set via the **glide.sourcecontrol.default_commit_mode** property.
     - Property can be set to **include_untracked** or **exclude_untracked**.
     - The **include_untracked** mode commits the updates to the application that do not generate sys_update_xml records, as well as any user-selected updates.
     - The **exclude_untracked** mode commits only updates selected by the user in the **Select files to commit to source control** dialog.
   - The base system setting for the property is **exclude_untracked**.
   - To hide the check box and use the value of the **glide.sourcecontrol.default_commit_mode** property, create the **sn_devstudio.vcs.allow_commit_mode_selection** property and set it to false.
   - Checking this check box may incur a performance penalty.

**Note:**
Commits always occur in **include_untracked** mode in the following cases:
   - Linking to Source Control for the first time. (To learn more, see Link an application or application-customization to source control.)
   - Publishing an application that's linked to Source Control from App Engine Studio. (To learn more, see .)
   - Selective commit mode is disabled.

4. Click **Continue**.

5. In **Commit comment**, enter a comment for the changes.

6. Click **Commit Files**.
   The following operations occur:
   - The system identifies all local changes.
   - The system commits all local changes to the remote repository.

**Note:** For list of known files that don’t have customer update records and are untracked, see Customer updates table
Stash local changes
Application developers can remove and save changes locally to apply them later.

Before you begin
• Role required: admin
• Link an application to source control
• Change one or more application files

About this task
Stashing changes removes them from the current application and saves them for a developer to later apply or delete.

Procedure
1. In your App Engine Studio app, select Source control > Stash local changes. The system displays a list of locally changed files.
2. Enter your description.
3. Click Stash Changes. The system saves the current changes and displays a success message.

263
What to do next
• Close dialog
• Manage stashes

To learn more see Getting started with credentials

Create tag
Create a tag in the repository to link to a particular application version.

Before you begin
• Role required: admin or sn_group_creator.app_creator
• Link an application or application-customization to source control

Procedure
1. In your App Engine Studio app, select Source control > Create tag.
   App Engine Studio opens the Create Branch window.

2. Enter the Tag Name.
3. Click Create Tag.
   App Engine Studio creates the tag.
4. Click Close.

What to do next
Commit changes to the new branch.
Switch branch
Application developers can switch to a different repository branch to work on another version of the application.

Before you begin
• Role required: admin
• GIT repository with one or more available branches.

Procedure
1. In your App Engine Studio app, select Source control > Switch branch.

   ![Source control menu with Switch branch option]

   The system displays the Switch Branch window.

2. Optional: If there any local changes on the instance, you can save or discard them.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Save local changes</td>
<td>Saves local changes before switching to an alternate branch. You can later merge or discard the saved changes.</td>
</tr>
<tr>
<td>Discard local changes</td>
<td>Permanently deletes all local changes before switching to an alternate branch.</td>
</tr>
</tbody>
</table>
Note: Use caution when discarding local changes. Since all application developers share repository credentials, there is no way to discard just one set of user changes. Note you cannot later restore discarded changes.

3. Select the branch you want to switch to.

4. Click **Switch Branch**.
   App Engine Studio updates the local application to match the branch version from repository.

Create branch
Application developers can create a branch to work on a new version of an existing application.

Before you begin
- Role required: admin or sn_group_creator.app_creator
- Link an application or application-customization to source control

Procedure
1. In your App Engine Studio app, select **Source control > Create branch**.
   App Engine Studio opens the Create Branch window.
   
   ![Create a branch]
   Creating a branch will result in a new branch being created in the remote repository that is configured for this application. This application, including any uncommitted changes, will switch to the new branch.

   Branch name:

   Create branch

2. Enter the **Branch Name**.

3. **Optional:** To create a branch from a tag, click the **Create from Tag** dropdown list and select an existing tag.

4. Click **Create Branch**.
   App Engine Studio creates the branch.
5. Click Close.

**What to do next**
Commit changes to the new branch.

**Set default branch**
Set a default branch when you want to use a branch other than main for new changes or for your main development repository.

**Before you begin**
- Role required: admin
- Link an application or application-customization to source control

**Procedure**
1. Follow the steps to Add a system property.
2. Add the `glide.source_control.default_branch_name` property, and specify the default branch name of the Git source control repository to work from (pull requests, code commits, etc.). Application developers’ work is managed from and saved into the default branch if not otherwise specified. If not changed, this value defaults to `sn_instances/<instance_name>`.

**Manage stashes**
Application developers can apply or delete stashed changes from App Engine Studio.
Before you begin
- Role required: admin
- Link an application to source control.
- Stash one or more application file changes.

Procedure
1. In your App Engine Studio app, select **Source control > Manage stashes**. The system displays a list of locally stashed changes.
2. Click the action next to the stash you want to manage.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Apply</td>
<td>Commits the stashed changes to the application and checks for conflicts.</td>
</tr>
<tr>
<td>Delete</td>
<td>Removes the stashed changes.</td>
</tr>
</tbody>
</table>

Resolve conflicts
Application developers can choose which application file version to use when applying remote or stashed changes.

Before you begin
- Role required: admin
- Link an application to source control
- Apply a stashed change

About this task
Conflicts occur when there are multiple change versions of the same application file: one set of changes in the remote or stashed version and another set of changes in the local version. App Engine Studio requires developers to resolve conflicts before applying remote or stashed changes.

Procedure
1. In your App Engine Studio app, pull from repository or stash local changes. If the system identifies a conflict, it displays the Resolve Conflicts dialog.
2. Select how to resolve the conflict.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select an action</td>
<td>Apply or discard all stashed changes. Go to step 3.</td>
</tr>
<tr>
<td>Manually merge changes</td>
<td>Individually select which changes to apply. Go to step 6.</td>
</tr>
</tbody>
</table>

3. If you want to apply or discard all stashed changes, select an **Action**.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Take Stashed Changes</td>
<td>Applies the application file version from the stashed changes.</td>
</tr>
<tr>
<td>Discard Stashed Changes</td>
<td>Applies the application file version from the most recent pull from the repository.</td>
</tr>
</tbody>
</table>

4. Click **Apply Stashed Changes**. The system applies the selected changes.

5. Click **Close Dialog**.

6. If you want to merge the conflicting changes, click **Manually Apply**. The system displays a list of version differences by field.

7. Select the field values you want the merged application file to have.

8. Click **Save Merge**. The system applies the selected changes.

**View commit history**

Application developers can view the commit history of applications linked to a source control repository.

**Before you begin**

- Role required: admin
- An existing link to a Git repository

**Procedure**

1. Navigate to **Source Control > View History**. The system displays the History window.

2. Select the commit sort order type.
3. Select the sort order direction.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Date</td>
<td>Sort by commit date.</td>
</tr>
<tr>
<td>Committer</td>
<td>Sort by user name.</td>
</tr>
</tbody>
</table>

Descending

Sort dates from the most recent to oldest date. Sort user names reverse-alphabetically from Z to A.

Ascending

Sort dates from the oldest to most recent date. Sort user names alphabetically from A to Z.

The system sorts commits by the selected sort order.

4. Select a commit.

The system displays the commit details for the selected commit.

5. Review the commit details.

<table>
<thead>
<tr>
<th>Commit Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Field</td>
</tr>
<tr>
<td>-------</td>
</tr>
<tr>
<td>Committer</td>
</tr>
<tr>
<td>Date</td>
</tr>
<tr>
<td>SHA-1</td>
</tr>
<tr>
<td>Message</td>
</tr>
<tr>
<td>Files</td>
</tr>
</tbody>
</table>

6. Close the History window.

Move application files in a GIT repository

Move application files linked to source control to any folder of the repository. Allow application developers to store supporting content such as automated tests in the same repository as the applications they support.
Before you begin

- Link an application or application-customization to source control
- Role required: Source control credentials with write access

About this task

Linking an application to source control generates a properties text file called `sn_source_control.properties` at the root level of the repository. The properties file specifies the folder containing the application files. The integration tracks changes to these application files by generating a `checksum.txt` file. When the checksum matches, the integration skips the validation and sanitization process. When the checksum does not match, the integration validates and sanitizes the application files as part of the source control operation. The integration ignores all repository content outside the application path.

Note: You can set system properties `glide.source_control.checksum_required` to enable optional checksum validations and sanitizations and `glide.source_control.checksum_quick_install` to bypass sanitization steps on checksum matches. See Available system properties for more information.

Procedure

1. Login to source control repository linked to the application.
2. Create the destination folder where you will move the application files.
   
   Example
   
   For example, create the folders `src/app`.
3. Move the folder containing your application files to the destination folder.
   
   Example
   
   For example, move the folder `demo_my_app` to `src/app`.
4. Navigate to the root level of the repository.
5. Open the `sn_source_control.properties` text file in a text editor.
6. For the `path=` property, enter the folder path where you moved the application files.
   
   Example
   
   For example, enter `path=src/app`.
7. Save the properties file.
What to do next
Login to your instance and perform Source control operations in App Engine Studio from App Engine Studio.

Reviewing App Engine Studio applications
Review the applications the developers build in App Engine Studio so that you can deploy with confidence.

Deployment requests
After a developer submits an application in App Engine Studio, a deployment request is created. A deployment request is a record to track the review of submitted applications. From the deployment request form, a reviewer can deploy the application to your test environment, reject an application, or publish an application.

For more information on reviewing a deployment request, see Deployment Request form.

Testing an application
Before you publish a submitted application, test it in a non-production instance. To begin testing, open the deployment request and deploy the application to
your test environment. For more information, see Move an application to your test environment.

The goal of testing the application is to ensure that it won’t break the production instance. You may consider using the ServiceNow Automated Test Framework to run these tests.

If the application doesn’t pass testing, then you reject the deployment request. For more information, see Reject an application.

Publishing an application

If an application passes testing, make it available to employees in your organization by publishing it in your production instance. To publish an application, open the deployment request and deploy the application to your production environment.

The administrator on-boards the team that requested the application. For example, if the developer specified a certain security role for the application, the administrator assigns that role to the relevant users.

For more information on publishing an application, see Deploy an application.

Related information

- Delegated development in App Engine Studio
- Automated Test Framework (ATF)

Move an application to your test environment

Test an application safely by moving it from your development environment to your test environment.

Before you begin

Role required: admin

Procedure

1. Log in to your production instance.
2. Navigate to **App Engine > App Engine Studio > App Deployment Request**.
3. Open the deployment request that is associated with the application.
4. In the **Action** field, select **Deploy to Test Env**.
5. Save the form.
6. From the Related Links, select **Set State to In Validation**.
Results
The application is available in the non-production instance that you’ve defined as your test environment. To learn which instance is your test environment, navigate to App Engine Studio > Configuration > Pipeline and view the active pipeline for your App Engine Studio implementation.

The developer can see that the application is being tested by viewing the application status in App Engine Studio.

"In Validation" status

![Office art loaner app in Validation](image)

Updated: 2021-01-22 12:43:58

What to do next
Optionally, provide the developer with accounts to test their application using various roles in their application.

Reject an application
Let a developer know that their application is not ready to publish.

Before you begin
Role required: admin

Procedure
1. Log in to your production instance.
3. Open the deployment request that is associated with the application.
4. From the Related Links, select Set State to Rejected.
5. On the dialog box that appears, enter comments for the developer and then select OK.
6. On the form, select **Update**.

**Results**
The developer can see that the application is rejected by viewing the application status in App Engine Studio.

"Rejected" status

The deployment request state is automatically set to **Rejected**.
Your review comments are sent via email to the address included in the **Requestor Email Address** field.

**Deploy an application**
After successfully testing an application, make it available to the requesting team by deploying it to your production environment.

**Before you begin**
Role required: admin, delegated developer with permissions

**Procedure**
1. Log in to your production instance.
2. Navigate to **App Engine > App Engine Studio > App Deployment Request**.
3. Open the deployment request that is associated with the application.
4. In the **Action** field, select **Deploy to Prod Env**.
5. Save the form.
6. From the Related Links, select Set State to Published.

Results
The application is available in your production instance.

What to do next
On-board the team that requested the application. For example, if the developer specified a certain security role for the application, assign that role to the relevant users.

App Engine Studio reference
Reference topics provide additional information about the lists and forms that you use to configure and administer App Engine Studio.

App Engine Studio glossary
Learn about terms and concepts that are unique to App Engine Studio.

Application template
Provides predefined data, experience, logic and automation, and security to support a certain use case. For example, the Travel Request template provides application content for submitting and approving employee travel requests.

For more information on the available templates, see Template library.

Logic and automation
Business automate application processes. You define logic and automation using flows. A flow includes a sequence of actions and a trigger. You can use a flow template or create a flow from scratch.

Data
Information that is stored in your application. For example, employee phone numbers or office locations. You configure application data using tables.

Deployment request
Ticket to track the review of submitted applications. From the deployment request form, a reviewer can deploy the application to different environments, accept or reject an application, and send feedback to a developer.
Environment

Instance that you use for the developing, testing, or launching an application. To set up App Engine Studio, you must define environments in each of the instances that you're using as environments. For more information, Define environments.

Experience

Graphical interface that your users interact with. For example, you can create a portal where users find information, submit requests, or complete business tasks. For more information on the available application experiences, see Experiences that you can create in App Engine Studio.

Pipeline

Configuration for deploying an application to different environments.

Security

Roles and access controls to limit who can use your application.

Components installed with App Engine Studio

Several types of components are installed with activation of the App Engine Studio plugin, including tables and user roles.

Note: The Application Files table lists the components that are installed with this application. For instructions on how to access this table, see Find components installed with an application.

Roles installed

<table>
<thead>
<tr>
<th>Role title [name]</th>

</table>

**App Engine Studio properties**

You can access system properties for App Engine Studio by navigating to **App Engine Studio > Configuration > System Properties**.

**sn_app_eng_studio.aes_admin_contact**

Defines the contact email for the App Engine Studio administrator. The system sends deployment request notifications to each email address listed in this property. For more information on setting this property, see [Set up the administrator contact email](#).

- **Type**: string
- **Default value**: none

**sn_app_eng_studio.delete_user_sync_queue_in_x_days**

Defines the number of days before a record is deleted from the User Sync Queue. The value reflects the number of days after the record has been created. For more information on user synchronization, see [Accessing App Engine Studio for the first time](#).
**sn_app_eng_studio.illustration_supported_content_types**
Defines the supported content types for Taxonomy Category illustrations. This property is read-only.
- Type: string
- Default value: image/svg+xml

**sn_app_eng_studio.mobile_studio_access**
Controls whether a developer can add a mobile experience to their custom application in App Engine Studio.
- Type: true | false
- Default value: true

**sn_app_eng_studio.user_sync_email_notification**
Enables the sending of an email notification to users who you add to the App Engine Studio Users group. For more information, see Grant access to App Engine Studio.
- Type: true | false
- Default value: true

**sn_app_eng_studio.user_sync_enabled**
Enables or disables the scheduled job that processes changes in the User Sync Queue. For more information on user synchronization, see Accessing App Engine Studio for the first time.
- Type: true | false
- Default value: true

**sn_app_eng_studio.user_sync_queue_enabled**
Controls whether App Engine Studio user information is queued up to synchronize with the development environment. This property doesn't control the actual synchronization, only the queuing of the changes. Changes can be queued while synchronization is disabled. If synchronization is re-enabled later, then all the changes are synchronized, including changes that were queued up
when synchronization was disabled. For more information on user synchronization, see Accessing App Engine Studio for the first time.

- Type: true | false
- Default value: true

Domain separation and App Engine Studio

Domain separation is unsupported for App Engine Studio. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

Support level: No support

- The domain field may exist on data tables but there is no business logic to manage the data.
- This level is not considered domain-separated.

For more information on support levels, see Application support for domain separation.

Related information

Domain separation for service providers

Deployment Request form

The Deployment Request form displays detailed information about the review status of an application that a developer submits for approval.

To view the Deployment Request form, navigate to App Engine > App Engine Studio > Configuration > App Deployment Request and open a record.

Deployment Request form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Number to track the deployment request.</td>
</tr>
<tr>
<td>Name</td>
<td>Name of the deployment request.</td>

Guided Application Creator

Guided Application Creator is an intuitive development interface for building applications on the Now Platform®. It provides a step-by-step process to guide you through your initial application construction.

Watch this four-minute video to learn about getting started with Guided Application Creator.

Explains how to use Guided Application Creator to create a new application for workspace, mobile, and classic with an imported spreadsheet.

Note: Although the video describes creating a workspace in Guided Application Creator, this feature is no longer supported. Instead, you can create a workspace using App Engine Studio. For more information, see Building applications in App Engine Studio.

Using Guided Application Creator

Setting up an application in Guided Application Creator involves:

- Creating an application record
- Defining user roles
- Designating data tables
- Designing the application for different user experiences
You can also use Guided Application Creator to create an application record and then configure it in Studio later. For more information, see Create an application record in Guided Application Creator.

**User experiences**
When you set up an application in Guided Application Creator, you can make your application available in the following user experiences.

<table>
<thead>
<tr>
<th>User experience</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mobile</td>
<td>ServiceNow Agent mobile app. Select this user experience to support users who work from a mobile device.</td>
</tr>
<tr>
<td>Classic</td>
<td>Classic Now Platform experience. Select this user experience to let your users work on your application via lists and forms.</td>
</tr>
</tbody>
</table>

**Guided Application Creator and the application creation process**
Setting up an application in Guided Application Creator does not capture the entire process of creating an application. It is just one step of the process. Before you set up an application in Guided Application Creator, plan what kind of application you need for your business requirements before you build it.

After you set up an application in Guided Application Creator, you can further develop the application using Studio, Flow Designer, and Team Development. After the application is fully built, you can test the application and then share the application with your users.

For more information on the application creation process, see Creating applications.

**Activation information**
Guided Application Creator is enabled via the Guided Application Creator (com.glide.sn-guided-app-creator) plugin, which is active by default in the Now Platform.

If you are using Microsoft Edge (non-Chromium) or a version of Internet Explorer that is IE11 or older, you can work only in the legacy application creator. To work in Guided Application Creator, use a different browser. For more detail on Internet Explorer 11 support, see KB0683275.

**Setting up an application in Guided Application Creator**
Set up an application in Guided Application Creator to store information and manage business processes.
Watch this nine-minute video to learn about creating a no-code application using Guided Application Creator. Shows how to create a no-code application on the ServiceNow platform quickly and easily through Guided Application Creator.

**Note:** Although the video describes creating a workspace in Guided Application Creator, this feature is no longer supported. Instead, you can create a workspace using App Engine Studio. For more information, see Building applications in App Engine Studio.

**Requirements**

Plan your application before you build it. Define the business requirements of your organization, and then identify what information you want the application to track. For more information on the application development process, see Creating applications.

If you are using Microsoft Edge (non-Chromium) or a version of Internet Explorer that is IE11 or older, you can work only in the legacy application creator. To work in Guided Application Creator, use a different browser. For more detail on Internet Explorer 11 support, see KB0683275.

You must have the sn_g_app_creator.app_creator or admin role to access Guided Application Creator.

**What to do**

1. **Create an application record in Guided Application Creator.**
   
   Create an application record in Guided Application Creator to identify a custom application.

2. **Define roles in Guided Application Creator.**
   
   Create or select roles in Guided Application Creator for the members of your organization who use your custom application.

3. **Select user experiences in Guided Application Creator.**
   
   Let users access your application via the ServiceNow Agent mobile app or lists and forms.

4. **Designate data tables in Guided Application Creator.**
   
   Select an existing table or create a custom table in Guided Application Creator to store data for your custom business application.

5. **Customize user experiences in Guided Application Creator.**
   
   Customize how the application appears in each user experience that you select.
Tip: Complete the entire process of setting up an application in Guided Application Creator. If you exit, you have to continue setting up your application in Studio and across various forms. You can't pick up where you left off in Guided Application Creator.

Next steps
Although your application is ready to use, you may need to customize your application to fit the needs of your organization.

In ServiceNow Studio, configure:
- System notifications
- Form layouts
- UI policy
- Reports

You can also learn how to automate your processes and create business logic for your application in Flow Designer.

Create an application record in Guided Application Creator
Create an application record in Guided Application Creator to identify a custom application.

Before you begin
By default, developers can't create applications in the global scope in Guided Application Creator. You can limit global application development to certain developers by assigning them an additional role. For more information, see Allow global application development in Guided Application Creator.

Role required: sn_g_app_creator.app_creator or admin

Procedure
1. Navigate to System Applications > Studio, and then select Create Application. If you are launching Guided Application Creator for the first time, select Let's get started on the welcome screen.
2. On the screen, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>

</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of your application.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of your application.</td>
</tr>
</tbody>
</table>
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Scope of your application. The application scope is set automatically when you name your application. If available, you can also select to create your application in the global scope. For more information on application scopes, see Application scope.</td>
</tr>
</tbody>
</table>

3. **Optional:** Give your application a logo image.
   You can drag and drop an image on the logo field, or you can select Drag and drop or browse to upload logo.

4. Select **Create** to assign roles for your application.
   To continue building your application in Guided Application Creator, follow the steps in Define roles in Guided Application Creator.
   You can optionally exit Guided Application Creator on the Let's create some roles for this app screen to save the application and add more functions to it later. To exit, select X to close the screen and then select Yes, close.

   ❗ **Tip:** Complete the entire process of setting up an application in Guided Application Creator. If you exit, you have to continue setting up your application in Studio and across various forms. You can't pick up where you left off in Guided Application Creator.

**Results**
Your application record is saved in the Custom Application [sys_app] table. You are added as a delegated developer for the application. To view your application later, navigate to System Applications > My Company Applications.

**Define roles in Guided Application Creator**
Create or select roles in Guided Application Creator for the members of your organization who use your custom application.
Before you begin
Complete the steps in Create an application record in Guided Application Creator.
Role required: sn_g_app_creator.app_creator or admin

About this task

Procedure
1. Define roles for your application.
   You can select existing roles or create roles.

<table>
<thead>
<tr>
<th>Option</th>
<th>Procedure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select an existing role</td>
<td>a. In the Roles field, enter the role name.</td>
</tr>
<tr>
<td></td>
<td>b. On the list, select the role name.</td>
</tr>
<tr>
<td>Create a role</td>
<td>a. Select + Create new role.</td>
</tr>
<tr>
<td></td>
<td>b. Enter a role name.</td>
</tr>
<tr>
<td></td>
<td>c. Select Create.</td>
</tr>
<tr>
<td>Option</td>
<td>Procedure</td>
</tr>
<tr>
<td>--------</td>
<td>-----------</td>
</tr>
</tbody>
</table>
| Select an existing role and then create a role | a. In the **Roles** field, enter the existing role name.  
b. On the list, select the existing role name.  
c. Select + **Create new role**.  
d. Enter a role name.  
e. Select **Create**. |

2. **Select Continue**.

You are taken to the screen in which you select user experiences for your application.

**Note:** If you created any roles, you must select **Continue** to save the roles to your instance. If you exit Guided Application Creator before selecting **Continue**, the roles that you created are not saved.

**What to do next**

Continue building your application by following the steps in Select user experiences in Guided Application Creator.

**Select user experiences in Guided Application Creator**

Let users access your application via the ServiceNow Agent mobile app or lists and forms.

**Before you begin**

Complete:

1. **Create an application record in Guided Application Creator**
2. **Define roles in Guided Application Creator**

Role required: **sn_g_app_creator.app_creator or admin**
Procedure

1. Select user experiences in which to make your application available.

<table>
<thead>
<tr>
<th>User experience</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mobile</td>
<td>ServiceNow Agent mobile app. Select this user experience to support users who work from a mobile device.</td>
</tr>
<tr>
<td>Classic</td>
<td>Classic Now Platform experience. Select this user experience to let your users work on your application via lists and forms.</td>
</tr>
</tbody>
</table>

There is no option to create a workspace in Guided Application Creator. Instead, you can create a workspace using App Engine Studio. For more information, see Building applications in App Engine Studio.

2. Select **Continue** to designate a data table for your application.

What to do next

Continue building your application by following the steps in Designate data tables in Guided Application Creator. If you exit Guided Application Creator, the user experiences that you selected are not saved to your application.
**Designate data tables in Guided Application Creator**

Select an existing table or create a custom table in Guided Application Creator to store data for your custom business application.

**Before you begin**

Complete:

1. Create an application record in Guided Application Creator
2. Define roles in Guided Application Creator
3. Select user experiences in Guided Application Creator

If you plan to create a custom data table, review the Data table guidelines for Guided Application Creator to ensure that your system performs as expected after you create a table.

Role required: sn_g_app_creator.app_creator or admin

**About this task**

---

**Procedure**

Designate data tables for your application.

You can select existing tables or create custom tables.
<table>
<thead>
<tr>
<th>Option</th>
<th>Procedure</th>
</tr>
</thead>
</table>
| Select an existing table without creating a custom table | a. In the **Tables** field, enter the table name.  
b. On the list, select the table name.  
c. Select **Done with tables**. |
| Create a custom table without selecting an existing table | a. Select **Create new table**.  
b. Select a table creation method.  
c. Follow the steps for the table creation method that you selected.  
  - Upload a spreadsheet in Guided Application Creator  
  - Extend a table in Guided Application Creator  
  - Create a table in Guided Application Creator |
| Select an existing table and then create a custom table | a. In the **Tables** field, enter the name of the existing table to designate for your application.  
b. On the list, select the table name.  
c. Select **Create new table**.  
d. Select a table creation method.  
e. Follow the steps for the table creation method that you selected.  
  - Upload a spreadsheet in Guided Application Creator  
  - Extend a table in Guided Application Creator  
  - Create a table in Guided Application Creator |

**What to do next**

Continue building your application by following the steps in **Customize user experiences in Guided Application Creator**. If you exit Guided Application Creator, the data tables that you designated are not saved to your application.
Upload a spreadsheet in Guided Application Creator

Turn your spreadsheet into a custom table in Guided Application Creator to store data for your custom application.

Before you begin

Complete:

1. Create an application record in Guided Application Creator
2. Define roles in Guided Application Creator
3. Select user experiences in Guided Application Creator
4. Designate data tables in Guided Application Creator

Review the spreadsheet guidelines to ensure that your data uploads as expected.

Role required: sn_g_app_creator.app_creator or admin

Procedure

1. To select a table creation method, on the screen, select Upload spreadsheet and then select Continue.

   ![Upload options]

   Ok. Let's create a table for this app
   If you want to create more than one, we'll do them one at a time.

   - Upload spreadsheet
   - Extend a table
   - Create table from scratch

2. Upload your spreadsheet.

   You can drag and drop the spreadsheet file or browse your system to select the spreadsheet file.

3. In Enter a row for the table header, enter the number of the header row on your spreadsheet.

   For example, if your spreadsheet has two columns in which the headers are in the second row (such as in the following image), you would enter 2.
4. Select the **Import spreadsheet data** option.

5. Select **Continue**.

   Your spreadsheet content is parsed into fields for your custom table.

6. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Field Label</td>
<td>Unique label for the field.</td>
</tr>
<tr>
<td>Field Name</td>
<td>Name of the field in the database.</td>
</tr>
<tr>
<td>Field Type</td>
<td>Type of field. For more information on the different field types, see <a href="#">Field types</a>. By default, there are only 18 field types to choose from. You can add a property to include more field types in Guided Application Creator. For more information, see <a href="#">Add field types in Guided Application Creator</a>.</td>
</tr>
<tr>
<td>Display</td>
<td>When used as a reference field, the field is used as the display value for the table. Only one field can be defined as the display value for a table.</td>
</tr>
<tr>
<td>Mandatory</td>
<td>Requires that the field must contain a value before the record can be saved.</td>
</tr>
</tbody>
</table>

7. Select **Continue** to define properties and permissions for your custom table.

8. On the form, fill in the fields.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table label</td>
<td>Unique label for the table (such as <strong>Laptops</strong> or <strong>Thin clients</strong>). The label appears on list and form views for the table. See Field Labels in <strong>Data dictionary tables</strong>.</td>
</tr>
<tr>
<td>Table name</td>
<td>Name of the table in the database. The table name is automatically populated based on the table label and the application scope that you defined earlier.</td>
</tr>
<tr>
<td>Make extensible</td>
<td>Option to enable other tables to extend this table. For more information on table extension, see <strong>Table extension and classes</strong>.</td>
</tr>
<tr>
<td>Auto-number</td>
<td>Option to add a number field to the table and automatically increment the ID numbers as they get added.</td>
</tr>
<tr>
<td>Manage access</td>
<td>User permissions for your application. For each role that you selected earlier, you can select to give your different levels of access.</td>
</tr>
</tbody>
</table>

**Create**

Enables users to insert new records (rows) into a table.

**Read**

Enables users to display records from a table.

**Write**

Enables users to update records in a table.

**Delete**

Enables users to remove records from a table or drop a table.

9. Select **Continue**.

10. On the confirmation screen, select **Continue**.

11. To add more tables to your application, follow the steps in **Designate data tables in Guided Application Creator**.

12. To finish designating tables, select **Done with tables**.
What to do next
Continue building your application by following the steps in Customize user experiences in Guided Application Creator. If you exit Guided Application Creator, the tables that you configured are not saved to the system.

Extend a table in Guided Application Creator
Extend a table in Guided Application Creator to create a custom table that copies an existing table. You can add more fields to your child table.

Before you begin
Complete:
1. Create an application record in Guided Application Creator
2. Define roles in Guided Application Creator
3. Select user experiences in Guided Application Creator
4. Designate data tables in Guided Application Creator

Plan which table to extend. Review the extension model so that you can track which database tables are created after you extend your table.

Role required: sn_g_app_creator.app_creator or admin

Procedure
1. To select a table creation method, on the screen, select **Extend a table**.

   ![Ok. Let's create a table for this app](image)
   If you want to create more than one, we'll do them one at a time.

   - **Upload spreadsheet**
   - **Extend a table**
   - **Create table from scratch**

2. In the **Table** field, select a table to extend.
3. Select **Continue**.
   The fields from the parent table are copied over to your custom table. You can't change the copied fields.
4. To add a field to your child table, select **Add a new field** and then fill in the fields.
## Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Field Label</td>
<td>Unique label for the field.</td>
</tr>
<tr>
<td>Field Name</td>
<td>Name of the field in the database.</td>
</tr>
<tr>
<td>Field Type</td>
<td>Type of field. For more information on the different field types, see <a href="#">Field types</a>. By default, there are only 18 field types to choose from. You can add a property to include more field types in Guided Application Creator. For more information, see <a href="#">Add field types in Guided Application Creator</a>.</td>
</tr>
<tr>

</table>

5. Select **Continue**.

6. On the confirmation screen, select **Continue**.

7. To add more tables to your application, follow the steps in **Designate data tables in Guided Application Creator**.

8. To finish designating tables, select **Done with tables**.

**What to do next**

Continue building your application by following the steps in **Customize user experiences in Guided Application Creator**. If you exit Guided Application Creator, the tables that you configured are not saved to the system.

**Customize user experiences in Guided Application Creator**

Customize how the application appears in each user experience that you select.

**Before you begin**

1. Create an application record in Guided Application Creator
2. Define roles in Guided Application Creator
3. Select user experiences in Guided Application Creator
4. Designate data tables in Guided Application Creator

Role required: sn_g_app_creator.app_creator or admin

**About this task**
Customize your application for the Mobile Agent app mobile app

If you selected the Mobile Agent app mobile app as a user experience for your application, you can customize how the application appears in the mobile app.

**Procedure**

1. Next to **Mobile**, select **Start** to configure application details.
2. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>App icon</td>
<td>Icon that appears on the application home page in the mobile app.</td>
</tr>
<tr>
<td>Available offline</td>
<td>Option to enable users to update application records while in offline mode. This option is available only if the SG Offline Support (com.glide.sg.offline) plugin is activated. For information on offline mode, see <a href="#">Updating records without an internet connection</a>.</td>
</tr>
<tr>
<td>Name</td>
<td>Name of your application as it appears on the application home page. By default, this value is the application name that you created earlier.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of your application. By default, this value is the application description that you created earlier.</td>
</tr>
<tr>
<td>Tables</td>
<td>Tables that appear as applets in the mobile app. Applets are subsections under your application that categorize the information and business processes in your application.</td>
</tr>
</tbody>
</table>
3. Select **Create**.

**What to do next**
You’ve finished customizing your application for the Mobile Agent app mobile app. If you selected another user experience, customize that user experience next. If you have no more user experiences left to customize, select **Done with apps**.

**Customize your application for the classic Now Platform experience**
If you selected the classic Now Platform experience for your application, you can customize how the application appears in the application navigator.

**Procedure**
1. Next to **Classic**, select **Start** to configure application details.
2. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of your application as it appears on the application navigator. By default, this value is the application name that you created earlier.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of your application. By default, this value is the application description that you created earlier.</td>
</tr>
<tr>
<td>Tables</td>
<td>Tables in your application. Application modules are created for each table. By default, these values are the data tables that you designated earlier.</td>
</tr>
<tr>
<td>Roles</td>
<td>User roles that can access your application. By default, these values are the roles that you defined earlier.</td>
</tr>
</tbody>
</table>

3. Select **Create**.

**What to do next**
You’ve finished customizing your application for the classic Now Platform experience. If you selected another user experience, customize that user experience next.
experience next. If you have no more user experiences left to customize, select **Done with apps.**

**Data table guidelines for Guided Application Creator**

When you create an application in Guided Application Creator, you can optionally create a data table for your application. To ensure that you are within the limits of your subscription and that your application performs as expected, consult the data table guidelines before you create a data table.

### Ok. Let's create a table for this app

If you want to create more than one, we'll do them one at a time.

- **Upload spreadsheet**
- **Extend a table**
- **Create table from scratch**

⚠️ **Note:**

Now Platform application subscriptions include custom table entitlements. You can create custom tables for any purpose, up to the entitlement limit in the subscription. To learn more about how your usage administrator allocates the custom tables that you create to subscriptions, see **Managing your custom applications and tables** in Subscription Management.

To allocate your custom tables to subscriptions and stay within the entitlement limit, follow the steps in **Map your custom tables**.

**Spreadsheet guidelines**

One way to create a new data table in Guided Application Creator is to upload an external spreadsheet. Prepare your spreadsheet beforehand so that you can transfer your data seamlessly and build custom applications faster.

Ensure your spreadsheet is:

- Formatted with horizontal columns and a header label for each
- Saved as an XLSX file type

For example, format your spreadsheet as follows.
In Guided Application Creator, you would designate the second row as the header row so that **Client name** and **Phone number** are uploaded as table fields.

**Table extension guidelines**

One option for creating a data table in Guided Application Creator is to copy an existing data table and then add more fields to the newly created table. Before you extend a data table, review the extension model for the table so that you can track which database tables are created after extension.

Extending a base table incorporates all the fields of the original table and creates system fields for the new table. If they are in the same scope or if they can be configured from other scopes, you can extend tables that are marked as extensible.

For more information on extension models, see [Table extension and classes](#).

**Table creation guidelines**

You can optionally create a new table in Guided Application Creator, but it’s possible to create more custom tables than your subscription permits. To ensure that you remain within the limits of your subscription, review the custom table entitlements for your organization.

**Allow global application development in Guided Application Creator**

By default, developers can’t create applications in the global scope in Guided Application Creator. You can limit global application development to certain developers by assigning them an additional role.
Before you begin

**Important:** Applications that you create in the global scope bypass scope protections and may cause licensing issues. For information on what to expect when you create an application in the global scope, see Application scope.

Role required: admin

About this task

You designate someone to use Guided Application Creator by assigning them the sn_g_app_creator.app_creator role. You can allow this user to create applications in the global scope by also assigning the sn_g_app_creator.global role.

Alternatively, to allow all users with the sn_g_app_creator.app_creator role to create applications in the global scope, add the `sn_g_app_creator.allow_global` system property and set it to `true`. For more information on adding a property, see Add a system property.

**Note:** Users with the admin role can create applications in the global scope, regardless of whether or not they have the sn_g_app_creator.global role.

Procedure

1. Navigate to User Administration > Users and open the user record of the developer.
2. On the Roles related list, select Edit....
3. On the Edit Members page, move the sn_g_app_creator.global role from Collection to Roles List.
Ensure that the sn_g_app_creator.app_creator role is also selected. The developer needs both the sn_g_app_creator.app_creator and sn_g_app_creator.global roles to create applications in the global scope in Guided Application Creator.

4. Select Save.

5. On the user record, select Update.

Results
The option to create an application in the global scope is available to developers with the sn_g_app_creator.global role.
Add field types in Guided Application Creator

When you add fields to a custom table in Guided Application Creator, there are only 18 field types available by default. You can add a property to include more field types.

Before you begin
Role required: admin

About this task
For a list of field types that are available in the Now Platform, see Field types.

Procedure
1. Add a system property with the following settings:
   - Name: sn_g_app_creator.field_types
   - Type: string
2. In the Value field, enter a comma-separated list of field type names. For example, to add the Image and Document ID field types, enter user_image,document_id.
3. Select Submit.
**ServiceNow Studio**

ServiceNow Studio provides an Integrated Development Environment (IDE)-like interface for application developers to work on custom applications in one centralized location. It offers a simple way to create, review, and update application files from a tabbed environment.

The system opens Studio whenever you edit a custom application.

**Capabilities**

- Create an application and application artifacts.
- Perform code search.
- Integrate with source control.
- Create your company's customizations to store applications that belong to other organizations.
- Use Virtual Agent Designer to create and manage topics, which are blueprints for conversations between a virtual agent and a user. You can design topics that help your users resolve common work issues or guide them through self-service tasks.

With Studio, application developers can:
• See exactly what files comprise their application in the **Application Explorer**.
• Add new files to their application using a single **Create Application File** interface.
• Navigate to files using familiar search-by-name or by-type behavior with the **Go To** dialog.
• Find code both within and outside an application using the **Code Search** tool.
• Operate on multiple files at once using the tabbed interface.
• Operate on multiple applications at once using multiple studio windows.
• Publish the application to company instances or the ServiceNow Store.
• View information about the current application from the **Status Bar**.

**Related information**

**Contextual development environment**

**Access ServiceNow Studio**

Application developers access ServiceNow Studio to create, import, or open applications.

**Before you begin**

Role required: admin

**Procedure**

1. Select the path available to your role.

<table>
<thead>
<tr>
<th>User role</th>
<th>Action to open Studio</th>
</tr>
</thead>
<tbody>
<tr>
<td>admin</td>
<td>Navigate to <strong>System Applications &gt; Studio</strong>.</td>
</tr>
</tbody>
</table>

The Studio opens in a new browser tab and displays the Select Application modal dialog.

- To create an application, click **Create Application**.
The system displays a list of application creation options.

- To import an existing application from source control, click **Import From Source Control** list.

Studio opens **Import From Source Control** page.

**Note:** In a few scenarios for scoped applications installed via plugins, the Name field in the Store Applications (sys_store_app) table doesn't match the plugin name. To make sure you are choosing the correct application, search the Select Store Application list picker with the Name of the application mentioned in the sys_store_app. For example: The plugin **Agile - Scaled Agile Framework - Essential SAFe** creates the sys_store_app record with the name "SAFe". Therefore you would search the Select Store Application list picker with the word "SAFe".

- To view an existing application, click the application name from the **Applications** list. The list also includes any store applications or scoped applications installed via plugins that are customized.

2. To open an installed store application so you can create your company's application-customization for it, click **Select Store application** and select the store application from the list picker display.
Studio opens the selected application.

**Note:** The linked icon 🔄 indicates that there are uncommitted local changes in the application. The property is ignored for your company applications in development. The **Can Edit Application in Studio** property for a store application or plugin determines if the application can be edited in Studio. If set to false, you see a warning that you cannot edit the application in Studio. But you can open the application in Studio to use Source Control features or to publish its customizations to the application repository. The default is true for new applications. The application’s owner can change the property value before releasing a new version.

---

### ServiceNow Studio keyboard shortcuts

ServiceNow Studio supports various keyboard shortcuts to manage and edit application files.

#### Studio keyboard shortcuts

<table>
<thead>
<tr>
<th>Keyboard combination</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Windows:</strong> Control+Shift +O</td>
<td><strong>Go To.</strong> Open any file in your application.</td>
</tr>
</tbody>
</table>
### Studio keyboard shortcuts (continued)

<table>
<thead>
<tr>
<th>Keyboard combination</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Mac</strong>: Command + Shift + O</td>
<td>Create New. Create an application file.</td>
</tr>
<tr>
<td><strong>Windows</strong>: Control + Shift + C</td>
<td>Code Search. Search for any file or value.</td>
</tr>
<tr>
<td><strong>Mac</strong>: Command + Shift + C</td>
<td>Close Tab. Close the current tab. If the tab contains unsaved changes, the system prompts the user to save them.</td>
</tr>
<tr>
<td><strong>Windows</strong>: Control + Shift + F</td>
<td></td>

### Add an application file to an application

Studio allows application developers to add new application files by type.

**Before you begin**

Role required: admin  
This procedure requires creating a scoped application.

**About this task**

You can add application files to update the features of a custom application.
Procedure

1. Navigate to **System Applications > My Company Applications**.

2. From the **Develop** tab, click the **Edit** button next to the application you want to modify.
   The system opens the application in the Studio.

3. From the content frame, click **Create Application File**.
   You can also use a Studio keyboard shortcut.

### Studio keyboard shortcut

<table>
<thead>
<tr>
<th>Keyboard combination</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Windows</strong>: Control+Shift+C</td>
<td><strong>Create New</strong>. Create an application file.</td>
</tr>
<tr>
<td><strong>Mac</strong>: Command+Shift+C</td>
<td></td>
</tr>
</tbody>
</table>

Studio opens the Create New Application File pop-up window.

![Create New Application File](image)

**Note:** Not all application file types will display in Studio. Some types of application files need to be created outside Studio, such as dashboards, even though they extend sys_metadata table.

4. Find the application file type you want to create.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Search by application file name</td>
<td>In the Filter entry field, enter the name of the application file.</td>
</tr>
<tr>
<td>Search by category</td>
<td>From the left pane, select a category name.</td>
</tr>
</tbody>
</table>

5. From the results pane, select the application file type you want to create.

6. Click Create.

   The system displays a blank form for the application file type in a new studio tab.

**What to do next**

Enter the necessary fields for the particular application file type you selected.

**Related information**

Application files

**Add an experience to UI Builder from Studio**

Create an experience from Studio for users to interact with your Now® Experience UI Builder application, such as a workspace experience.

**Before you begin**

Role required: System Administrator

**Procedure**

1. Navigate to System Applications > Studio.

2. Open an existing app, or create an app. For more information, see Legacy application creator.

3. Click Create Application File.

4. Select Now Experience > UX Application to add a UI Builder experience, and then click Create.
a. Add a title for the new experience. For example, New UI Experience for new application.

b. Choose an app shell for the experience, such as Agent Workspace App Shell. For more information on app shells, see App Shells for UI Builder.

c. Type a URL path for the experience, such as newhome.

d. Ensure the Active check box is selected, then click Submit.

5. Click Create Application File again.

6. Select Now Experience > UX App Configuration to configure the new UI Builder experience, and then click Create.
Configure UX experience
Create Application File

- Add a name for the configuration. For example, `New UI Experience for new application - app config`.
- Add a landing path. This is the same name as the URL path of your experience. For example, `newhome`.
- Ensure the Active check box is selected, then click Submit.

The new experience for the new application, and the application config files show in the Application Explorer.

7. Select the UX Application tab that has your new experience. You need to tie the experience file together with the application configuration file you created.
8. Click the search icon next to the Admin panel. Search for and select your experience. Click OK > Update.

Now, when you go back to the new experience that you created, you can open it in UI Builder from Studio. You can also delegate a developer to have UI
Builder application access. For more information, see Delegated development and deployment.

**Open experience in UI Builder**

- **New UI Experience for new application**
- **Test**
- **newhome**
- **Open in UI Builder**

**Related information**

- Delegated development and deployment
  - Delegate development and deployment permissions to personnel

**Publish an application from ServiceNow Studio when linked to Source Control**

You can publish a custom application from ServiceNow Studio when linked to Source Control.

**Before you begin**

Role required: admin

**About this task**

When you publish an application from ServiceNow Studio that is linked to Source Control, there is a different outcome than when you publish via the sys_app or sys_store_app Publish related link.
Procedure

1. When you select Publish, the sys_app or sys_app_customization record for the application is updated with the new version.

2. The current state of the application is committed to Source Control, including any untracked or uncommitted changes. The value of the glide.sourcecontrol.default_commit_mode property is ignored. This occurs because when the application is published, all the untracked and uncommitted changes are also published. Therefore, the state of the application in the Git repository matches what is published. See the Commit changes topic for more information about the glide.sourcecontrol.default_commit_mode property.

3. A Source Control tag is created for the new version and the application is published. If needed, the sys_app record is updated with the new store correlation ID.

   Note: If your application is linked to Source Control and you publish a new version outside of Studio, a source control commit and tag are not created.

Search for an application file by name or type

Application developers can use Studio to search for application files.

Before you begin

Role required: admin
This procedure requires creating a scoped application.

About this task

You can search for application files to add, remove, or update the features of a custom application.

Procedure

1. Navigate to System Applications > Applications.

2. From the Develop tab, click the Edit button next to the application you want to modify.
   The system opens the application in the Studio.

3. From the header, click Go To.
   You can also use a Studio keyboard shortcut.
**Studio keyboard shortcut**

<table>
<thead>
<tr>
<th>Keyboard combination</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows: Control+Shift+O</td>
<td><strong>Go To.</strong> Open any file in your application.</td>
</tr>
<tr>
<td>Mac: Command+Shift+O</td>
<td></td>
</tr>
</tbody>
</table>

Studio opens the Go To window.

4. Enter a search string.

![Go To window](image)

Studio displays a list of matching application files as you type.

5. From the list of search results, click a record name.
   Studio opens the application file record in a new tab in the content frame.

**Search within application files**

Studio allows application developers to search within application files for matching record values.

**Before you begin**
- Role required: admin
- This procedure requires creating a scoped application.

**About this task**
- You can search within application files to add, remove, or update application file values.

**Procedure**
1. Navigate to **System Applications > Applications**.
2. From the **Develop** tab, click the **Edit** button next to the application you want to modify.
   The system opens the application in the Studio.
3. From the header, click **Code Search**.
   You can also use a Studio keyboard shortcut.
Studio keyboard shortcut

<table>
<thead>
<tr>
<th>Keyboard combination</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows: Control+Shift+F</td>
<td>Code Search. Search for any file or value.</td>
</tr>
<tr>
<td>Mac: Command+Shift+F</td>
<td></td>
</tr>
</tbody>
</table>

Studio opens the Search pop-up window.

4. In **Search term**, enter a search string.

5. **Optional:** Select any additional search criteria.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select a table to search</td>
<td>Search for matches only within the selected file type.</td>
</tr>
<tr>
<td>Search in all applications</td>
<td>Search for matches throughout the instance, not just within the current application.</td>
</tr>
</tbody>
</table>

⚠️ **Note:** Searches across all applications can take a long time.

6. Click **Search**.

   The Studio conducts a case-insensitive search of the application files you selected. While the search is running, Studio displays a search progress indicator. You can click the cancel icon to stop the search. When the search is complete, the system opens a new tab in the content frame to display the search results by application file type. Each application file type displays the number of matching search results.
7. From the search results tab, expand an application file type and click a record name. Studio opens the application file record in a new tab in the content frame.

**Update a custom application record**

You can update a custom application record to add new features or change application functionality.

**Before you begin**

Role required: admin or a delegated developer role granting full access

**About this task**

You can only update applications in development on your local instance. You cannot edit applications downloaded from your company application repository or the ServiceNow Store.

**Procedure**

1. Navigate to **System Applications > Applications > Develop**.
2. Click the application name or the **Edit** button for the application you want to update. The system displays the application and application files in Studio.
3. Click **File > Settings**.
   Studio opens a tab containing the Custom Application record for the current application.

4. Fill in the fields, as appropriate.

<table>
<thead>
<tr>
<th>Custom Application form</th>

<td>View or specify which other applications have design access to tables or records in this application. See Application design access record.</td>
</tr>
</tbody>
</table>

5. Click **Update**.

**Switch between applications**

Application developers can switch between applications without leaving the Studio environment.

**Before you begin**

Before starting this procedure, you must create at least one custom application with its own application scope.

Role required: admin

**About this task**

The contextual development environment restricts some changes when the application files belong to another application. Switching to the application that owns the application files ensures that you change the proper application.

**Procedure**

1. Navigate to **App Options Menu > Switch Applications**.
   The system displays the list of applications.

2. Click the application you want to switch to.
   The system reloads Studio to display the selected application.

**Global application file management**

Once you create a globally scoped application in the ServiceNow Studio, you can add existing globally scoped files to it, remove files from it, or move application files between global applications.
Add a file from the global scope to a global application

Add existing globally scoped files into a selected global application. You can search for files in another globally scoped application by the update set name, table, or file name.

Before you begin
The Global App File Management plugin must be activated.
Role required: admin or a delegated_developer role that grants full access to the application.

About this task
When you select an application in the application picker, application files are automatically assigned to it. You cannot move an application file into or out of a scoped application. See Application scope.

Procedure
1. Navigate to System Applications > Applications > In Development.
2. To the right of the application name, click Edit in Studio.
3. In Studio, click File, then select Add Existing Files.
4. Use any of the following options to find existing globally scoped application files that you can add into the current globally scoped application:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Search by update set</td>
<td>Search and filter application files that are associated with an update set.</td>
</tr>
<tr>
<td>Search by table</td>
<td>Search and filter application files that are associated with a specific table. For example, if you select Incident, the search returns application files that are associated with that table.</td>
</tr>
<tr>
<td>Search by name</td>
<td>Perform a custom name search for application files that contain a specified update name (sys_update_name) or an actual file name (sys_-name).</td>
</tr>
</tbody>
</table>

Note: You can view up to 250 files at a time. If you want to view more files, perform another search with more specific search criteria.

5. Click Continue to list application files that are associated with the selected update set, table, or name. You can filter the results as needed.
The system displays the filtered results but omits any files that are already associated with the current global application. The system displays the file type, application, when the file was last updated, and if it is a customized file.

6. Select the files that you want to add, and then click **Add**.
   The Confirm Changes dialog appears, stating that the files being moved are now considered customizable files and may appear on a skip list during an upgrade.

7. Click **Continue** to add the selected files.

**Results**
The system moves the selected files to the selected application from the global scope, and flags them as customizable files. For example, if you select the sys_ui_policy file, the associated sys_ui_policy_actions file is also added to the selected application, and flagged as customizable. You see error messages when errors occur in the add process, or a confirmation when your files are successfully added to the globally scoped application.

**Remove a file from a global application**
Remove selected files from the selected global application and return them to the previous global application that owned the file. If there is no previous owner, file is returned back to global scope. The removed files are still considered customized files.

**Before you begin**
This option is only available if the Global Application File Management plugin is active.
Role required: admin or a delegated_developer role that grants full access.

**Procedure**

1. Navigate to **System Applications > My Company Applications > In Development**.
2. To the right of the application name, select **Edit in Studio**.
3. In Studio, select **File > Remove Files**.
4. The system displays a list of the files in this global application. Select the file that you want to remove from this application.
5. Click **Remove**.
Move an application file between global applications

Move selected application files and their descendant files to a selected global application. When you select a global application, the selected application files are automatically assigned to it. You cannot move an application file into or out of a scoped application.

Before you begin
This option is only available if the Global App File Management plugin is active. Role required: admin or a delegated_developer role that grants full access.

Procedure
1. Navigate to the application file in a list or form view. For example, navigate to System UI > UI Policies to select UI policy files to move.
2. Select the check box beside each file you wish to move, and then select Move to Application in the Actions on selected rows choice list.
3. Select the global application.

![Move to application](image)

4. Click Move.

The selected application files and its descendant files are moved to the selected global application.

Review claimed or skipped global files
This topic explains what to do when one or more of your files has been skipped or claimed by another application.

During the development of a global application, warnings about skipped or claimed files may display on various progress screens. Skipped or claimed files can occur when the files in one application are claimed by other application(s).
These warnings display during the installation of an application from the Application or Git repositories or when you publish your application. When you see that your application files have been either skipped or claimed by another application, contact the team that owns the other application to determine the best course of action for both teams.

What are your options?
Only one version can be loaded for production so your options are:

• Decide with the other team from which application the file should be removed so that only one file is loaded for production.

• Use the Merge tool: If changes to files in both apps are needed in production, use the merge tool to pull the files into a new common application that serves both parties effectively.

To learn more see the Resolve conflicts topic.

Automatic recovery of draft records
Studio can maintain a version of any open existing record with unsaved changes. Users can recover unsaved changes when their user session ends unexpectedly due to network latency, session timeout, or service interruption.

Automatic recovery only applies to:

• Records open in Studio. The system does not save all draft records.

• Changes made in desktop (non-mobile) browsers. The system does not save draft records from mobile browsers.

• Changes made to existing records. The system does not save draft changes to new records.

• Records containing unsaved changes that are the most recent update to the record. The system discards draft changes when another user has updated the same record.

• Records for tables that extend the Application File [sys_metadata] table.

After the user re-establishes a session, Studio displays a message for each record with recovered changes.
For each recovered record, users can:
  • Continue editing and save the record.
  • Clear the changes from the recovery cache.

The system automatically clears changes from the recovery cache when a user:
  • Saves the record. The system removes the saved record from the recovery cache.
  • Confirms navigating away from a record without saving changes. The system removes the abandoned record from the recovery cache.
  • Reaches the recovery cache limit of 5 MB of changes. The system removes the record with the oldest update date-time stamp.

By default, automatic recovery is enabled for all Application File [sys_metadata] tables while working from Studio.

Administrators can configure automatic recovery properties to:
  • Disable or re-enable automatic recovery.
  • Specify a list of field types to exclude from automatic recovery.

Users can enable or disable automatic recovery as a user preference.

Source Control integration

Enable application developers to integrate with a Git Source Control repository. Save and manage multiple versions of an application from a non-production instance.

Linking an application to Source Control enables all application developers on a non-production instance to:

- Import applications from a Git repository.
- Pull and apply remote changes from a Git repository.
- Commit all local changes on the instance to a Git repository.
- Create tags to permanently link to a given version of an application.
- Create branches to maintain multiple versions of an application simultaneously.

Integration requirements

To link an application to source control:

- The user must have the admin role.
- The non-production instance must have network access to the Git repository.
- Each application must be within its own Git repository.
- The repository user credentials must grant read and write access.

⚠️ Note: All application developers on the instance share a single set of credentials per repository.

Options available from ServiceNow Studio

After linking an application to Source Control, application developers can use ServiceNow Studio to manage the repository. From Studio, developers can:

- Edit the application repository credentials.
- Commit all local changes on the instance.
- Apply remote changes from the repository.
- Create a branch.
- Switch branches.
- Import an application from a remote repository.

Source Control integration does not support managing applications on a production instance. Instead, you can manage applications on a production instance using the application repository, an update set, or the ServiceNow
Options available from a Git repository
The ServiceNow platform offers limited support for modifying linked application files outside of an instance. From Git, developers can:

- Move application files to a different Git directory structure.
- Edit application files outside of ServiceNow Studio.

The system generates a properties text file called `sn_source_control.properties` at the root level of the repository. To move application files to a different Git directory structure, application developers can set the `path` parameter to specify the subfolder path containing their application files. For example, if you moved your application to the `src/app` subfolder, set the `path` to `path=src/app`.

The system generates a `checksum.txt` file in the Git repository to determine if any application files have been changed outside of Studio. When the checksum value from the file matches the current checksum value, the integration skips the validation and sanitization process. When the checksum values do not match, the integration validates and sanitizes the application files as part of the Source Control operation. The sanitization process:

- Creates upgrade log entries for each sanitization action taken.
- Removes unsupported folders and files from the repository.
- aborts all Source Control operations when a system application file fails XML schema validation. For example, if a database dictionary record fails XML schema validation, the system aborts all operations.
- Skips the current Source Control operation when a non-system application file fails XML schema validation.

The Source Control integration sanitizes only content within the application path listed in the `sn_source_control.properties` file. Repository content outside the application path is ignored.

MID Server support
Use an existing MID Server to connect to a Source Control repository. Linking or importing an application through a MID Server enables access to repositories behind a firewall.

Production deployment tips
When you develop customizations to applications on the ServiceNow® platform, you deploy them via the application repository to a production instance. This
topic examines and provides cautions for the tradeoffs between installing an application from the application repository versus Git repository with source control.

**Overview**

Technically, you can still “deploy” an application from a Git repository to a production instance using source control. This can have unintended consequences.

**Glossary of terms**

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Metadata or application files</td>
<td>The sys_metadata records that define configuration in ServiceNow and are packaged in an application. These records alter the behavior of the instance but do not contain data such as incident or CMDB records. (See Note below)</td>
</tr>
<tr>
<td>Scoped applications</td>
<td>ServiceNow applications that restrict allowing only updates and operations within the boundary of the scope. This mechanism is used for most new development.</td>
</tr>
<tr>
<td>Global applications</td>
<td>Global applications are developed in the legacy global scope. Work is often done in this scope to customize existing ServiceNow applications such as IT Service Management (ITSM).</td>
</tr>
<tr>
<td>Application repository</td>
<td>Applications are typically published here for deployment in production instances. Although the application repository has separate entitlement rules, it operates similarly to the ServiceNow Store.</td>
</tr>
<tr>
<td>ServiceNow Store</td>
<td>Repository for third-party (vendor) applications as well as ServiceNow published applications. Most customers do not publish to the Store, but often install applications from it.</td>
</tr>
<tr>
<td>Term</td>
<td>Definition</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Update sets</strong></td>
<td>Standard method of packaging customizations for deployment in each successive instance. They contain the incremental collection of insertions, updates, and deletions.</td>
</tr>
<tr>
<td><strong>Delta loading</strong></td>
<td>The most efficient method of loading because it changes only from source control rather than earlier uninstall/reinstall methods.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Definition of tables and columns in the tables.</td>
</tr>
<tr>
<td><strong>Rollback</strong></td>
<td>Administrators can roll back the last installation of a selected application. A rollback removes all code, table, and file updates from the initial installation.</td>
</tr>
</tbody>
</table>

**Note:** The `sys_metadata` table is the parent table of all application files in the ServiceNow platform using the table inheritance model. You can view summary information for metadata by visiting the parent table or tables that extend directly or indirectly as indicated by the Extends table(super_class) field on the Table(sys_db_object record). You can also see the whole schema by visiting the Table(sys_db_object) form for the `sys_metadata` table and selecting the Show Schema Map related link at the bottom of the form. The schema is large and so takes some time to render.
Installation location

When you install source control, it facilitates the ongoing development of a custom application. Therefore, the application is managed as an “In development” application in the Custom Application [sys_app] table rather than as an “Installed” application in the Store Application [sys_store_app] table. Both tables are extensions of sys_scope so they both provide the same
protections and restrictions as the scope. So when you search for the installation of a source control deployed application, refer to the System Application [sys_app] table and the **in development** section of the Application Manager page.

You cannot have a sys_app record on the instance while deploying that same application from the ServiceNow Store or application repository. The two deployment models are mutually exclusive. If at any point the deployment model changes, the sys_app record must be converted to a sys_store_app record first. You can contact ServiceNow Support for help with performing that operation.

**Delta loading**

Prior to the ServiceNow Paris release, application installation from source control always removed and reinstalled the entire application when triggered, including the Apply Remote Changes function. With **Delta loading**, now only the changes update, simplifying the process considerably.

The Delta loading process loads the changes from source control incrementally. When you apply remote changes, you don’t drop existing tables or columns unless they were removed from the repository. This preserves the data for tables and fields that continued to be present.

Note: The `glide.source_control.allow_delta_loading_in_scopedapp` property allows you to disable Delta loading in Paris; however, this will revert to the more destructive behavior of removing and reinstalling the application. Global applications in Paris always use Delta loading.

Below is a table of the different expected outcomes in an instance using Delta loading.

<table>
<thead>
<tr>
<th>Application type</th>
<th>Install source</th>
<th>Schema present in package</th>
<th>Schema contains data</th>
<th>Claim by another app (Global)</th>
<th>Expected outcome for data and schema</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scoped</td>
<td>Application repository or Store</td>
<td>Yes</td>
<td>Yes/No</td>
<td>N/A</td>
<td>Preserved</td>
</tr>
<tr>
<td>Scoped</td>
<td>Application repository or Store</td>
<td>No</td>
<td>Yes/No</td>
<td>N/A</td>
<td>Preserved</td>
</tr>
<tr>
<td>Application type</td>
<td>Install source</td>
<td>Schema present in package</td>
<td>Schema contains data</td>
<td>Claim by another app (Global)</td>
<td>Expected outcome for data and schema</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------------------</td>
<td>----------------------------</td>
<td>----------------------</td>
<td>-------------------------------</td>
<td>-------------------------------------</td>
</tr>
<tr>
<td>Scoped</td>
<td>Source control</td>
<td>Yes</td>
<td>Yes/No</td>
<td>N/A</td>
<td>Preserved</td>
</tr>
<tr>
<td>Scoped</td>
<td>Source control</td>
<td>No</td>
<td>Yes/No</td>
<td>N/A</td>
<td>Removed</td>
</tr>
<tr>
<td>Global</td>
<td>Source control, Application repository, or Store</td>
<td>Yes</td>
<td>Yes/No</td>
<td>Yes/No</td>
<td>Preserved</td>
</tr>
<tr>
<td></td>
<td></td>
<td>No</td>
<td>Yes</td>
<td>No</td>
<td>Preserved (1)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>No</td>
<td>No</td>
<td>Yes</td>
<td>Preserved (2)</td>
</tr>
<tr>
<td>Source control</td>
<td></td>
<td>No</td>
<td>No</td>
<td>No</td>
<td>Removed (3)</td>
</tr>
<tr>
<td>Application repository</td>
<td></td>
<td>No</td>
<td>No</td>
<td>No</td>
<td>Preserved</td>
</tr>
</tbody>
</table>

**Note:** 1: While the database schema and the data are preserved, they will be moved into the default global application.

**Note:** 2: While the database schema and the data are preserved, they will be moved into the global application which previously held claim to these files if installed. Otherwise, they will move into default global application.

**Note:** 3: Applicable only on custom columns with `u_` prefix. ServiceNow platform-authored columns are not dropped.

When switching branches in source control for a scoped application, use extreme caution in a production environment. If the target branch is missing schema elements found in the current branch, the related schema is dropped, destroying any data it contains. (Global applications do not drop schema when data is present.)

Just as with update sets, only a subset of the incremental changes needs to be applied with Delta loading. Unlike update sets, the application package represents the complete application. Files that are absent from the new package are deleted. This can alter functionality and delete data. Update sets
and applications upgraded from the application repository or ServiceNow Store must have an explicit **DELETE** payload to remove a file or drop a schema.

If application files are being generated dynamically in any fashion, the next install/apply remote changes the operation of an application deletes those records. They are considered absent from the incoming application package. If you stash local changes, the application files may be recoverable by a stash commit, but if data is lost as a result of the changes, the data is not recovered.

**Note:** Removing or suppressing sys_update_xml records prevents them from being removed by Delta loading; however, this action can have other severe or undesirable results.

Direct edits to the repository, especially to remove files, can have significant ramifications, including loss of data and cascading deletes. Perform this action with care.

**Author elective and customer updates**

When you install an application from the application repository or ServiceNow® store, you can set a series of properties to define the behavior of delete and choice processing. These kinds of choices are called an "author-elective" feature.

**Overview**

You can find details on these properties in the Skipped records that occur during application installation topic. With these properties, you can opt in and out of deletes and choice updates depending on whether you are using your own or a third-party application.

When you install from source control, however, these records do not skip, except when a global application file is claimed by a different global application. Other than `com.glide.apps.include_my_deletes` and `com.glide.apps.include_global_deletes` that disable the processing of the author_elective_update folder altogether, those properties are not effective for source installed apps.

**Note:** An “absent” file detected in Delta loading for source control is vastly different than a Delete payload housed inside the author_elective_update folder. Author_elective_update properties do not prevent Delta loading in source control from deleting the file.

Similarly, update sets protect customizations that you make in an instance against incoming changes that force a preview decision. Before you commit an update set, a preview must be run to attempt to detect collisions. You must address all preview problems before committing the changes. Source control
may ask you to stash a local change, but the outcome of the installation is to load what is present in the source even if a change had been made locally.

Loading what is present in the source is challenging when properties must have different versions based on the target of the installation. For example, it’s difficult to resolve when a property containing an integration URL differs based on instance production role. The `is_private` flag is effective with a source control installation and does not overwrite the property if set, mitigating this concern.

### Roll back, back out, and uninstall

The application installation from the application repository is recorded for rollback, which means as an administrator, you can roll back the last installation of a selected application. When you roll back an application, you remove all code, table, and file updates from the initial installation.

Source control installations are not recorded for rollback, which means that the rollback feature to undo an application repository, store installation, or an in-family upgrade is not available for source control installations. They also cannot be uninstalled in the same sense that ServiceNow® Store applications can be (that is, with the option to retain tables and columns). They can be deleted by deleting the `sys_app` record. However, for scoped applications, this destroys the underlying schema and its data.

You cannot delete global applications until all application files are moved to another global application. Deleting a `sys_app` record for an application also creates `sys_update_xml` records with `DELETE` payloads. These payloads can generate skips if the same application is then installed via the application repository or ServiceNow Store.

To avoid these skips, the `sys_update_xml` records must be manually deleted before the application is installed from the application repository. Installing from source control also does not have the Back out option that update sets contain to remove a subset of new changes. That means that recoverability in this model is limited to installing a corrected version (older or newer) of the application on top of the current version. This action restores only metadata or configuration. Data lost as a result of a poor installation must be recovered from a database restore.

### Upgrade history

Upgrade history records and history line dispositions are generated as part of the source control installation providing a record of the install.

The source control installation is more aggressive and generally doesn’t skip unless there is a global claim or `is_private` protection on a property. Global applications also protect columns containing data, or those from the ServiceNow base installation, from being removed.
Packaging system-generated changes

When an application is published to an application repository, its current state on the instance is packaged, including any system-generated changes. When you install this version in higher instances, these changes are included as part of an application package.

Excluding changes

The ServiceNow® Rome release introduced a new feature in source control to exclude system-generated changes to the application files. In other words, these changes don’t generate `sys_update_xml` during the commit. This allows only user changes, which generate `sys_update_xml` to be committed to the Git repository. To learn more about the feature see the Commit changes topic.

If you exclude the system changes when you commit to the Git repository, then installing applications from source control will be missing the changes as well.

Development considerations

When you are developing code, consider some of these suggestions for the most efficient performance.

Production instances shouldn’t publish to the Git repository

To protect the integrity of production, you shouldn’t push changes to publish to the Git repository from production even though technically you can open and commit changes in the application in ServiceNow® Studio. The “Can Edit Application in Studio” option can be disabled in production on the `sys_app` record. But it resets at the next source code operation that triggers an update (that is, when you apply remote changes or switch branches).

Dependencies are not installed when installing an application from the Git repository

Source-controlled applications do not automatically install or upgrade if they are listed as the dependency of your application. Instead, the customer must install or upgrade the source-controlled application on its own. The customer is also responsible for installing and upgrading the applications in the correct order.

Tight control on source control privileges in production

The source code operations are generally available to those with development privileges in the instance. Since production environments shouldn’t have ongoing development, be sure to tightly control admin and delegated development privileges to avoid data loss and other serious consequences.
Available source control operations

The source control integration primarily supports operations from Studio, but can also support some operations directly from the GIT repository.

### Available source control operations

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
<th>Available from</th>
</tr>
</thead>
<tbody>
<tr>
<td>Import from Source Control</td>
<td>Imports an application from the repository to the local instance.</td>
<td>Studio</td>

**Import application or application-customization from source control**

Import an application or application-customization from a source control repository to continue developing it on this instance.

**Before you begin**

- Role required: admin
- Verify that the non-production instance has network access to the Git repository.
- Verify that the repository contains a valid application.
- Ensure that users add the email address to their respective Users Table (ServiceNow sys_user) record that they use in their commits to the Git repository.
- Learn more about application-customizations Managing application-customizations.

**About this task**

The source control integration does not support importing an application on a production instance. Instead install applications on a production instance from the application repository, an update set, or the ServiceNow Store.

**Procedure**

1. Navigate to **System Applications > Studio**.
   The system displays the Welcome to Studio page.
2. Click **Open Studio > Go**.
   The system opens Studio and the Switch Applications window.
3. Click **Import from Source Control**.
   Studio displays the Import from Source Control fields.
4. Enter the following field values.

### Import from source control fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Network protocol</td>
<td>Https or ssh credential type that enables secure channel data exchange.</td>
</tr>
<tr>
<td>URL</td>
<td>The URL to the Git repository where the application files reside.</td>
</tr>
</tbody>
</table>

**Note:** If the Git repo URL for SSH provided by your Git server does not work, check with your Git server owner or provider for the correct URL. There may be additional specifications such as scheme protocol prefixes, port numbers, and so on, required for your Git repo URL to function.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Credential</td>
<td>Select the credential for your Git repository. (See Getting started with Credentials.)</td>
<td>If you select the ssh network protocol, enter a valid credential of the SSH Private Key type. If you select the https protocol, enter a valid credential of the Basic Auth Credentials type.</td>
</tr>
<tr>
<td>Branch</td>
<td>The repository branch to work on within the application.</td>
<td>The default branch is named after your instance. If you do not choose a name, the branch defaults to master.</td>
</tr>
<tr>
<td>MID Server Name</td>
<td>Select an existing MID Server to link to a Git repository stored behind your corporate firewall.</td>
<td>Use a separate MID Server to prevent conflicts with Discovery activities.</td>
</tr>
<tr>
<td>Default email</td>
<td>The committer email address is defined by the sys_user record if available. But if a committer's sys_user record email field is empty, the system generates an alternate email (<a href="mailto:username@instancename.service-now.com">username@instancename.service-now.com</a>). You can also enter a default email address and change it later. To use that default email address in all cases, select the check box.</td>
<td>All application developers on the instance share the credential used to link a Git repository to an application.</td>
</tr>
</tbody>
</table>

**Note:** All application developers on the instance share the credential used to link a Git repository to an application.

5. Click **Import**.

The system compares the checksum in the `checksum.txt` file to current checksum. When the checksum values match, the integration skips validation and imports the application. When the checksum values do not match, the integration first validates and sanitizes the application files before importing them.

6. Click **Select Application**.

Studio displays the application as a new choice in the Switch Applications window.
What to do next

- Review the upgrade logs for any sanitization applied to application files during the import.
- Select the imported application to edit it.

Link an application or application-customization to source control

Linking an application or application-customization to source control allows application developers to manage changes from a Git repository.

Before you begin

- Role required: admin
- Learn more about Managing application-customizations.
- Create a dedicated Git repository for the application. For increased security, enable multi-factor authentication for the Git repository.
- Generate an access token that the source control integration can use instead of a password and multi-factor authentication passkey. Search for personal access token on GitHub or GitLab.
- Restrict permissions on the access token to allow read and write access to the Git repository.
- Verify that the non-production instance has network access to the Git repository.
- Ensure that users add the email address to their respective Users Table (ServiceNow sys_user) records that they use in their commits to the Git repository.
- Learn more: Migrate completed update set history to Source Control

About this task

The source control integration does not support linking to an application or customization on a production instance. Instead, install applications on a production instance from the application repository, an update set, or the ServiceNow Store.
Procedure

1. Open the application you want to link to source control in Studio.

2. Navigate to **Source Control > Link to Source Control**.
   Studio displays the Link to Source Control dialog box.

3. Enter the connection details for the Git repository.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Network protocol</td>
<td>Https or SSH credential type that enables secure channel data exchange.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>URL</td>
<td>The URL to the Git repository where you want to save application files. For SSH protocol, use command to generate private key ssh-keygen -t rsa -m PEM -b 4096 -C “email@address”.</td>
</tr>
<tr>
<td>Credential</td>
<td>The credential to be used with the selected protocol. See Getting started with Credentials to learn more about creating credentials.</td>
</tr>
<tr>
<td>Branch</td>
<td>The repository branch to work on within the application.</td>
</tr>
<tr>
<td>MID Server name</td>
<td>The name of the existing MID Server to link through.</td>
</tr>
<tr>
<td>Default email</td>
<td>The committer email address is defined by the sys_user record if available. But if a committer’s sys_user record email field is empty, the system generates an alternate email (<a href="mailto:username@instancename.service-now.com">username@instancename.service-now.com</a>). You can also enter a default email address and change it later. To use that default email address in all cases, select the check box.</td>
</tr>
<tr>
<td>Commit Comment</td>
<td>An optional description of the repository or application.</td>
</tr>
</tbody>
</table>
Note: All application developers on the instance share a single set of repository credentials.

4. Click Submit.
   The system validates the connection and user credentials and displays a success message.
   All application developers on the instance can use the linked Git repository to manage changes.

   Getting started with credentials

Using MID Server with source control
The ServiceNow® MID Server enables communication and the movement of data between a ServiceNow instance and external applications, data sources, and services.

How bundle files work with MID Server
The .bundle file helps source control function with a MID Server. A bundle file is the way Git packages a local repository in a single file. This makes sharing or moving the repository simpler and more streamlined. The file is then sent to the MID Server, which passes it on to the remote repository.

The outgoing.bundle (commit operations) and incoming.bundle (apply remote changes) are attached to the MID Server attachment table [ecc_agent_attachment] for any request that goes to the MID Server. The outgoing.bundle is created on the instance while the incoming.bundle is created on the MID Server.

After an operation completes successfully, the bundle file is “promoted” into a golden.bundle that is attached to the Repository configuration table [sys_repo_config]. There is one golden bundle per repository and it’s used to initialize the repository on a node that has not performed any Source Control operations yet.

The Auto Flush tool [sys_auto_flush] is a “table cleaner” that removes any ecc_agent_attachment record older than 30 days by default. This action removes the corresponding attachment as well, as they are not necessary after the cleanup operation.

Note: If you want to customize the cleanup operation for bundle files, it is best to create and configure an additional auto-flush tool rather than changing any of the default settings.
The bundle files are kept on the MID Server and then saved to the Import directory on the MID Server.

On the MID Server, the bundle file is saved in the Import folder. This folder is under the user directory defined by the system property (user.dir), which users can configure. The bundle file is removed as part of the system flushing at the end of every operation.

**Working with the MID Server**

- Avoid conflicts with Discovery and create files for the system attachment [sys_attachment] table: **MID Server**
- Learn about system properties restrictions: **Configure attachment system properties**

**Migrate completed update set history to Source Control**

When linking to Source Control, this feature allows application developers the choice of migrating the information in completed update sets to Source Control history.

**Before migrating**

Make sure that you have fulfilled these criteria before attempting to migrate your update sets:

- Role required: admin
- Read the Link an application or application-customization to source control topic
- Complete any update sets for your application that you want to export as Source Control history.
- Export the completed update set if you want to preserve it.

When you link an application to Source Control, the update sets and customer update records are deleted. After you link to Source Control, if the application has any completed update sets, you will be asked to make a choice in the dialog box below.

- If you select “Yes, do retain update set history as commits”, the update set history is preserved as Source Control commits.
- If you select “No, do not retain update set history as commits,” they are not preserved as commits.

Regardless of which option you select, if you select **Continue**, the Link to Source Control operation starts, and all completed update sets and all Customer...
Update records are deleted. If you need to complete any additional update sets or choose not to continue, select **Cancel**.

For every completed update set with updates to the application that you are linking to Source Control, commits are generated automatically by the system based on the `sys_update_xml` records in the update sets. The commits are ordered by the `sys_recorded_at` timestamp. For Global applications: Any `sys_update_xml` records that belong to the application and are part of a completed Global update set are captured as historical commits.

When the Link to Source Control operation is complete, the most recent commit is the current state of your application in its entirety. You can view historical commits in your Git repository or by clicking the Source Control menu option and selecting **View History**. Updates are separated into multiple commits:

- If there are updates for a file that are out of order between different update sets.
- If an update set contains multiple update records for a single file.

The commits for an update set are split into multiple commits ([Historical Commit 1], [Historical Commit 2]...) to represent each update. This is done so that each file has an ordered history of updates.

⚠️ **Warning:** Any commit prefixed by [Historical Commit] is generated solely to display its history. Do not attempt to check out these commits in the development process as they do not necessarily represent a stable snapshot of the application.

The `author_elective_update` folder is not created until the initial commit. That means that in the initial commit you might see files such as `sys_choice` files being renamed and moved from the update folder to the `author_elective_update` folder. Any files that are deleted from update sets in historical commits are
deleted, and not moved to the `author_elective_update` folder as they would be for actual commits. During the initial commit, DELETE payloads are also created for any DELETE `sys_update_xml` records that were deleted as part of completed update sets.

Example commit message:

<table>
<thead>
<tr>
<th>[Historical Commit 1]</th>
<th>&lt;Name of update set that this commit belongs to&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description:</td>
<td>&lt;Description of update set that this commit belongs to&gt;</td>
</tr>
<tr>
<td>Update Set was completed on</td>
<td>&lt;date&gt;</td>
</tr>
<tr>
<td>Update Set was completed by</td>
<td>&lt;sys_user user_name &gt; &lt;sys_user email&gt;</td>
</tr>
</tbody>
</table>

Additional values from `sys_update_set` record (see **Customization** section below)

Batch update set information (See the **Batch update sets** section below) }

**Batch update sets**

If an update set is part of a batch update set, that information is appended to the commit message in the following format, with the highest number being the Batch Base:

```json
{
  "1": {
    "parent": "<name of parent update set>",
    "description": "<description of parent update set>"
  },
  "2": {
    "parent": "<name of parent 1’s parent update set> ",
    "description": "<description of parent 1’s parent update set> "
  }
}
```

**Customization**

You can add additional fields to include in the commit message by adding a `glide.source_control.historical_commit_fields` property. The value is a comma-separated list of fields the user wants to include from `sys_update_set` XML fields. Spaces and invalid or misspelled field names are ignored. This property is used for all applications that are linked to Source Control from the instance if the committer chooses to retain update set history.
Note: If the value of a field references another table or sys_id, only the value of the field is added. For example: sys_id for a user instead of the name of the user.

XML example:

```xml
<sys_update_set>
  <application display_value="test_app2">a3885a8735be720107c7899b8b601c7d8</application>
  <sys_created_by display_value="System Administrator">6816f79cc08016401c5a33be04bde41</sys_created_by>
  <sys_created_on>2021-04-22 22:14:38</sys_created_on>
  <sys_mod_count>1</sys_mod_count>
  <sys_updated_by display_value="System Administrator">6816f79cc08016401c5a33be04bde41</sys_updated_by>
  <sys_updated_on>2021-04-22 22:14:38</sys_updated_on>
  <is_default>false</is_default>
</sys_update_set>
```

Value of the property:

```
<glide.source_control.historical_commit_fields>
  glide.source_control.historical_commit fields
<is_default,sys_created_by,
  sys_id>
```

Result in commit message:
Edit a Git repository configuration

You can edit a Git repository to change the network protocol selection, credentials or other field entries.

Before you begin
Role required: admin

Procedure
1. In Studio, select Edit Repository Configuration.

2. Choose https or ssh Network protocol and enter the URL address of your repository.
3. Change your credential or MID Server name if you wish.

!!! Note: If you have no MID server name, you can select a new one from the drop-down list. If you choose a new MID server, **Apply remote changes** in the Source Control menu before making any further Source Control operations to avoid errors.

4. Default email field: The committer email address is defined by the sys_user record if available. But if a committer's sys_user record email field is empty, the system generates an alternate email (username@instancename.service-now.com). You can also enter a default email address and change it later. To use that default email address in all cases, select the check box.

5. Click **Save**.

**Apply remote changes**

Application developers can pull changes from a linked GIT repository to apply remote changes to the local instance.

**Before you begin**

- Role required: admin
- Link an application or application-customization to source control
Procedure

Navigate to **Source Control > Apply Remote Changes**.

The following operations occur:

- The system fetches the most recent changes from the remote repository.
- The system applies the remote changes to the instance.
- The system identifies any change conflicts requiring resolution.

If there are conflicts, the system displays the **Resolve Conflicts** window.

Delta loading is enabled by default in sys properties so your data isn't removed. You can disable this feature if you want data automatically deleted.

**What to do next**

Resolve any change conflicts.

**Commit changes**

Application developers can commit their changes on the instance to the linked Git repository. You can either select a few changes to commit, or commit all changes on the instance at once.

**Before you begin**

- Role required: admin
- Link an application or application-customization to source control

**Procedure**

1. Navigate to **Source Control > Commit Changes**.

   The system displays the **Select files to commit to source control** window. The file changes from all the updates sets display. By default, the file changes from the current update set display.
2. Select the file changes you wish to commit.

3. To include untracked changes, select the **Include changes not tracked via the Customer Update [sys_update_xml] table** check box.

   - The default for this check box is set via the `glide.sourcecontrol.default_commit_mode` property.
     - Property can be set to **include_untracked** or **exclude_untracked**.
     - The **include_untracked** mode commits the updates to the application that do not generate sys_update_xml records, as well as any user-selected updates.
     - The **exclude_untracked** mode commits only updates selected by the user in the **Select files to commit to source control** dialog.
   - The base system setting for the property is **exclude_untracked**.
   - Prior to the ServiceNow Rome release, only the **include_untracked** mode is used.
   - To hide the check box and use the value of the `glide.sourcecontrol.default_commit_mode` property, create the `sn_devstudio.vcs.allow_commit_mode_selection` property and set it to false.
   - Checking this check box may incur a performance penalty.
Note:
Commits always occur in `include_untracked` mode in the following cases:

- Linking to Source Control for the first time. (To learn more, see [Link an application or application-customization to source control.](#))
- Publishing an application that's linked to Source Control from ServiceNow Studio. (To learn more, see [Publish an application from ServiceNow Studio when linked to Source Control.](#))
- Selective commit mode is disabled.

4. Click **Continue**.

5. In **Commit comment**, enter a comment for the changes.

6. Click **Commit Files**.
   The following operations occur:
   - The system identifies all local changes.
   - The system commits all local changes to the remote repository.

   Note: For list of known files that don’t have customer update records and are untracked, see **Customer updates table**

---

**Stash local changes**

Application developers can remove and save changes locally to apply them later.

**Before you begin**

- Role required: admin
- Link an application to source control
- Change one or more application files

**About this task**

Stashing changes removes them from the current application and saves them for a developer to later apply or delete.

**Procedure**

1. From Studio, navigate to **Source Control > Stash Local Changes**.
   The system displays a list of locally changed files.

2. Enter your description.
3. Click **Stash Local Changes.**  
The system saves the current changes and displays a success message.

![Stash Local Changes window](image)

### What to do next
- Close dialog
- Manage stashes

To learn more see [Getting started with credentials](#)

### Switch branch

Application developers can switch to a different repository branch to work on another version of the application.

#### Before you begin
- Role required: admin
- GIT repository with one or more available branches.

#### Procedure

1. Navigate to **Source Control > Switch Branch.**  
The system displays the Switch Branch window.

2. **Optional:** If there any local changes on the instance, you can save or discard them.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Save local changes</td>
<td>Saves local changes before switching to an alternate branch. You can later merge or discard the saved changes.</td>
</tr>
<tr>
<td>Discard local changes</td>
<td>Permanently deletes all local changes before switching to an alternate branch.</td>
</tr>
</tbody>
</table>
Note: Use caution when discarding local changes. Since all application developers share repository credentials, there is no way to discard just one set of user changes. Note you cannot later restore discarded changes.

3. Select the branch you want to switch to.

4. Click **Switch Branch**. Studio updates the local application to match the branch version from repository.

Create branch

Application developers can create a branch to work on a new version of an existing application.

Before you begin

- Role required: admin or sn_group_creator.app_creator
- Link an application or application-customization to source control

Procedure

1. Navigate to **Source Control > Create Branch**. Studio opens the Create Branch window.

   ![Create Branch Window](image)

2. Enter the **Branch Name**.

3. Optional: To create a branch from a tag, click the **Create from Tag** drop-down list and select an existing tag.

4. Click **Create Branch**. Studio creates the branch.
5. Click **Close**.

**What to do next**
Commit changes to the new branch.

**Set default branch**
Set a default branch when you want to use a branch other than main for new changes or for your main development repository.

**Before you begin**
- Role required: admin
- Link an application or application-customization to source control

**Procedure**

1. Follow the steps to **Add a system property**.

2. Add the `glide.source_control.default_branch_name` property, and specify the default branch name of the GIT source control repository to work from (pull requests, code commits, etc.). Application developers' work is managed from and saved into the default branch if not otherwise specified. If not changed, this value defaults to `sn_instances/<instance_name>`.

**Manage stashes**
Application developers can apply or delete stashed changes from Studio.

**Before you begin**
- Role required: admin
- Link an application to source control.
- Stash one or more application file changes.
Procedure

1. From Studio, navigate to Source Control > Manage Stashes.
   The system displays a list of locally stashed changes.
2. Click the action next to the stash you want to manage.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Apply</td>
<td>Commits the stashed changes to the application and checks for conflicts.</td>
</tr>
<tr>
<td>Delete</td>
<td>Removes the stashed changes.</td>
</tr>
</tbody>
</table>

Resolve conflicts

Application developers can choose which application file version to use when applying remote or stashed changes.

Before you begin

- Role required: admin
- Link an application to source control
- Apply a stashed change

About this task

Conflicts occur when there are multiple change versions of the same application file: one set of changes in the remote or stashed version and another set of changes in the local version. Studio requires developers resolve conflicts before applying remote or stashed changes.

Procedure

1. From Studio, apply remote or stash changes.
   If the system identifies a conflict, it displays the Resolve Conflicts dialog.
2. Select how to resolve the conflict.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select an action</td>
<td>Apply or discard all stashed changes. Go to Step 3.</td>
</tr>
<tr>
<td>Manually merge changes</td>
<td>Individually select which changes to apply. Go to Step 6.</td>
</tr>
</tbody>
</table>

3. If you want to apply or discard all stashed changes, select an Action.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Take Stashed Changes</td>
<td>Applies the application file version from the stashed changes.</td>
</tr>
<tr>
<td>Discard Stashed Changes</td>
<td>Applies the application file version from the most recent pull from the repository.</td>
</tr>
</tbody>
</table>

4. Click **Apply Stashed Changes**. The system applies the selected changes.

5. Click **Close Dialog**.

6. If you want to merge the conflicting changes, click **Manually Apply**. The system displays a list of version differences by field.

7. Select the field values you want the merged application file to have.

8. Click **Save Merge**. The system applies the selected changes.

**View commit history**

Application developers can view the commit history of applications linked to a source control repository.

**Before you begin**

- Role required: admin
- An existing link to a GIT repository

**Procedure**

1. Navigate to **Source Control > View History**. The system displays the History window.
2. Select the commit sort order type.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Date</td>
<td>Sort by commit date.</td>
</tr>
<tr>
<td>Committer</td>
<td>Sort by user name.</td>
</tr>
</tbody>
</table>

3. Select the sort order direction.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Descending</td>
<td>Sort dates from the most recent to oldest date. Sort user names reverse-alphabetically from Z to A.</td>
</tr>
<tr>
<td>Ascending</td>
<td>Sort dates from the oldest to most recent date. Sort user names alphabetically from A to Z.</td>
</tr>
</tbody>
</table>

The system sorts commits by the selected sort order.

4. Select a commit.
   The system displays the commit details for the selected commit.

5. Review the commit details.
Commit Details

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Committer</td>
<td>The user who committed the change.</td>
</tr>
<tr>
<td>Date</td>
<td>The date-time stamp of the commit.</td>
</tr>
<tr>
<td>SHA-1</td>
<td>The secure hash value identifying this commit in the repository.</td>
</tr>
<tr>
<td>Message</td>
<td>The commit message associated with this commit.</td>
</tr>
<tr>
<td>Files</td>
<td>The list of application files changed in this commit.</td>
</tr>
</tbody>
</table>

6. Close the History window.

Move application files in a GIT repository

Move application files linked to source control to any folder of the repository. Allow application developers to store supporting content such as automated tests in the same repository as the applications they support.

Before you begin

- Link an application or application-customization to source control
- Role required: Source control credentials with write access

About this task

Linking an application to source control generates a properties text file called `sn_source_control.properties` at the root level of the repository. The properties file specifies the folder containing the application files. The integration tracks changes to these application files by generating a `checksum.txt` file. When the checksum matches, the integration skips the validation and sanitization process. When the checksum does not match, the integration validates and sanitizes the application files as part of the source control operation. The integration ignores all repository content outside the application path.

⚠️ Note: You can set system properties `glide.source_control.checksum_required` to enable optional checksum validations and sanitizations and `glide.source_control.checksum_quick_install` to bypass sanitization steps on checksum matches. See Available system properties for more information.

Procedure

1. Login to source control repository linked to the application.
2. Create the destination folder where you will move the application files.
Example
For example, create the folders src/app.

3. Move the folder containing your application files to the destination folder.

Example
For example, move the folder demo_my_app to src/app.

4. Navigate to the root level of the repository.

5. Open the sn_source_control.properties text file in a text editor.

6. For the path= property, enter the folder path where you moved the application files.

Example
For example, enter path=src/app.

7. Save the properties file.

What to do next
Login to your instance and perform source control operations from Studio.

Collision avoidance
Avoid modifying an application file across different update sets to ensure seamless experience during the commit process.

When the logged in user opens an application file that was modified in an update set different from the user’s current update set for the corresponding application:

• Collision is detected in the application file and a warning message is displayed.
• Logged in user to prompted to choose an update set.
• Read-only protection policy is applied to the application file.
User can make changes to the application file only after selecting the required update set.

Note: This feature is applicable to only those applications that are linked to GIT.

Enable or disable the collision avoidance feature using the glide.ui.vcs.collision_avoidance property in the System Property [sys_properties] table. By default, the feature is enabled. See Available system properties for more information.

When the feature is enabled, users can’t work in the default update set of the application. If a user is assigned the default update set, a unique update set is created when the user logs in to the application for the first time after the collision avoidance feature is enabled. This new update set is specific to the user in current application.

Name of the update set specific to the logged in user is, User ID or user name based on the value specified for the glide.ui.vcs.updateidentifier property in the System Property [sys_properties] table. See Available system properties for more information. By default, the update set name is set to user name of the logged in user. However, users can rename the update set.

Delta loading

"Delta loading" is an optimized way to load an application from a Git repository. When you switch branches and apply remote changes, the Delta loading feature makes sure only changed updates load. Rather than having to perform a full uninstall and reinstall of the application, only the changes update. This speeds and eases the process for developers and does away with the need to use all branches during development. Data stored in tables is retained during these operations, lowering the need to load demo data back into the application after a reinstall or branch change operation.
Benefits of Delta loading

Time savings

Typically, the longest part of an application uninstall or reinstall is dropping and creating tables. Delta loading prevents that from occurring. Depending on the size of the application, not having to drop or create tables can significantly improve an operation's completion time.

Test and demo data retained

Tables that contain test and demo data are no longer deleted, so data is not lost. Developers can save time if they don't need to reimport demo data each time.

Cross-scope dependent references preserved

Items that are cross-scoped and share references are no longer lost when you apply changes. This used to occur when an item in scope B was associated to a parent item in scope A. Applying remote changes on scope A would delete the parent item and reinstall it, breaking the reference between both items, but not restoring that relationship. Delta loading prevents the uninstall, so the reference is not lost.

Recommended practice

Delta loading is enabled by default on all instances starting with the ServiceNow Paris release. The feature is designed to help in application development and receives continued support and upgrades.

Service Creator

Service creator enables a department to offer custom services through the service catalog, such as the HR department offering tuition reimbursement for further education.

Each published service has an associated record producer catalog item. Users designated as managers and editors create and design these catalog items. End users can request services by ordering the catalog item.

All services belong to a published service category, which has an associated application and modules. When a user orders the catalog item for a service, the ServiceNow system creates a new task record within the application for that service category. Users designated as service fulfillers for the department complete these tasks to fulfill the service request.
Service creator process

The service creator process involves requesting and publishing a service category, designating editors and service fulfillers, creating and publishing services, and submitting and fulfilling service requests.

Request and publish a service category

A user, typically the department manager, can request a service category for the department. This user provides high-level information regarding the service category, such as the name, the department, and the manager for the service category.

A catalog administrator can approve the request which publishes the service category, creates a ServiceNow application for managing service requests associated with the category, and creates system components for the application.

Designate editors and service fulfillers

After a service category is published, the associated manager designates editors and service fulfillers. Editors can create and modify services within that service category. Service fulfillers can complete tasks that are generated by service requests.

The manager, editors, and service fulfillers must be members of the department the service category belongs to.

Create and publish services

The manager and editors create services within a service category. The service design interface provides a work area for creating and modifying services.

When the service is complete, the manager publishes the service to the service catalog.

Submit and fulfill service requests

End users can request published services by submitting a service catalog request. This request creates a new task record within the service category application. Service fulfillers then complete the task to fulfill the service request.

Related information

Service Creator

Activate Service Creator

If the Service Creator plugin is not already activated, an administrator can activate it to access the application.
Procedure

1. Navigate to System Applications > All Available Applications > All.

2. Find the plugin using the filter criteria and search bar.
   
   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel. For more information, see Request a plugin.

3. Click Install, and then in the Activate Plugin dialog box, click Activate.

   Note: When domain separation and delegated admin are enabled in an instance, the administrative user must be in the global domain. Otherwise, the following error appears: Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.

Installed with Service Creator

Several types of components are installed with Service Creator.

Demo data is available with Service Creator. The demo data provides the Departmental Services service catalog category.

Creating a new service category also creates components for that service category.

The following components are added with Service Creator:

Tables

<table>
<thead>
<tr>
<th>Table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service Category [catalog_category_request]</td>
<td>Stores all service categories.</td>
</tr>
<tr>
<td>Service Category Request User [catalog_category_request_user]</td>
<td>Tracks fulfillers for a service category. Use these records to grant or remove roles as needed.</td>
</tr>
<tr>
<td>Service [sc_cat_item_producer_service]</td>
<td>Stores all services.</td>
</tr>
<tr>
<td>Service Category App Menu [service_category_app_menu]</td>
<td>Stores the application menus for each service category.</td>
</tr>
</tbody>
</table>
### Service Creator tables (continued)

<table>
<thead>
<tr>
<th>Table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service Category User Role</td>
<td>Tracks users who have been granted a role due to being an editor of a service category.</td>
</tr>
<tr>
<td>[service_category_user_role]</td>
<td></td>
</tr>
</tbody>
</table>

### UI actions

<table>
<thead>
<tr>
<th>UI action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Category and Table</td>
<td>Approves a requested service category and creates system components for that category.</td>
</tr>
<tr>
<td>Request Category Publication</td>
<td>Lets a service creator request their category be published.</td>
</tr>
<tr>
<td>Create New Service</td>
<td>Creates a new service within the service category.</td>
</tr>
<tr>
<td>View Table Definition</td>
<td>Opens the task table definition [sys_db_object] for a service category.</td>
</tr>
<tr>
<td>View Task List</td>
<td>Opens the list of tasks associated with the service category.</td>
</tr>
</tbody>
</table>

### UI policies

<table>
<thead>
<tr>
<th>UI policy</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hide Due Date</td>
<td>Hides the Due date field on the Service Category form if State is Requested or Due date is empty.</td>
</tr>
<tr>
<td>Hide Category If Empty</td>
<td>Hides the Category field, if empty, on the Service Category form.</td>
</tr>
<tr>
<td>Show Published</td>
<td>Shows the Published check box on the Service Category form if State is Created but Unpublished or Ready for Publication.</td>
</tr>
<tr>
<td>Hide Table name</td>
<td>Shows Table and hides Table name on the Service Category form if Table has a value.</td>
</tr>
<tr>
<td>UI policy</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Hide Category Name</td>
<td>Hides Name on the Service Category form if State is Requested or Rejected.</td>
</tr>
<tr>
<td>Table name read only</td>
<td>Makes Department and Table name read only on the Service Category form if State is not Requested.</td>
</tr>
<tr>
<td>Hide Editors</td>
<td>Hides the Editors field on the Service Category form if State is Requested or Rejected.</td>
</tr>
</tbody>
</table>

### Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.citizen_developer.category.auto_publish</td>
<td>Automatically adds new service categories to the service catalog as subcategories of the Departmental Services category.</td>
</tr>
<tr>
<td></td>
<td>• Type: true</td>
</tr>
<tr>
<td></td>
<td>• Default value: true</td>
</tr>
<tr>
<td></td>
<td>• Location: System Properties [sys_properties] table</td>
</tr>
<tr>
<td>glide.citizen_developer.set_category_roles</td>
<td>Comma-separated list of roles that can set the category for a new service.</td>
</tr>
<tr>
<td></td>
<td>• Type: String</td>
</tr>
<tr>
<td></td>
<td>• Default value: admin, catalog_admin</td>
</tr>
<tr>
<td></td>
<td>• Location: System Properties [sys_properties] table</td>
</tr>
<tr>
<td>glide.service_creator.auto_add_to_category</td>
<td>Automatically adds new services to the Departmental Services service catalog category, in addition to the department-specific category.</td>
</tr>
</tbody>
</table>

### Email notifications

#### Service Creator email notifications

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service Category Published</td>
<td>Notifies the manager of a service category when the category request is approved.</td>
</tr>
<tr>
<td>Service Category Rejected</td>
<td>Notifies the manager of a service category when the category request is rejected.</td>
</tr>
<tr>
<td>Service Category Request Inserted</td>
<td>Notifies catalog administrators when a new category request is created.</td>
</tr>
<tr>
<td>Service Category Created</td>
<td>Notifies the manager of a service category when the category is created.</td>
</tr>
</tbody>
</table>
## Service Creator email notifications (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service Category Publication Requested</td>
<td>Notifies catalog administrators when publication of a category has been requested.</td>
</tr>
<tr>
<td>Service Category Request Opened</td>
<td>Notifies the manager of a service category when a new category request is created on their behalf.</td>
</tr>
</tbody>
</table>

## Components created with new service categories

When you publish a new service category using the Service Creator application, the ServiceNow system creates components for the services in that category.

These components are distinct from the components installed with the Service Creator application. The following components are added for each new service category:

### Tables created with new service categories

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;Department Name&gt; Tasks [&lt;service category table name&gt;]</code></td>
<td>The table that stores request task records for the service category. This table extends the Task table. The name of this table is defined by the department the service category is associated with, and the Table name field on the service category record. A new application menu and modules are created to allow users to access records on this table. Records on this table are numbered using a new Numbers [sys_numbers] record.</td>
</tr>
</tbody>
</table>

### User roles created with new service categories

<table>
<thead>
<tr>
<th>Role</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;service category table name&gt;_user</code></td>
<td>The user role required to access request records for a service category. The Table name for the service category determines the name of the role. Users designated as the manager, editors, or service fulfillers for a service category automatically receive this role. Only users with this role can be assigned task records for the service category. ACLs are created to allow users with this role to access the relevant service task table.</td>
</tr>
</tbody>
</table>
### Email notifications created with new service categories

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Task commented for group</td>
<td>Notifies the group a service task record is assigned to when a user adds a comment.</td>
</tr>
<tr>
<td>Task commented for assignee</td>
<td>Notifies the user a service task record is assigned to when a user adds a comment.</td>
</tr>
<tr>
<td>Task closed for group</td>
<td>Notifies the group a service task record is assigned to when the record is closed.</td>
</tr>
<tr>
<td>Task worknoted for assignee</td>
<td>Notifies the user a service task record is assigned to when a user adds a work note.</td>
</tr>
<tr>
<td>Task assigned to group</td>
<td>Notifies the group a service task record is assigned to when the record is assigned to that group.</td>
</tr>
<tr>
<td>Task assigned to assignee</td>

### Forms created with new service categories

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;department name&gt; Task</td>
<td>The form for viewing request task records for the service category. By default, this form uses a layout that includes a formatter to display the questions for the service and the answers provided by the requesting user.</td>
</tr>
</tbody>
</table>
### Service catalog categories

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;service category name&gt;</td>
<td>The default service catalog category for new services created within a service category.</td>
</tr>
</tbody>
</table>

### Service Creator roles

The Service Creator application uses the specific roles.

### Roles

<table>
<thead>
<tr>
<th>Role Title [Name]</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Service Category&gt; User [&lt;service category table name&gt;_user]</td>
<td>Accesses request records for a service category. The table name for the service category determines the name of the role. Users designated as the manager, editors, or service fulfillers for a service category automatically receive this role.</td>
</tr>
<tr>
<td>Catalog Administrator [catalog_admin]</td>
<td>Creates, edits, and publishes service categories and services, and creates and edits notifications including template notifications. Catalog administrators are primarily responsible for approving service category requests.</td>
</tr>
<tr>
<td>Catalog Manager [catalog_manager]</td>
<td>Creates, edits, and publishes services, and designates editors and service fulfillers. A user designated as the manager of a service category receives this role automatically.</td>
</tr>
<tr>
<td>Catalog Editor [catalog_editor]</td>
<td>Creates and edits services. A user designated as an editor of a service category receives this role automatically.</td>
</tr>
</tbody>
</table>

### Manage a service

Using the Service Creator, department managers can request a new service category, designate editors and service fulfillers for that category, and create and publish services.

**About this task**

Editors create and modify services. Service fulfillers complete the tasks generated from service requests.

A service category request involves assigning a service category manager, which is typically the department manager who makes the request. After the request is submitted, a catalog administrator approves the request to publish...
the service category. When the category is published, the service category manager can assign service category editors and service fulfillers, and create services to offer in the service catalog.

To request a new service category:

**Procedure**
1. Navigate to **Self-Service > Service Catalog**.
2. Select the **Departmental Services** category.
   
   The *Departmental Services* category is part of the demo data available with service creator. If this category does not exist, a catalog administrator must add the *Service Category Request* catalog item to an existing category.
3. Select the **Service Category Request** item.
4. Change the default values, as necessary (see table).
5. Click **Submit**.

---

**Managing Services**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Department</td>
<td>Department this category request is for. By default this value is the department of the current user. Changing this value also changes the Category name and Category manager values.</td>
</tr>
<tr>
<td>Category name</td>
<td>Name for the new service category. By default, ServiceNow uses a name based on the Department value.</td>
</tr>
</tbody>
</table>
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Category manager</td>
<td>Designated manager for the new service category. By default, ServiceNow uses the manager for the selected department.</td>
</tr>
<tr>
<td>Needed by</td>
<td>Date that the new service category should be available.</td>
</tr>
<tr>
<td>Comments</td>
<td>Additional comments describing the service category. This information appears as a journal entry on the Service Category form.</td>
</tr>
</tbody>
</table>

### Designing services

Service creator includes an interface for designing services.

Using this interface, service category managers and editors can create and publish services, and edit service details.

All services must belong to a service category. If your department or group does not have an existing service category, you must create a new service category before you can design services for that category.

### Add a template notification

Adding a template notification.

**Procedure**

1. Navigate to **Service Creator > Template Notifications**.
2. Click **New**.
3. In the **Send when** field, select **Event is fired**.
4. In the **Event name** field, select **ccrTemplate**.
5. Enter other notification details.
6. Click **Submit**.

The new template notification creates a notification for all service categories published after that point.

### Notification configurations

All service categories start with a set of associated notifications, such as the notification when a task to fulfill a service request is assigned.

Notifications defined in the **Service Creator > Template Notifications** module are copied when a user creates a new service category.

Template notifications are distinct from the notifications for the Service Creator application itself, such as the notification when a new service category is
approved or rejected. Notifications for the Service Creator application are defined in Service Creator > Notifications.

A system administrator can add and delete template notifications.

Create the category and table

After the request has been submitted, a catalog administrator can approve or reject the request.

About this task

Approving the request creates a new table for the service category, adds an application to the application navigator using the Category name as the application label, and sets the State of the service category to Published to Catalog.

Procedure

1. Navigate to Service Creator > Category Requests.
2. Open a record with a State of Requested.
3. Review the requested service category. ServiceNow provides a suggested Table name based on the Department.
   - If a service category exists with the specified category name or table name, a message appears under that field. Use a unique value for these fields.
4. Click Create Category and Table to approve the request or Reject to reject the request.
   If notifications are enabled for the instance, the service category Manager is notified of the approval or rejection.
After publishing the service category, you can access the new table by navigating to the new application in the application navigator, or by clicking the View Task List related link on the Service Category form.

Related information
  Manage a service

Delete a template notification
Deleting a template notification prevents new service categories from using the notification, but does not delete notifications for service categories that have already been created.

Procedure
1. Navigate to Service Creator > Template Notifications.
2. Select a notification record.
3. Click Delete.
4. Click OK to confirm.

Designate an editor
Editors can create and modify services within a service category.

About this task
Editors automatically receive the catalog_editor role.
The service category manager can designate editors for a published service category.

**Procedure**

1. Navigate to **Service Creator > My Service Categories**.
2. Select a record with a **State** of **Published to Catalog**.
3. Click the lock icon beside the **Editors** field.
4. Select users to designate as editors using the reference lookup icon. Only users in the appropriate department are available for selection.
5. After adding all editors, click **Update**. Editors receive the Catalog Editor role.

**Designate a service filler**

Service fillers can complete service requests submitted for a service category.

**About this task**

Service fillers can access applications for service categories they are assigned to, but cannot access the Service Creator application.

The **Service Fulfillers** related list on the Service Category form displays all users assigned as fillers for that service category. The service category manager can designate service fillers for a service category.
Procedure
1. Navigate to Service Creator > My Service Categories.
2. Select a service category with a State of Published to Catalog.
3. In the Service Fulfillers related list, click Edit.
4. Use the slushbucket to add the appropriate service fulfillers.
   Only users in the appropriate department are available for selection.
5. Click Save.

Create New Service
View Task List

Fulfill a service request
End users can request published services through the service catalog.

About this task
When a user requests a service, the ServiceNow system creates a new task for that service category. Service fulfillers complete these tasks to fulfill the request.

New request tasks are automatically assigned to the group or user specified in the Fulfillment Group or Fulfillment User Service setting. If no fulfillment group or user is set, new records are assigned to the service category manager.

Questions for a particular service and the answers entered by the requesting user appear in the Variables section on the fulfillment task record.

Procedure
1. Navigate to <Your service application> > Assigned to me.
2. Select a record.
3. Review the information presented.
4. Complete the task in accordance with department policies and procedures.
5. Set the state of the service request record to **Closed Complete**.
6. Click **Update**.

**Publish a service**

A service must be published to appear in the service catalog. When first created, new services appear in the Draft Services related list for the service category. Published services appear in the Services related list for the service category. The manager of a service category can publish draft services.

**Procedure**

1. Navigate to **Service Creator > My Service Categories**.
2. Select a service category with a State of **Published to Catalog**.
3. On the Service Category form, right-click a service in the **Draft Services** related list.
4. Select **Publish**.

**Team Development**

Team Development supports parallel development on multiple, non-production ServiceNow instances.

**Important:** Team Development note here.

Team Development provides the following features:

- Branching operations, including pushing and pulling record versions between instances.
- The ability to compare a development instance to other development instances.
- A central dashboard for all Team Development activities.

**Team Development overview**

Team Development allows developers to work on separate development instances while sharing code and resolving collisions throughout the development process.
After setting up the instance hierarchy, you can develop changes on your local development instance. Use the team dashboard to manage Team Development activities, such as:

- Tracking local changes and determining which changes to promote to the parent development instance.
- Pulling changes from the parent instance and resolving any collisions with local changes.
- Comparing your instance with other development instances and resolving any collisions with other development projects.
- Pushing changes when a feature is tested and ready to promote to the parent development instance.

Developers with admin access to their development instance and the parent instance can use team development. For alternative access settings, see Granting access rights to developers.

Requires developers to manually merge colliding changes.  
Works only for instances owned by the same organization.  
**Note:** If used with the application repository, publish applications from a parent instance. |

---

**Local changes**

The Local Changes table tracks which customized records have current versions that exist on the development instance but not on the parent instance.

Use local changes to collect changes in preparation for a push.

You queue local changes that are ready to push. Each development instance maintains a single queue, regardless of who develops or queues the changes. You ignore local changes that you do not want to push. For example, you may want to ignore changes to the color scheme that visually distinguish a development instance from the production instance. You can remove a change from the queue or stop ignoring a change.
Changing the parent instance or reconciling recreates the list of local changes that have not been queued or ignored. If you had previously queued or ignored a local change, that designation is maintained.

**Local change lists**

On the team dashboard, the *Local Changes* list shows the local changes that have not been queued for the next push or ignored for all pushes. The *Ready to Push* list shows the changes that are queued, and the *Ignored* list shows the changes that are ignored. Use any of these methods to navigate a list of local changes.

<table>

</tr>
</tbody>
</table>

Team dashboard

The team dashboard provides a central place to manage all Team Development activities on your development instance.

You can track local changes, pull and push changes between the local and parent instances, compare the local instance to other development instances, and resolve any collisions. You can also reconcile with the current parent instance or change the parent instance.

To access the dashboard, navigate to Team Development > Team Dashboard.
The control panel in the top left provides status indicators and Team Development actions.

- **Parent**: indicates the status of the connection to the parent instance. If a problem or warning is detected, point to the indicator to view the error messages, or click the indicator to open the remote instance record.

- **Change**: changes the parent instance. See Changing the Parent Instance.

- **Reconcile**: compares the development instance to the parent instance. See Reconciling.

- **Ready to Pull**: indicates the number of changes on the parent that have not been pulled to the local instance.

- **Pull**: initiates a pull. See Pulling Versions.

- **Push**: opens a page that allows you to review the changes before a push. See Pushing Versions.

- **Refresh**: updates the status indicators on the control panel. The dashboard updates only when you reload or refresh the page.

- **Local**: indicates the status of the most recent comparison with another instance. If collisions are detected, click the indicator to open the list and resolve the collisions. See Resolve a collision in Team Development.

- **Collisions**: appears only if any local changes collide with versions pulled from the parent and indicates the number of collisions. Click the indicator to open the list and resolve the collisions. See Resolve a collision in Team Development.

- **Compare to**: allows you to select another development instance to compare with the local instance. See Comparing to Peer Instances.
• Ready to Push: indicates the number of local changes that are queued for the next push. See Queuing and Ignoring Local Changes.

• Local changes: indicates the number of local changes that have not been queued or ignored. Click the indicator to open a list of these changes.

• Ignored: appears only if any local changes are ignored and indicates the number of ignored changes. Click the indicator to open a list of these changes.

The team dashboard includes lists for tracking local changes and viewing the history of Team Development activities.

• Local changes: lists the local changes that have not been queued or ignored.

• Pushes and Pulls: provides a history of pushes and pulls. Expand a row to see the customized records for which versions were transferred as part of the push or pull.

• Instance Comparisons: provides a history of comparisons with other development instances.

• Collisions: lists the collisions that must be resolved before the next pull or push. You can right-click a row and select Resolve Collision. See Resolving Collisions.

• Ready to Push: lists the local changes that have been queued for the next push.

• Ignored: lists the local changes that are ignored for all pushes.

Approve or reject a push

Code reviewers must approve or reject a push from the Team Development application.

About this task
Although reviewers can see the individual versions within a push, they must approve or reject the push as a whole.

Procedure
1. Log in to the parent instance that requires code review.
2. Navigate to **Team Development > Code Review Requests**.
3. Select a change in the **Awaiting Code Review** stage.
4. Review the changes in the **Push or Pull Versions** related list.
5. Click **Approve or Reject**.
6. Optional: Enter review comments in **Comments**. These comments are visible to anyone who can see the Pushes and Pulls history.
7. Click either **Approve** or **Reject**, as appropriate.

Note: The **URL** and **Remote Instance** fields list the address and name of the instance where the change originated.
Back out a local change

Back out all local changes and restore the last version reconciled with the parent instance.

Procedure

1. Define a parent instance.
2. Pull changes from the parent instance.
3. Navigate to Team Development > Team Dashboard.
4. Filter the Local Changes list to show only the changes that you want to back out.
5. Do one of the following actions:
   - Click Back Out All.
   - Right-click the local change you want to back out, and then click Back Out.

Cancel a code review request

Developers can cancel any push they submitted that is in the Awaiting Code Review stage.

About this task

Canceling a request sets the push to the Code Review Request Cancelled stage on the submitting instance. The submitting instance retains a version history of the push but the parent instance does not.

Procedure

1. Log in to the instance that pushed the changes.
2. Navigate to Team Development > Pushes and Pulls.
3. Filter for the push you want to cancel.

   ☑️ **Note:** You cannot cancel a push that has been approved or rejected.

4. Select the Push or Pull record.

5. Click **Cancel Code Review**.

**Change the parent instance**

If it becomes necessary to modify the instance hierarchy, you can change the parent for a development instance.

**About this task**

Changing the parent initiates a complete comparison between the development instance and the new parent instance. To optimize comparison speed and reduce the number of collisions and local changes that need review afterwards, ensure that the new parent instance was cloned recently from an appropriate instance (for example, the production instance). Before you change the parent instance, ensure that the change does not conflict with your change management process or other development efforts.

To change the parent for a development instance:

**Procedure**

1. On the development instance, navigate to **Team Development > Team Dashboard**.

2. In the control panel, click **Change**.

3. Select the remote instance you want to use as the parent and click **Select**.

   Alternatively, click the link to define a new remote instance. Then, repeat steps 1–3 and select the remote instance you defined.

![Change current parent instance](image)

The system initiates a reconcile, which compares the local instance to the parent, and then generates the list of local changes and calculates the number of changes that are ready to pull from the parent.

4. On the completion page, click **Team Dashboard**.
5. Pull versions from the parent instance and resolve any collisions.
6. Review the local changes list and queue or ignore changes, as appropriate.

Check the review status of a pushed change

If the parent instance requires pushed changes to undergo code review, changes are placed in the Awaiting Code Review stage.

About this task

If you configure the parent instance to send notifications, it sends the submitting developer a notification when the pushed changes are approved or rejected. Developers can also manually check the status of their pushed changes from the Pushes and Pulls module on the submitting instance.

Procedure

1. Log in to the instance that submitted code for review.
2. Navigate to Team Development > Pushes and Pulls.
3. Filter for the push you want to review.
   • Pushes in the Complete stage are approved and applied to the parent instance.
   • Pushes in the Collided stage are rejected because of a collision.
   • Pushes in the Awaiting Code Review stage are awaiting review.
   • Pushes in the Code Changes Rejected stage are rejected by a reviewer.
   • Pushes in the Code Review Request Canceled stage are canceled by the submitting developer.
4. Click the Reviews related list to see the following information.
• Who submitted a review decision.
• What the decision was: either approved or rejected
• What comments if any the reviewer provided.

Compare a pushed version to a local version

Code reviewers can compare the pushed versions to the local versions to see the potential effect of incoming changes.

Procedure
1. Log in to the instance requiring code review.
2. Navigate to Team Development > Code Review Requests.
3. Select a change in the Awaiting Code Review stage.
4. Review the changes in the Push or Pull Versions related list.
5. Right-click a row in the list and click Compare to Current. A comparison of the differences between the pushed and local versions appears.

Related information

Merge tool
Compare to the current version
Compare two versions of an article
Resolve conflicts for an individual record
Resolve a collision in Team Development
Compare to peer instances
You can compare the local instance to any other remote instance and commit any current versions from the remote instance on your development instance.

About this task
Comparing allows you to share code between instances without pushing to a common parent.

Comparing instances does not automatically commit any versions on the local instance. It initiates a full comparison of all changes on the remote instance and all changes on the local instance, and then reports which customized records have different current versions. You can selectively commit a version from the remote instance or compare it with the version on your local instance. You can delete the instance comparison record when you finish evaluating the differences.

To compare the local instance to a peer instance:

Procedure
1. Ensure that the peer instance is defined as a remote instance.
2. Navigate to Team Development > Team Dashboard.
3. In the control panel, click Compare to.
4. Select the peer instance you want to compare to the local instance and click Compare.
5. On the completion page, click Show Results. The instance comparison record opens.
6. Review the On Remote and not Local related list, which shows the customized records where the current version on the peer instance is not on the local instance. For each customized record, you can:

- Compare the current remote version to the current local version by right-clicking a row and selecting **Compare to Current**.
- Load the current remote version as the current local version by right-clicking a row and selecting **Load This Change**.

**Ignore a local change**

Ignoring a local change prevents updates to a record from generating new versions in the Local Changes list.

**About this task**

An ignored local change always points to the current version for the record. You cannot push ignored records to another instance.

**Local change action list**

<table>
<thead>
<tr>
<th>Action</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ignore a record that has a version queued for push</td>
<td>The queued change is deleted</td>
</tr>
<tr>
<td>Ignore a record that has a version queued for code review</td>
<td>The queued change is deleted</td>
</tr>
<tr>
<td>Pull changes for an ignored record</td>
<td>Collision</td>
</tr>
</tbody>
</table>

</tr>
<tr>
<td>To stop ignoring changes and add them to the queue instead</td>
<td>Select the check boxes beside the rows and select <strong>Queue for Push</strong> from the Actions choice list.</td>
</tr>
</tbody>
</table>

### Pull a version

Pulling retrieves versions of customized records from the parent instance and adds them on the development instance. Pulling does not retrieve any versions for changes made by system upgrades, but it retrieves all versions for changes made by users, not just the current version.

### About this task

Pulling retrieves all versions for changes made by users that have not already been pulled onto the development instance, and you cannot choose which versions to pull. The first time you pull from a parent instance, the pull retrieves all versions for changes made by users. Subsequent pulls retrieve the new versions since your last pull. Each pull is recorded in the Push or Pull [sys_sync_history] table on the development instance. Historical versions are saved with a state of **History**.

### Procedure

1. Navigate to **Team Development > Team Dashboard**.
2. In the control panel, click **Pull**.
3. On the completion page, click **Show Results**. The Push or Pull form opens.

   The **Push and Pull Versions** related list shows the customized records for which versions were retrieved and indicates if any pull exceptions exist.
4. Resolve any collisions.

**Push a version**

Pushing promotes changes from the development instance to the parent instance and commits the current version of a customized record on the development instance as the current version on the parent instance.

**About this task**

Pushing adds only the current development version to the parent, not all the development versions.

⚠️ **Note:** Updates to records from different applications cannot be pushed/pulled in the same push/pull. To resolve the error in the case that updates to other applications are mixed in: De-queue the updates to other applications. Push for one application. Re-queue the updates to one application. Push and then repeat as needed.

Pushing creates a local Update Set on the parent that is marked as complete. Pushed changes are also tracked as local changes on the parent. Therefore, you can promote changes through your development and test hierarchy by transferring the Update Set or by pushing the local changes. Each push is recorded in the Push or Pull table on the development instance.
Procedure

1. Navigate to **Team Development > Team Dashboard**.

2. **Queue the local changes** that are ready to push.

3. **Pull versions** from the parent instance and **resolve any collisions**.

   You cannot push changes to the parent instance if collisions are detected.

4. In the control panel, click **Push**. The Push Changes page opens.

5. **Provide a Name** for the changes.

6. **Review the list of changes** to ensure that the correct changes are included.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>To remove changes that you do not want to push</strong></td>
<td>Select the check boxes beside the rows and select <strong>Do Not Push</strong> from the <strong>Actions</strong> choice list</td>
</tr>
<tr>
<td><strong>To add changes</strong></td>
<td>Click <strong>Cancel</strong> and repeat the procedure from step 2</td>
</tr>
</tbody>
</table>

7. **Optional**: Edit the name. The name identifies the push record on the development instance and the local Update Set record on the parent instance.
8. **Optional:** Enter comments. The comments are added to the push record on the development instance and the local Update Set record on the parent instance.

9. Click **Push Changes.** The system initiates a pull to ensure that there are no collisions before the push proceeds.
   - If collisions are detected, the push is automatically canceled and you must repeat the procedure from **step 3.**
   - If no collisions are detected, the changes are staged on the parent instance. On the parent, each version is validated and then committed in the correct order to maintain dependencies between records. For example, a new table is committed before a field on that table to ensure the field is properly created.

**Note:** You cannot push if there is a version conflict between instances or the pushing instance has changes in the Awaiting Code Review stage.

10. On the completion page, click **Show Results.**

11. Review the push record for any errors or skipped changes.
   - Changes with a state of **Pushed** were committed on the parent instance.
   - Changes with a state of **Skipped** were not committed on the parent instance and remain queued as local changes on the development instance.

12. For each skipped change, review the log message to determine why the change was skipped. Develop any changes that are necessary to commit the desired version on the parent instance, and then push them. Some examples of why a change may be skipped include:
   - A table does not exist on the parent because it was created when you activated a plugin on the development instance. Ensure the plugin is activated on the parent and push the change again.
   - An error occurred during the push. Try to push again.
• The current version is invalid. Revert to a previous version and make the change again to ensure the version is valid.

• An error occurred on the parent during the push. The Log field on the push record contains the exception message. Review the system logs on the parent instance and troubleshoot any problems with the instance.

Back out a push
Application developers can back out a push to remove unwanted changes.

Procedure
1. Navigate to **Team Development > Pushes and Pulls**.
2. Select the push to back out.
3. Click **Back Out**.
4. Click **OK** when the confirmation message appears.

Queue a local change for a push
Application developers can queue a local change for a push to ensure the changes are available to other developers.
Procedure
1. Navigate to Team Development > Team Dashboard.
2. Filter the Local Changes list to show only the changes that are ready to push.
   For example, filter the list to show only the changes associated with a particular application.

3. Click Queue All For Push.
4. [Recommended] Review the Ready to Push list to ensure that the correct changes are in the queue.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>To remove changes from the queue</td>
<td>Select the check boxes beside the rows and select <strong>Do Not Push</strong> from the Actions choice list.</td>
</tr>
<tr>
<td>To remove changes from the queue and choose to ignore them instead</td>
<td>Select the check boxes beside the rows and select <strong>Ignore This Change</strong> from the Actions choice list.</td>
</tr>
</tbody>
</table>
Note: For the Local Changes list, click Reset Filter to remove any filter conditions you added and see all the local changes that have not been queued or ignored.

Reconcile changes
Reconciling first compares the local instance to the parent, and then generates the list of local changes and calculates the number of changes that are ready to pull from the parent.

About this task
A reconcile occurs automatically whenever you select a parent instance. You may need to manually reconcile after an external disruptive event on the parent instance, such as a clone or failover.

Note: This process may take a while to complete depending on the size and age of the instance.

Procedure
1. Navigate to Team Development > Team Dashboard.
2. In the control panel, click Reconcile.
3. In the confirmation dialog box, click OK.
   The list of local changes that have not been queued or ignored is recreated. If you had previously queued or ignored a local change, that designation is maintained.
4. Optional: On the completion page, click Show Results. Review the instance comparison record.
- The **On Remote and not Local** related list shows the versions that are ready to pull from the parent.
- The **On Local and not on Remote** related list shows the local versions that are ready to queue or ignore.

5. Click **Team Dashboard**.

6. Pull versions from the parent instance and then resolve any collisions.

7. Review the local changes list and queue or ignore changes, as appropriate.

**Resolve a collision in Team Development**

A collision is detected when the pulled version and the current local version are modifications of a different version, indicating that someone else has modified the same record that you have modified. The team dashboard displays the number of collisions between the local and the parent instance.

**About this task**

To ensure that your changes do not conflict with other development efforts, you should resolve collisions as soon as they are identified. You must resolve all collisions before you can pull or push.

**Procedure**

1. Navigate to **Team Development > Team Dashboard**.

2. In the control panel, click **Collisions** or click the count of collisions. A list of collisions opens.
3. Right-click a row and select **Resolve Collision**. (Alternatively, open the record and click the **Resolve Collision** related link.) The Resolve Collision page displays a comparison between the version that was pulled from the parent and your local record. The page highlights the differences.

4. Review the differences. You have the following options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>To maintain the local record as the current version</td>
<td>Click <strong>Use Local Version</strong>. The pulled version is added to the version history for the record.</td>
</tr>
<tr>
<td>To load the version pulled from the parent as the current version</td>
<td>Click <strong>Use Pulled Version</strong>.</td>
</tr>
<tr>
<td>To move a setting from the selected version to update the current version</td>
<td>To move a change, click the &gt; (Move Right) button for the field. To work with scripts and text fields, click in the field and modify the text as needed. When the records meet your needs, click <strong>Save Merge and Resolve Collision</strong>.</td>
</tr>
</tbody>
</table>

| Note: Some types of record do not support this method. See **Limitations on updating records** for more information. |

The system performs that action and also clears the collision for future push/pulls.

5. Repeat the process for every remaining collision.

**Results**
The system saves the merged changes and resolves the collision.

**Related information**
- Compare to the current version
- Compare a pushed version to a local version
- Compare two versions of an article
- Resolve conflicts for an individual record
- Revert a change
- View customizations and compare with current version
Limitations on updating records

There are some types of records that you cannot merge while resolving differences on the Compare to Current and Resolve Collision pages.

Record types that allow a choice only between reverting or accepting the pulled or current record

The following record types do not allow you to merge individual values. Instead, differences involving the following record types display a read-only comparison and allow a choice between updating and reverting:

- sys_choice [Choice]
- sys_choice_set [Choice Set]
- sys_ui_form [Form]
- sys_ui_list [List]
- sys_ui_related_list [Related List]
- sys_ui_section [Form Section]
- wf_workflow [Workflow]
- wf_workflow_version [Workflow Version]

Team Development, Resolve Collision page: Use Pulled Version and Use Local Version options.

Upgrade History, Compare to Current page: Comparing non-current update versions to current update version. Allows only Revert to Base System option.

Field types that do not support merging

The following field types do not support individual merging between versions or updates:

- auto_increment [Auto Increment]
- auto_number [Auto Number]
- breakdown_element [Breakdown Element]
- catalog_preview [Catalog Preview]
- collection [Collection]
- color_display [Color Display]
- composite_field [Composite Field]
- compressed [Compressed]
- counter [Counter]
• currency [Counter]
• data_array [Data Array]
• data_object [Data Object]
• data_structure [Data Structure]
• date [Other Date]
• datetime [Basic Date/Time]
• days_of_week [Days of Week]
• document_id [Document ID]
• due_date [Due Date]
• Email [Email]
• external_names [External Names]
• field_list [Field List]
• float [Floating Point Number]
• glide_action_list [UI Action List]
• glide_precise_time [Precise Time]
• glide_var [Glide Var]
• image [Basic Image]
• index_name [Index Name]
• int [Integer String]
• integer_time [Integer Time]
• ip_address [IP Address]
• journal [Journal]
• journal_input [Journal Input]
• journal_list [Journal List]
• long [Long Integer String]
• mask_code [Mask Code]
• metric_absolute [Metric Absolute]
• metric_counter [Metric Counter]
• metric_derive [Metric Derive]
• metric_gauge [Metric Gauge]
• mid_config [MID Server Configuration]
• month_of_year [Month of Year]
• multi_small [Multiple Line Small Text Area]
• name_values [Name/Values]
• nl_task_int1 [NL Task Integer 1]
• order_index [Order Index]
• password [Password (1 Way Encrypted)]
• percent_complete [Percent Complete]
• ph_number [Phone Number]
• phone_number [Phone Number (Unused)]
• phone_number_e164 [Phone Number (E164)]
• price [Price]
• reference_name [Reference Name]
• related_tags [Related Tags]
• reminder_field_name [Reminder Field Name]
• repeat_count [Repeat Count]
• repeat_type [Repeat Type]
• replication_payload [Replication Payload]
• schedule_date_time [Schedule Date/Time]
• short_field_name [Short Field Name]
• short_table_name [Short Table Name]
• Slushbucket [slushbucket]
• source_id [Source ID]
• source_name [Source Name]
• source_table [Source Table]
• string_boolean [<none>]
• sys_class_name [System Class Name]
• sysrule_field_name [System Rule Field Name]
• table []
• text []
• time []
• timer [Timer]
Resolve a collision in Team Development

Related information

Resolve multiple collisions

You can resolve multiple collisions without reviewing the differences between the local and pulled versions.

Procedure

1. Navigate to **Team Development > Team Dashboard**.
2. In the control panel, click the number of collisions. A list of collisions opens.
3. Select the check boxes beside the rows you want to resolve.
4. In the **Actions** choice list, use one of the following methods to resolve the collision:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>To load the version pulled from the parent as the current version for all selected collisions</strong></td>
<td>Select <strong>Use Pulled Version</strong></td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>To maintain the local version (local record) as the current version</td>
<td>Select <strong>Use Local Version</strong></td>
</tr>
<tr>
<td>for all selected collisions.</td>
<td></td>
</tr>
<tr>
<td>The pulled versions are added to the version history for the records.</td>
<td></td>
</tr>
</tbody>
</table>

**Team Development setup**

To enable parallel development on multiple non-production instances, administrators can set up the Team Development instance hierarchy and grant access rights for developers.

**Access rights for developers**

To use Team Development, application developers must have a set of credentials for each instance in the Team Development hierarchy.

An instance’s placement in the **team development hierarchy** determines the credentials it requires.

**Credentials for Team Development access**

<table>
<thead>
<tr>
<th>Desired Access</th>
<th>Credential Requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access to the Team Development application</td>
<td>A user with the admin role on the instance you are accessing</td>
</tr>
<tr>
<td>Right to register a remote instance</td>
<td>One of following:&lt;br&gt;• A user with the admin role on the instance you are registering&lt;br&gt;• A user with the teamdev_user role on the instance you are registering</td>
</tr>
<tr>
<td>Right to push changes to the parent instance from a</td>
<td>One of following:&lt;br&gt;• A user with the admin role on the parent instance&lt;br&gt;• A user with the teamdev_user role on the parent instance</td>
</tr>
<tr>
<td>development instance</td>
<td>Right to compare to a registered remote instance &lt;br&gt;One of following:&lt;br&gt;• A user with the admin role on the instance you are accessing</td>
</tr>
</tbody>
</table>
Credentials for Team Development access (continued)

<table>
<thead>
<tr>
<th>Desired Access</th>
<th>Credential Requirements</th>
</tr>
</thead>
</table>
| • A user with the admin role on the registered development instance
• A user with the teamdev_user role on the registered development instance |

Access to the Code Review Requests module

<table>
<thead>
<tr>
<th>Access to the Code Review Requests module</th>
<th>One of following:</th>
</tr>
</thead>
</table>
| • A user with the admin role on the parent instance
• A user with the teamdev_code_reviewer role on the parent instance |

⚠️ Note: The teamdev_user role does not grant access to the Team Development application and is not intended for developers to work on local development instances. It is intended to grant developers non-admin access to remote instances such as the parent instance or a peer development instance.

Create an exclusion policy

Application developers can create an exclusion policy to prevent pushes or pulls to particular instances in the team development hierarchy.

Procedure

1. Navigate to Team Development > Exclusion Policy.
2. Click New.
3. Complete the Exclusion Policy form (see table).
4. Click Submit.

Exclusion policy form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a unique description of the policy.</td>
</tr>
<tr>
<td>Policy</td>
<td>Select when the policy applies. Options include:</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>• Push only</td>
<td></td>
</tr>
<tr>
<td>• Push and Pull</td>
<td></td>
</tr>
<tr>
<td>• Pull only</td>
<td></td>
</tr>
<tr>
<td>Remote Instance</td>
<td>[Optional] Select a specific remote instance to ignore changes from during pull operations. Leaving this field blank ignores changes from all remote instances.</td>
</tr>
<tr>
<td>Table</td>
<td>Select which table to ignore changes for.</td>
</tr>
<tr>
<td>Conditions</td>
<td>Select any additional criteria a change must meet to be ignored other than the table name. This field is only visible when the Policy is Push only.</td>
</tr>
</tbody>
</table>

**Define a remote instance**
For each instance, define other instances in the hierarchy as remote instances.

**About this task**
For example, to set up remote instances for Sub-Dev 1:

**Procedure**
1. If IP address access control is enabled, log in to the remote instance and add Sub-Dev 1 as an exception.
2. On Sub-Dev 1, navigate to Team Development > Remote Instances.
3. Click New.
4. Define the remote instance, such as Dev-Parent, by completing the form (see table).

**Related Links**
Retrieve Completed Update Sets
Compare to Local Instance
Make This Your Parent
5. Click **Submit**.

6. Repeat step 1 through step 5 for each instance in the hierarchy that this instance needs to push and pull with (for example, Sub-Dev 2 and Sub-Dev 3).

Remote instance form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a unique name describing the instance.</td>
</tr>
<tr>
<td>Type</td>
<td>Specify whether the remote instance is a development, test, or UAT instance.</td>
</tr>
<tr>
<td>Active</td>
<td>Specify whether the local instance communicates with the remote instance as a member of Team Development. Team Development operations such as comparing changes between instances or selecting a parent instance are only available for active remote instances.</td>
</tr>
<tr>
<td>URL</td>
<td>Specify the URL of the remote instance using the appropriate transfer protocol. Each remote instance record should have a unique URL. Creating duplicate records with the same URL can cause errors.</td>
</tr>
<tr>
<td>Username</td>
<td>Enter the user on the remote instance who authorizes Team Development operations on the instance. This user account must have an appropriate role on the remote instance.</td>
</tr>
<tr>
<td>Password</td>
<td>Enter the password of the authorizing user.</td>
</tr>
<tr>
<td>Short description</td>
<td>[Optional] Enter any other relevant information about the remote instance.</td>
</tr>
</tbody>
</table>

Enable a code review

You can require a code review of all changes pushed to an instance.

Procedure

1. Navigate to **Team Development > Properties**.

2. Select the **Yes** check box for *If this property is set to Yes, code review is required before pushing to this instance* (com.snc.teamdev.requires_codereview).

3. Click **Save**.
Setting this property adds the Code Review Requests module to the application menu and requires all changes pushed to this instance to remain in the Awaiting Code Review stage until someone in the Team Development Code Reviewers group approves them.

Select the parent instance
An instance can have multiple peer instances but only one parent instance.

About this task
The parent instance is the only instance you can pull changes from and push changes to.

The parent instance must be on the same release family as the local instance. For example, a development instance on the Geneva release family must have a parent instance also on the Geneva release family. If you select a parent from a different release family, the Team Development dashboard displays an error message and prevents you from pulling changes and reconciling. If you select a parent from a different patch release, the dashboard displays a warning message but allows you to pull changes and reconcile.

Do not use Team Development with production or test instances.

• Do not use a test or production instance as the parent instance in Team Development.
• Do not make any instance the parent of a production instance.
• Production instances should never have a parent.

When you back out a change on a Team Development instance, it backs out the change all the way back down the chain, including undoing the work on the source instance. This behavior can cause major problems on test and production instances.

Procedure
1. Navigate to Team Development > Team Dashboard.
2. In the control panel, click the appropriate link:

<table>
<thead>
<tr>
<th>Team dashboard control panel options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use &lt;instance name and URL&gt;</td>
<td>Selects the most recently defined remote instance as the parent instance.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Select a different instance</td>
<td>Opens a dialog box where you can select another remote instance or define a new remote instance.</td>
</tr>
<tr>
<td>Register a new instance or List all remote instances</td>
<td>Opens the remote instance form or list, where you can define a new remote instance. These options are available when no remote instances are defined.</td>
</tr>
</tbody>
</table>

3. If you defined a new remote instance in step 2, repeat step 1 through step 2 and select the remote instance you defined.

The system initiates a reconcile, which compares the local instance to the parent. It then generates the list of local changes and calculates the number of changes that are ready to pull from the parent. The reconcile also validates the instance versions.

4. Pull all changes from the parent instance if both instances are in the same release family.

   **Note:** The parent instance is saved in the `glide.apps.hub.current` system property.

### Set up an instance hierarchy

Set up an instance hierarchy that best supports your development life cycle.

**About this task**

This example demonstrates how to set up an instance hierarchy where several peer sub-development instances have the same parent development instance, but a more complex configuration may be required to handle multiple project teams or other customer requirements.

Do not use Team Development with production or test instances.

- Do not use a test or production instance as the parent instance in Team Development.
- Do not make any instance the parent of a production instance.
- Production instances should never have a parent.
When you back out a change on a Team Development instance, it backs out the change all the way back down the chain, including undoing the work on the source instance. This behavior can cause major problems on test and production instances.

**Procedure**

1. Provision a parent development instance on the same software version, such as Dublin, as the target instance, such as production.
2. [Recommended] Clone the production instance to the parent development instance.
3. Provision sub-development instances on the same software version as the parent development instance.
4. **Optional:** Log in to the parent development instance and clone it to the sub-development instances.
5. On each sub-development instance:
   a. Define remote instance connections to other instances in the hierarchy that this instance needs to push and pull with.
   b. Select the parent instance.
   c. Pull all changes from the parent instance.
   d. Grant access rights to appropriate developers.

**Code reviews**

Team Development administrators can require that pushes undergo code review before accepting pushes.
When code review is enabled, pushing a change to the parent instance triggers the code review workflow. By default, users with the teamdev_code_reviewer role receive notifications to review changes and can approve or reject changes. The Team Development Code Reviewers has the teamdev_code_reviewer role.

For each change, reviewers can see the following information.

- Which remote instance the pushed change comes from.
- Who pushed the change to the parent.
- What the change is called.
- When the change was created.
- Which versions the change includes.

Reviewers must approve or reject a push from the Team Development application.

While changes are being reviewed on the parent instance, a child instance cannot do the following activities involving the parent instance:

- Push changes to the parent instance.
- Pull changes from the parent instance.
- Reconcile changes with the parent instance.
- Change the parent instance to another instance.
- Delete the remote instance record for the parent instance.

**Code review notifications**

You must enable email notifications on the instance requiring code review for that instance to send code review notifications.

The Team Development Code Review workflow sends notifications to members of the Team Development Code Reviewers group when:

- A push requires code review.
- A user cancels a push.

If the user who pushed the changes has a user record with an email address on the instance where code review was required, the user receives a notification when the approval stage is set to Complete (approved) or Code Changes Rejected.

The code review notifications contain the following information:
### Code review notification table

<table>
<thead>
<tr>
<th>Notification name</th>
<th>Table</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>Code review update for developer</td>
<td>Push or Pull [sys_sync_history]</td>
<td>• The push name&lt;br&gt;• The approval stage of the push (approved or rejected)&lt;br&gt;• A link to the instance where the code review request was made</td>
</tr>
<tr>
<td>Notify code reviewer of canceled review</td>
<td>Push or Pull [sys_sync_history]</td>
<td>• The user who canceled review&lt;br&gt;• The push that was canceled</td>
</tr>
</tbody>
</table>

### Code review workflow

The Team Development Code Review workflow manages how changes are pushed to the parent.

By default this workflow:

- Starts when changes are pushed to the parent instance.
- Verifies that the code review property is active on the parent instance.
- Sets the stage of changes requiring approval to **Awaiting Code Review**.
- **Notifies** the Team Development Code Reviewers group to review pushed changes, if configured.
- Loads approved changes or sets the stage to **Code Changes Rejected**.

⚠️ **Warning:** Use caution when modifying this workflow, as the code review feature may not function properly.
Exclusion policies
You can exclude certain files from change tracking by creating an exclusion policy.

When a change matches an exclusion policy, the change does not generate records in the local changes list. The change still generates local version records and Update Set records as normal. See Creating an Exclusion Policy.

Note: The exclusion policy applies to changes identified during a reconciliation operation. If you create an exclusion policy after a reconciliation, Team Development still tracks the changes until the next reconciliation.

Instance hierarchies
Team Development allows you to set up a distributed version control system between multiple ServiceNow instances where each instance acts as a source repository, or branch.

Developers use separate instances to work on different features, applications, or product releases at the same time. With Team Development, developers can share code between these instances and resolve collisions throughout the development process.

Team Development allows you to establish hierarchical relationships between instances and provides a mechanism for transferring changes between instances that integrates with the Update Set process where necessary. In a Team Development instance hierarchy, each non-production instance has a parent instance. Instances that have the same parent instance are peer instances. The shared parent instance becomes the central hub, or repository, and all peer instances synchronize to it.

Pulls and pushes
Developers synchronize their instances to the parent instance by pulling and pushing versions of customized records and resolving collisions between versions on the parent instance and the development instance.

Developers can compare peer instances to one another and share code or resolve collisions before pushing versions to the parent instance.

Pulling from the parent retrieves versions of records that have customer updates. Pulling retrieves all versions that have not already been pulled onto the development instance, including historical versions, and you cannot choose which versions to pull. You must resolve any collisions before proceeding with further pulls or pushes.
Pushing to the parent adds only the current development version to the parent, not all the development versions. You can choose which changes to push to the parent. Pushing creates a local Update Set on the parent that is marked as complete. Pushed versions are also tracked as local changes on the parent. Therefore, you can promote changes through your development and test hierarchy by transferring the Update Set or by pushing the local changes.

Comparing reports the differences between two peer instances. You can choose which versions to pull from a peer instance.

The Pushes and Pulls related list on the team dashboard displays the user who created a change and the remote instance where the change was created.

**Team Development process**

The basic Team Development process sets up the instance hierarchy, grants developer access rights, manages the movement of development changes from development instances to test instances, and promotes applications to the production instance.

**Procedure**

1. Set up the development instance hierarchy as described in Set up an instance hierarchy.
   - a. Provision development instances on the same software version as the target instance. For example, use the software version that is running on your production instance.
   - b. [Recommended] Clone the target to the development instances.
   - c. For each instance, define the parent instance.
   - d. [Optional] For each instance, define the peer instances.
   - e. For each instance, pull all changes from the parent instance.
2. For sub-development instances, grant access rights to appropriate developers.
3. Develop customizations on sub-development instances. Use the team dashboard to track development activities.
   - Pull versions from the parent instance, such as versions that were pushed from other sub-development instances. Reconcile any conflicts with the current local version, as necessary.
   - Track local changes. Queue changes that are ready to push to the parent development instance.
   - Compare versions on peer instances. Reconcile any conflicts.
4. When a feature is ready to promote to the parent development instance, push the current version of the customized records.

5. [Optional] Have code reviewers approve or reject the pushed version.

6. Test and promote the feature into production according to your testing and release management process.

**Related reference**
- Access rights for developers

**Related information**
- Team Development
- Push a version

**Team Development roles**
To use Team Development, developers must have admin access to their development instance.

To allow pushes to the parent instance, a remote instance connection must be defined with a user account that has admin access to the parent instance.

To limit developer access to the parent instance, see Granting Access Rights to Developers.

To use code review features, users must have the teamdev_code_reviewer role. See Code Review.

**Versions**
Version records track changes to a customized record over time so that administrators can compare or revert to specific versions later.

Administrators can also transfer versions between instances with Update Sets or team development.

**Version record navigation**
There are a variety of methods for viewing a list of versions for an object.

- For forms, right-click the header and select **Configure > Form Layout**.

- For lists, perform the appropriate action for the list version.
  - List v2: Right-click the header and select **Configure > List Layout**.
  - List v3: Open the list title menu and select **List Layout**.
• Click the **Show Versions** related link.

• For tables that use the update_synch attribute, add the **Versions** related list to the form. This list is on several forms by default, including, business rules, UI actions, and client scripts.

• For any customizable object, right-click the form header and select **Show Application File**, then scroll down to the **Related Record Versions** related list.

You can navigate from a version record to:

• The customized object: Click the **Show Related Record** related link.

• The application file record for the object: Click the **Show Application File** related link.

---

- Show Related Record
- Show Application File

---

**Version List**

![Version list screenshot](image)

---

**Versions transferring**

Administrators transfer version records between instances by moving customizations with Update Sets or the Team Development application.
• Update sets: committing an Update Set adds versions. For each update in the Update Set, the version that corresponds to the update is added on the local instance.

• Team Development:
  ◦ Pulling retrieves from the parent instance all versions of customized records that have not already been pulled and then adds them on the local instance.
  ◦ Pushing adds to the parent instance only the current local version, not all the local versions.
  ◦ Loading changes from peer instances adds selected versions to the local instance.

Version records

The Update Versions [sys_update_version] table contains records that represent the state of a customizable object at a particular time.

A customizable record is any object that is tracked by Update Sets, such as business rules or script includes. A new version record is created automatically whenever a user changes a customizable record or changes the application file for the customizable record.

A baseline version record represents the version of a base system object as it was delivered in the most recent upgrade. Baseline versions are created only for objects that have been modified by a user, and they are updated each time the system is upgraded.

Related information

Team Development
**Merge tool**

The Diff Merge tool enables administrative users to compare differences between two versions of a record. Administrators can compare field-level changes between two versions, apply changes using Move Right field-level copy functionality and then merge results, or choose to revert to the non-current version. You can access the Diff Merge tool by comparing versions, resolving conflicts, or resolving collisions, during development or after upgrades.
Accessibility Functions

The platform includes accessibility features that support Web Content Accessibility Guidelines (WCAG) 2.0 level A and make the interface accessible to users with disabilities. These features improve the user experience when accessing platform functions with screen readers and keyboard navigation.

In general, you can use the following set of standard keyboard navigation functions:

- Press **Tab** to navigate major groupings in a pre-defined sequence, including moving between standard interface controls (fields and lists) in a module, or between records within a tab.

- Press **Shift Tab** to move backwards in a pre-defined sequence.

Visually impaired users can navigate the Diff Merge tool. Screen readers can read all critical page content. All links and buttons can be reached when a section that is critical must be read. VoiceOver audible cues describe the content of the section that is necessary to read.

To enable accessibility functions, administrators should set these sys_properties:
1. Setting `glide.ui.javascript_editor` to false makes the following functions accessible:
   - Script fields (such as Script Include).
   - Side-by-side script comparison.

2. Setting `sys_properties` color settings enables high contrast visibility, which makes the left and right columns more accessible and easier to read by visually impaired users.
   - `mergetool.bg.left.highlight` - Left column cell color when values differ between versions.
   - `mergetool.bg.right.highlight` - Right column cell color when values differ between versions.
   - `mergetool.bg.left` - Left column cell color when version values are the same.
   - `mergetool.bg.right` - Right column cell color when version values are the same.

Related information

- Compare to the current version
- Compare a pushed version to a local version
- Compare two versions of an article
- Resolve conflicts for an individual record
- Resolve a collision in Team Development
- Revert a change
- View customizations and compare with current version

**Compare to the current version**

You can compare a version to the current version for any customizable object that a user has modified, such as a form layout or business rule. You can also compare the local and current pulled version of an object in Team Development. Administrators can suppress versions for specific tables.

**About this task**

To compare a version to the current version of an object:
Procedure

1. Open the Compare to Current page using one of the following methods:

<table>
<thead>
<tr>
<th>Option</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>From a Versions list</td>
<td>Right-click the version and select <strong>Compare to Current</strong>.</td>
</tr>
<tr>
<td>From the Update Versions form</td>
<td>Click the <strong>Compare to Current</strong> related link.</td>
</tr>
</tbody>
</table>

2. The Compare to Current page highlights the fields that differ. Review the differences. You have the following options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>To resolve the differences by choosing the previous version</td>
<td>• Team Development: Click <strong>Revert to Selected Version</strong>.</td>
</tr>
<tr>
<td></td>
<td>• For a version of an object: Click <strong>Use Local Version</strong> to maintain the local record as the current version. The pulled version is added to the version history for the record.</td>
</tr>
</tbody>
</table>
To resolve the differences by modifying the current version and saving the merged changes

**Note:** Some types of record do not support this method. See Limitations on updating records for more information.

<table>
<thead>
<tr>
<th>Option</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>You can either update the setting in the current record or move a setting from the selected version to the current version. To move a change, click the &gt; (Move Right) button for the field in the diff/merge tool. To work with scripts and text fields, click in the field and modify the text as needed. When the records meet your needs, click:</td>
<td></td>
</tr>
<tr>
<td>• Team Development: Click <strong>Save Merge</strong> to save the changes to the current version.</td>
<td></td>
</tr>
<tr>
<td>• Team Development: Click <strong>Use Pulled Version</strong> or <strong>Use Local Version</strong> option to accept or reject all changes, as appropriate.</td>
<td></td>
</tr>
<tr>
<td>• On the upgrade history Compare to Current form, the only option is <strong>Revert to Base System</strong></td>
<td></td>
</tr>
</tbody>
</table>

**Related information**

- Compare to the current version
- Compare a pushed version to a local version
- Compare two versions of an article
- Resolve conflicts for an individual record
- Resolve a collision in Team Development
- Revert a change
- View customizations and compare with current version

**Revert a change**

You can undo changes to a customized record by reverting to an older version.
Procedure

1. View a list of version records for an object.

2. Optional: Compare the current version to the older version to ensure that you are reverting the desired changes.

3. Right-click the older version and select **Revert to this version**. A confirmation dialog box appears.
   If reverting to this version results in data loss due to a database schema change, a warning message appears in the dialog box.

4. Click **OK** to confirm the action.

   - The current version is marked as a previous version.
   - A new version record is added that duplicates the version that you selected in the preceding step. This new version is marked as the current version.

**Note:** You can revert to the most recent baseline version. You cannot revert to an older baseline version.

Suppress versions

Administrators can configure a table so that it does not track customizations in the **Versions [sys_update_version]** table.

About this task

⚠️ **Warning:** If you suppress versions for tables, Team Development may work incorrectly, and you may be unable to compare and revert versions of records on the tables.
Procedure

1. Navigate to `sys_properties.list`.

2. Create a new property:
   - Name: `glide.update.suppress_update_version`
   - Type: string
   - Value: a comma-separated list of tables. The default value is `sys_user,sys_import_set_row`.

Versions and local changes

Version records track changes to a customizable record over time so that you can compare or revert to a specific version later.

A version record is created every time a developer changes a customizable record, so a single record can have multiple version records associated with it. A local change record is created or updated to reference the current version every time a developer modifies a customizable record, so a single record can have only one local change record associated with it.

Local change records track which customized records have changes on the development instance that are not on the parent instance so that you can collect changes in preparation for a push.
Team Development concepts

Developers can back out a local change to restore a previous version of a customizable record. The back out action sets the local customizable record to the last revision identified by a reconciliation action.

Custom applications tables

Custom applications table can help you review specific changes you have made during upgrades and determine ways to resolve conflicts.

You may learn that your file in the application has either been claimed by another application or skipped. Use these custom application tables to help you review your changes or determine how to take action for conflicts.
• Skipped Changes to Review related list
• Claim Outcomes to Review related list
• Upgrade Details related list

System update sets

An update set is a group of configuration changes that can be moved from one instance to another. This feature allows administrators to group a series of changes into a named set and then move them as a unit to other systems for testing or deployment.

An update set is an XML file that contains:

• A set of record details that uniquely identify the update set.
• A list of configuration changes.
• A state that determines whether another instance can retrieve and apply configuration changes.

Update sets track changes to applications and system platform features. This allows developers to create new functionality on a non-production instance and promote the changes to another instance.

⚠️ Warning: Update sets allow moving changes between instances that may be running different family release versions and different features. You can always load an update set created on an older family release on an instance running a newer family release. Loading an update set created on a newer family release on an instance running an older family release requires additional testing to determine compatibility. Updates from newer family releases may not produce the same functionality when moved to older family releases. In extreme cases, newer family release updates may cause outages or data loss on an older family release instance. Where possible, avoid moving updates from newer family releases to older family releases. Similar constraints apply to moving updates between instances running different versions of ServiceNow Store apps.

System properties

Administrators can exclude system properties from update sets by making them private. Keeping system properties private prevents settings in one instance from overwriting values in another instance. For example, you may not want a system property in a production instance to use a particular value from a development instance. See Add a system property.
Applications
Application developers have additional options with update sets such as:

• Create an update set for a specific version of an application.
• Specify which application tables to track in update sets.

Update set tables
Each update set is stored in the Update Set [sys_update_set] table, and the customizations that are associated with the update set, which are entries in the Customer Update [sys_update_xml] table, appear as a related list on the update set record.

When a tracked object is customized, a corresponding record is added or updated in the Customer Update [sys_update_xml] table and is associated with the user current update set. The associated application file properties are tracked and transferred along with the customized object in a single update record. A corresponding record is also added to the Versions [sys_update_version] table.

The Customer Update table contains one record per customized object, per update set. The Versions table contains one record per change to a customized object.

• Administrators can compare two versions and revert to a specific version of an object.
• Administrators can suppress versions for specific tables.
• Administrators can specify fields on tracked tables that you can change without skipping updates to the rest of the record (exclude the field from the update).

⚠️ Note: Do not directly modify Customer Updates [sys_update_xml] records.

Customizations tracked by update sets
Update sets can track customizations to application tables, fields, and records.

Update sets track customizations under these conditions:
• Where the table has an update_synch dictionary attribute.
• Where there is a special handler to track changes to multiple tables.
• Where the administrator has not excluded a field from updates.
In general, update sets capture configuration information but not task or process data. For example, update sets track service catalog item definitions and related configuration data like variables and variable choices. However, if you test the service catalog by placing orders, update sets do not track order requests, items, and catalog tasks.

Update sets have a limited capacity to transfer data as application files. For larger data transfers, export data and import it with an import set or web service.

**update_synch attribute**

To see the list of tables where customizations are tracked, navigate to System Definition > Dictionary and filter on attributes CONTAINS update_synch.

⚠️ Warning: Do not add the `update_synch` attribute to a dictionary record. When improperly used, this attribute can cause major performance issues or cause the instance to become unavailable. Adding this attribute is not supported.

A default rule blocks the use of the `update_synch` attribute on a table for which it is not predefined to avoid the following issues:

- Some core tables require special update handling because they represent information on multiple tables. When the `update_synch` attribute is added to these tables, duplicate update records are created, causing major conflicts that are difficult to troubleshoot and repair.

- Using the `update_synch` attribute to migrate data records between instances can cause performance issues, because it is not intended for this purpose. To migrate data, use an instance-to-instance import.

See Import sets.

**Special handlers**

Some changes require special handlers because they represent information on multiple tables. These changes are packaged into one update set entry so that all records are properly updated when the customization is committed. The following changes are tracked with special handlers:

- Workflows
- Form sections
- Lists
- Related lists
- Choice lists
• System dictionary entries
• Field labels

⚠️ **Warning:** The form sections, lists, related lists, choice lists, and field labels special handlers delete and reinsert records. This might cause unexpected results and data loss if there are fields referencing the tables.

### Choice lists

Update sets store both new and updated choice options as separate records in the Update Version [sys_update_version] and Customer Update [sys_update_xml] tables. For example, you create a new Activity [u_activity] table that extends the Task table. You then add a new choice option to the Task state field that is only visible for your extended table (for example, My State).

When you publish these changes as an update set, the update only contains update and version records for the choice you added to the u_activity table. The choice options in the task table are unaffected.

### Dictionary changes

Usually, using update sets prevent you from applying dictionary changes that result in data loss. Blocked dictionary changes include:

• Removing tables
• Changing a column data type

Update sets do not track the removal of tables from the system dictionary. Instead, customers must manually remove tables from the target instance. While update sets track data type changes, the target instance skips any change that results in data loss and instead adds a log message about the action. Customers can use the log to manually make data type changes on the target instance.

⚠️ **Note:** Update set previews do not check for type mismatch problems since the target instance skips changes resulting in data loss. Also, using update sets to delete a column from a table can cause data loss in certain circumstances. If there is data in the column on the target instance, that data is deleted, as well as the column itself, when the update set is committed. A warning message appears if you attempt to commit an update set that deletes a column. The message states that there are one or more delete updates that cause the data to be deleted, and it specifies what delete updates there are.
Homepages and content pages
Homepages and content pages are not added to update sets by default. Add pages to the current update set by unloading them.

Application changes
The system creates a separate update set for each application that only contains changes associated with the application. This ensures that access settings for each application are properly evaluated and applied when committing update set changes.

Default update set
Only one update set can be the default set for any application scope.

To set an update set to be the default set, you set the Default set field to true. When you set Default set = true, the following actions occur:

- The update set becomes the default update set for its scope.
- The system sets Default set = false for all other update sets with the same scope. This ensures that there is only one default update set for each scope.

Global default set
Use the global default update set to make changes to an instance without adding the changes to any user-created update sets. The global default update set is the set where Default set = true and application scope is global. The global default set (regardless of the Name of the set) provides system functionality and should not be changed, deleted, or moved between systems. Use this update set to make changes to an instance without adding the changes to any user-created update sets.

Auto-generated default set
At all times, to ensure that no updates to an instance are lost, the system ensures that there is a default set for the user’s current scope. If the system finds that a default update set does not exist (or is marked Ignored or Completed) for the current scope, then the system auto-generates an update set and sets Default set = true.

These are some common cases where the system auto-generates a default update set.
The very first time that an admin logs in, the system sets the system’s global default update set as the administrator’s update set. In addition, the application picker sets the administrator’s application scope to global. If a global default update set does not exist (or is marked *Ignored* or *Completed*), the system creates a new update set for the global application scope and performs the following actions:

- The system sets *Default set = true* for the new set.
- The system sets the name of the new set to start with the name of the former default set and appends the next numeral (in the sequence SetName, SetName 1, SetName 2, …, SetName n).
- The system sets the newly created set as the administrator’s update set.

When a user marks the default set for a scope as *Ignored* or *Completed* (not a recommended practice), the system immediately auto-generates a new default set for the scope.

The system auto-generates a new default update set for a scope when all the following conditions occur:

- You change application scope.
- Your preferred update set is *Complete* or *Ignored*.
- There is no In-Progress default update set for the new scope.

**Get started with update sets**

Because update sets make changes to an instance, review this information to avoid errors and performance issues. Learn how to plan the update process and avoid common mistakes.

**When to use update sets**

<table>
<thead>
<tr>
<th>Deployment option</th>
<th>Good for</th>
<th>Future considerations</th>
</tr>

<td>Storing changes to a baseline or installed application.</td>
<td>You can manually create update sets to store a particular application version. Use update sets to deploy patches or changes to installed applications.</td>
</tr>
<tr>
<td></td>
<td>Storing and applying a</td>
<td></td>
</tr>
<tr>
<td>Deployment option</td>
<td>Good for</td>
<td>Future considerations</td>
</tr>
<tr>
<td>-------------------</td>
<td>----------</td>
<td>-----------------------</td>
</tr>
<tr>
<td></td>
<td>particular version of an application. Producing a file for export.</td>
<td><strong>Note:</strong> Do not use update sets to install applications. Instead, use the application repository or the ServiceNow Store to install applications.</td>
</tr>
<tr>
<td><strong>Application Repository</strong></td>
<td>Installing and updating applications on all company instances. Automatically managing application update sets. Restricting access to applications to the same company. Deploying completed applications to end users.</td>
<td>Consider uploading an application to the ServiceNow Store to share it with other users. Allows installation of and update to the latest application version only. Use update sets to store prior application versions. <strong>Note:</strong> If used with team development, publish applications only from a parent instance.</td>
</tr>
<tr>
<td><strong>Team Development</strong></td>
<td>Providing change management across multiple instances. Allowing multiple developers to work on applications. Organizations that have access to several non-production instances.</td>
<td>Consider providing each development team access to a dedicated development instance. Requires developers to manually merge colliding changes. Works only for instances owned by the same organization. <strong>Note:</strong> If used with the application repository, publish applications from a parent instance.</td>
</tr>
</tbody>
</table>

**Plan the update process**
Before working with update sets, create a standard process for moving customizations from instance to instance using this check list:
1. Check that both instances are on the same version. Customizations may not work if they rely on code that has changed between versions.

2. Determine the changes to make in a single update set. Complete your update sets as you finish small to medium-sized tasks. As update sets get larger, it becomes harder to review them, takes longer to identify specific changes within them, increases the risk of conflicts with other update sets, and takes more time to preview and commit them. This is especially true if the update sets contain schema changes or revisions to large workflows or if the set has to be backed out.

3. Ensure that all base system records have matching sys_id fields. Some base system records are created on an instance after provisioning and do not match between different instances, leading to problems with update sets. The best way to avoid this issue is to:
   - Provision production and non-production instances.
   - Clone the production instance onto the non-production instance.

4. Identify a common path for update sets to move from instance to instance and maintain that model. Never migrate the same update set from multiple sources. Move update sets from dev to test and then from test to production.

5. Plan for when to commit the update sets to production. Avoid committing an update sets to a production instance during business hours. The instance may perform slower temporarily as the update sets applies.

6. Make sure update set names are clear. Create a naming convention to coordinate changes from multiple developers and to reference when committing the changes to another instance.
   - If update sets are being generated as fixes for problems, consider including the problem ticket in the name (for example, PR10005 - Duplicate Email Issues Fix).
   - If you need more than one update set to address a problem, include a sequence number in the naming convention so that update sets are applied in the order that they were created (for example, PR10005 - Duplicate Email Issues Fix and PR10005.2 - Duplicate Email Issues Fix).

7. Understand the following about update sets:
   - What records are generated.
   - Which customizations are tracked.
• Which dictionary changes are valid.
• Which customizations can be backed out (reversed) once applied.

8. Before making any customizations, double-check that the correct update set is selected.

Working with update sets
Review this information to avoid errors and performance issues.

• Do not delete update sets. If an update set is deleted, any updated records may be overwritten in the next update.

• Do not include the system_id field from the ldap_server_config record in an update set. An update set from a working configuration points to the wrong system_id node for the target instance and does not work.

• Do not back out the Default update set. This action causes damage to the system.

• Never change the Update Set field value (update_set) in a Customer Update record (sys_update_xml). If a customization is made in the wrong update set, take the following action:
  1. Switch to the desired update set.
  2. Modify the object (record) that was originally changed. You can make a trivial change, such as adding a field.
  3. Save the record.
  4. Back out the change just performed, and then save the record again.

     This action ensures that the latest version of the object is included in the desired update set and prevents duplicate updates for the same object in a single update set.

• Do not mark an update set as Complete until it is ready to migrate. Once an update set is complete, do not change it back to In progress. Instead, create another update set for the rest of the changes, and make sure to commit them together in the order that they were created. Naming conventions may help in this case (for example, Performance Enhancements and Performance Enhancements 2).

• Do not manually merge updates into an update set. Always use the Merge Update Sets module. This tool compares duplicate files between update set and selects the newest version.

• If a committed update set has a problem in the test instance, build the fix in another update set in the development instance. Commit this set to the test instance, and then make sure both sets are migrated to the production instance and committed in the order they were made.
Always preview an update set before committing it.

Set completed update set on the production instance to **Ignore**. This state ensures the update set is not reapplied when cloning the instance.

Keep a to-do list of manual changes and data loads that need to be completed after an update set is applied.

Do not make too many changes at one time. Verify that the correct changes have been made incrementally.

### Update set administration

Manage how update sets store, retrieve, preview, and apply configuration changes between instances.

Administrators have the following options with update sets.

- Create an update set to store local changes.
- Select the current update set to store local changes.
- Commit an update set to prepare it for distribution.
- Compare update sets to determine what differences they contains.
- Merge separate update sets into a single update set.
- Create an external file from an update set.
- Retrieve update sets from remote instances.
- Apply retrieved update sets.
- Back out changes applied from an update set.
- Set system properties related to update sets

### Grant access to the update set picker

The update set picker allows users to choose an update set for making and tracking customizations. By default, only administrators can use the update set picker. You can **grant access to additional users**.

### Automatically preview retrieved update sets

By default, the system automatically previews update sets as soon as it has retrieved them. To turn off this behavior, set the system property `glide.update_set.auto_preview` to **false**: in the navigator filter, type
sys_properties.list then navigate to the glide.update_set.auto_preview property and edit the value field.

Track an application table
Application developers can track application changes in an update set to save or distribute a particular version of an application. During table creation, set Extends Table to Application File [sys_metadata].

Grant access to the update set picker
Enable a non-administrative user to use the update set picker.

Before you begin
Role required: admin

About this task
The update set picker appears on the Settings panel. The picker allows users to choose an update set for making and tracking customizations. By default, only administrators can use the update set picker. You can grant access to additional users.
Procedure

1. Grant the user role read access to the Update Set table [sys_update_set].

2. Enable users to see the update set picker on the Settings panel.
   a. Add the system property `glide.ui.update_set_picker.role` to the System Properties table.
   b. Set the value of `glide.ui.update_set_picker.role` to the role for which you want to give access.
Overwrite customizations during an upgrade

Specify which customized objects you want to replace during the next upgrade. By default, the upgrade process skips changes to customized objects.

About this task

The systems tracks the configuration changes you make such as modifying the dictionary record for a table or field. Each configuration change you make has a corresponding record in the Customer Update [sys_update_xml] table where the Replace on upgrade field is set to false. You may want to overwrite your customizations with the next software version. For example, you may change a script to implement a temporary workaround for a problem that is fixed in the next version. You would want to overwrite your workaround when upgrading to the next version to ensure that you receive any future enhancements to the script.

Procedure

1. Open the customized object (for example, the ArrayUtil script include).
2. Right-click the header and select Show Latest Update.
3. Configure the form to add the Replace on upgrade field, if necessary.
4. Select the Replace on upgrade check box and click Update.
   The customized object will be replaced on the next upgrade.

Creating, testing, and moving customizations

Use these procedures to create, test, and move customizations from a development system to a production system.

Three-step import process

A common process for developing customizations with update sets involves moving changes from development, to test, to production instances.

1. Create an update set on the development instance.
2. Make customizations and changes on the development instance.
3. Mark the update set as Complete.
4. Log in to the test instance and retrieve the completed update set from the development instance.
5. Commit the update set on the test instance, and test customizations thoroughly.
6. If the update set has problems in the test instance, repeat steps 1 - 5 to develop the fix on the development instance with another update set.
7. Log in to the production instance and retrieve the completed update set from the development instance. If the update set required a fix, retrieve both update sets.

8. Commit the update set on production. If the update set required a fix, commit both update sets in the order they were made.

**Two-step import process**
If your development environment consists of only two instances, you can combine your development and testing instances into a single staging instance.

1. Create an update set on the staging instance.
2. Make customizations and changes on the staging instance.
3. Mark the update set as Complete.
4. Test customizations thoroughly on the staging instance.
5. If the update set has problems, repeat steps 1 - 4 to develop the fix on the staging instance with another update set.
6. Log in to the production instance and retrieve the completed update set from the staging instance. If the update set required a fix, retrieve both update sets.
7. Commit the update set on production. If the update set required a fix, commit both update sets in the order they were made.

**Update set use**
These procedures help you manage your customizations and resolve potential collisions before you move them to another instance.

Before using update sets, review Get started with update sets to learn when to use and when not to use update sets, and how to plan the update process and avoid common mistakes. Then, create an update set and use it to make changes on a development instance. You can report on updates, merge update sets, and compare update sets to ensure the desired changes are ready to move.

When the update set is completed, you can transfer the update set to another instance according to your test process. See Update set transfers for details.

**Create and select an update set as the current set**
Create an update set to store customization changes and select it as the current set.
About this task
You can select an update set as the current set when you create it, or you can select it later from the Settings panel.

Procedure
1. Navigate to System Update Sets > Local Update Sets and click New.
2. Complete the form from the fields in the table.
3. Click Submit to create the update set. If the picker is enabled and the update set is in the In progress state, click Submit and Make Current to select the new update set as the target for configuration changes.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a unique name for the update set. You can use naming conventions to organize update sets. For example, add the problem number to the name of the update that fixes it, identify the application scope, or use sequence numbers to keep track of the order in which update sets need to be committed.</td>
</tr>
<tr>
<td>State</td>
<td>Select <strong>In progress</strong> for a new update set. Selecting an In progress update set tracks customizations in the update set. The update set picker only displays In progress update sets. Select <strong>Completed</strong> only when you are certain that the update set is complete. After it is marked Completed, do not set it back to In progress. Instead, create a new update set with further customizations, and make sure to commit the update sets in the order that they were marked Completed. Use Completed update sets to transfer changes from one instance to another.</td>
</tr>
</tbody>
</table>
Field | Description
--- | ---
Select **Ignore** when you are no longer working on an update set but do not want it to be transferred to another instance. You should always set **Completed** update sets on the production instance to **Ignore**. This state ensures the update set is not committed again when cloning the instance.

Update set picker only displays **In progress** update sets. See **Select the current update set in System Settings**.

Select **Completed** only when you are certain that the update set is complete. After it is marked **Completed**, do not set it back to **In progress**. Instead, create a new update set with further customizations, and make sure to commit the update sets in the order that they were marked **Completed**. Use **Completed** update sets to transfer changes from one instance to another.

Select **Ignore** when you are no longer working on an update set but do not want it to be transferred to another instance. You should always set **Completed** update sets on the production instance to **Ignore**. This state ensures the update set is not committed again when cloning the instance.

| Release date | Enter the date on which you plan to release the update set. |
| Application | Populates the application scope that is currently selected in the Application picker. All changes in the update set apply only to the current scope. |
| Description | Enter a description of the update set. |

**Select the current update set in System Settings**

You can change the current update set at any time, using the update set picker in the System Settings panel.

**Before you begin**
Role required: admin
Procedure

1. To select the update set from the picker, click the gear icon in the header bar to open the System Settings panel.

2. In the System Settings panel, select **Developer**.

3. Select the update set you want to make current from the choice list in the **Update Set** field and close the settings panel.
View customizations and compare with current version

View the customizations that make up an update set and compare the update to the current version.

Before you begin
Role required: admin

About this task
The Customer Update \[sys_update_xml\] table contains one record per customized object.
The customer update record specifies:
• The update set containing the customized object.
• The type of action applied to the customized object.
  ◦ INSERT
  ◦ INSERT_OR_UPDATE
  ◦ UPDATE
  ◦ DELETE
• The type of object customized.
• The target object of the update.
• The sys_id of the customized object (if it is a change to a particular record).
• The user who customized the object.
• The date and time the object was customized.

Procedure
1. Navigate to System Update Sets > Local Update Sets.
2. Click the update set name.
3. View the Customer Updates related list.
You can compare any update to the current version. Right-click the update record and select **Compare to Current**.

### Related information

- Merge tool
- Compare to the current version
- Compare a pushed version to a local version
- Compare two versions of an article
- Resolve conflicts for an individual record
- Resolve a collision in Team Development
- Revert a change

### Navigation between records

You can navigate between a customer update record and the customized object or the application file for the object.

Navigate from an update record to:
• The customized object, such as the application menu record: Click the Show Related Record related link.

• The application file record for the object: Click the Show Application File related link.

Navigating to the application file

To navigate from a customized object or an application file to the current customer update record: Click the form header and selecting Show latest Update.
View a report on customizations and configuration changes

The base system provides reports for changes to the Incident table and changes by the current user.

Procedure

1. Navigate to **Reports > View / Run** and locate the **Customer Update** section.
2. Run any of the available reports or create a new report. The following reports are available:
   - **Application Changes (Incident)**: Displays all changes made to the Incident table. Select a different table and run the report again to view all changes to another application.
   - **My Changes**: Displays all changes created or updated by the current user, grouped by table name.

Merge update sets

You can merge multiple update sets into a single update set. This capability is supported for backward compatibility with earlier releases of the ServiceNow® platform. The newer batch update sets feature accomplishes the same outcome with a more predictable and robust solution.

Before you begin

ℹ️ **Note**: You cannot "unmerge" update sets once they have been merged. To learn more, see [Update set batching](#).

Procedure

1. Navigate to **System Update Sets > Merge Update Sets**. By default, the list is filtered to only show update sets that are **In progress**.
   Alternatively, navigate to **System Update Sets > Merge Completed Sets**. By default, the list is filtered to only show update sets that are in the **Complete** state. For example, you may want to use this filter after pushing changes or transferring update set from a development to a test instance.
2. Filter the list to show only the update set that you want to merge. You can only merge update sets that belong to the same application.
3. Enter a **Name** for the new update set. Updates are moved to this new update set during the merge process.

4. **Optional:** Enter a **Description** for the update set.

5. Click **Merge**.

6. In the confirmation dialog box, click **OK**.
   - The new update set is created.
   - The most recent change for each object is moved from the original sets to the new set. Only changes that are not merged into the new set remain in the original sets. A message indicates how many updates were moved and how many were skipped. For example, if both update sets modify the Incident form, only the most recent change is moved to the new update set. The other modification remains in its original update set to provide a record of the changes that were not moved.

   **Note:** The system determines which record is the most recent by comparing the **Updated** field for the records, NOT the **sys_updated_on** value in the payload.

7. [Recommended] Verify that the correct changes were moved to the new set by scrolling down to the **Merged Update Sets** related list and opening the old update set records.
8. [Recommended] Delete or empty the original update sets to avoid committing an older change by mistake. The system does not remove updates that were not merged into the new set. DO NOT move updates "left behind" in old sets into the new set.

Compare local update sets
Administrators can preview local and remote (retrieved) update sets and compare the sets with one another to resolve conflicting changes.

About this task
Compare local update sets to identify collisions and ensure that the proper changes are being committed. Resolve all conflicts before moving an update set between instances.

Procedure
1. Navigate to System Update Sets > Local Update Sets.
2. Select the check boxes beside the update sets to compare.
3. In the Action choice list, select Compare Update Sets. The progress screen appears as ServiceNow generates the collision report.
4. Click Go to the Collision Report when the report is complete.
   The Update Set Collisions list appears, showing all the changes in the selected sets.
5. Inspect the list for collisions by locating duplicate Collision Numbers that show the same change in separate update sets.
6. Resolve the collision by deleting the unwanted update record from one of the update sets.

   a. Click the link in the Sys update column for the unwanted update (sys_ui_list_incident_null in the example).
   
   b. Click Delete.

   **Note:** You must open the update record to delete the record. You cannot delete the update by selecting the check box for the entry in the Update Set Collisions list and using the Delete action. When you delete the update record, the customization is not backed out of the instance. Only the record of the customization is deleted.

   **Customer updates**

   ![Customer updates](image)

7. Run the comparison again to make sure all collisions have been resolved.

**Update set collision resolution**

A collision is an update that has a newer local update.

The platform detects collisions by comparing the values in the Name and Updated fields of the customer update record from each update set. If the name matches but there are different update date values, then there is a collision.

When a customer update is moved from one instance to another, it may be re-written to match the target instance. The re-write can involve changing the update name of the customer update and one or more sys_ids within the update. The re-writes are done when the record or the reference field is for a table that uses a coalesce strategy. This ensures that the customer update will...
be applied to the correct record. For example, if the sys_dictionary record for tablename.fieldname has sys_id 123456789 on instance A and sys_id 987654321 on instance B, when a customer update that refers to that record is retrieved from instance A and recorded in the sys_update_xml table on instance B, references to 123456789 are updated to read 987654321.

Coalesce strategies

Update sets can detect collisions between identical records that you independently create on separate instances. To detect such collisions, the record must have a coalesce strategy based on coalescing columns. Because collision detection depends on uniqueness of tables, the tables must be unique when the coalescing columns are combined. Records that are not listed here will not collide if the same record is created separately on different instances.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

How customer update record names affect collisions

To understand coalescing, it helps to understand how records that do not coalesce work. For most record types, when a customer update is moved to a new instance, the system does not detect collisions for the following reason:
• When you create a record, it receives a unique sys_id. For most record types, the sys_id becomes part of the customer update record name. For example: sysevent_email_template_9e1998c078b71100a92ecac80df1d39.

• Creating an identical record in the same table on another instance produces a customer update record name with a different sys_id. For example: sysevent_email_template_10b958c8653311005840134572f8e020

As a result, even though the records might be otherwise identical, the records have different names so the system does not detect the collision.

Coalescing records, in contrast, use the following approach to naming records and determining collisions: The following customer update record types use some or all of their coalescing columns instead of the sys_id in their names.

• sys_dictionary
• sys_documentation
• sys_choice_set
• sys_ui_list
• sys_ui_related_list

The resulting identical record name in each instance helps the system to identify collisions even if the records have different sys_ids.

When a customer update is moved from one instance to another, it may be re-written to match the target instance. The re-write can involve changing the update name of the customer update and one or more sys_ids within the update. The re-writes are done when the record or the reference field is for a table that uses a coalesce strategy. This ensures that the customer update will be applied to the correct record. For example, if the sys_dictionary record for tablename.fieldname has sys_id "123456789" on instance A and sys_id "987654321" on instance B, when a customer update that refers to that record is retrieved from instance A and recorded in the sys_update_xml table on instance B, references to "123456789" are updated to read "987654321".

Preventing duplicate records

• Transfer data with update sets rather than recreating it on separate instances to ensure the records have the same sys_id.

• Export and import records as XML files to ensure the records have the same sys_id. See Export and import XML files.

• Enable a unique index for the table from the system dictionary. See Table administration.
Note: The default records included in the baseline system will always have the same Sys ID because the instance imports the records as XML files during instance provisioning.

Mark an update set complete

When you have completed the customizations and compared local update sets to resolve conflicts, mark the update set as Complete.

About this task

Mark an update set as Complete only when it is ready to migrate. Once an update set is complete, do not change it back to In progress. Instead, create another update set for the rest of the changes, and be sure to commit them together in the order that they were created. Naming conventions may help in this case (for example, Performance Enhancements and Performance Enhancements 2).

Procedure

1. Open the update set record.
2. Change the State of the update set from In progress to Complete.
   • The update set is available for other instances to retrieve.
   • No additional customizations are tracked in the update set.

Save an update set as a local XML file

Administrators can export an update set as an XML file to save a specific version of an application or set of changes.

About this task

Typically you create an XML file of an update set when one of the following conditions apply:

• The two instances do not have network connectivity so you cannot retrieve update sets from the remote instance nor create a data source to pull, or import, data directly from the source instance.

• You do not want to provide administrator credentials to the source instance (for example, you do not want to share an administrator password with
people outside your company) so you cannot retrieve update sets nor create a data source.

- You want to back up important customizations locally.

The ability to export and import customizations as an XML file is provided by the following UI Actions:

- **Export to XML** on the Update Set [sys_update_set] table.

The **Export to XML** UI Action on Update Set [sys_update_set] table calls a processor called `UnloadRetrievedUpdateSet`, which transforms a local update set into a retrieved update set, exports the retrieved update set with its related list, and then deletes the temporary update set, if necessary.

Both **Export to XML** UI actions depend on the script include `ExportWithRelatedLists`, which exports a record and manually defined related lists to a single XML file.

**Procedure**

1. Navigate to **System Update Sets** and click either **Local Update Sets** or **Retrieved Update Sets**.
2. Select an update set that is in the **Complete** state.
3. On the Update Set form, click the **Export to XML** Related Link.
4. Save the XML file.
   An XML file is created. When the file is uploaded to another instance, it appears as a retrieved update set regardless of whether it is local or retrieved on the instance where it is created.

**Load customizations from a single XML file**

Administrators can load an update set XML file to apply a specific version of an application or set of changes.

**Procedure**

1. Elevate privileges to the security_admin role.
2. Navigate to **System Update Sets > Retrieved Update Sets**.
3. Click the link **Import Update Set from XML**.
4. Click **Choose File** and select an XML file.

5. Click **Upload**.

   The customization is now available as a retrieved update set with state **Loaded**.

6. Follow standard procedure to commit the update set.

### Retrieved update sets

- Import Update Set from XML

### Update set transfers

When an update set is completed, you can transfer it between instances to move customizations from development, through testing, and into production.

⚠️ **Warning:** Update sets allow moving changes between instances that may be running different family release versions and different features. You can always load an update set created on an older family release on an instance running a newer family release. Loading an update set created on a newer family release on an instance running an older family release requires additional testing to determine compatibility. Updates from newer family releases may not produce the same functionality when moved to older family releases. In extreme cases, newer family release updates may cause outages or data loss on an older family release instance. Where possible, avoid moving updates from newer family releases to older family releases. Similar constraints apply to moving updates between instances running different versions of ServiceNow Store apps.

### Transferring with IP access control

If IP address access control is enabled on the source instance or the source instance resides in a different datacenter than the target instance, complete these tasks before transferring an update set:

1. Contact Customer Service and Support to find out the IP addresses of all application nodes supporting your instance.

2. On the source instance, navigate to System Security/IP Address Access Control. Add the IP address from step one as an exception.
Transferring with basic authentication
If the source instance has basic authentication turned on for SOAP requests, you must use valid credentials to retrieve update sets.

Transferring with an XML file
You can unload an update set as an XML file and then transfer it to another instance. See Save an update set as a local XML file for details.

Retrieve an update set
Retrieve completed update sets from another instance.

About this task

⚠️ Warning: Update sets allow moving changes between instances that may be running different family release versions and different features. You can always load an update set created on an older family release on an instance running a newer family release. Loading an update set created on a newer family release on an instance running an older family release requires additional testing to determine compatibility. Updates from newer family releases may not produce the same functionality when moved to older family releases. In extreme cases, newer family release updates may cause outages or data loss on an older family release instance. Where possible, avoid moving updates from newer family releases to older family releases. Similar constraints apply to moving updates between instances running different versions of ServiceNow Store apps.

Procedure
1. If IP address access control is enabled on the source instance, set up the target instance as an exception.
2. On the target instance, navigate to System Update Sets > Update Sources and click New.
3. Specify the connection settings as described in the table.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a unique name for the instance.</td>
</tr>
<tr>
<td>Type</td>
<td>Specify whether the remote instance is a development, test, or UAT instance.</td>
</tr>
</tbody>
</table>
### Field | Description
--- | ---
Active | Specify whether the local instance can transfer update sets to the remote instance. You can transfer update sets only to active remote instances.
URL | Specify the URL of the remote instance using the appropriate transfer protocol. Each remote instance record should have a unique URL. Creating duplicate records with the same URL can cause errors. The remote instance must be on the same release family as the local instance.

**Note:** You cannot change the URL after the system verifies the connection. Use the Active field to deactivate unwanted remote instances.
Username | Enter the user on the remote instance who authorizes transferring update sets to this the instance. This user account must have the admin user role on the remote instance.
Password | Enter the password of the authorizing user.
Short description | [Optional] Enter any other relevant information about the remote instance.

4. Click **Test Connection**.
   - If the connection is successful, a confirmation message appears.
   - If the connection fails, a warning message identifies the cause of the failure.
5. If the connection fails, modify the settings to establish connectivity.
   - You must establish connectivity before you can save the connection settings.
   - You may want to modify the source instance (for example, change the password).
6. Right-click the form header and select **Save**.
   - Any update sets marked as **Completed** are transferred from the source instance to the target instance. Update sets that already exist on the target instance are skipped.
   - The confirmation page provides detailed messages about how many update sets were transferred and how many were skipped.
   - To view retrieved update set, navigate to **System Update Sets > Retrieved Update Sets**.
What to do next

If the system property `glide.update_set.auto_preview` is set to `true`, the system automatically starts the preview process after the update set is retrieved. If this property is `false`, you must start the process manually. For more information on the preview process, see Preview a remote update set.

Preview a remote update set

Previewing compares an update set retrieved from a remote instance to updates on the local instance to detect potential problems. You must preview an update set and address all problems before you can commit the update set.

Procedure

1. If the system property `glide.update_set.auto_preview` is set to `true`, the system automatically starts the preview process after the update set is retrieved. If this property is `false`, the preview process must be started manually.

   
   b. Click Preview Update Set.

   For large update sets, the preview process may require a significant amount of time. If necessary, you can cancel the preview process by clicking the Cancel button on the progress dialog box.

   The Update Set Preview page shows results and lists problems. Read the information and click Close.

2. On the Retrieved Update Set form:

<table>
<thead>
<tr>
<th>Option</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>If no problems were detected</td>
<td>Click Commit Update Set to commit all changes on the instance without reviewing the preview results.</td>
</tr>
<tr>
<td>If problems were detected</td>
<td>Address each problem in the Update Set Preview Problems related list.</td>
</tr>
</tbody>
</table>
3. Optional: Open the update set record and click **Show All Preview Records** to make sure the correct updates are being committed.

4. Optional: Open the update set record and click **Run Preview Again** to run the comparisons again. Review the **Update Set Preview Problems** related list to ensure that the correct updates are being committed.

**Review a preview record for an update set**

The process of previewing an update set creates a preview record for each update. You can review the preview records to make sure that the correct updates are being committed.
Procedure

1. Open the Update Set record and preview the update set.
2. Click the Show All Preview Records related link.
3. Click the Disposition to open a preview record and then review the information (see table).
4. Fill in the fields on the form, as appropriate.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disposition</td>
<td>Indicates when a collision is detected:</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>• <strong>Collision/Update. Collision/Insert, or Collision/Delete:</strong> the change is older than a change to the same object on the local instance.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Update, Insert, or Delete:</strong> the change does not conflict with a change on the local instance.</td>
</tr>
<tr>
<td>File differences</td>
<td>Compares the most recent version of the object on the local instance with the version in the update set. Differences are marked with a color key. Deletions are highlighted in red, additions in green, and modifications in yellow.</td>
</tr>
<tr>
<td>Proposed action</td>
<td>Indicates how to handle the change when the update set is committed.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Commit:</strong> Accept the change in the remote update. The default proposed action for every preview record is Commit, even if a newer update exists on the instance.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Skip:</strong> Reject the change.</td>
</tr>
</tbody>
</table>

5. If necessary, resolve any problems listed in the **Update Problems** related list.
6. In the Proposed action field, select the action to take when committing the update set.
7. Click **Update** to save the action.
8. Repeat the process for every preview record.

**Resolve a preview problem in an update set**

Preview an update set to detect and resolve problems that may occur if you commit the updates on the local instance.

**Procedure**

1. Navigate to **System Update Sets > Retrieved Update Sets**.
2. Open the update set record and scroll to the **Update Set Preview Problems** related list.
3. Review each problem description to determine the cause and resolve the problem.

**Update Set Preview Problems**

**Missing Object**

**Example problem text:** Could not find a record in sys_ui_policy referenced in this update.

**Description:** The object or a referenced object does not exist on the target instance. For example:

- An update modifies the form layout for a table that has not been created in the local instance.
- A UI policy action is included in the update set, but the parent UI policy is not.

**Resolution:** Create another update set on the source instance to transfer the missing object to the local instance, or create the object on the local instance. Use these **Available Actions** to assist in problem resolution:

- **Find missing field** or **Find missing record:** Opens a new window and searches the source instance for the missing field (dictionary entry) or record.
- **Find missing update:** Opens a new window and searches the source instance for the update record that corresponds to the missing field or record.

**Collision**
Example problem text: Found a local update that is newer than this one

Description: A change in the update set is older than a change to the same object on the local instance.

Resolution: Compare the two updates and determine which version to use. To use the version on the local instance, select **Skip remote update**. To use the version in the update set, select **Accept remote update**. Use these **Available Actions** to assist in problem resolution:

- **Compare with local**: opens the preview record, which provides a comparison of the differences between the local version and the version in the update set.
- **Show local field** or **Show local record**
- **Show local update**

### Uncommitted update

Example problem text: Could not find a table field (u_case.u_reference) referenced in this update, but did find it in another uncommitted update set

Description: The object exists in another remote update set that has not been committed.

Resolution: Commit the other remote update set first or move this update to the other update set. Use these **Available Actions** to assist in problem resolution:

- **Show uncommitted update**: opens the update record in the other remote update set.
- **Show uncommitted Update Set**: open the other remote update set record.

### Table to be deleted has data

Example problem text: Found a row in the table that is going to be deleted

Description: One difference between table deletes and other metadata deletes is that the table data is lost when the table is deleted. (If the table is empty (no rows), then no problem is generated.)
Resolution: The problem must be ignored (delete will happen) or skipped (delete will not happen) before the update set can be committed. You can restore the table, but the restore does not bring back the data.

You are not allowed to delete system tables (ServiceNow tables) or tables outside your application scope.

Application scope validation issue
Description: The previewer identifies the following combination of states as a problem:
• The scope for the update set is not Global and
• The application is not found on the target instance and
• The application is not included with the update set and
• The application is not found on the ServiceNow Store.

Resolution: Transfer the update set only to instances that include the application scope or ensure that the update set includes the application.

Conflict within a single batch
Example problem text: This update has conflicts within the update set with the same name. Resolve the issue on the source system and re-preview or choose a specific update to use.

Description: Two or more update sets within the same batch have conflicting changes. The Update Set Preview Problems list contains a record for each update set with a conflicting change.

Resolution: Compare the conflicting update sets and determine which version to use. If you know which update set is the correct one to use, select the row for that set and click Accept this collision. Otherwise, click Compare Collisions to compare the conflicting update sets.
Compare two Updates

From this screen, you can compare any two of the conflicting update sets and choose the update set to commit.

Commit an update set

When you have previewed an update set and have resolved any issues, commit the update set. Committing an update set applies all changes to the instance and creates a local copy of the update set that contains an update record for every change.

Procedure

1. Navigate to **System Update Sets > Retrieved Update Sets** and open the update set.

2. Resolve any problems. You cannot commit an update set until all problems are resolved.

3. Click **Commit Update Set**.
   - Click **Cancel** to return to the preview and reevaluate the change. None of the updates are committed.
   - Click **OK** to skip the change and continue committing the changes that are marked as **Commit**.

If the update set contains one or more DELETEs for schema, the system displays a warning. The warning lists up to five updates that may contain problems. If more than five updates have potential problems, the system provides a link.

When the system successfully commits an update set, it displays a completion page.

4. [Recommended] Click **Commit log** on the confirmation page, or navigate to **System Update Sets > Update log** and filter for the update set name.
• Look for warnings that contain the text **unsafe edit**. The system automatically skips any changes that results in data loss, such as changing the type of a field that contains data. You must manually make any of these changes, if necessary. Use caution when making changes that affect production data.

• Look for errors that indicate which records failed to commit and why.
Create a new update set to address those failures, if necessary.

5. **Recommended** When you are no longer working on the update set but do not want it transferred to another instance, navigate to **System Update Sets > Local Update Sets** and open the local update set record. Change the State to **Ignore**.

**What to do next**
For completed update set on the production instance, you should always change the state to **Ignore**. This state ensures that the update set is not committed again when cloning the instance.

**Back out an update set**
You can back out changes to existing records for any committed update set.

**About this task**
Backing out an update set creates delete updates in the current update set. If you commit, back out, and then reapply a remote update set, errors appear in the previewer because the deleted updates are considered more recent changes and cause collisions.

⚠️ **Warning:** Do not back out the **Default** update set. This action can damage the configuration of the instance.

The back out process reverses both record-level updates and changes to the dictionary. Some changes caused by a back-out can result in data loss. These are the expected results of the back-out process:

<table>
<thead>
<tr>
<th>Customer Update</th>
<th>Result of the back out action</th>
</tr>
</thead>
<tbody>
<tr>
<td>A new table</td>
<td>The table is dropped from the database, deleting any data from it.</td>
</tr>
<tr>
<td>A new field</td>
<td>The field is dropped from the database, deleting any data from it.</td>
</tr>
<tr>
<td>Customer Update</td>
<td>Result of the back out action</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
<tr>
<td>A deleted field</td>
<td>The field is restored to the database, but the original data is lost.</td>
</tr>
<tr>
<td>A resized field</td>
<td>The field resize is reversed. If the field has been increased, data is</td>
</tr>
<tr>
<td></td>
<td>truncated first to avoid errors.</td>
</tr>
<tr>
<td>A configured form</td>
<td>The form is reverted to its previous state.</td>
</tr>
<tr>
<td>A record is inserted</td>
<td>The record is deleted. (See Note below)</td>
</tr>
<tr>
<td>A record is deleted</td>
<td>The record is restored with its original data.</td>
</tr>
</tbody>
</table>

⚠️ **Warning:** Backing out an update set that belongs to an update set batch may affect other update sets in the batch. For more information, see Back out batched update set.

⚠️ **Note:** Regarding a record being deleted:
- If the sys_package is global, it is deleted.
- If the sys_package is not global, and it has a value, a warning displays that there is no deletion. Rather, the sys_update_xml is put into the default update set and the record is left in place.

### Procedure

1. Navigate to **System Update Sets > Retrieved Update Sets** or **System Update Sets > Local Update Sets**.

2. Open the update set record.

   ⚠️ **Note:** The currently selected application affects what options are available for the update set. Make sure you select the application, such as Global, that matches the contents of the update set.

3. Carefully review the contents of the update set and consider whether there will be problems if it is backed out.
   If backing out an update set is not sufficient or will cause issues, then, instead, create and commit a new update set to reverse the customizations.

4. Click **Back Out**.
A Progress page displays actions, progress, and problems. Problems are changes in more recent update sets that affect the update set that is being backed out. The backout preview process generates a warning for each problem.

5. Resolve each problem before proceeding with the back out.

- To keep the latest version, click **Decide to Keep Current**.
- To back out to the previous version, click **Decide to Use Previous**.

All changes are reversed as described in the table. The current update set tracks all of the new changes that occur.

The update set and all associated update records are deleted. If needed, you can still navigate to the retrieved update set, preview it, and commit it again.

**Note:** If you commit, back out, and then reapply a remote update set, errors appear in the previewer because backing out an update set creates delete updates in the current update set. The deletes are considered more recent changes and cause collisions.

### Cautions about deleting update sets

Deleting an update set is a bad practice. To revert a customization, back out the update set rather than deleting it.

Administrators can delete an update set only when it is not the current update set and it is empty (no `sys_update_xml` entries are associated with it). For example, after merging update sets, you might want to delete the original sets. This function is restricted by an access control rule (ACL) on the Update Set [sys_update_set] table.

ServiceNow strongly recommends that you do not delete `sys_update_xml` entries, because this action:

- Does not undo the updates.
- Removes any record of who applied the customizations.
- Removes the `sys_update_xml` entries associated with the update set, so customizations are overwritten when the instance is upgraded.

When you try to delete an update entry, a warning message appears. Click **OK** to confirm the deletion.

### Update set batching

Batch update sets enable you to group update sets together so you can preview and commit them in bulk.
Dealing with multiple update sets can lead to problems, including committing update sets in the wrong order or inadvertently leaving out one or more sets. You can avoid these problems by grouping completed update sets into a batch.

The system organizes update set batches into a hierarchy. One update set can act as the parent for multiple child update sets. A given set can be both a child and parent, enabling multiple-level hierarchies. One update set at the top level of the hierarchy acts as the base update set.

When you preview or commit the base update set, you preview or commit the entire batch. The system determines the processing order, and checks for collisions, based on the dates the changes were recorded, and on their sequential ancestry. Their ancestries are the specific instances in which the changes in the update sets took place.

Note: For more details, see Compare local update sets and View customizations and compare with current version.

Example of batched update sets
The list of update set records reflects the batch hierarchy in the Parent and Batch Base columns.

List of batched update sets

![List of batched update sets screenshot]

Diagram of batched update set hierarchy
Create a batch update set
You include an update set in a batch by specifying another update set as its parent.

Before you begin
Role required: admin
Adding a WIP update set to a completed batch resets the batch base to WIP.

Procedure
1. Navigate to System Update Sets > Local Update Sets.
2. Select the record for an update set that you want to include as a child in the batch.
3. On the Update Set record, navigate to the Parent field and select the update set to act as the parent.
4. Click Update.
   The system returns to the list of Update Sets. If the Parent column is visible, it shows the parent for the newly-created child.
Retrieve batched update sets
You retrieve a batch of update sets using the same process you would as for any individual update set.

Before you begin
Role required: admin

Procedure
To retrieve a batch of update sets, follow the same process for the batch base as you would for any individual update set. The system will process the entire batch at once. For details, see Retrieve an update set.

Preview a batch of update sets
You can preview at once all the update sets belonging to a batch.

Before you begin
Role required: admin
You must have retrieved the update sets from the source instance.

Procedure
1. Navigate to System Update Sets > Retrieved Update Sets
2. From the list of retrieved update sets, select the batch base for the batch you want to preview.
   You cannot separately preview an update set that is a child in a batch. You must preview the entire batch by previewing the batch base. If necessary, you can remove the child update set from the batch by editing its record’s parent field.
3. Click Preview Update Set Batch.
4. If the system found problems, click the Preview Problems for Batch and resolve the problems as you normally would for any update set. When you have resolved all the problems, click Run Preview Again for Batch.

Commit a batch of update sets
You can commit at once all the update sets belonging to a batch.

Before you begin
Role required: admin
Before committing, you must have previewed the update sets from the source instance and resolved any collisions.
Procedure
1. Navigate to **System Update Sets > Retrieved Update Sets**

2. From the list of retrieved update sets, select the batch base for the batch you want to preview.

   You cannot separately commit an update set that is a child in a batch. You must commit the entire batch by committing the batch base. If necessary, you can remove the child update set from the batch by editing its record’s **parent** field.

3. Click **Commit All Update Sets**.

**Reorganize a batch of update sets**

You can remove an individual update set from the batch or change its parent.

**Before you begin**

Role required: admin

Procedure
1. Navigate to **System Update Sets > Local Update Sets**.

2. Select the record for an update set that you want to move or remove as a child in the batch.

3. On the update set record, navigate to the **Parent** field and select the new update set to act as the parent. To remove the update set from the batch, delete any text from the **Parent** field and leave it blank.

4. Click **Update**.

   The system returns to the list of update sets. If the **Batch Base** column is visible, it shows the parent for the newly-created child.

**What to do next**

If the system property `glide.update_set.auto_preview` is set to **true**, the system automatically starts the preview process after the record is updated with a new parent. If this property is **false**, you must start the process manually. For more information on the preview process, see **Preview a batch of update sets**.

**Back out batched update set**

Back out a batched update set by following the backout procedure for the base update set for the batch. You can also back out any child update set independently.

The following rules apply when backing out an update set that belongs to a batch:
• If the update set has a parent value, the system clears the parent value and treats the update set as an independent update set, or as a new batch base if it has any children.

• The system backs out the selected update set, plus any children of the backed-out update set.

To learn more, see Back out an update set and Update set batching

**Example of backing out a batched update set**

If you back out Update Set 1.1 from the batch shown in List of batched update sets before backing out an update set., the result is the batch shown in List of batched update sets after backing out Update Set 1.1.

List of batched update sets before backing out an update set.
Hierarchical diagram of Update Set batch shows the hierarchy both before and after the back out. The red boxes show the update sets the system backs out if you back out Update Set 1.1.
Automated Test Framework (ATF)

The Automated Test Framework (ATF) enables you to create and run automated tests to confirm that your instance works after making a change. For example, after an upgrade, during application development, or when deploying instance configurations with update sets. Review failed test results to identify the changes that caused the failure and the changes that you should review.

ℹ️ **Note:** By default, the system property to run automated tests is disabled to prevent you from accidentally running them on a production system. Run tests only on development, test, and other non-production instances to avoid data corruption and outage.

For developer training, see Using the Automated Test Framework on the ServiceNow Developer Site.

**Benefits**
Automated Test Framework provides these benefits for change managers and developers.

- Reduce upgrade and development time by replacing manual testing with automated testing.
- Design tests once and reuse them in different contexts and with different test data sets.
- Keep test instances clean by rolling back test data and changes made after each test run.
- Create test suites to organize and run tests in batches.
- Schedule test suite runs.
- Enable non-technical test designers to create tests of standard Now Platform functionality.
- Reduce test design time by copying quick start tests and test suites.
- Create custom test steps to expand test coverage.

**Automated Test Framework records and components**
The Automated Test Framework consists of these records and components.

**Test**

A test is a logical grouping of related automated test steps that verify some functionality or feature. Each test is a record in the Test [sys_atf_test] table. Test designers typically create a test to verify one feature or a group of related features. For example, the **CSM: Create Product Case** test validates the creation of Product Case records. Each test has a related list of test steps and test results.
Test suite

A test suite is a collection of tests that run in a specific order. Test designers typically create a test suite to test an application or a group of related features. For example, the CSM: Case Management test suite validates the functionality of the Customer Service Management application. Test designers can schedule running test suites and starting any required client test runners.

Quick start test

A quick start test is a ServiceNow-provided test or test suite installed with the demo data of an application. Use quick start tests as templates to build your own tests and test suites.

Test step

A test step combines a step configuration with the runtime test data necessary to run a step. The test step always specifies the order in which it runs in the test. Test steps have their own related list of step results. Each test step is a record in the Test Step [sys_atf_step] table that specifies a test action, the step configuration, and an execution order. Test designers add test steps to tests to verify functionality. For example, the first test step of the CSM: Create Product Case test is to impersonate the demo user John Jason who is authorized for Case Management.

Step configuration

A step configuration is a specific test action the Automated Test Framework can run. Step configurations do not contain any runtime test data and can only be run when test designers add them as part of a test step. Each step configuration is a record in the Test Step Config [sys_atf_step_config] table that specifies the input variables used to run the step configuration and the output variables available to other step configurations. For example, the Impersonate step configuration allows a test to impersonate another user.

The Automated Test Framework provides a default list of step configurations for most use cases and allows test designers to create their own custom step configurations.

Step variable

A step variable stores step-specific input and output values. For example, the Open a New Form step configuration has variables to specify the table and form view names. Use step variables to specify a particular test step target or to pass information to other test steps.
Test result

A test result stores the output of a test or test suite run. Each test result is a record in the Test Result [sys_atf_test_result] table that specifies the duration of the test run, the status of the test, and screenshots where available. Use test results to identify failing or non-running tests, and use the test logs to see more information about test results. By default, the system deletes test and test suite results 30 days after creation unless you enable the option to retain the test result indefinitely.

Step result

A step result stores the output of a test step run. Each step result is a record in the Step Result [sys_atf_test_result_step] table that specifies the status of the test step, a summary of the output, and a complete log of the output generated by the test step. Use step results to identify failures and functionality needing review.

Assert type

The Assert type field specifies the conditions that must be met for a test to pass. Test designers can use assertions to specify whether the results of an operation are expected or unexpected. For example, suppose you want to test that a record cannot be updated. In this case, you would add a Record Insert test step and set the Assert type field to Record was not inserted. The test passes when the record insert fails.

Some test step categories that include steps with an Assert type field include:

- **Server category**: Assert which CRUD operations cause a test to pass or fail.
- **Custom UI category**: Assert which component states cause a test to pass or fail, and whether visible text causes a test to pass or fail.
- **Forms in Service Portal category**: Assert whether a form canceled in the browser due to validation errors, or a form successfully submitted to the server causes a test to pass.

Client test runners

A client test runner is a browser tab that runs client-side test steps within a Now Platform user interface. Client test runners require a browser tab to function. If no client test runner is available when you run a test, the system prompts you to open one. Testers can manually start a client test runner or select an existing client test runner. Test designers can schedule starting client test runners when they schedule running a test suite.

User roles

Assign roles to define Automated Test Framework permissions.
<table>
<thead>
<tr>
<th>Role Title [name]</th>
<th>Role Description</th>
</tr>
</thead>
</table>
| atf_test_admin   | Create or edit Automated Test Framework properties. Has permission to:  
|                  | • View the tests page  
|                  | • Create/edit/delete tests  
|                  | • Create/edit/delete test steps  
|                  | • View the step config page  
|                  | • View the test runner page  
|                  | • View the test suite results, test results and result items pages  
|                  | • Execute user tests  
|                  | • View, create, edit, delete and execute test suites  
|                  | • Create/edit step config records  
|                  | • Create/edit Automated Test Framework properties  
| atf_test_designer| View Automated Test Framework properties only (cannot create or edit properties). Has permission to:  
|                  | • View the tests page  
|                  | • Create/edit/delete tests  
|                  | • Create/edit/delete test steps  
|                  | • View the step config page  
|                  | • View the test runner page  
|                  | • View the test suite results, test results and result items pages  
|                  | • Execute user tests  
|                  | • View, create, edit, delete and execute test suites  
|                  | • View Automated Test Framework properties  
| atf_ws_designer  | View or set basic authentication profiles needed for REST endpoints that require authentication. See REST category for more information. |
Getting started with the Automated Test Framework

If you are new to the Automated Test Framework, read this overview to learn what the framework can do. Next, follow the tutorial to create and run a test that uses the most basic of ATF features. After you feel comfortable with the basics, explore more advanced features provided by the ATF.

ATF features provide flexibility in how you test your instance.

Test step configuration categories

<table>
<thead>
<tr>
<th>Category</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service Catalog in Service Portal</td>
<td>Perform end-to-end testing for a catalog item in the Service Portal. • Open a record producer, catalog item, or order guide. • Set variable values and catalog item quantity. • Validate variable values, states, price, and items included in an order guide. • Navigate in an order guide. • Open and toggle catalog items in an order guide. • Add an item or an order guide to a shopping cart. • Order a catalog item or an order guide. • Submit a record producer.</td>
</tr>
<tr>
<td>Application Navigator</td>
<td>Create tests to check navigation features. • Verify that application menus are listed in the left navigation bar. • Verify that application modules are listed in the left navigation bar. • Navigate to a module as if a user clicked the module in the left navigation bar.</td>
</tr>

Output variables
Many test steps return output variables whose values you can use as inputs to a later step. For example, you can use output variables to accomplish the following tasks:

- Perform a server-side assert on a record that you previously inserted.
- Create a record as one user, and then reopen its form as a different user.

Custom test step configurations
In addition to the steps built into the Automated Test Framework, you can create custom test step configurations. These custom steps can take input variables and return output variables that you define.

ℹ️ Note: You can only define custom test steps that run on the server. The Automated Test Framework does not support creating custom step configurations that run on the browser.

Data preservation
The Automated Test Framework automatically tracks and deletes any data created by running tests, and automatically rolls back changes after testing.

Test suites
Test suites enable you to execute a batch of tests in a specified order. In addition, test suites can be hierarchical, with suites nested within other suites. You can associate test suites with schedules that determine when the system runs the test suites.

Build and run your first automated test
Follow these step-by-step instructions to create and run your first automated test. This test creates a new user record.

Before you begin

- The Automated Test Framework (com.glide.automated_testing_framework) plugin must be activated. It is activated by default on zboot or upgrade.
- If necessary, enable test execution. For instructions, see Enable or disable executing Automated Test Framework tests.

ℹ️ Note: By default, the system property that is used to run automated tests is disabled to prevent you from accidentally running these tests on a production system. To avoid data corruption or an outage, run tests only on development, test, and other non-production instances.

- Role required: admin

© 2021 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
Create new test
Create a new automated test record.

Procedure
1. Navigate to Automated Test Framework > Tests.
2. Click New.
3. On the Test new record form, enter a name for your test in the Name field. The system identifies this test by this name whenever it displays a list of tests (for example, under the Tests module).

Example

4. In the Description field, enter a description for your test.
5. Click Save.

Results
The system creates a new test record and returns to the list of tests. For more information about creating new automated tests, see Create a new automated test.

Add the first step to the new test
Add the first of three steps to the automated test.

About this task

Procedure
1. Navigate to Automated Test Framework > Tests.
2. Click the test that should contain the new test steps.
3. In the Test Steps related list at the bottom of the Test form, click Add Test Step.
4. In the middle column, click the row for the step type Open a new form, then click Next.
The system displays the Add Test Step form for the Open a new form step.

5. From the Table field, select the User [sys_user] table. Then click Submit.
The system creates the new step and returns to the test record.

6. Click **Update**.

**Results**
The system creates a new test record and returns to the list of tests. For more information about adding steps to automated tests, see [Add steps to an automated test](#).

**What to do next**
For some ideas on how to continue learning about the Automated Test Framework, see [Next steps with the Automated Test Framework](#).

**Add the second step to your automated test**
Add the second of three steps to the automated test.

**Procedure**

1. Click the test that should contain the new test steps.
2. In the Test Steps related list at the bottom of the Test form, click **Add Test Step**.
3. In the middle column, click **Set Field Values**, then click **Next**. The system displays the **Add Test Step** form for the **Set values** step.
4. In the field values section, set **Last name** to **Test** and **First name** to **Otto** (or other names of your choice).
5. Click **Submit**.

### Results

The system creates the new step and returns to the test record. For more information about adding steps to automated tests, see [Add steps to an automated test](#).

### Add the third step to your test

Add the last of three steps to the automated test.

### Procedure

1. Click the test that should contain the new test steps.
2. In the Test Steps related list at the bottom of the Test form, click **Add Test Step**.
3. In the middle column, click **Submit a Form**, then click **Next**. The system displays the **Add Test Step** form for the **Submit a form** step.
4. Leave all values as set by default and click **Submit**.

### Example
The system creates the new step and returns to the test record. The test record should now show the three steps you just added.

5. Click **Update**.
Results
The system returns to the list of tests. For more information about adding steps to automated tests, see Add steps to an automated test.

Run your test
After adding test steps, run and monitor the progress of the automated test.

Procedure
1. If necessary to view the Tests list, click Tests.
2. Click the row containing the test you just created.
   The system displays the Test form.
3. Click Run Test.
   Because this test includes a form step (any step involving a UI), the system displays a dialog box asking you to choose among any currently-running test clients or start a new test runner. To continue, select start a new test runner and click Run Test.

Results
The system displays the Run Test progress dialog. For more information about running automated tests, see Run an automated test.

Monitor test progress and view test results
Monitor the progress of the automated test and view its test results.

Procedure
1. Monitor the progress of the test in the Run Test progress dialog. If needed, you can cancel a test even while it’s running.

2. Note: If your test creates data, the system rolls back that data after all steps in the test complete.
   When complete, click Go to Results on the Run Test progress dialog to display the Test Results list, where you can view and analyze the results.

Next steps with the Automated Test Framework
After you feel comfortable creating and running simple tests, explore the more advanced features of the Automated Test Framework.

Batch tests together with test suites
If you commonly run a set of tests together, you can group them using test suites. To learn about test suites, see Building and running automated test suites.
Pass data from one test step to another with input and output variables

You can pass data from one test step to another using input variables and output variables. For more information, see Passing data from one automated test step to another.

Reuse common sequences of steps with templates

If you frequently add the same sequence of steps to your tests, save time by creating a template. To learn more about templates, see Add a predefined list of steps (template) to an automated test.

Domain separation and Automated Test Framework

Domain separation is supported in the Automated Test Framework. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

Support level: Standard*

The support level is Standard but has some exceptions or special conditions.

- Includes Basic level
- Business logic: The service provider (SP) creates or modifies processes per customer. The use cases reflect proper use of the application by multiple SP customers in a single instance.
- The instance owner must be able to configure minimum viable product (MVP) business logic and data parameters. This configuration is done per tenant, as expected for the specific application.

Sample use case: An admin must be able to make comments required when a record closes for one tenant, but not for another.

For more information on support levels, see Application support for domain separation.

ATF use case

Automated test framework design and runtime access are solely for the owner of the instance to validate domain-specific processes. By designing tests for my customers we confirm results per tenant.

Domain separation for service providers
Headless Browser for Automated Test Framework

In the Rome release, ServiceNow® improved UI testing by automating the creation of browsers to process Automated Test Framework (ATF) User Interface (UI) tests. This feature is known as a headless browser, and helps you test UI functionality without having to manually open a browser to the Client Test Runner, which is what processes the UI tests in your local browser.

Background

ServiceNow customers use Automated Test Framework (ATF) to test applications and instances. When developing in the ServiceNow platform, your changes both have the desired behavior and don’t break existing features.

Since the ServiceNow Orlando release, customers can automate the testing and deployment of their applications via the Continuous Integration/Continuous Delivery (CI/CD) API.

Overview

The automation provided by the ServiceNow Headless Browser for ATF skips the step of manually opening a browser during testing. There are several sequential procedures to follow in the one-time setup. Below are the instructions for both Linux and Windows setup.

Headless browser setup for Linux

The ServiceNow® headless browser for Automated Test Framework provides automation so you can skip having to manually open a browser during testing. The headless browser setup is available in both Linux and Microsoft Windows. This topic covers the setup for Linux.

There are several sequential procedures to follow in the one-time setup. Below are the instructions for the Linux setup. There are several sequential procedures to follow in the one-time setup.

Prerequisites

Role required: admin on your ServiceNow® instance and local administrator on the host machine.

- Docker application installed
- Java keytool installed
- OpenSSL
• Two-way communication
  ◦ There must be two-way communication between the instance URL and your server.
  ◦ Find the IP address of your server and get your hostname. You can use one or both of them, but you need at least one.

⚠️ Note: If you don’t have a hostname and are connecting via the IP address, you can enter the IP address and put “localhost” in the Hostname environment variable.

💡 Tip: To make remembering these easier, set the following environment variables:
  ◦ export PASSWORD="<password to generate the certificates with>"
  ◦ export SERVERIP="<THIS SERVER’S IP ADDRESS>"
  ◦ export HOSTNAME="<HOSTNAME OF THIS SERVER>"

• Port
  ◦ Use Port 2376 or your own default port for this procedure. Make sure your firewall rules allow inbound requests on this port.

• To learn more, see Use TLS (HTTPS) to protect the Docker daemon socket.

Generate certificates for Headless Browser setup for Linux

Step 1 in the Linux setup for the ServiceNow® Headless Browser for Automated Test Framework: Generate TLS/SSL certificates to secure the Docker REST API and authenticate HTTP requests.

Before you begin
By default when exposing the Docker API, requests are not authenticated, which can leave your host machine vulnerable to attack. Docker API, however, does support TLS authentication where requests are verified against public private keys provided in the HTTPS encryption. In this step you create those keys for the server and the client.

Role required: admin on your ServiceNow® instance and local administrator on the host machine.

• Docker application installed
• Java keytool installed
• OpenSSL
About this task

- Two-way communication
  - There must be two-way communication between the instance URL and your server.
  - Find the IP address of your server and get your hostname. You can use one or both of them, but you need at least one.

⚠ Note: If you don’t have a hostname and are connecting via the IP address, you can enter the IP address and put "localhost" in the Hostname environment variable.

💡 Tip: To make remembering these easier, set the following environment variables:
  - export PASSWORD="<password to generate the certificates with>"
  - export SERVERIP="<THIS SERVER'S IP ADDRESS>"
  - export HOSTNAME="<HOSTNAME OF THIS SERVER>"

⚠️ Warning: It is recommended to get self-signed certificate authority keys from a trusted certificate authority.

- Port
  - Use Port 2376 or your own default port for this procedure.

⚠ Note: Make sure your firewall rules allow inbound requests on this port.

- To learn more, see Use TLS (HTTPS) to protect the Docker daemon socket.

Procedure

1. Open a command line.
2. Generate a self-signed certificate authority key or retrieve a keypair from a trusted certificate authority. To generate a self-signed certificate, see the example below; your configuration may vary:
   - openssl genrsa -aes256 -passout pass:$PASSWORD -out ca-key.pem 4096
   - openssl req -passin pass:$PASSWORD -new -x509 -days 365 -key ca-key.pem -sha256 -out ca.pem
   - chmod 0400 ca-key.pem
   - chmod 0444 ca.pem
3. Generate the server keypair using the certificate authority key. See the example below; your configuration may vary:
• openssl genrsa -out server-key.pem 4096
• openssl req -subj "/CN=$HOSTNAME" -new -key server-key.pem -out server.csr
• echo "subjectAltName = DNS:$HOSTNAME,IP:$SERVERIP,IP:127.0.0.1" > extfile.cnf
• openssl x509 -passin pass:$PASSWORD -req -days 365 -in server.csr -CA ca.pem -CAkey ca-key.pem -CAcreateserial -out server-cert.pem -extfile extfile.cnf

4. Create the client keypair using the certificate authority key. See the example below; your configuration may vary:
• openssl genrsa -out client-key.pem 4096
• openssl req -subj "/CN=$HOSTNAME" -new -key client-key.pem -out client.csr
• echo "extendedKeyUsage = clientAuth" > extfile.cnf
• openssl x509 -passin pass:$PASSWORD -req -days 365 -in client.csr -CA ca.pem -CAkey ca-key.pem -CAcreateserial -out client-cert.pem -extfile extfile.cnf

Now you’ve created all your encryption keys.

5. Import the CA Public Key and Client Keypair to a java keystore. See the example below; your configuration may vary:

Create the keystore file and create a password for it (and save for later use).

• keytool -genkey -keyalg RSA -alias dse -keystore my.keystore

Delete a default entry from the keystore file.

• keytool -delete -alias dse -keystore my.keystore

Import the CA public key to the keystore.

• keytool -import -keystore my.keystore -trustcacerts -alias ca -file ca.pem
• keytool -importkeystore -destkeystore my.keystore -srckeystore clientkeypair.p12 -srcstoretype pkcs12 -alias clientkeypair

Now that you have added all of the certificates to the keystore file, save this file for later, as it will be uploaded to the ServiceNow instance. In addition, be

Note: You are creating a new pkcs12 keystore file and importing the keypair to it. Then copy the contents to your original keystore file.
sure to remember the password that you entered when prompted to create the keystore file; you will need to enter that into a form in the ServiceNow instance.

**Configure Docker for Headless Browser setup in Linux**

Step 2 in the Linux setup for the ServiceNow® Headless Browser for Automated Test Framework: Configure Docker Server to authenticate all requests.

**Before you begin**

After creating your client and server keys as directed in Step 1, now you configure the Docker Server to authenticate all requests using those keys, and expose the Docker API on port 2376.

Role required: admin on your ServiceNow instance and local administrator on the host machine.

Complete step 1: Generate certificates for Headless Browser setup for Linux

**Procedure**

1. Configure Docker to use the certificates you generated in Step 1.
   
a. Find or create the `/etc/docker/daemon.json` file. You can run: `touch /etc/docker/daemon.json`

b. Edit the daemon.json file and add the following JSON values. Be sure to replace with the correct paths to your certificates:

   ```json
   {
     "debug": true,
     "tlscacert": "<path to your certificates>/ca.pem",
     "tlscert": "<path to your certificates>/server-cert.pem",
     "tlskey": "<path to your certificates>/server-key.pem",
     "tlsverify": true
   }
   
   To learn more, see https://docs.docker.com/config/daemon/#configure-the-docker-daemon.
   
2. Configure Docker to expose the remote API on a port (Port 2376 is recommended).
   
   You can configure Docker to accept remote connections with the docker.service systemd unit file for Linux distributions using **systemd**, such as recent versions of RedHat, CentOS, Ubuntu and SLES, or with the daemon.json file, which is recommended for Linux distributions that do not use systemd.

   If using **systemd (systemctl)**:
a. Use the command `sudo systemctl edit docker.service` to open an override file for `docker.service` in a text editor.

b. Add or modify the following lines, substituting your own values.

```
[Service]
ExecStart=
ExecStart=/usr/bin/dockerd -H tcp://0.0.0.0:2376
```

c. Save the file.

d. Reload the systemctl configuration.

```
sudo systemctl daemon-reload
```

e. Restart Docker

```
sudo systemctl restart docker.service
```

3. To enable Docker access for the current user via a command line, copy certificates to the user's Docker home directory:

- `mkdir -pv ~/.docker`
- `cp ca.pem ~/.docker`
- `cp client-key.pem ~/.docker/key.pem`
- `cp client-cert.pem ~/.docker/cert.pem`

4. Set `DOCKER_HOST` and `DOCKER_TLS_VERIFY` environment variables for your user:

```
export DOCKER_HOST=tcp://${SERVERIP}:2376
export DOCKER_TLS_VERIFY=1
```

source ~/.bash_profile

To learn more, see Manage Docker as a non-root user.

Create the Docker image and containers for Headless Browser setup in Linux

Step 3 in the Linux setup for the ServiceNow® Headless Browser for Automated Test Framework.

Before you begin
In this step you will pull the Docker image from the Public Registry.

Role required: admin on your ServiceNow instance and local administrator on the host machine.

Complete Step 2: Configure Docker for Headless Browser setup in Linux
Procedure

1. In the command line, run `docker ps` to verify that Docker is working. Your results should look like this:

![docker ps output]

2. Pull the Docker image from the DockerHub repo Docker ATF Headless Runner using this command: `docker pull docker.pkg.github.com/servicenow/atf-headless-runner/atf-headless-runner:<tagname>`

   **Note:** Make sure you find the correct tag name. To learn more, see Headless Browser image-instance version compatibility.

Add secrets to Docker for Headless Browser setup in Linux

Step 4 in the Linux setup for the ServiceNow® Headless Browser for Automated Test Framework. Docker Secrets is a feature for securely storing the passwords that will be used in containers. You will be creating a Docker secret, which stores the password of the ServiceNow user who will log into the instance to execute the tests.

**Before you begin**

Inside of the Docker container is an automation script that opens a web browser, logs into the instance, and opens the client test runner page. In order to log into the ServiceNow instance, you will need a user password. In this step you use a Docker feature called Docker Secrets so you can securely store passwords. Then when you run containers, the password is automatically available to log in to your instance.

Role required: admin on your ServiceNow instance and local administrator on the host machine.

Complete Step 3: Create the Docker image and containers for Headless Browser setup in Linux

**Procedure**

1. In the command line, enter `docker swarm init`

2. Enter `echo "<your users password>" | docker secret create my_secret_data -`

   **Note:** Replace `<your users password>` with the user's ServiceNow password.

   Your results should look like this:
3. The result is your secret ID, which you must save for later use. The secret ID will be added to the ServiceNow instance in the `sys_property sn_atf.headless.secret_id`

**Set up your instance for Headless Browser in Linux**

Step 5 in the Linux setup for the ServiceNow® Headless Browser for Automated Test Framework. Set up your instance so it can support the Headless Browser.

**Before you begin**

Now that you have configured the host machine, you will set up the instance so that it successfully communicates and authenticates with the host machine.

Role required: admin on your ServiceNow instance and local administrator on the host machine.

Complete Step 4: Add secrets to Docker for Headless Browser setup in Linux.

**Procedure**

1. Create a user - User ID, which can be whatever you want, as well as a browser name and password. The password should be the same as the one you created for your Docker Secret container.

2. Add the role `atf_test_designer` for this user. (To learn more, see the User Roles section in the Automated Test Framework (ATF) topic.)

3. Navigate to **System Definition > Certificates** to open the `sys_certificate` table. Create a new certificate (the name can be whatever you prefer):
   - **Type**: javakeystore
   - **Password**: Password for the keystore that you created in Step 2 (Add secrets to Docker for Headless Browser setup in Linux).

4. Upload the keystore file you saved earlier and attach it to this record.

5. Select **Submit**.

6. Click **Validate certificate**, which returns a success message.

7. Navigate to **System Security > Protocol Profiles** to open the `sys_protocol_profile` table. Create a new protocol profile record:
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Protocol</td>
<td>One word &quot;myname&quot;</td>
</tr>
<tr>
<td>Default port</td>
<td>2376 (or the one you chose to use)</td>
</tr>
<tr>
<td>Keystore</td>
<td>Docker host keystore</td>
</tr>
</tbody>
</table>

8. Select **Submit**.

9. Create a Connections alias: Navigate to **Connections & Credentials > Connection & Credential Aliases** to open the **sys_alias** table.

10. Select the alias with the name **Docker**.

11. Under the Connections related list, select **New**.

12. Fill in these fields:
   - **Name**: Any text you prefer
   - **Credential field**: Leave blank

13. Select the **URL Builder** check box.

14. Select the **Mutual authentication** check box.

15. In the **Protocol profile** field, select the protocol profile you created earlier.

16. In the Host field, add the IP address or Host name of your server.

17. Select **Submit**.

   The Connection URL is automatically created by the system.

   **Note**: You only need to do this when using self-signed certificates. To learn more see **Generate certificates for Headless Browser setup for Linux**.

18. Modify properties:

   **Warning**: By default, the `com.glide.communications.trustmanager_trust_all` property is set to **false**. The Now Platform only trusts certificates that it can verify against the JVM certificate store. Self-signed and enterprise-signed certificates are not trusted. To learn more see the **Certificate trust** topic.

   - `com.glide.communications.httpclient.verify_hostname`: **false**
   - `com.glide.communications.trustmanager_trust_all`: **true**
Configure ATF for Headless Browser in Linux

Step 6 in the Linux setup for the ServiceNow® Headless Browser for Automated Test Framework.

Before you begin
Now that your connection and authentication are set up, you will configure ATF with several properties so that it can start containers successfully on the host machine.

Role required: admin on your ServiceNow instance and local administrator on the host machine.

Complete Step 5: Set up your instance for Headless Browser in Linux.

Procedure

1. In your instance, navigate to **ATF > Administration > Properties**.

2. Enable the top two properties: **Enable test/test suite execution** and **Enable scheduled test suite execution**.

3. Scroll down to the **Headless Runner Properties** section.

4. Enable the top check box.

5. Enter the following values in the Headless Browser Properties form:
### Form label

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Value to Imput</th>
</tr>
</thead>
<tbody>
<tr>
<td>sn_atf.headless.username</td>
<td>Username of the integration user that you created in Add secrets to Docker for Headless Browser setup in Linux</td>
</tr>
<tr>
<td>sn_atf.headless.secret_id</td>
<td>Docker “Secret ID” that you obtained earlier, as well as the Docker secret name that you created in Step 2 of Add secrets to Docker for Headless Browser setup in Linux.</td>
</tr>
<tr>
<td>sn_atf.headless.docker_image_name</td>
<td>Image name, with tag that you downloaded: servicenowdevx/atf-headless-runner:tagname</td>
</tr>
</tbody>
</table>

**Note:** If you forgot the secret ID, go to the Docker host and run the command `docker secret list`.

6. Leave the rest of the fields as they are.

7. Select **Save**.

To verify:

a. Go to **ATF Schedules** > and next to the Suite Schedules link select **New**.

b. In the Run box select **On Demand**.

c. Select **Save**.

d. In the Scheduled Suite related list, add a new record for your test suite by double-clicking the + sign and choose your browser name of **Chrome** or **Firefox**. Use **Child A** as a good example to run.
e. OS name: Linux  
f. Select **Execute Now**.  
g. Verify that your test passed.  
   When your verification is successful, any suites with UI tests run by scheduled suites or via CICD now automatically create headless test runners without the need to manually open the "scheduled client test runner" page.

**Headless Browser setup for Microsoft Windows**

The ServiceNow® Headless Browser for Automated Test Framework provides automation so you can skip having to manually open a browser during testing. The Headless Browser setup is available in both Linux and Microsoft Windows. This topic covers the setup for Windows.

There are several sequential procedures to follow in the one-time setup. Below are the instructions for the Microsoft Windows setup.

**Prerequisites**

Role required: admin on your ServiceNow instance and local administrator on the host machine.

⚠️ **Warning:** The only ServiceNow-supported version of Microsoft Windows as a host is: Windows Server 2019 v10.0.17763.737. No other versions are supported. If you are unable to meet these requirements, a Linux host is recommended.

- Make sure that the following programs are installed on your Windows server:
  - Install Docker for Headless Browser setup for Windows
  - Java keytool Chocolatey tool for javaruntime
  - OpenSSL Chocolatey tool for openssl
• Two-way communication
  ◦ There must be two-way communication between the instance URL and your server.
  ◦ Find the IP address of your server and get your hostname. You can use one or both of them, but you need at least one.

  **Note:** If you don’t have a hostname and are connecting via the IP address, you can enter the IP address and put "localhost" in the Hostname environment variable.

  **Tip:** To make remembering these easier, set the following environment variables:
  ◦ set PASSWORD=<password>
  ◦ set SERVERIP=<server ip>
  ◦ set HOSTNAME=<hostname>

• Port
  ◦ Use Port 2376 or your own default port for this procedure. Make sure your firewall rules allow inbound requests on this port.

• To learn more, see Use TLS (HTTPS) to protect the Docker daemon socket.

Install Docker for Headless Browser setup for Windows

Before you begin setting up your ServiceNow® Headless Browser for Automated Test Framework for Microsoft Windows, you must install Docker.

**Before you begin**
Role required: admin
Install Docker for Windows before you begin Step 1 of the Headless Browser for Windows setup.

**Warning:** The only ServiceNow-supported version of Microsoft Windows as a host is: Windows Server 2019 v10.0.17763.737. No other versions are supported. If you are unable to meet these requirements, a Linux host is recommended.

**Procedure**

1. Open an elevated PowerShell session and install the Docker-Microsoft PackageManagement Provider from the PowerShell Gallery.

© 2021 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
Install-Module -Name DockerMsftProvider -Repository PSGallery -Force
If you're prompted to install the NuGet provider, type Y to install it as well.

2. Use the PackageManagement PowerShell module to install the latest version of Docker.
PowerShell
Install-Package -Name docker -ProviderName DockerMsftProvider
When PowerShell asks you whether to trust the package source 'DockerDefault', type A to continue the installation.

3. After the installation completes, restart the computer.
PowerShell
Restart-Computer -Force

Generate certificates for Headless Browser setup for Windows
Step 1 in the Microsoft Windows setup for the ServiceNow® Headless Browser for Automated Test Framework: Generate TLS/SSL certificates to secure the Docker REST API and authenticate HTTP requests.

Before you begin
By default when exposing the Docker API, requests are not authenticated, which can leave your host machine vulnerable to attack. Docker API, however, does support TLS authentication where requests are verified against public private keys provided in the HTTPS encryption. In this step you create those keys for the server and the client.

Role required: admin on your ServiceNow instance and local administrator on the host machine.

⚠️ Warning: The only ServiceNow-supported version of Microsoft Windows as a host is: Windows Server 2019 v10.0.17763.737. No other versions are supported. If you are unable to meet these requirements, a Linux host is recommended.

- Make sure that the following programs are installed on your Windows server:
  - Docker application for Windows
  - Java keytool Chocolatey tool for javaruntime
  - OpenSSL Chocolatey tool for openssl
About this task

• Two-way communication
  ◦ There must be two-way communication between the instance URL and your server.
  ◦ Find the IP address of your server and get your hostname. You can use one or both of them, but you need at least one.

⚠ Note: If you don’t have a hostname and are connecting via the IP address, you can enter the IP address and put "localhost" in the Hostname environment variable.

⚠ Tip: To make remembering these easier, set the following environment variables:
  ◦ set PASSWORD=<password>
  ◦ set SERVERIP=<server ip>
  ◦ set HOSTNAME=<hostname>

⚠ Warning: It is recommended to get self-signed certificate authority keys from a trusted certificate authority.

• Port
  ◦ Use Port 2376 or your own default port for this procedure.

⚠ Note: Make sure your firewall rules allow inbound requests on this port.

• To learn more, see Use TLS (HTTPS) to protect the Docker daemon socket.

Procedure

1. Open a command line.

2. Generate a self-signed certificate authority key or retrieve a keypair from a trusted certificate authority. To generate a self-signed certificate, see the example below; your configuration may vary:

   • openssl genrsa -aes256 -passout pass:%PASSWORD% -out ca-key.pem 4096
   • openssl req -passin pass:%PASSWORD% -new -x509 -days 365 -key ca-key.pem -sha256 -out ca.pem

3. Generate the server keypair using the certificate authority key. See the example below; your configuration may vary:

   • openssl genrsa -out server-key.pem 4096
   • openssl req -subj /CN=%HOSTNAME% -new -key server-key.pem -out server.csr
4. Create the client keypair using the certificate authority key. See the example below; your configuration may vary:
• openssl genrsa -out client-key.pem 4096
• openssl req -subj /CN=%HOSTNAME% -new -key client-key.pem -out client.csr
• echo extendedKeyUsage = clientAuth > extfile.cnf
• openssl x509 -passin pass:%PASSWORD% -req -days 365 -in client.csr -CA ca.pem -CAkey ca-key.pem -CAcreateserial -out client-cert.pem -extfile extfile.cnf

Now you've created all your encryption keys.

5. Import the CA Public Key and Client Keypair to a java keystore. See the example below; your configuration may vary.
Create the keystore file and create a password for it (and save for later use).
• keytool -genkey -keyalg RSA -alias dse -keystore my.keystore
Delete a default entry from the keystore file.
• keytool -delete -alias dse -keystore my.keystore

ℹ️ Note: This entry is auto-generated, so is not needed.
Import the CA public key to the keystore
• keytool -import -keystore my.keystore -trustcacerts -alias ca -file ca.pem
Import the client keypair

ℹ️ Note: You are creating a new pkcs12 keystore file and importing the keypair to it. Then copy the contents to your original keystore file.
• openssl pkcs12 -export -name clientkeypair -in client-cert.pem -inkey client-key.pem -out clientkeypair.p12
• keytool -importkeystore -destkeystore my.keystore -srckeystore clientkeypair.p12 -srcstoretype pkcs12 -alias clientkeypair

Now that you have added all of the certificates to the keystore file, save this file for later, as it will be uploaded to the ServiceNow instance. In addition, be
sure to remember the password that you entered when prompted to create the keystore file; you will need to enter that into a form in the ServiceNow instance.

**Configure Docker for Headless Browser setup in Windows**

Step 2 in the Microsoft Windows setup for the ServiceNow® Headless Browser for Automated Test Framework: Configure Docker Server to authenticate all requests.

**Before you begin**

After creating your client and server keys as directed in Step 1, now you configure the Docker Server to authenticate all requests using those keys, and expose the Docker API on port 2376.

Role required: admin on your ServiceNow instance and local administrator on the host machine.

Complete Step 1: Generate certificates for Headless Browser setup for Windows

**Procedure**

1. Configure Docker to use the certificates you generated in Step 1.
2. Find or create the C:\ProgramData\docker\config\daemon.json file.
3. Add the following properties to the daemon.json file. Be sure to replace with the correct paths to your certificates:

   ```json
   {
       "tlscacert": "C:\Users\Administrator\certs\ca.pem",
       "tlscert": "C:\Users\Administrator\certs\server-cert.pem",
       "tlskey": "C:\Users\Administrator\certs\server-key.pem",
       "tlsverify": true,
       "hosts": ["tcp://0.0.0.0:2376", "npipe://"]
   }
   ``

   To learn more, see [https://docs.docker.com/config/daemon/#configure-the-docker-daemon](https://docs.docker.com/config/daemon/#configure-the-docker-daemon).

4. In administrator PowerShell, run: `#restart-service *docker*`
Create the Docker image and containers for Headless Browser setup in Microsoft Windows

Step 3 in the Microsoft Windows setup for the ServiceNow® Headless Browser for Automated Test Framework: Pull the Docker image from the Public Registry.

Before you begin
In this step you will pull the Docker image from the Public Registry.
Role required: admin on your ServiceNow instance and local administrator on the host machine.
Complete Step 2: Configure Docker for Headless Browser setup in Windows

Procedure
1. In an administrator command line, run `docker ps` to verify that Docker is working.
   Your results should look like this:

2. Pull the Docker image from the DockerHub repo Docker ATF Headless Runner using this command: `ghcr.io/servicenow/atf-headless-runner:<tagname>`

   Note: Make sure you find the correct tag name. To learn more, see Headless Browser image-instance version compatibility.

Add secrets to Docker for Headless Browser setup in Microsoft Windows

Step 4 in the Microsoft Windows setup for the ServiceNow® Headless Browser for Automated Test Framework. Docker Secrets is a feature for securely storing the passwords that will be used in containers. You will be creating a Docker secret that stores the password of the ServiceNow user who will log into the instance to execute the tests.

Before you begin
Inside of the Docker container is an automation script that opens a web browser, logs into the instance, and opens the Client Test Runner page. In order to log into the ServiceNow instance, you will need a user password. In this step you use a Docker feature called Docker Secrets so you can securely store passwords. Then when you run containers, the password is automatically available to log in to your instance.

Role required: Go to your ServiceNow instance and create a new user to be used by the Docker container to log in. Give this user the roles of admin
or `atf_test_admin`. Save the password to be used in Step 2 of the following procedure.

Complete Step 3: Create the Docker image and containers for Headless Browser setup in Microsoft Windows

**Procedure**

1. In the admin command line, enter `docker swarm init`
2. In the admin command line, enter `echo <your users password> | docker secret create sn_password`

   **Note:** Replace `<your users password>` with the user's ServiceNow password.

   Your results should look like this:

   ![Command Line Output](image)

3. The result is your secret ID, which you must save for later use. The secret ID will be added to the ServiceNow instance in the `sys_property sn_atf.headless.secret_id`

**Set up instance for Headless Browser in Microsoft Windows**

Step 5 in the Microsoft Windows setup for the ServiceNow® Headless Browser for Automated Test Framework: Set up your instance so it can support the Headless Browser.

**Before you begin**

Now that you have configured the host machine, you will set up the instance so that it successfully communicates and authenticates with the host machine.

Role required: admin on your ServiceNow instance and local administrator on the host machine.

Complete Step 4: Add secrets to Docker for Headless Browser setup in Microsoft Windows.
Procedure

1. Create a user - User ID, which can be whatever you want, as well as a user name and password. The password should be the same as the one you created for your Docker Secret container.

2. Add the role `atf_test_designer` for this user. (To learn more, see the User Roles section in the Automated Test Framework (ATF) topic.

3. Navigate to **System Definition > Certificates** to open the `sys_certificate` table. Create a new certificate (the name can be whatever you prefer):
   - **Type**: `javakeystore`
   - **Password**: Password for the keystore that you created in Step 2 (*Add secrets to Docker for Headless Browser setup in Microsoft Windows*).

4. Upload the keystore file you saved earlier and attach it to this record.

5. Select **Submit**.

6. Click **Validate certificate**, which returns a success message.

7. Navigate to **System Security > Protocol Profiles** to open the `sys_protocol_profile` table. Create a new protocol profile record:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Protocol</td>
<td>One word “myname”</td>
</tr>
<tr>
<td>Default port</td>
<td>2376 (or the one you chose to use)</td>
</tr>
<tr>
<td>Keystore</td>
<td>Docker host keystore</td>
</tr>
</tbody>
</table>

8. Select **Submit**.

9. Create a Connections alias: Navigate to **Connections & Credentials > Connection & Credential Aliases** to open the `sys_alias` table.

10. Select the alias with the name `Docker`.

11. Under the Connections related list, select **New**.

12. Fill in these fields:
   - **Name**: Any text you prefer
   - **Credential field**: Leave blank

13. Select the **URL Builder** check box.

14. Select the **Mutual authentication** check box.

15. In the **Protocol profile** field, select the protocol profile you created earlier.

16. In the Host field, add the IP address or Host name of your server.
17. Select **Submit**.
   The Connection URL is automatically created by the system.

18. Modify properties:

   **Warning:** By default, the
   `com.glide.communications.trustmanager_trust_all` property is set to `false`.
   The Now Platform only trusts certificates that it can verify against the JVM
   certificate store. Self-signed and enterprise-signed certificates are not
   trusted. To learn more see the Certificate trust topic.

   • `com.glide.communications.httpclient.verify_hostname`: false
   • `com.glide.communications.trustmanager_trust_all`: true

Configure Automated Test Framework (ATF) for Headless Browser in Microsoft Windows

Step 6 in the Microsoft Windows setup for the ServiceNow® Headless Browser for
Automated Test Framework (ATF): Configure ATF with properties.

**Before you begin**
Now that your connection and authentication are set up, you will configure ATF
with several properties so that it can start containers successfully on the host
machine.

Role required: admin on your ServiceNow instance and local administrator on
the host machine.

Complete Step 5: Set up instance for Headless Browser in Microsoft Windows.

**Procedure**
1. In your instance, navigate to **ATF > Administration > Properties**.
2. Enable the top two properties: **Enable test/test suite execution** and **Enable
   scheduled test suite execution**.
3. Scroll down to the **Headless Runner Properties** section.

4. Enable the top check box.

5. Enter the following values in the Headless Runner Properties form:

<table>
<thead>
<tr>
<th>Form Label</th>
<th>Property Name</th>
<th>Value to Input</th>
</tr>
</thead>
<tbody>
<tr>
<td>The user account used to login from the headless Client Test Runner and begin the tests</td>
<td>sn_atf.headless.username</td>
<td>Username of the integration user that you created in Add secrets to Docker for Headless Browser setup in Microsoft Windows</td>
</tr>
<tr>
<td>The Docker secret ID that has the password stored of the user account</td>
<td>sn_atf.headless.secret_id</td>
<td>Docker “secret ID” that you obtained earlier, as well as the Docker secret name that you created in Step 2 of the Add secrets to Docker for Headless Browser setup in Microsoft Windows procedure.</td>
</tr>
</tbody>
</table>
### Form Label | Property Name | Value to Imput
---|---|---
The Docker image that is used for headless Client Test Runner | sn_atf.headless.docker_image_name | Image name with tag that you downloaded: ghcr.io/servicenow/atf-headless-runner:<tagname>

**Note:** If you forgot the secret ID, go to Windows host and run the command docker secret list.

6. **At the The absolute path of the secret file on a docker container** field, enter: C:\ProgramData\Docker\secrets\<YOUR_SECRET_NAME>

7. Leave the rest of the fields as they are.

8. Select Save.
   To verify:
   a. Go to **ATF Schedules** and next to the Suite Schedules link select **New**.
   b. In the Run box select **On Demand**.
   c. Select **Save**.
   d. In the Scheduled Suite related list, add a new record for your test suite by double-clicking the + sign and choose your browser name of **Chrome** or **Firefox**. Use **Child A** as a good example to run.

![Scheduled Suites](image)

   e. **OS name:** Windows
   f. Select **Execute Now**.
   g. Verify that your test passed.

   When your verification is successful, any suites with UI tests run by scheduled suites or via CICD now automatically create headless test runners without the need to manually open the “scheduled client test runner” page.
Headless Browser image-instance version compatibility

The instance-to-image compatibility makes sure that the automation script inside the Docker image is compatible with the instance code. Elements such as the user interface might change over time to support new features or upgrades.

Image-instance version compatibility

Below is a list of the image tags to install based on the ServiceNow instance version that you have.

<table>
<thead>
<tr>
<th>Docker image tag</th>
<th>Compatible instance versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>lin-1.0.0</td>
<td>Rome +</td>
</tr>
<tr>

ServiceNow® Headless Browser system properties

Below is a table of the properties you must have as you set up the ServiceNow® Headless Browser for Automated Test Framework.

<table>
<thead>
<tr>
<th>Property properties</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property name</strong></td>
</tr>
<tr>
<td>sn_atf.headless.browser_options</td>
</tr>
<tr>
<td>sn_atf.headless.default_browser</td>
</tr>
<tr>
<td>sn_atf.headless.default_os</td>
</tr>
<tr>
<td>sn_atf.headless.docker_image_name</td>
</tr>
<tr>
<td>sn_atf.headless.docker_window_seconds</td>
</tr>
</tbody>
</table>
System properties (continued)

<table>
<thead>
<tr>
<th>Property name</th>
<th>Type</th>
<th>Default value</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>sn_atf.headless.enabled</td>
<td>boolean</td>
<td>false</td>
<td>Determines whether the instance attempts to create headless client test runners for scheduled UI test runs</td>
</tr>
<tr>
<td>sn_atf.headless.heartbeat_enabled</td>
<td>boolean</td>
<td>true</td>
<td>When property is true, Docker container sends a REST API request every minute to check that the sys_atf_agent is still online, and stops the container if the record status is &quot;offline&quot; or the record no longer exists.</td>
</tr>
<tr>
<td>sn_atf.headless.heartbeat_uri</td>
<td>string</td>
<td>/api/now/atf_agent/online</td>
<td>The URL of the heartbeat endpoint so container can verify browser is still responsive</td>
</tr>
<tr>
<td>sn_atf.headless.images_check.enabled</td>
<td>boolean</td>
<td>false</td>
<td>When this property is true, the instance verifies that the requested Docker image:tag is present on the</td>
</tr>
</tbody>

Headless Browser for Automated Test Framework
Automated Test Framework (ATF)

Headless Browser troubleshooting

These tips can help you troubleshoot your Linux or Microsoft Windows setup of the ServiceNow® Headless Browser for Automated Test Framework.

There are three basic areas to examine when troubleshooting your Headless Browser setup.

Docker container

Error logs: When the headless test completes, if there are errors they are generated in the Docker container. Whether the operation fails or succeeds, the container’s stdout/stderr logs are placed in the sn_atf_docker_service table.

Headless client test runner did not start in the time allotted message: This message generally means an error occurred in the Docker container while it was initializing or starting up. This may indicate something is incorrect in your Docker container setup. Navigate to the sn_atf_docker_service table to read the logs and see the error message.

Instance

Error caught running Docker flow when starting the ATF tests messages: Follow the URL address to find the flow context, which contains the error logs. For example, the above error message can display when the instance can’t access the Docker host.

Network errors

Firewalls: Make sure your firewalls are set up so that the instance can access the host and port and the server can access the instance.
Building and running automated tests with the Automated Test Framework

Basic tasks in the Automated Test Framework.

To build and run any test, you always perform certain operations:

- Create a new automated test
- Add steps to an automated test
- Run an automated test
• View the progress of automated tests
• View test results

You perform other operations often, but not necessarily for every test.
• For tests involving form steps, you might need to View results screenshots from an automated test.
• For some tests, you might need to know about Passing data from one automated test step to another.
• Some steps frequently occur in the same sequence in many different tests, so you can Add a predefined list of steps (template) to an automated test.

Create a new automated test
Create a named automated test containing a series of steps to execute.

Before you begin
Role required: atf_test_admin or atf_test_designer

Procedure
1. Navigate to Automated Test Framework > Tests.
2. Click New.
3. On the Test new record form, enter a Name for your test. The system identifies this test by this name wherever it displays a list of tests (for example, in the Tests module).
4. Optional: Enable parameterized testing to run a test multiple times with different test data for each run. For more information, see Parameterized tests.
5. Enter a Description for your test.
6. Click Save.
   The system creates a new test record and returns to the list of tests.

What to do next
Add steps to an automated test.

Add a predefined list of steps (template) to an automated test
With test templates you can add a predefined list of steps to a test. Any list of steps that follows a set pattern makes a good candidate for a template.
Before you begin
You must have created the test to which you want to add steps.
Role required: atf_test_admin or atf_test_designer

About this task
Many tests follow similar patterns. One common pattern, for example, is to open a form, set some field values, validate some field values, click a UI action, and submit the current form. If a template exists containing these steps, you can add them to a test all at once. The Automated Test Framework comes with default templates. You can also create custom test templates.

Procedure
1. Navigate to Automated Test Framework > Tests.
2. Click the row for the test to which you want to add steps.
   The system displays the Test form.
3. On the Test Steps related list, click Add Test Template.
   The system displays the Add a test template dialog.
4. From the Table field, select the table you want to test with these steps.
5. From the Template field, select the template containing the steps you want to add.
6. Click Add.
   The system adds the template steps to the test. It also adds to the test description a set of instructions on how to complete the test from this template.
7. Following the instructions in the test description, edit each step added by the template to include the necessary information.

What to do next
Proceed to edit or save the test as you normally would.

Related information
Create an automated test steps template

Add steps to an automated test
Create a series of steps for an automated test to run in a specified order.

Before you begin
You must create a test before you can add steps to the test.
Role required: atf_test_admin or atf_test_designer
About this task
This procedure lets you add one step at a time. You can also add a batch of steps at once. For more information, see Add a predefined list of steps (template) to an automated test.

Procedure
1. Navigate to Automated Test Framework > Tests.
2. Click the test that should contain the new test steps.
3. In the Test Steps related list at the bottom of the Test form, click Add Test Step.
4. From the left panel of the Add Test Step form, select the test step category, or select All Steps to view all available test steps for all test categories. For example, if selecting a specific test step category, select Form for form-related test steps, Application Navigator to test application menu or module visibility, or Server for tests executed on the server.

   ☢️ Note: When selecting certain types of server tests, you can specify whether a positive or negative test result constitutes a successful test outcome. For more information, see Assert type in Automated Test Framework (ATF).

5. Click the type of test step you want to select. For example, if you select the Form category, select Set Field Values to set the field values on a form.

   Start any sequence of steps that work with forms with the Open a new form or Open an existing form step. Close with the Submit form step.

6. If applicable, from the Insert after drop-down list, select the step that you want to precede this step. If this is the first step in a test, the Insert after drop-down list does not appear.

7. Click Next.

8. From the Table list on the Add Test Step form, select the table that you want to test in this step.

9. Optional: In the Execution Order field, enter an integer representing the order in which you want the test to execute this step. For more information on Execution Order, see Edit automated test step order.

10. Fill in the fields that apply to this step. For instructions, see Test step categories. Some steps return output values that you can pass to the inputs for a subsequent step. For more information, see Pass values from one automated test step to another.

11. Click Submit.
The system creates the step and displays the test record.

12. Repeat Steps 3 through 11 to add additional steps for this test.

What to do next
Run an automated test.

Related information
Automated Test Framework use case examples

Change automated test step
If necessary, edit a test step after you create it.

Before you begin
Role required: atf_test_admin or atf_test_designer

Procedure
1. Navigate to Automated Test Framework > Tests.
2. Click the row containing the test you want to edit.
3. On the Test Steps related list, click the row containing the step you want to edit.
   The system displays the Set Field Values form.
4. Edit the fields you want to change.
5. Click Update.

Edit automated test step order
By default, steps execute in the order in which you created them. You can change this order by editing the Execution Order field.

Before you begin
Role required: atf_test_admin or atf_test_designer

About this task
By default, the system assigns the value 1 to Execution Order for the first step created for a test. When you add a step, the system assigns it the next-highest available integer value. In other words, if the highest Execution Order for any step in the test has the value 7, the system assigns 8 to the new step. By editing these values, you can change the order in which the test executes the steps.
**Procedure**

1. Navigate to **Automated Test Framework > Tests**.
2. Click the row containing the test you want to edit. The system displays the **Test** form.
3. In the **Test Steps** related list, edit the values in the **Execution order** column to determine the new order for the steps.
4. Click **Update**.

**Copy automated test**

Copy an existing test, which you can then re-name and modify.

**Before you begin**

Role required: atf_test_admin or atf_test_designer

**Procedure**

1. Navigate to **Automated Test Framework > Tests**.
2. Click the row containing the test you want to copy. The Test record form opens.
3. Near the top-right of the Test record form, click **Copy Test**. An annotation displays confirming that the system has copied the test. After you dismiss this annotation, the system displays a new test record identical to the copied record, with the exception of the **Name**.
4. In the **Name** field, enter the name you want to assign to this new test.
5. Edit the test steps as desired and proceed as you would for any new test.
6. When you are finished making changes, click **Update**.

**Note:** Scope management in ATF tests helps identify and restrict copying of tests in other scopes. If you want to copy a test, you must be in the same scope as the test. See **Application Scope** for more information.

**Run an automated test**

After creating an automated test, run it on a non-production instance.

**Before you begin**

You must have created the test you want to run.

The **test execution property** must be enabled. You must have an admin or atf_test_admin role to do so.
Note: The test execution property is disabled by default to prevent running tests on a production system. Run tests only on development, test, and other sub-production instances.

Role required: atf_test_admin, atf_test_designer, or admin

Procedure

1. Navigate to Automated Test Framework > Tests.
2. If necessary to view the tests list, click Tests.
3. Click the row containing the test you want to run. The system displays the Test form.
4. Click Run Test.

Note: If the test execution property is not enabled, the Run Test button does not appear. In this case, see the annotation at the top of the form, and click the link to enable running tests.

5. If the test includes a form step (any step involving a UI), or other kinds of UI test steps, the Pick a browser dialog appears before executing the tests. Use it to choose among any currently running test clients, or start a new runner. For more information, review Browser recommendations for all tests and suites. If the test only includes server test steps, the system executes the tests without displaying the Pick a Browser dialog.

What to do next

Monitor the progress of the test in the Run Test progress dialog. When complete, click Go to Results (on the Run Test progress dialog) to display the Test Results list, where you can view and analyze test results.

Note: If your test creates data, the system rolls back that data after all steps in the test complete.

Related information

Cancelling automated tests and test suites

View test results

View test results from completed test and test suite runs. Carefully consider the results of automated test runs and perform any corrective actions required to resolve any revealed issues.
About this task
Test and test suite results show how long it took the system to execute a test, which steps failed, and can include screenshots of form steps. You can also view reports comparing different runs of the same test suites.

View automated test results
You have multiple options for navigating to the test results, depending on where you are in the user interface. For example, if the Run Test progress dialog is displayed, you can click Go to Result. This procedure enables you to view test results from any location in the user interface.

Procedure
1. Navigate to Automated Test Framework > Test Results.
2. Click a row to access the results for a specific test. The system displays the Test results record.
3. Click the Step Results related list to view step results for the selected test. Scroll down and click the row for the step result you want to view. The system displays the Step results record.
4. Click the Test Log related list to view test logs for this test result. Scroll down and click the row for the test log you want to view. The system displays the Test logs record.

What to do next
Note: When viewing test results, step results or test logs, you can allow client errors as ignored or warning entries in the Allowed Client Errors table. This allows test executions to continue past client errors in future test runs.

View results screenshots from an automated test
If the test has a UI component, the system takes screenshots of the UI. View these screenshots to gain further insight into the test results.

Before you begin
You must have run the test whose results screenshots you want to view.
Note: For best results with screen shots, leave the browser zoom level set to 100%.

Role required: atf_test_admin or atf_test_designer

Procedure
1. Navigate to Automated Test Framework > Test Results.
2. Click the row containing the test whose results you want to view.
The system displays the **Test Results** form.

3. To view a screenshot taken during the test, find the screenshot you want in the attachments list. Screenshots are named with the word **screenshot** followed by the timestamp (always in UTC time) for when the system recorded the shot. You can match the screenshot to the test step by comparing the step and screenshot timestamps.

**View automated test suite results**
View results from an automated test suite.

**About this task**

ℹ️ **Note:** You have multiple options for navigating to the test suite results, depending on where you are in the user interface. For example, if the Run Test progress dialog is displayed, you can click **Go to Result** instead. The procedure described here enables you to view test suite results from any location in the user interface.

**Procedure**

1. Navigate to **Automated Test Framework > Suite Results**.
2. Click the row containing the test whose results you want to view. The system displays the **Test suite results record**.

**Related information**

- Identify and resolve client errors
- Allow client errors from test results
- Allow client errors from step results
- Allow client errors from the test logs

**Identify and resolve client errors**
Identify client errors and resolve them in client-side scripts.

**Before you begin**
Role required: admin

**About this task**

When client errors occur, the Automated Test Framework fails the test on the step that was executing when the error occurred. Even though client-side scripts can fail silently on JavaScript errors while procedures are executing, the error may still impact data, and the procedure being executed. The Automated Test Framework considers these errors as validation failures.
Procedure

1. Navigate to Application > Automated Test Framework > Tests and run an Automated Test Framework test that interacts with a form.

2. In the test results for this test, check for a step result with the following summary:

   This step failed because the client error 'DETAILED ERROR MESSAGE' was detected on the page being tested. See failing Test Logs. To ignore these errors in the next test run, use ‘Add all client errors to warning/ignored list’ links.

   This step result appears only on a step that interacts with the UI.

3. To identify and resolve these script errors, open the developer tools browser console on the Client Test Runner page.

   Note: For information about how to open the browser console, see the following article: http://webmasters.stackexchange.com/questions/8525/how-to-open-the-javascript-console-in-different-browsers

4. If you can see the error, try to identify and troubleshoot the problematic client-side script, which may be on any of the following base system tables:
   - ServiceNow Client Script
   - UI Action
   - UI Macro (HTML script)
   - UI Page (HTML script)
   - UI Policy
   - UI Script
   - Tables that extend the preceding base system tables

5. Review the script for errors and once you've fixed them, run your test again.

What to do next
Determine the source of the client error by reviewing the script version history. If you customized a base system script, it's possible that the script has new versions that were skipped during upgrade.

Example client errors
There are several types of common client error.
**Client JavaScript errors**

When a client script causes an error, the browser console displays an error similar to the following example:

```
***************************************************
A script has encountered an error in render events
TypeError: Cannot read property 'id' of undefined
Script ends. Continuing happily
***************************************************
[00:00:00.002] onLoad Modify Comments Label
```

In this example, the client script Modify Comments Label caused the error.

**Other client script errors**

Any other type of script error reports directly to the browser console with any formatting upon occurrence.

`TypeError: callbacks(id) is undefined`

**Script resource links by Sys ID**

In some cases, the console error provides a link to the script resource file using its Sys ID. Following this link may give context to which script had executed it.

```
Uncaught ReferenceError: myobj is not defined
  at incident.do?sys_id=12345678901234567890123456789012
(anonymous) @ incident.do?sys_id=12345678901234567890123456789012  <----- LINK
```

**Script access permissions**

While identifying problematic scripts, be sure the script has permission to access data. Check:

- Access control rule permissions for tables and fields.
- Application access permissions if the script accesses applications in a private scope.
- Domain separation permissions if domain separation is configured.

**Related information**

- [Allowed client errors](#)

**UI test steps**

Test user interfaces by mimicking user actions and interacting with the visible components of a page.
Client test runner dependency
UI test steps require an active client test runner to act directly on the visible components of a page. A tester must manually start one or more client test runners for UI testing. Test designers can schedule selecting an open client test runner from a test suite. See Working with client test runners.

Intelligent wait mechanism
UI test steps have an intelligent wait mechanism triggered by UI changes such as clicking a component or setting a value. The wait mechanism requires the UI change to complete before the next UI test step can proceed. Test designers do not need to manually add wait mechanisms between UI test steps.

Custom UI test steps
Test customized user interfaces such as UI pages and UI macros by retrieving their HTML and JavaScript page components and identifying the test actions they support.

Custom UI test steps require the Automated Test Framework to retrieve and identify the testable components from a target web page.

Testable components
Testable page components consist of standard HTML and JavaScript with these characteristics.

Are set or clicked by user interaction
Testable page components allow users to set a value or click them.

Are accessible from the Document Object Model (DOM)
Testable page components are accessible from the DOM and support JavaScript manipulation of the DOM. Custom UI test steps cannot access page components in the shadow DOM.

Are accessible to JavaScript
Testable page components are accessible to JavaScript. Custom UI test steps cannot access page components that interact directly with the operating system such as file fields or display non-HTML content such as Excel or PDF files.

New browser tabs or windows are not supported by Custom UI test steps.

Are not excluded from custom UI testing
Testable page components are not excluded from custom UI testing. Automated Test Framework excludes page components
that are already testable by other test step categories and also excludes page components associated with Now Platform features.

**Are accessible to the Page Inspector**

Testable page components must return results when viewed from the Page Inspector. Test designers can use the Page Inspector to identify the testable components of a page.

Examples of testable page components include these UI elements.

- Buttons
- Links
- Page text
- UI controls
- UI macros
  - ui_date
  - ui_date_time
  - ui_reference
- UI pages
- Wizards

Examples of untestable page components include these UI elements.

### Example untestable page components

<table>
<thead>
<tr>
<th>Reason untestable</th>
<th>Untestable page components</th>
</tr>
</thead>
<tbody>
<tr>
<td>Are not settable or clickable</td>
<td>Hidden controls</td>
</tr>
<tr>
<td></td>
<td>HTML comments</td>
</tr>
<tr>
<td></td>
<td>HTML layout elements such as div, section, and span.</td>
</tr>
<tr>
<td></td>
<td>HTML script elements</td>
</tr>
<tr>
<td>Are inaccessible from DOM</td>
<td>Dashboards</td>
</tr>
<tr>
<td></td>
<td>Images</td>
</tr>
<tr>
<td></td>
<td>Lists</td>
</tr>
<tr>
<td></td>
<td>Reports</td>
</tr>
<tr>
<td></td>
<td>Shadow DOM</td>
</tr>
</tbody>
</table>
Example untestable page components (continued)

<table>
<thead>
<tr>
<th>Reason untestable</th>
<th>Untestable page components</th>
</tr>
</thead>
<tbody>
<tr>
<td>Are inaccessible to JavaScript</td>
<td>Excel files</td>
</tr>
<tr>
<td></td>
<td>File fields</td>
</tr>
<tr>
<td></td>
<td>PDF files</td>
</tr>
<tr>
<td>Are Now Platform features</td>
<td>Flow Designer</td>
</tr>
<tr>
<td></td>
<td>Studio</td>
</tr>
<tr>
<td></td>
<td>Upgrade Monitor</td>
</tr>
<tr>
<td>Are testable by other test step categories</td>
<td>Form field labels</td>
</tr>
<tr>
<td></td>
<td>Form field values</td>
</tr>
<tr>
<td></td>
<td>Service Catalog</td>
</tr>
<tr>
<td></td>
<td>Workspaces</td>
</tr>
</tbody>
</table>

Settable page components

A _settable_ component is a UI element that has a dynamic value such as a text input field. Settable components support these test actions and test steps.

Test options for settable components

<table>
<thead>
<tr>
<th>Page Inspector actions</th>
<th>Custom UI test steps</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set Component Value</td>
<td>Set Component Values (Custom UI)</td>
</tr>
<tr>
<td>Get Component Value</td>
<td>Assert Text on Page (Custom UI)</td>
</tr>
<tr>
<td></td>
<td>Component Value Validation (Custom UI)</td>
</tr>
<tr>
<td>Is Component Disabled</td>
<td>Component State Validation (Custom UI)</td>
</tr>
</tbody>
</table>

Settable components have a _data type_ that determines what values a Custom UI test step can set. For example, a page component intended to display a reference to a particular record can have a reference data type to only display Sys ID values.

Automated Test Framework allows UI developers to specify a data type to use during custom UI testing. UI developers can assign page components a data type to ensure that a test step sets a valid value. These data types are supported.
• Date
• Date Time
• Reference

See Override component data type for more information.

**Clickable page components**

A clickable component is a UI element that users can interact with by clicking, such as inputs of type check box or radio. Clickable components support these test actions.

<table>
<thead>
<tr>
<th>Test options for clickable components</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Page Inspector actions</strong></td>
</tr>
<tr>
<td>Click On Component</td>
</tr>
<tr>
<td>Get Component Value</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>Is Component Disabled</td>
</tr>
</tbody>
</table>

Clickable components do not have a data type since they do not have dynamic values.

**Retrieved page components**

Automated Test Framework stores a list of the retrieved page components for each custom UI page you test. Custom UI test steps display the list of retrieved components from the **Component** and **Component values** fields.

By default, the list of page components is static and is only updated when Test designers manually click **Retrieve Components**. Administrators can enable the system property **sn_atf.page_data_capture.enabled** to refresh the list of page components every time a Custom UI test step is run. Enabling this property during test design ensures that your test designers always have access to the most current list of page components. Disabling this property after test design is complete allows your tests to run faster because test steps can use the previously retrieved list of page components.

The Now Platform treats the list of retrieved page components as data and does not include them in update sets or applications files. When transferring tests from one instance to another, test designers must manually retrieve page components again.

Design considerations

Follow these design considerations when testing custom UI pages and page components.

Use the page inspector to identify testable page components

The page inspector determines which page components are available for custom UI testing. Page components that are unavailable to the page inspector are unavailable to custom UI testing.

Navigate to the custom UI you want to test

Use existing test steps to navigate to the target custom UI. For example, to test a Knowledge Base article, use the existing test steps to navigate to a module or to open an existing record. Most custom UI testing requires using existing test step categories as part of the test.

Use the component area to identify page components

The component area describes the HTML layout element containing the component such as a `<div>` or `<section>` element. The area helps test designers distinguish between components by providing the location in the page layout.

Test your custom UI rather than Now Platform UI

The Automated Test Framework prevents custom UI testing of Now Platform features. For example, you cannot test dashboards or graphical designers. Instead, build tests to validate your custom UI pages and elements since you have direct control over these user interfaces.

Use HTML attributes to override page component testing properties

Change the testing properties of a particular page component using Automated Test Framework-specific HTML attributes. See Override component test actions.

Retrieve page components again when you move tests to another instance

Custom UI test steps do not store UI components as metadata. Testers must manually retrieve page components again when moving tests between instances.

Example custom UI testing

You can use the list of retrieved components to design custom UI test steps. For example, suppose that you want to test reviewing and commenting on
a Knowledge Base article. A Knowledge Base article contains several page components that require custom UI steps to test.

For example, these page components require custom UI test steps.

1. The number of article views.
2. The buttons to mark the article as Helpful.
3. The text area to Leave a comment.

These steps demonstrate custom UI testing on a Knowledge Base article. The example test consists of these existing and custom UI test steps.

1. **Navigate to Module.** Navigate to the 'Published' module in the 'Knowledge' application.
2. **Open an Existing Record.** Open the 'Knowledge' form with id 'Knowledge: KB0011110'.
3. **Click a UI Action.** Click UI Action 'View Article' on 'Knowledge' form.
4. **Assert Text on Page (Custom UI).** Assert that the text 'developers' is on the page.
5. **Set Component Values (Custom UI).** Set the components on the page as follows: `Textarea <textarea> [article_comments]` = Update with actual article rather than URL to article elsewhere.

6. **Click Component (Custom UI).** Click the component: 'Button <button>: Comment'.

7. **Assert Text on Page (Custom UI).** Assert that the text 'Update with actual article rather than URL to article elsewhere.' is on the page.

### Example test steps for a knowledge base article test

![Example test steps for a knowledge base article test](image)

**Custom UI component version and order**

When you select a component in any of the custom UI test steps, the Custom UI version might show up. If there are multiple
duplicate components, the order of the components show up.

⚠️ **Note:** The Custom UI version shows up only if there are at least two different components with different Custom UI versions.

⚠️ **Note:** The Order shows up only if there are duplicate components in the component drop-down menu. You can disambiguate them according to the displayed order.

⚠️ **Note:** Both Custom UI version and Order show up if there are multiple duplicate components from different versions.

**Identifying components**
Implement an alternative way to identify your component by using the sn-atf-id attribute. This is useful if the name or id attribute of your component is dynamic and changes every time a test runs. Add the sn-atf-id attribute with a consistent value to allow ATF identify your component when running a test. It also allows you to identify your component when building a test. For example, in a button component

```html
<button sn-atf-id="consistentValue">Test</button>
```

⚠️ **Note:** Starting with the Rome release, if you have exactly one component on the page that has sn-atf-id attribute, ATF finds that component irrespective of any other attributes on that component.
**Improve ATF component identification**

Identify your component using the label path included in the **Page area** column. Starting with the Rome release, the `sn_atf.element.use_label_path` property has been set to true by default.

If a component has the `sn-atf-area` attribute, the **Page area** column displays the `sn-atf-area` value. If the `sn-atf-area` attribute is not present, the label path for that component is shown in the **Page area** column.

⚠️ **Note:** If you have multiple, identically named Label values, the label path helps you identify the correct component.

⚠️ **Note:** If a component doesn't have an `sn-atf-area` attribute or a label path, the value is displayed as default.

When you select the required component from the list and click **Submit**, the description of the test step also gets updated with more details.
Page Inspector

Identify the HTML and JavaScript page components in your user interfaces that are available for custom UI testing. Enable automated testing by ensuring that your user interfaces only contain testable page components.

The Page Inspector is a developer setting that opens a new pane beside any currently displayed Now Platform page.

The Page Inspector provides these features.

1. A highlighted frame to identify the currently inspected page.
2. A banner icon to display or hide the Inspector pane.
3. A button to refresh the list of page components.
4. A button to hide the Inspector pane.
5. An inspector button to identify specific components on a page.
6. A list of page components available for custom UI testing.
7. A page component search filter.
8. A row to click to see more information about a page component.
9. A highlighted row and tooltip to preview information about the currently inspected component.
10. A highlighted page component to identify the currently inspected component on the page.
11. A component label and back button to return to the list of page components.
12. A list of actions to take on the current page component.
13. A list of attribute information for the current page component.
14. An attribute name and value pair for a page component.

**Page Inspector view of component details**

The page inspector launcher helps you select and launch a specific page within the page inspector. See *Inspect different page types* for more information.
Testable page components

The Page Inspector retrieves the list of testable page components when you first load a page. Testable components consist of standard HTML and JavaScript that are accessible to the Automated Test Framework. Test designers can use these components as part of custom UI testing.

Untestable page components

The Page Inspector identifies these types of untestable page components.

Exclusion listed

Exclusion listed page components can't be tested using any Custom UI test steps. Exclusion listed page components typically include specialized Now Platform user interfaces and components already testable by other means. Test designers can't create custom UI tests for exclusion listed page components. To test these components, they must use another supported test category such as Forms or Service Catalog.

In the Page Inspector, the exclusion listed interfaces are indicated by a grey background color when the inspect icon is dragged over them. A detailed message about the step category that needs to be used to test these components is displayed by dropping the inspect icon on an exclusion listed component.

- Lists can't be tested using custom UI test steps. Use List and Related List test step category to test lists.

Sample exclusion listed list message

© 2021 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
• Forms can't be tested using custom UI test steps. To test forms, use Form category test steps.

**Sample exclusion listed form message**

1. Forms are not supported by Custom UI steps. Use the Form category to test forms

**Note:** The UI formatters within forms can be accessed and tested using custom UI test steps. See Create a custom UI test for more information.

• Service Catalog items can't be tested using custom UI test steps. To test catalog items, use Service Catalog category test steps.

**Sample exclusion listed catalog item message**

1. Service Catalog is not supported by Custom UI steps. Use the Service Catalog step category

• Certain components are excluded from custom UI pages and are forbidden from being tested.

**Sample exclusion listed component message**

1. This component is not accessible

• Workspaces can't be tested using custom UI test steps. To test forms in an available workspace, use Form category test steps.

**Sample exclusion listed workspace message**

1. Workspaces are not supported by Custom UI steps. Use the Form Step category to test forms in workspaces

---

**Inaccessible**

**Inaccessible** page components are elements that Automated Test Framework either cannot identify or does not have permission to test because of some configuration issue. Inaccessible page components typically include third-party JavaScript libraries or elements with a Shadow DOM. Test designers cannot create custom UI tests for inaccessible page components, but may be able to redesign the page to use components accessible to Automated Test Framework.

• Certain components are not accessible in the Automated Test Framework

**Sample inaccessible component message**

1. This component is not accessible

• Team development is not supported in the Automated Test Framework
Inspect different page types

Inspect and troubleshoot the functionality of different page types like UI Pages, Service Portal, Standard UI, and Custom URL using the Page Inspector.

Before you begin
Role required: admin, atf_test_designer, atf_test_admin

Procedure
2. Select the Page Type you want to inspect.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UI Pages</td>
<td>Existing UI pages. Select a starting page from the available list.</td>
</tr>
<tr>
<td>Standard UI</td>
<td>Standard platform forms, lists, and some UI pages. Select a form or a list or a UI page in the Starting Page field. Note: The optional Record field shows up only if you select a form in the Starting Page field.</td>
</tr>
<tr>
<td>Service Portal</td>
<td>Any available portal in the instance. Select an available portal and a starting page to be inspected. Note: Portal field shows up only if you select Service Portal as the Page Type.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>Custom</td>
<td>Custom Platform URL to be inspected.</td>
</tr>
</tbody>
</table>

⚠️ **Note:** Don’t copy-paste the complete URL onto the Starting Page URL field. For example, include only `/home.do` as the input if you want to inspect `https://instance.service-now.com/home.do`

3. Click **Inspect**.

### Enable and use the page inspector

Enable a developer setting to inspect UI pages that open within the platform. Use the Manual Page Inspector to inspect pages that open in a new tab, such as Service Portal pages.

**Before you begin**

Role required: admin

**About this task**

Identify the HTML and JavaScript page components in your user interfaces that are available for custom UI testing. Enable automated testing by ensuring that your user interfaces only contain testable page components.

**Procedure**

1. Enable the Page Inspector depending on the type of custom UI page you need to inspect. Some custom UI pages open in a new tab and can only be inspected manually.

<table>
<thead>
<tr>
<th>Option</th>
<th>Procedure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inspect page opening in the Now Platform.</td>
<td><strong>a.</strong> Navigate to the record or URL for the page you would like to inspect.</td>
</tr>
<tr>
<td></td>
<td><strong>b.</strong> Open System Settings and select the Developer tab.</td>
</tr>
<tr>
<td></td>
<td><strong>c.</strong> Enable Automated Test Framework Page Inspector.</td>
</tr>
<tr>
<td>Option</td>
<td>Procedure</td>
</tr>
<tr>
<td>--------</td>
<td>-----------</td>
</tr>
<tr>
<td>Inspect page opening in a new tab, such as a Service Portal page.</td>
<td>The page opens in the Page Inspector and the inspect icon appears in the banner frame.</td>
</tr>
</tbody>
</table>

b. Set the Page Type and select the page. If the page type is Service Portal, select the portal in which the page opens.  
c. Click Inspect.  
The page opens in the page inspector.

2. Select a component to inspect.  
   - Drag the inspect icon (✠) from the Page Inspector pane to a component on the page.  
   - Select an available component from the Page Inspector pane.  
The Page Inspector retrieves the list of testable page components when you first load a page. Testable components consist of standard HTML and JavaScript that are accessible to the Automated Test Framework. Test designers can use these components as part of custom UI testing.

3. View component information and perform actions available in the Action field.  
Performing available actions helps you manually confirm which test steps are available to a component. For example, when you select Click On Component, the Page Inspector selects the component and displays the resulting page.

What to do next  
Create a custom UI test

Create a custom UI test
Test components in custom UI pages.

Before you begin  
- Use the Page Inspector to identify testable custom UI components. See Enable and use the page inspector.  
- Role required: admin
Procedure
1. Navigate to Automated Test Framework > Tests.
2. Click New.
3. Enter a name and description for your test.
4. Click Save.
5. In the Test Steps related list, click Add Test Step.
6. Add test steps to navigate to the target custom UI page.

Example
Use the Navigate to Module step to open a page that has an application navigator module. Use the Open Service Portal Page step to open a portal page.
To open a UI page, use these test steps:

a. Open an Existing Record: Open the record for the page.

b. Click UI Action: Click the Try It UI action to open the page.

7. Add test steps from the Custom UI category to validate the behavior of custom UI components. For a list of available Custom UI test steps, see Custom UI category.

8. Retrieve UI components when adding a test step.

Identify the testable page components on a custom UI page by retrieving a list of UI components for test steps. You can collect the components of the current page by selecting Retrieve Components.

The system retrieves the components using an existing or a new client test runner. Ensure that the client test runner tabs used in the retrieval process are running in the foreground. For tests that don’t yield any components after selecting Retrieve Components, the following warning message is displayed and the Next button is disabled.
If you have already retrieved a list of page components, click **Next** to use the previously retrieved list. You can also click **Retrieve Components** to rerun the current steps and refresh the list of testable page components. If the test fails while retrieving components, the following warning notification is displayed. You can review the test results by clicking the link in the notification.

Automated Test Framework stores the list of page components and displays the list in the **Component values** or **Component** field on the test step form. The field displays this information about each component:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>HTML element description and tag. For example, <code>Text&lt;input&gt;</code>.</td>
</tr>
<tr>
<td>Label</td>
<td>HTML component label.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Value</td>
<td>Value of the component. For example, if the component is a search input, the value might be <strong>Search</strong>.</td>
</tr>
<tr>
<td>Page area</td>
<td>HTML layout element that contains the component such as a <code>&lt;div&gt;</code> or <code>&lt;section&gt;</code> element.</td>
</tr>
</tbody>
</table>

If you create a parameterized test that includes Custom UI test steps, the system only uses the first data set to retrieve components.

**What to do next**
Consider adding tests to a test suite. For more information, see Building and running automated test suites.

**Override component test actions**
Change the testing properties of a particular page component using Automated Test Framework-specific HTML attributes.

**Before you begin**
Role required: admin

**About this task**
When Automated Test Framework retrieves a component, it determines which interactions it supports, such as whether it is a settable or clickable component. If the component is settable, Automated Test Framework determines the field type that can be set. If Automated Test Framework incorrectly determines your custom component's actions or field types, or your component contains multiple DOM elements that should be treated as one entity, explicitly set them using Automated Test Framework-specific HTML attributes.

**Using sn-atf-clickable and sn-atf-settable attributes**
Use `sn-atf-clickable` and `sn-atf-settable` attributes to specify that an element and its child elements should be treated as a custom clickable or custom settable component.

**Before you begin**
Role required: admin

**Procedure**
1. Open the custom UI page you would like to test.
2. Add the `sn-atf-clickable` or `sn-atf-settable` attribute to the element being tested.
Example

```html
<div sn-atf-clickable="true" sn-atf-disabled id="customClickable">
    <button id="customButton">Click me</button>
</div>

<div sn-atf-settable="true" id="customSettable" sn-atf-component-value="A default value">
    <input id="customInput" value="A default value"></input>
</div>
```

**Note:** You can use either `sn-atf-clickable` or `sn-atf-settable` attribute to specify if an element should be treated as a custom clickable or custom settable component. You can’t use both attributes on the same element.

3. Use either the `sn-atf-clickable` or `sn-atf-settable` attribute.

- **sn-atf-clickable**: If you added the `sn-atf-clickable` attribute, ATF clicks the component by sending an `sn-atf-click` event to the DOM element with the `sn-atf-clickable` attribute. You should add an event listener (for example, using `addEventListener`) to this DOM element, and implement your custom click logic for the component. You can interact with a custom clickable component using Click Component test step.

<table>
<thead>
<tr>
<th>Attribute name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sn-atf-disabled</code></td>
<td>The presence of this optional attribute (regardless of its value) tells ATF that this component is disabled</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> If this attribute is missing, ATF considers that this component is enabled by default.</td>
</tr>
<tr>
<td><code>sn-atf-component-value</code></td>
<td>A string or JSON object that tells ATF the current value of this component</td>
</tr>
</tbody>
</table>

- **sn-atf-settable**: If you added the `sn-atf-settable` attribute, ATF sets the component value by sending an `sn-atf-setvalue` event to the DOM element with the `sn-atf-settable` attribute. You should add an event listener (for example, using `addEventListener`) to this DOM element, and implement your custom set value logic for the component. The value that needs to be set can be accessed with `event.detail.newvalue`. The `event` argument is passed to your event handler. You can interact with a custom settable component using Set Component Values test step.
## Settable component attributes

<table>
<thead>
<tr>
<th>Attribute name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sn-atf-disabled</td>
<td>The presence of this optional attribute (regardless of its value) tells ATF that this component is disabled.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> If this attribute is missing, ATF considers that this component is enabled by default.</td>
</tr>
<tr>
<td>sn-atf-component-value</td>
<td>A string or JSON object that tells ATF the current value of this component.</td>
</tr>
<tr>
<td>sn-atf-data-type</td>
<td>Optional type of field to present to user when building a step. It defaults to string. For example, glide_date_time, reference, boolean, etc.</td>
</tr>
<tr>
<td>sn-atf-data-type-params</td>
<td>JSON object with more data type details.</td>
</tr>
</tbody>
</table>

### Example:

```html
//A custom clickable component

<div sn-atf-clickable="true" sn-atf-disabled id="customClickable">
  <button id="customButton">Click me</button>
</div>

<script>
  var customClickableDiv = document.getElementById("customClickable");
  customClickableDiv.addEventListener('sn-atf-click', function() {
    document.getElementById('customButton').click();
  });
</script>

//A custom settable component

<div sn-atf-settable="true" sn-atf-component-value="A default value">
  <input id="customInput" value="A default value"/>
</div>

<script>
  var customSettableDiv = document.getElementById("customSettable");
  customSettableDiv.addEventListener('sn-atf-setvalue', function(event) {
```
Using sn-atf-class attribute

Use the `sn-atf-class` attribute to specify the JavaScript object to use when testing a custom clickable or settable component. Write a custom JavaScript object to specify the test actions available for a custom component.

Before you begin
Role required: admin

About this task
Test designers can manually specify the test actions available for a custom component by writing a custom JavaScript object and assigning the component a `sn-atf-class` attribute. Set the value of the attribute to the name of the JavaScript object containing the component test actions. Testable custom components must be either clickable or settable, and this classification determines the functions and properties your JavaScript object requires. See Custom UI test steps for testable page component requirements.

Procedure
1. Open the custom UI page you would like to test.
2. Add the `sn-atf-class` attribute to the element being tested. Set the value to the name of the JavaScript object embedded in the page that handles `getValue()`, `setValue()`, `click()`, or `isDisabled()` functions.

Example

```html
<div sn-atf-class="MyClickableComponent">
  <label for="a_clickable_checkbox">MyClickableComponent</label>
  <input type="checkbox" id="a_clickable_checkbox" checked="true"/>
</div>
```

3. Create the JavaScript object specified in the `sn-atf-class` attribute.
   Add the functions and attribute needed to identify your custom page component as either a clickable or settable page component.

   **Clickable component functions**

<table>
<thead>
<tr>
<th>Function name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>initialize()</code></td>
<td>Gets the initial values of the component. Enter:</td>
</tr>
<tr>
<td>Function name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------</td>
</tr>
<tr>
<td>$super(element, area)</td>
<td></td>
</tr>
</tbody>
</table>
| click() | Selects the component. Returns a JSON object with these properties:  
| • success: true if the component can be clicked.  
| [Note: Triggers the UI test step intelligent wait mechanism.](#) |
| getValue() | Gets the value of the element. Returns a JSON object with these properties:  
| • success: true if the value is retrieved.  
| • result: the value of the component. |
| isDisabled() | Whether the component is disabled. Returns a JSON object with these properties:  
| • success: true if the component is disabled.  
| • result: true if the component is disabled. |

### Settable component functions

<table>
<thead>
<tr>
<th>Function name</th>
<th>Description</th>
</tr>
</thead>
</table>
| initialize() | Gets the initial values of the component. Enter:  
| $super(element, area) |
| setValue(newValue) | Sets the value of the component. See the second example below. Returns a JSON object with these properties:  
| • success: true if the value is set.  
| [Note: Triggers the UI test step intelligent wait mechanism.](#) |
| getValue() | Gets the value of the element. Returns a JSON object with these properties:  
| • success: true if the value is retrieved.  
<p>| • result: the value of the component. |
| isDisabled() | Whether the component is disabled. Returns a JSON object with these properties: |</p>
<table>
<thead>
<tr>
<th>Function name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• success: true if the component is disabled.</td>
<td></td>
</tr>
<tr>
<td>• result: true if the component is disabled.</td>
<td></td>
</tr>
</tbody>
</table>

**Settable component attribute**

<table>
<thead>
<tr>
<th>Attribute name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>isSettable: true</td>
<td>Identifies the component as a settable page component.</td>
</tr>
</tbody>
</table>

4. When creating your custom component in Jelly, add `<g2:atf_only>` tags around the JavaScript object specified in the `sn-atf-class` attribute. These tags ensure the system only runs the JavaScript object during automated testing.

**Example:**

```javascript
//A custom clickable component

<form>
  <div sn-atf-class="MyClickableComponent">
    <label for="a_clickable_checkbox">MyClickableComponent</label>
    <input type="checkbox" id="a_clickable_checkbox" checked="true"/>
  </div>
</form>

<script>
var MyClickableComponent = {
  // The constructor must have this signature, but you can perform additional setup after
  // the $super(element, area) call
  initialize: function($super, element, area) {
    $super(element, area);
  },

  click: function() {
    document.getElementById('a_clickable_checkbox').click();
    return {success: true};
  },

  getValue: function() {
    var isChecked = document.getElementById('a_clickable_checkbox').checked ? "true" : "false";
    return {success: true, result: isChecked};
  }
};
```

© 2021 ServiceNow, Inc. All rights reserved. ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc. in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
// The function returns an object with a result attribute of type Boolean
isVisible: function() {
  if (document.getElementById('a_clickable_checkbox').disabled)
    return {success: true, result: true};

  return {success: true, result: false};
},

};
</script>

// A custom settable component

<form>
  <div sn-atf-class="MySettableComponent">
    <label for="a_settable_checkbox">MySettableComponent</label>
    <input type="checkbox" id="a_settable_checkbox" checked="true"/>
  </div>
</form>

<script>
var MySettableComponent = {

  // This attribute is required for settable components
  isSettable: true,

  // The constructor must have this signature, but you can perform additional setup after
  // the $super(element, area) call
  initialize: function($super, element, area) {
    $super(element, area);
  },

  // The value parameter is a string
  setValue: function(value) {
    document.getElementById('a_settable_checkbox').checked = (value == "true");
    return {success: true};
  },

  // The function returns an object with a result attribute of type String
  getValue: function() {
    var isChecked = document.getElementById('a_settable_checkbox').checked ? "true" : "false";
    return {success: true, result: isChecked};
  }
};
</script>
Reference and record picker

Use custom UI steps to manipulate the values of the `sn-reference-picker` and `sn-record-picker` angular directives. The value on a reference picker returns the `sys_id` of the chosen record. The value on a record picker returns the value field chosen for that record picker. Both elements can be set by selecting a record to set as their value.

Override component data type

Use the `sn-atf-data-type` and `sn-atf-data-type-params` attributes to override the type of field displayed in a Set Component Value test step.

Before you begin
Role required: admin

About this task
Settable components have a data type that determines what values a Custom UI test step can set. For example, a page component intended to display a reference to a particular record can have a reference data type to only display Sys ID values.

Procedure
1. Open the custom UI page you would like to test.
2. Add the `sn-atf-data-type` attribute to the settable component. Set the value to the field type you would like displayed in the Set Component Value test step.
   
   This attribute contains a string of the testable data type. Available values include:
<table>
<thead>
<tr>
<th>Attribute value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide_date</td>
<td>Contains a string specifying a particular day.</td>
</tr>
<tr>
<td>glide_date_time</td>
<td>Contains a string specifying a particular day and time of day.</td>
</tr>
<tr>
<td>reference</td>
<td>Contains a Sys ID to a related record. This data type requires specifying additional information in the <code>sn-atf-data-type-params</code> attribute.</td>
</tr>
</tbody>
</table>

3. Add the `sn-atf-data-type-params` attribute to provide additional information when the value of `sn-atf-data-type` is `reference`.

This attribute contains a string of JSON formatted key-value pairs. Available key-value pairs include:

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>reference</td>
<td>Name of the table that contains the records you want the reference field to display. For example, add &quot;reference&quot;:&quot;incident&quot; to display records from the Incident table.</td>
</tr>
<tr>
<td>reference_qual</td>
<td>Filter to apply to the query. For example, add &quot;reference_qual&quot;:&quot;active=true&quot; to display only active Incident records. See Reference qualifiers</td>
</tr>
</tbody>
</table>

**Example:**

```html
<input id="someTextField" value="someSysId" sn-atf-data-type="reference" sn-atf-data-type-params='{"reference":"incident","reference_qual":"active=true"}'/>
```

**Select2 functionalities in ATF**

Use the Select2 component to search and select your option from a drop-down menu easily.

You can set the value of select2 in a test. The test then searches for the value in the search bar of Select2. The first valid result in the component drop-down gets selected.

Drag and drop the page inspector on the required drop-down menu. The right panel for the selected component opens. You can specify the text you want to search in the set component value step within the page inspector.
Select the **Set Component Value** option under **Action** to search for a component. Type in the text in the right panel and click **Submit**. This enables the code to open the select2 to search for that component and pick the first option that shows up.

<details>
<summary>Note:</summary>
If multiple, similarly named component options show up on searching a term, only the first option is selected.

</details>

### Limitations of the select2 support
- Only certain versions (3.5.1-3.5.4 and 4.0.0-4.0.13) of the select2 library are supported.
- The select2 support depends on the jquery library. So, if you try to set a value of select2 and the name of the jquery library is changed, it causes the test to fail.
- Searching through Select2 won’t work when there is no search bar.

### Design considerations
Search and select your options efficiently with the following design considerations:
- It is recommended to use uniquely searchable test data
- Use a Component Value Validation step to validate the value set for select2
- Prevent failing of tests by avoiding jquery library name change
- Select2 Adapter and Decorator features are not supported
Browser recommendations for Automated Test Framework

Configure client test runner browsers to run automated tests and avoid performance degradations.

Periodic browser restarts
These browsers have memory-management limitations that make it necessary to occasionally close and restart the browser when running the client test runner.

- Internet Explorer
- Edge
- Older versions of Firefox

How often you should close the browser depends on the memory allocation in the browser application.

Browser CPU throttling
Some browsers throttle CPU usage for windows that are out of focus. Follow these guidelines to avoid CPU throttling issues.

- Run each client test runner in its own browser window.
- Ensure that the client test runner browser window is always partially visible on the screen.
- Ensure that the system screen is not locked or shut off.

Browser zoom level
Client test runners take screen shots as they run tests. For best results with screen shots, leave the browser zoom level set to 100%.

OS X CPU throttling
On OS X with the client test runner on Chrome or Safari: If the screen is locked or the client test runner tab is occluded when the system attempts to run the test suite, tests run significantly slower and may time out. For best performance, run client test runners for scheduled suites in a virtual machine (VM) environment in which the screen does not become locked or disabled.

Rollback in browser sessions
The session cookies roll back all the changes made during a test. When a test is running, everything performed in that session is recorded for rollback. Don't modify your instance when a test is running in the same browser session. For example, if you modify records while a test is running in the same session, the changes are rolled back after the test completes. If you navigate around in
other tabs in the same session, your work may be rolled back and interfere with
tests that rely on implicit navigation.

Parallel testing

Follow these guidelines to avoid issues when running multiple tests in parallel.

- **Run each client test runner in an incognito or private window**
  Because parallel tests roll back all changes tied to the same
  browser session, it's possible for legitimate changes made in another
  browser tab to be rolled back during parallel testing. To prevent
  unwanted rollback of changes, always run client test runners in their
  own browser session. Opening client test runners in an incognito or
  private window ensures that they always have their own browser
  session.

- **Close client test runner windows when testing is complete**
  To prevent unwanted rollback of changes, always close client
  test runners after testing is complete. Closing the browser window
  ensures that test rollback doesn’t revert any legitimate changes
  made in another browser tab.

Working with client test runners

If an automated test includes steps that involve a form or any other user-
interface (UI) element, it runs those steps in a browser tab or window called a
test runner or client test runner. The Automated Test Framework supports two
types of client test runners: Client Test Runners for manually started tests and
Scheduled Client Test Runners for tests started by a schedule.

When test execution is enabled, clicking the Client Test Runner module opens
the client test runner in the current browser session. If tests are waiting to be
run, the Client Test Runner runs a waiting test. If no test is running, the message
Waiting for a test to run displays in the client test runner.

While the client test runner is idle, it checks every five seconds for waiting tests to
start. This ensures that the system runs any tests it may have been unable to start
because no client with the proper configuration was available.

Note: The client test runner monitors for tests from the current session and
runs those tests as the logged-in user (unless it executes an Impersonate
User step). If you start a client test runner, log out from the current session,
and then log in again, the client test runner executes using the new session.

When the client runner is active, it displays the activity of the currently running
test in the **Execution Frame**.
Note: To prevent conflicts, the system allows only one test to run at a given time. This is true even if you have multiple client test runner windows open. If you submit tests to run when another test is already running, the system holds the new tests to run later. If a test remains waiting for more than ten minutes, the system cancels the test.

Test execution property
To work with the client test runner module, the test execution property must be enabled.

Note: By default, the system property that is used to run automated tests is disabled to prevent you from accidentally running these tests on a production system. To avoid data corruption or an outage, run tests only on development, test, and other non-production instances.

If the test execution property is disabled when you select this module, the system displays a message and a link to the automated test framework properties page where you can enable it.

Additional debugging functionality
If you have enabled additional debugging functionality, the client test runner module displays two tabs: Execution Frame and Debug Info. The Execution Frame displays the information normally shown by the client test runner and the Debug Info displays additional debugging information.

The system takes screen shots from the tests in the Execution Frame tab and records them to the test result record.

Browser recommendations for all tests and suites
• Some browsers have memory-management limitations that make it necessary to occasionally close and restart the browser when running the client test runner. These browsers include Internet Explorer, Edge, and older versions of Firefox. How often you should close the browser depends on the memory allocation in the browser application.

• Some browsers have features that throttle CPU time. To avoid problems, follow these guidelines:
  ◦ Run the client test runner in its own browser window.
  ◦ Keep the client test runner at least partially visible on the screen.
  ◦ Make certain the screen is not locked or shut off.

• The client test runner takes screen shots as the tests run. For best results with screen shots, leave the browser zoom level set to 100%.
**Browser recommendations for scheduled suites**

The client test runners for scheduled suites have additional browser requirements.

- On OS X with the client test runner on Chrome or Safari: If the screen is locked or the client test runner tab is occluded when the system attempts to run the test suite, tests run significantly slower and may time out. For best performance, run client test runners for scheduled suites in a virtual machine (VM) environment in which the screen does not become locked or disabled.

- The browser must meet the criteria you specified on the *Scheduled suite run record*.

- A client test runner meeting the criteria you specified on the *Scheduled suite run record* must be available to run the test suite at the scheduled time. The system cannot automatically open a client test-runner session.

**Javascript window command intercepts**

The Client Test Runner captures window object commands including `console.log`, `console.error`, `alert`, `confirm`, and `prompt`, with default responses where necessary.

- Any script that calls `window.confirm` receives a boolean response of `true`.

- Any script that calls `window.prompt` receives the string response `test value`.

**Active Test Runners table**

When you start a client test runner, the system registers that runner in the Active Test Runners table. You can view this table in the *Active Manual Test Runners* module and the *Active Scheduled Test Runners* module. These two modules provide views of the same table, filtered to show only manual or only scheduled test runners.

The Active Scheduled Test Runner module is useful when you create a scheduled suite run. For scheduled suite runs, you can specify the browser to use. To determine the name and version of a browser you want to use, start a scheduled test runner with that browser, then inspect that runner's record in the Active Scheduled Test Runners module.

The data in this table is transient. While the runner is active, it reports in to the system at a specified interval. If the runner does not report in at the expected time, the system marks the runner as inactive. After a period of time the system
deletes the runner. You can modify these intervals on the Automated Test Framework properties page.

Pick a browser
If the test or test suite you are running contains steps that work with a form (any step involving a UI), or any other UI test step element (such as Automated Service Catalog test steps), the Pick a Browser dialog appears after you click Run Test or Run Test Suite. The dialog asks you to choose among any currently-running test clients or start a new test runner.

Before you begin
You must have created the test you want to run.

The test execution property must be enabled. You must have an admin or atf_test_admin role to do so.

Note: The test execution property is disabled by default to prevent running tests on a production system. Run tests only on development, test, and other sub-production instances.

Role required: atf_test_admin, atf_test_designer, or admin

Procedure
1. All registered client test runners that are currently active appear in the Pick a Browser dialog. Choose the browser in which the test or test suite should run (or re-rerun, in the case of failed tests).
   - (Current session) indicates that the browser is currently running. See Working with client test runners.

2. Click Manage your test runners here as needed to view all client test runners registered for the current user.
   - See Active manual test runners.

3. When client test runners are only available in other browsers for the current user, Start a new test runner appears. Click it if you want to open a client test runner in this browser session.

4. Click the appropriate button to run the test. The button that appears is dependent on the type of test you are running:
a. Click **Run Test** if running a single test.

b. Click **Run Test Suite** if running a test suite.

c. Click **Re-run failed tests** if re-running failed tests.

**Results**
The test, test suite or failed tests run in the selected browser or client test runner. The Progress viewer appears for monitoring of the progress of the test run.

**Server test steps**
Test business logic and background processes by performing operations on the server.

Server test steps mimic non-interactive actions such as impersonating users, submitting or saving records, running server-side script, or making REST calls. Since server test steps run directly on the server, they do not require a client test runner. For more information about the server test steps, see **Server category**.

**REST test steps**
Test custom inbound web services and backwards compatibility by making REST calls.

REST requests can only be sent to the current instance. You cannot send a request to another instance or third-party at a remote address.

The REST test configuration only supports the XML and JSON response formats. Binary formats are not supported.

You can create tests that include steps from each of the test step configuration categories. The REST test configuration category contains the Send REST Request - Inbound and assert test configurations. Assert steps must immediately follow a **Send REST Request - Inbound** step. You can have multiple REST assert steps following a **Send REST Request - Inbound** step, but the assert steps cannot be separated from the **Send REST Request - Inbound** step by steps from other test categories. For more information about the REST test steps, see **REST category**.

**Authentication**
As part of the Automated Test Framework, there are two situations when you send REST requests:

- When you use the REST API Explorer to create and test a request
- When you run a test that contains a **Send REST Request - Inbound** step
When you use the REST API Explorer to create and test a request, and the request requires authentication, the REST API Explorer uses your credentials. When the ATF runs the test, the REST API Explorer uses the credentials of the user who scheduled the test. This means that a test might fail unintentionally because of the difference in privileges between the user who created the test and the user who runs the test.

To address the issue of user credentials, you can create a basic-authentication profile for a test user and then on the **Send REST Request - Inbound** form, specify that the profile be used when the test is run.

**Attachment test steps**

Test an attachment-dependent business rule by uploading an attachment either from a form or from a server-side API call. For example, you can have a business rule that doesn’t let you close an incident without an attachment such as a screenshot.

**Upload from form**

As a UI test step, the upload attachment step requires navigation to a form, which you can open using either **Open a New Form** or **Open an Existing Record**. Use **Upload Attachments** to select from the attachments that the test step adds to the form. When you select attachments to add to a form, the system waits to load the attachments before proceeding to the next test step. For more information on UI test dependency and wait mechanism, see **UI test steps**.

**Upload from Server API**

As a Server test step, the upload attachment step has no UI dependencies. Use **Upload Attachments** to select from the attachments that the test step adds to the record. When you select attachments to add to a form, the system waits for the attachments to be loaded before proceeding to the next test step. For more information, see **Server test steps**.

**Design considerations**

Follow these design considerations for attachment test steps:

- All attachment steps require adding one or more attachments.
- The system rolls back any attachments by the step after the test completes.
- The system cannot roll back any existing attachments after the test completes.
- Avoid testing records with existing attachments to eliminate data dependency.
• If UI testing is involved, add the attachment to a form.
• When no UI is involved, add the attachment to the Server API.

List UI actions test steps
Select a UI action from a list to perform different actions on a list or a related list. You can create a new UI action of the following types. See Create a UI action for more information.

• **List banner button**: Creates a button on the banner of a list.

![List banner button example](image)

• **List bottom button**: Creates a button at the bottom of the list.

![List bottom button example](image)

• **List context menu**: Adds an option to the context menu of the list.

![List context menu example](image)

• **List choice**: Adds an option to the list choice at the bottom of the list. You need to select one or more tests to enable the recently added list choice.
• **List link**: Adds a link to the **Related Links** list.

**Related Links**

- **Test_choice_&_link**
- **Test_list banner button**

**Design considerations**

- To use the **Click a List UI Action** test step, the test first needs to navigate to the list or the form with the related list containing the UI action.
- The **Related list** field appears only when you select Related list as the **List type**.
- **Action type** is mostly auto-filtered depending on the **List action** chosen.
- The **Record** field appears only when you select **Single record** for the UI action to be applied.
- Identify the specific record if you have selected **Single record** to apply the UI action.
- For the **Timeout** field to appear, select **Page reloaded or redirected** as the **Assert** type.

**Parameterized tests**

Run a test multiple times with different test data for each run. Create parameters to store test data for each test run.

Parameterized testing offers test designers these benefits.
• Eliminates the need to duplicate test steps just to change test data.
• Increases test reuse by separating test actions from test data.
• Produces a separate test result for each data set.

When the test runs, Automated Test Framework replaces the parameters with data set values. For example, you can create a test of the incident form that uses parameter values for the subcategory and priority fields. You can use one data set to test that the Antivirus category produces a high priority incident, and another data set to test that the Email category produces a low priority incident.

Note: The Run Server Side Script test step is not supported in parameterized tests.

Parameterized test components
Parameterized tests consist of these components.

Parameter

A parameter is a variable that stores a particular type of test data. Each parameter has a unique label and a data type. For example, you can create a parameter to store the Sys ID of a reference field or the integer value of a choice field. Define parameters during test design.

Parameters can be shared or exclusive. Shared parameters can be used in any parameterized test. Exclusive parameters can only be used with the test for which they were created. Each shared parameter is a column in the Test Run Data Sets [sys_atf_parameter_set] table. Each exclusive parameter is a record in the Parameter Variables [sys_atf_parameter_variable] table.

Data set

A data set, also known as a test run data set, includes runtime data used when the test runs. You can set a value for every parameter available to the current test. Data sets specify the parameter value during test runs. You can manually create data sets for a test, or import data from a file. Each data set is a record in the Test Run Data Sets [sys_atf_parameter_set] table.

Parameterized tests fail if data sets are not defined.

Design Considerations

Follow these design considerations when creating parameterized tests.
• Parameterized tests support standard Automated Test Framework features, such as reports, test suites, and data rollback. Copying a parameterized test copies all parameters, test run data sets, and test steps.

• If you create a parameterized test that includes Custom UI test steps, the system only uses the first data set to retrieve components.

Parameterized test runs
Automated Test Framework runs each parameterized test once per data set, using the same test steps and execution order. For example, if a parameterized test has five data sets, Automated Test Framework runs the test five times, once for each data set.

Parameterized test results
Parameterized tests display test results by the execution order of the data sets. Open each test result record to view the test details.

The Parameterized Test Result record Description field lists the parameters and data sets used in the test run.

Create a parameterized test
Build a test that uses variables to store test data.
Before you begin
Role required: atf_test_admin, atf_test_designer, or admin

Procedure
1. Navigate to Automated Test Framework > Tests.
2. Click New.
   A blank Test record opens.
3. Complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a name for the test.</td>
</tr>
<tr>
<td>Active</td>
<td>Enable</td>
</tr>
<tr>
<td>Enable parameterized testing</td>
<td>Enable</td>
</tr>
<tr>
<td>Description</td>
<td>Enter a description for the test.</td>
</tr>
</tbody>
</table>

4. Click Save.
   Parameterized testing related lists appear.

5. Create a parameter to hold test run data.
   A parameter is a variable that stores a particular type of test data. Each parameter has a unique label and a data type. For example, you can create a parameter to store the Sys ID of a reference field or the integer value of a choice field.

   a. In the Parameter Definitions related list, add a parameter.
      
      • Add Exclusive Parameters: Adds a parameter available to this test only.
      
      • Add Shared Parameters: Adds a parameter available to any parameterized test.

   b. Define the name of the variable and the data type. When creating parameters for a form, the parameter data type must match the field data type. For example, if you are creating a parameter to test a reference field on a form, you must create a parameter of type Reference. For more information on Now Platform data types, see Field types.

   c. Click Submit.

What to do next
Add a parameter to a test step
Add a parameter to a test step

Add a variable to a test step to hold a particular type of data when the test runs.

Before you begin

• Create a parameterized test
• Role required: atf_test_admin, atf_test_designer, or admin

About this task

⚠️ Note: The Run Server Side Script test step is not supported in parameterized tests.

Procedure

1. Navigate to Automated Test Framework > Tests.
2. Open a parameterized test.
3. In the Test Steps related list, create a test step or open an existing step.
4. Click to open a list of available parameters. Select a parameter to add it to a field. The parameter displays in the field.

Results

When the test runs, Automated Test Framework replaces the parameter with test run data.

What to do next

Add parameterized data sets.

Add parameterized data sets

Add or import test data to specify parameter runtime values.
Before you begin

- Create a parameterized test
- Add a parameter to a test step
- Role required: atf_test_admin, atf_test_designer, or admin

About this task

A data set, also known as a test run data set, includes runtime data used when the test runs. You can set a value for every parameter available to the current test. Data sets specify the parameter value during test runs.

Test designers can add data sets manually, or import data from a file.

Note: If you create a parameterized test that includes Custom UI test steps, the system only uses the first data set to retrieve components.

Procedure

1. Navigate to Automated Test Framework > Tests.
2. Open a parameterized test.
3. In the Test Run Data Sets related list, add or import data sets.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| Add    | The New Parameter Value Set form opens. This form includes all parameters available to the current test.  
  
a. Define the Order field to set the order in which data sets run.  
b. Specify the parameter value when the test runs.  
c. Click Submit. |
| Import | The Import Test Run Data Sets form opens.  
a. Define the import behavior.  
  
  • Add: Adds the data in the file to existing test run data sets in the Test Run Data Sets table. For more information, see Add a record in the template.  
  
  • Replace: Downloads a template that includes any existing data sets in the Test Run Data Sets table. Replaces all existing da-
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>a.</td>
<td>Data sets that have matching Sys IDs in the Test Run Data Sets table with data from the uploaded file. For more information, see Update a record in the template.</td>
</tr>
<tr>
<td>b.</td>
<td>In the Upload Test Run Data File section, select <strong>Yes</strong> to download an Excel template with the required fields, then upload a completed file. Alternately, select <strong>No</strong> to upload a completed file. Each row in the file becomes an entry in the Test Run Data Sets table.</td>
</tr>
</tbody>
</table>

**What to do next**

Click **Run Test**. Automated Test Framework runs each parameterized test once per data set, using the same test steps and execution order. For example, if a parameterized test has five data sets, Automated Test Framework runs the test five times, once for each data set.

Parameterized tests display test results by the execution order of the data sets. Open each test result record to view the test details.

**Allowed client errors**

Add known client errors to the allowed client errors list to allow tests and steps to continue running when a specific error occurs. Set the report level to specify what the Automated Test Framework does when the error occurs in future tests.

**Scenarios for allowing client errors**

Test designers and developers typically allow client-side JavaScript errors to prevent certain types of known failures from impacting test design and results. Scenarios to allow client errors include:

- **Timing constraints**
  
  Temporarily allow a client error until your developers have time to investigate and resolve the issue. For example, when testing an old form containing a longstanding bug.

- **Minimizing the impact of old libraries**
  
  Ignore client errors that cannot be fixed or are unimportant to your operations to eliminate their impact on future test runs. For example, when you find a bug in an old library.

- **Test design time**
  
  Temporarily allow client errors until you finish writing tests and have time to investigate the error. For example, one of your developers modifies a UI policy and the change generates an error.
Possible platform bug

Temporarily allow client errors until a fix is available. Prior to reporting a platform bug to ServiceNow Technical Support, investigate the error, verify it is not a customization error, and identify the type of platform bug involved. For example, a UI policy generates an error during a test. Your investigation verifies that the issue is not a customization error and identifies a platform issue with the UI policy.

Note: While adding client errors to the allowed client errors list allows the test framework to continue testing, it does not guarantee that your tests pass. Test designers and developers should always investigate client errors to determine if there are issues with your business process. For more details, see Identify and resolve client errors.

Report levels for allowed client errors

The report level indicates whether the test framework reports future occurrences of the error as a warning or ignores them altogether. You can change the report level of an allowed error at any time. For example, if you originally add an error as a warning, you can later change the report level to ignored.

<table>
<thead>
<tr>
<th>Report level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Warning</td>
<td>Test steps containing the allowed client error report a status of <strong>Success with warning(s)</strong>. The error message appears in the test result output, and is recorded in the test logs with the status <strong>Warning</strong>.</td>
</tr>
<tr>
<td>Ignored</td>
<td>Test steps containing the allowed client error report a status of <strong>Success</strong>. The error is recorded in the test logs with an <strong>Ignored</strong> status.</td>
</tr>
</tbody>
</table>

Matching process

The Automated Test Framework identifies allowed client errors using a contains search rather than an exact string match. A match occurs when a client error contains a message from an Allowed Client Error [sys_atf_whitelist] record. For example, if you create an Allowed Client Error record for the error message "Test message" with a report level of Ignored, then any client error containing this string is ignored.

Note: When you create or modify an Allowed Client Error record, the Client Test Runner automatically gets the update.
Identifying and resolving client errors

When client errors occur, the Automated Test Framework fails the test on the step that was executing when the error occurred.

Allow client errors from test results

Allow client errors as you review test results.

Before you begin
Role required: atf_test_admin, atf_test_designer, or admin

About this task
You can allow multiple or individual client errors. For each client error, you must decide how to report future instances of the client error. Report level options include:

• Warning: Test steps containing the allowed client error report a status of Success with warning(s). The error message appears in the test result output, and is recorded in the test logs with the status Warning.

• Ignored: Test steps containing the allowed client error report a status of Success. The error is recorded in the test logs with an Ignored status.

Procedure
1. Navigate to Automated Test Framework > Test Results.
2. Select the test result for a specific test.
   The system displays the Test Result record.
3. From the Related links, select one of the following options:
   • Add all client errors to warning list: Allow all client errors in this test with a report level of Warning.
   • Add all client errors to ignored list: Allow all client errors in this test with a report level of Ignored.
   The Automated Test Framework allows the selected client errors and displays a status message at the top of the form.

Related information

Allowed client errors

Allow client errors from step results
Allow client errors as you review step results.

Before you begin
Role required: atf_test_admin, atf_test_designer, or admin
About this task
You can allow multiple or individual client errors. For each client error, you must decide how to report future instances of the client error. Report level options include:

- **Warning**: Test steps containing the allowed client error report a status of Success with warning(s). The error message appears in the test result output, and is recorded in the test logs with the status Warning.

- **Ignored**: Test steps containing the allowed client error report a status of Success. The error is recorded in the test logs with an Ignored status.

Procedure
1. Navigate to **Automated Test Framework > Test Results**.
2. Select the test result for a specific test. The system displays the Test Result record.
3. Select the client errors to be allowed.

<table>

Allowed client error records

**View the progress of automated tests**

When an automated test is running, view its progress in the Run Test progress dialog.

**Before you begin**

The system must be running a test.
Role required: atf_test_admin or atf_test_designer
About this task
When you execute a test or test suite, the system automatically displays the Run Test progress dialog. If you close this dialog, you can re-display it from either the results list or the results page for the currently-running test or test suite.

Procedure
1. If necessary, navigate to the Test Results list or Test Results page for the currently-running test or test suite.
   - If the system is currently running a test suite, navigate to Automated Test Framework > Suite Results. If desired, you can click the row for the running test suite to view the Suite Results page for that test suite.
   - If the system is currently running a test that’s not part of a test suite, navigate to Automated Test Framework > Test Results. If desired, you can click the row for the running test to view the Test Results page for that test.

2. Display the Run Test dialog.
   - If you are currently viewing the Test Results page or the Suite Results page, click Show Progress under Related Links.
   - If you are currently viewing the Test Results list or Suite Results list, right-click the row for the running test or test suite, then click Show Progress.

Passing data from one automated test step to another
Some automated test steps create data that you can use as an input to a subsequent step.

You can pass data from one test step to another using input variables and output variables.

The term input variables is another name for the field values associated with a step. These values are input variables because they provide the input the step needs to accomplish its task. For example, the Open Form step has these input variables: Table, Record, and View.
Example test step showing input variables

<table>
<thead>
<tr>
<th>Description</th>
<th>Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open the &quot;incident&quot; form with id &quot;[step 1: Record insert:Record]&quot;</td>
<td>Table: Incident[incident]</td>
</tr>
<tr>
<td>Record: Step 1: Record insert:Record</td>
<td>Document_id</td>
</tr>
</tbody>
</table>

Some step types also have output variables. These are the values that later steps in the same test can use as input. For example, the Record Insert step has an output variable called Record which contains the sys_id of the newly created record.

**Note:** Input data can also be passed to an automated test case from an external source such as a .csv file.

The test step form doesn’t indicate if a test step has output variables or not. You can easily tell if any output variables are available to provide a value to any given input variable. If you can map the value of one step’s output variable to the current step’s input variable, the system displays the mapping icon (🔗) to the right of that input field. When you click the variable mapping icon, the system displays a tree giving you access to any available output variables from previous steps.
Example test step showing output variables

For step-by-step instructions on how to assign the value of an output variable to another step's input variable, see Pass values from one automated test step to another.

For an example of a test that passes variables using input and output variables, see Automated Test Framework use case: reference a value from a previous step.

Pass values from one automated test step to another

Assign a form field the value of an output variable returned from a previous step.

Before you begin
You must have a previous test step that returns an appropriate output variable.

Role required: admin, atf_test_admin and atf_test_designer

Procedure
1. To the right of the field whose value you want to assign, click the input value icon.

   The input value mapping control lists previous steps that create output variables. If no previous steps create output variables, the control displays the message: There are no elements to show.

2. Click the row for the step that contains the output variable you want to use as an input.
3. Click the output variable you want to use.
   If the output variable is an id for a glide record, the control displays a tree
   picker providing access to fields for this record.

4. Navigate through the tree picker hierarchy until you find and select the value
   you want.

Related information

 Automated Test Framework use case: reference a value from a previous step

Building and running automated test suites

Run a group of tests in a specific order to test an application or a group of
related features.

A test suite can contain both individual tests and other test suites. A test suite
that contains another test suite is called a parent, and the test suite contained
within the parent is called a child. While a test suite can have both individual
tests and test suites as children, tests cannot have other tests as children. Tests
can only contain test steps.

Benefits

Grouping tests into test suites offers these benefits.

• Allows testers to run every test in a test suite with one action.
• Allows testers to run all child test suites in a parent test suite.
• Allows testers to see test results for every test in a test suite.
• Allows test designers and testers to schedule when to run test suites.
• Allows test designers and testers to schedule starting client test runners to
  support test runs.

Hierarchies

Automated Test Framework supports building a multi-level hierarchies where a
test suite can be both a parent and child. For example, this figure illustrates Test
Suite 1 as the parent at the top of the hierarchy. Test Suite 1.3 is a child of Test
Suite 1 and also a parent of Test Suite 1.3.1 and Test Suite 1.3.2.
Schedules
To schedule a test suite, you need three components:

- a test suite record
- a schedule record specifying when you want the system to run the test suite
- a scheduled suite run record that associates the test suite to run with the schedule for running it

With this model, you can associate a schedule with many different test suites, and vice versa.

⚠ Note: You can schedule only test suites, not individual tests. Scheduled tests will run only if there is an open Scheduled Client Test Runner page matching the scheduled suite’s browser conditions. Scheduled tests cannot run on a machine that is locked, powered down, or does not already have the browser open.

The watchlist on the test suite run record also allows you to specify users to receive an email when the system finishes executing the test suite run.

If the test suite contains one or more form steps (steps involving a user interface), you must ensure that a scheduled client test runner is actively running in a browser when the schedule triggers the suite run.
Filters
Automate the creation of test suites by using a filter to dynamically add tests to a test suite when they match the filter conditions. Reduce the time that your test designers spend manually creating and maintaining test suites.

Related information
Suites
Create an automated test suite
Group automated tests into a suite you can execute as a batch.

Before you begin
The tests you want to include in the test suite must exist.
Role required: atf_test_admin or atf_test_designer

Procedure
1. Navigate to Automated Test Framework > Suites.
2. Click New.
   The system displays the Test Suite New Record form.
3. In the Name field, enter a name for this suite.
4. Select the tests to be included in this suite.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Filter</td>
<td>Add tests dynamically using a filter:</td>
</tr>
<tr>
<td></td>
<td>a. In the Filter field, use the condition builder to create the conditions a test must match for inclusion in the test suite.</td>
</tr>
<tr>
<td></td>
<td>b. Click Save.</td>
</tr>
<tr>
<td></td>
<td>All tests that match the filter conditions appear in the Test Suite Tests related list. Because the suite is dynamic, any</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>-------------</td>
</tr>
<tr>
<td>new test that matches the conditions is automatically added to the suite.</td>
<td></td>
</tr>
<tr>
<td>Add tests manually:</td>
<td></td>
</tr>
<tr>
<td>a. In the Test Suite Tests related list, click Insert a new row....</td>
<td></td>
</tr>
<tr>
<td>b. In the Test field, enter the name of the test to add to this test suite.</td>
<td></td>
</tr>
</tbody>
</table>

5. In the Description field, enter a description for this test suite.
6. In the Test Suite Tests related list, specify options for a test.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Enter a value to specify the order in which this test should execute within the test suite.</td>
</tr>
<tr>
<td>Abort on Failure</td>
<td>Enter a value that indicates whether you want the test suite to stop or continue if this test fails.</td>
</tr>
<tr>
<td></td>
<td>• By default, the system assigns the value false to this field. If this test fails, the system still executes any further tests in the test suite.</td>
</tr>
<tr>
<td></td>
<td>• Set the value to true to stop the test suite if this test fails.</td>
</tr>
</tbody>
</table>

7. Repeat steps 4 - 6 for every test you want to include in this test suite.
8. Click Submit.

**Copy an automated test suite**

Reduce time in creating tests by copying an entire test suite. Rename and modify the test suite after copying. The Copy Test Suite button on the Test Suite form copies all the nested tests and child test suites within the test suite.

**Before you begin**
Role required: atf_test_admin or atf_test_designer

**Procedure**
1. Navigate to Automated Test Framework > Suites.
2. Select the row containing the test suite that you want to copy.
   The Test Suite form opens.
3. Near the top-right corner of the Test Suite form, click Copy Test Suite.
A progress tracker appears to confirm the status. If you click **Go to Copy**, the system displays a new test suite record identical to the copied record, except for the **Name**.

**Note:** If you apply filter conditions, copied tests are added to the test suite if the conditions are met.

If any tests or child test suites fail to copy, they are skipped and copying of the remaining tests and child test suites continues. A warning message showing a partial success appears below the progress bar.

**Note:** You can copy a test suite only when its in the same scope as the current scope. The **Copy Test Suite** button appears only when the test suite is in the same scope. The scopes of the tests in a suite are preserved when copying a test suite. See **Application Scope** for more information.

If the copy operation fails, an error message appears below the progress bar.

4. In the **Name** field, enter the name that you want to assign to this new test suite.

5. Edit the tests and test suites within the copied test suite.

6. When you are finished making changes, click **Update**.

**Results**

A copy of the test suite along with all the nested tests and child test suites is created.
Add tests to a suite with a filter
Automate the creation of test suites by using a filter to dynamically add tests to a test suite when they match the filter conditions. Reduce the time that your test designers spend manually creating and maintaining test suites.

Before you begin
The tests you want to include in the test suite must exist.
Role required: atf_test_admin or atf_test_designer

Procedure
1. Navigate to Automated Test Framework > Suites.
2. Click New.
   The system displays the Test Suite New Record form.
3. In the Name field, enter a name for this suite.
4. For Filter, use the condition builder to specify the conditions a test must meet to be added to the test suite.
5. Click Save.

Results
All tests that match the filter conditions appear in the Test Suite Tests related list. Because the suite is dynamic, any new test that matches the conditions is automatically added to the suite.

Add test to an existing automated test suite
Add a test to a test suite that already exists.

Before you begin
The tests you want to include and the test suite must exist.
Role required: atf_test_admin or atf_test_designer

Procedure
1. Navigate to Automated Test Framework > Suites.
2. Click the row containing the test suite you want.
   The system displays the Test Suite form.
3. In the Test Suite Tests related list, click Insert a new row....
4. In the Test field, enter the name of the test to add to this test suite.
5. In the **Order** field for this row, enter a value to determine the order in which this test should execute within the test suite. By default, the system assigns a value to this field according to the order in which you add the tests.

6. In the **Abort on Failure** field for this row, enter a value that indicates whether you want the test suite to stop or continue if this individual test fails. By default, the system assigns the value **false** to this field. **False** means that if this test fails, the system still executes any further tests in the test suite.

7. Repeat steps 3 - 6 for every test you want to include in this test suite.

8. Click **Submit**.

**Add child test suite to parent test suite**

Add to a multi-level test suite by including a child test suite within a parent test suite.

**Before you begin**
The parent test suite must exist.
Role required: atf_test_admin or atf_test_designer

**Procedure**

1. Navigate to **Automated Test Framework > Suites**.

2. If the child test suite exists, open the child test suite form for editing. If the child test suite does not yet exist, create it. In both cases, leave the test suite form open.

3. In the **Parent suite** field, enter the name of the test suite you want to act as the parent to this child.

4. If desired, add one or more tests to the child test suite.

5. Click **Submit**.

**Run an automated test suite**

After creating an automated test suite, run it in a non-production instance.

**Before you begin**
You must have created the test suite you want to run.
The **test execution property** must be enabled. You must have an admin or atf_test_admin role to do so.
**Note:** The test execution property is disabled by default to prevent running tests on a production system. Run tests only on development, test, and other sub-production instances.

Role required: atf_test_admin, atf_test_designer, or admin

**About this task**
This procedure outlines how to start a test suite manually. You can also schedule test suites to run at a later time. For more information, see Working with scheduled test suites.

**Procedure**
1. Navigate to **Automated Test Framework > Suites**.
2. If necessary to view the Test Suites list, click **Test Suites**.
3. Click the row containing the test suite you want to run. The system displays the **Test Suite** form.
4. Click **Run Test Suite**.

   **Note:** If the test execution property is not enabled, the **Run Suite** button does not appear. In this case, see the annotation at the top of the form, and click the link to enable running tests.

5. If the tests associated with the test suite include a form step (any step involving a UI), or other kinds of UI test steps, the **Pick a Browser** dialog appears before executing the tests. Use it to choose among any currently-running test clients, or start a new runner. For more information, review **Browser recommendations for all tests and suites**.
   If the tests associated with the test suite only include server test steps, the system executes the tests without displaying the Pick a Browser dialog.

**What to do next**
Monitor the progress of the tests. When complete, click **Go to results** on the progress dialog window to display the **Test Results** list, where you can view and analyze the results.

**Schedule an automated test suite**
Schedule one or more test suites to run at a specific date and time.

**Before you begin**
You must have created the test suites you want to schedule.
Role required: atf_test_admin or atf_test_designer
About this task
To schedule a test suite, you need three components:

- a test suite record
- a schedule record specifying when you want the system to run the test suite
- a scheduled suite run record that associates the test suite to run with the schedule for running it

For more information about the capabilities of and requirements for scheduled test suites, see Working with scheduled test suites.

Procedure

1. Navigate to Automated Test Framework > Schedules.
   The system displays the list of existing test suite schedules.

2. To create a new schedule, click New.
   The system displays the Suite Schedule record form.

3. On the Suite Schedule record form, enter the name of the schedule, the frequency with which to run associated suites, the time at which to run associated suites, and the timezone for this schedule.

4. Optional: To specify a condition that must be met for running associated test suites, check Conditional, then fill in the Condition text box with the appropriate script.

5. To add a test suite to run, navigate to the Scheduled Suites related list, then click New.
   The system displays Scheduled Suite Run record form.

6. On the Scheduled Suite Run record form enter the appropriate data.
   a. Enter the test suite to run.
   b. If the suite contains UI steps, enter any client constraints you wish to apply (such as browser to use). For more information on client constraints, see Scheduled Suite Run.
   c. Add to the record's watchlist users you want the system to inform (by email) when the scheduled suite has finished.
   d. Click Submit.

7. Optional: To add more test suites to this schedule, repeat steps 5 and 6.

8. Click Update.

9. If your suite includes any test steps that work with a form – or any other element on the client side – follow these steps to open a browser window for running the client portion of the scheduled tests.
a. Review **Browser recommendations and requirements** for all tests and suites, as well as those that apply only to scheduled suite runs.

b. In the **Navigator**, right-click **Scheduled Client Test Runner**, and then click the option to open in a separate tab or window, as you prefer.

c. Leave open the browser window that’s running the client test runner and return to the browser window that contains the **Navigator**.

### Run a scheduled test suite using a script

Execute a scheduled UI test suite immediately using a script without having to wait for the scheduled time. You can use this method while trying to automate the process of running a test.

**Before you begin**

You’ve created and scheduled the test suites that you want to run. See [Create an automated test suite](#) and [Schedule an automated test suite](#), for more information.

Role required: **atf_test_admin** or **atf_test_designer**

**About this task**

The following steps might not be in line with your software configurations.

**Procedure**

1. Spin up a virtual machine (VM) on an operating system with the necessary browsers.

2. Open a browser on the instance and navigate to the Scheduled Client Test Runner.

3. Call the scriptable method `new sn_atf.ScheduledRunsExecutor().setScheduleSysId("SYS_ATF_SCHEDULE_SYS_ID_HERE").start();` to run the scheduled suite immediately.

   **Note:** The `start()` method returns `sys_progress_worker.sys_id` of the progress worker.

   To run a test only when the script is called, set the Run field to **On Demand** in the Schedule form.

**Re-run failed tests in an automated test suite**

Re-run failed tests within a test suite without rerunning the entire suite.
Before you begin
Role required: atf_test_admin, atf_test_designer, or admin

About this task
The **Re-run failed tests** button appears on the Suite Result form and on the Suite Execution Progress Viewer after a suite with failed tests completes. It does not appear if test execution is disabled, the suite is deactivated, the suite passed, or the user does not have one of the required roles.

**Re-run failed tests** button actually re-runs all non-passing tests. This includes tests with the following status: canceled, skipped, failure, and error. It does not include the test results with a *Success with warning(s)* status.

Procedure
1. Navigate to either the suite result form or suite execution progress viewer for the completed suite that had failed tests.
2. Click **Re-run failed tests**.
3. If the re-run tests include a form step (any step involving a UI), or other kinds of **UI test steps**, the **Pick a Browser** dialog appears before executing the tests. Use it to choose among any currently running test clients, or start a new runner. For more information, review **Browser recommendations for all tests and suites**. If the re-run tests include only **server test steps**, the system executes the tests without displaying the Pick a Browser dialog.

Results
The system re-runs the failed tests:

- The system creates a new suite result hierarchy for the re-run tests. The Progress Workers, Test Result, and Test Suite Result forms show the same suite hierarchy as the previous test suite. They do not include the tests or suites that passed in a previous run.
- If you delete or deactivate a child suite or test that failed, and then re-run it, the system does not execute that suite or test in the re-run.
- If you add a child suite or test to the suite to a failed test, and then re-run it, the system does not execute the added suite or test in the re-run.

What to do next
To view the results from the previous run of a test or suite, click **Previous test result** on the test result form or **Previous suite result** on the test suite result form. These fields only appear for tests and suites that have been re-run.
Parallel testing
Reduce test design time by running multiple tests and test suites in parallel. Design tests to run in parallel by avoiding resource conflicts and data dependencies.

⚠️ Note: If two or more users are developing tests simultaneously, parallel testing reduces test design time. After test design completes, it is recommended to organize tests into a single hierarchical suite structure, and run the tests as a single base suite.

Parallel testing limit
Parallel testing enables users to run multiple automated tests simultaneously. This process continues until the number of parallel running tests is as per the following formula.

\[
\text{Number of parallel tests} = \max(1, \text{number of worker threads} - 2)
\]

⚠️ Note: If your instance has 2 or less worker threads, configuration improvements review is recommended.

The actual number of parallel tests that a non-production instance can support depends on the system resources that the instance has when it is provisioned. The parallel testing limit ensures that an instance always has system resources available for other non-testing tasks.

Test waiting queue
When the system reaches the parallel testing limit, it reschedules tests to run later. It automatically places the tests back in sys_trigger until a worker thread is available to pick them up. Each test in the waiting queue has a schedule the next time the test runs.

Design considerations
Run multiple tests and test suites in parallel to reduce test design time. Avoid resource conflicts and data dependencies by designing parallel running tests. Avoid resource conflicts and data dependencies by designing tests that rely only on newly generated or self-created data, or have mutual exclusion rules defined between tests that share resources.

 Prevent resource conflicts between parallel tests
Prevent resource conflicts by running tests that create their own data. Tests that run with existing data prevent other tests that need the same data from running in parallel.
Note: If you have two or more tests with resource conflicts, see Mark tests as mutually exclusive to create a mutual exclusion rule that prevents the tests from running in parallel.

Mutually exclusive tests

Prevent conflicting tests from running in parallel by marking them as mutually exclusive. For example, when the system identifies tests that modify the same record, the system makes these tests mutually exclusive. You can also manually mark tests as mutually exclusive.

The system marks tests as mutually exclusive when there is a potential resource conflict. When the system can't detect resource conflicts automatically, you can create your own mutual exclusion rules that can prevent conflicting tests from running in parallel. For example, if a test changes a sys_properties record, the record shows up under Records Modified of that test. If the validation path of another test depends on the same sys_properties record without any change, that test fails. This can occur if the previous test runs at the same time.

You can view mutually exclusive tests on the Mutually Exclusive Tests related list in the test form. This related list shows all tests that don't run in parallel with the current test and the reason. The same test might appear more than once in the list if there are multiple reasons.

Mutually exclusive tests reasons
Tests are marked mutually exclusive for the following reasons.
• Two or more tests modify the same record.
• A test that runs in parallel with itself.
• You can create your own mutual exclusion rules when the system can’t detect resource conflicts automatically.

Mark tests as mutually exclusive
You can mark tests as mutually exclusive using any of the following methods.

Mutually Exclusive Tests tab
Select a test from the Tests list and navigate to Mutually Exclusive Tests > Add Mutual Exclusion to make the selected test mutually exclusive with another test.

Tests list
Select one or more tests from the Tests list and choose Add mutually exclusive test from the Action on selected rows context menu. Enter one test in the Add mutually exclusive test dialog box to make the selected tests mutually exclusive with the current test.

Parallel Test Runs tab
When two or more tests run in parallel, navigate to Test Results > Parallel Test Runs. Select one or more tests and choose Add mutually exclusive test from the Action on selected rows context menu to mark the selected tests as mutually exclusive.

Note: The Parallel Test Runs tab is visible only if the test runs in parallel with one or more tests.

Automated Test Framework design considerations
Create reliable, scalable, and efficient tests by following these design considerations.

General testing
Avoid modifying ServiceNow system tables or tables extending the Application File [sys_metadata] that can potentially change the behavior of the system. Avoid using or modifying any existing records to prevent unexpected results between tests. The following are some of the common examples of system data changes that can cause unexpected results.
• Impersonate an existing account
• Delete an existing record.
• Run a test that disables a business rule or system property
• Validate with an existing record

Parallel testing
Reduce test design time by running multiple tests and test suites in parallel. Design tests to run in parallel by avoiding resource conflicts and data dependencies.

Prevent resource conflicts between parallel tests
Prevent resource conflicts by running tests that create their own data. Tests that run with existing data prevent other tests that need the same data from running in parallel.

Note: If you have two or more resource conflicting tests, see Mark tests as mutually exclusive to create a mutual exclusion rule that prevents them from running in parallel.

Parameterized testing
Run a test multiple times with different test data for each run. Create parameters to store test data for each test run. See Parameterized test components for more information.

• Create parameters to store test data for each test run.
• Ensure that the parameterized tests support standard Automated Test Framework (ATF) features, such as reports, test suites, and data rollback. Copying a parameterized test copies all parameters, test run data sets, and test steps.

Note: If a parameterized test including Custom UI test steps is created, the system only uses the first data set to retrieve components.

Custom UI testing
Test customized user interfaces such as UI pages and UI macros by retrieving their HTML and JavaScript page components and identifying the test actions they support.

Use the page inspector to identify testable page components
The page inspector determines which page components are available for custom UI testing. Page components that are unavailable to the page inspector are unavailable to custom UI testing.

Navigate to the custom UI you want to test
Use existing test steps to navigate to the target custom UI. For example, to test a Knowledge Base article, use the existing test steps to navigate to a module or to open an existing record. Most custom UI testing requires using existing test step categories as part of the test.

**Use the component area to identify page components**

The component area describes the HTML layout element containing the component such as a `<div>` or `<section>` element. The area helps test designers distinguish between components by providing the location in the page layout.

**Test your custom UI rather than Now Platform UI**

The Automated Test Framework prevents custom UI testing of Now Platform features. For example, you cannot test dashboards or graphical designers. Instead, build tests to validate your custom UI pages and elements because you have direct control over these user interfaces.

**Use HTML attributes to override page component testing properties**

Change the testing properties of a particular page component using Automated Test Framework-specific HTML attributes. See [Override component test actions](#).

**Retrieve page components again when you move tests to another instance**

Custom UI test steps don’t store UI components as metadata. Testers must manually retrieve page components again when moving tests between instances.

**Clone tests from production system**

Move your tests to the production system to clone the most updated instances for testing. Speed up the testing time by directly copying or cloning a test from the production system to a subproduction instance.

**Note:** By default, the system property that is used to run automated tests is disabled to prevent you from accidentally running these tests on a production system. To avoid data corruption or an outage, run tests only on development, test, and other non-production instances.
## Warning messages for all testing

<table>
<thead>
<tr>
<th>Warning messages</th>
<th>Design considerations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Impersonating an existing user may cause unexpected behavior for this test. Avoid potential issues by adding a 'Create a User' step instead. See the documentation for Test Design Considerations.</td>
<td>Create a new user to ensure proper roles and groups and avoid using existing records. See General testing for more information.</td>
</tr>
<tr>
<td>Using a table that extends Application File [sys_metadata] may cause unexpected behavior for other tests running in parallel. See the documentation for Test Design Considerations.</td>
<td>Avoid running a test with a table that extends the Application File because it might affect other tests. See Parallel testing for more information.</td>
</tr>
<tr>
<td>Using a system table may cause unexpected behavior for other tests running in parallel. See the documentation for Test Design Considerations.</td>
<td>Avoid using a system table because it might affect other tests running in parallel. See Parallel testing for more information.</td>
</tr>
<tr>
<td>Using an existing record may cause unexpected behavior for this test. See the documentation for Test Design Considerations.</td>
<td>Avoid using existing records because these records might not have the state and values as expected by the test. Use records created during the test to ensure proper state and values. See General testing for more information.</td>
</tr>
<tr>
<td>Modifying an existing record may cause unexpected behavior for other tests running in parallel. See the documentation for Test Design Considerations.</td>
<td>Avoid using existing records because it might affect other tests. Use records created during the test. See General testing for more information.</td>
</tr>
<tr>
<td>Using assert type '--None--' may cause unexpected behavior for server UI actions. Avoid potential issues by setting the assert type and using a timeout. See the documentation for Test Design Considerations.</td>
<td>Server UI actions cause the current form to submit and the page to reload. Select an assert type other than None to avoid any unexpected behavior for server UI actions. Set a timeout to ensure that your test waits for the form to be submitted or not submitted before moving on to the next step. When testing server</td>
</tr>
</tbody>
</table>
### Cancelling automated tests and test suites

You can cancel automated tests and automated test suites that are running or are queued to run.

How you cancel an automated test or automated test suite depends on whether the test or test suite is currently running or is queued to run.

#### Cancel queued automated test suite

You can cancel an automated test suite that is queued but has not yet run.

**Before you begin**
Role required: atf_test_admin or atf_test_designer

**Procedure**

1. Navigate to **Automated Test Framework > Run > Waiting/Running Test Runs**.
2. Select the action check boxes for the test suites to cancel.
3. From the action choice list, select **Delete**.

#### Cancel running and pending tests in an automated test suite

Cancel running and pending tests in a running suite test.

**Before you begin**
Role required: atf_test_admin or atf_test_designer

**Procedure**

1. If necessary, display the Run Test progress dialog.
2. Click **Cancel Pending Steps**.
   
   The system displays a dialog asking you to confirm that you want to cancel this test execution.
3. In the Confirmation dialog, click **Yes**.

---

**Results**
The system cancels any running and pending tests in this test suite and rolls back any data that tests in the test suite may have changed.

**Cancel running automated test**
You can cancel a running test from the Run Test progress dialog.

**Before you begin**
The system must be running a test.
Role required: atf_test_admin or atf_test_designer

**Procedure**
1. If necessary, display the Run Test progress dialog.
2. Click **Cancel Pending Steps**. The system displays a dialog asking you to confirm that you want to cancel this test execution.
3. In the Confirmation dialog, click **Yes**.

**Results**
The system cancels the running test and rolls back any data changes the test made.

**Cancel waiting automated test**
You can cancel a waiting automated test from the Waiting/Running Test Runs module.

**Before you begin**
Role required: atf_test_admin or atf_test_designer

**Procedure**
1. Navigate to **Automated Test Framework > Run > Waiting/Running Test Runs**.
2. Select the action check boxes for the tests to cancel.
3. From the action choice list, select **Delete**.

**Administering the Automated Test Framework**
Enable or disable the Automated Test Framework, modify retention policies, move tests between instances, control user access to the Automated Test Framework, and create custom test step configurations and step environments.
For details about individual properties that control how the Automated Test Framework works, see Properties.

Creating custom test step configurations

Step configuration records (or step configs) define how each step type behaves. You can create new step configurations that define custom steps that run on the server.

When you add a step to an automated test, that step has a defined type such as Set Field Values, or Record Insert. Each step configuration has a number of characteristics that affect how steps of that type behave, including the inputs required, the actions performed, and so on.

These characteristics are defined in the step’s step configuration record.
The Step execution script field determines the actions the system executes when a step with this config runs.

Related information

- Step configurations
- Step execution scripts

Create custom step configuration

Create a custom step configuration that can form the basis of new steps that run on the server.

Before you begin

Role required: atf_test_admin

About this task

The Automated Test Framework includes specific types of steps such as Open Form, Set Value, Assert Value and so forth. With the Step Configurations module, you can create steps that perform actions you specify. You can only create configurations for steps that run on the Server. You cannot create configurations for steps that run on the browser.

Procedure

1. Navigate to Automated Test Framework > Administration > Step Configurations.
2. Click New.
   The system displays the Test Step Config form.
3. In the Name field, enter a name for your step type.
4. Leave Active checked.
5. Leave Step environment set to Server-Independent. You can only define step configurations that run on the server; you cannot define step configurations that run in the browser.
6. Optional: In the Category field, select the category to which you want to assign this step. Categories are used for filtering the step list in the Add Step dialog. For more information, see Category field example.
7. Optional: In the Batch Order Constraint field, choose one of the following values.
   - None: A step based on this configuration can appear at any point in a test.
   - Start Batch Execution: If this test includes a batch with this step, this step must be the first in the batch.
• **Run in the middle of an execution**: If a test includes a batch with this step, this step must appear after the first and before the last step of the batch.

• **Stop Execution**: If a test includes a batch with this step, this step must be the last step in the batch.

8. In the **Order** field, enter an integer specifying where steps with this configuration appear in the step list on the Add Test Step dialog. For more information, see the example using the Order field.

9. In the **Template reminder** field, enter the instructions you want to appear when this step is included in a test as part of a template. For more information, see the example of using the Template reminder field.

10. In the **HTML description** field, enter the text you want to appear when the cursor highlights this step on the Create New Step dialog. For more information, see the example using the HTML description field.

**Note:** You may find it convenient to skip the next two steps, both of which involve writing scripts, until after you have added any input and output variables.

11. In the **Description generation script** field, add code to the provided template to generate the description assigned to a Test Step record when a step of this type is included in a test. For more information about writing this script, see Step description generation script. To see an example of where the system displays this description, see Description generation script example.

12. In the **Step Execution Script** field, add code to the provided template to define the script that executes when a step of this type runs. The script template provides instructions and examples for working with step inputs, outputs, and step results. For more details on the step execution script, see Step execution scripts.

13. Click **Submit**. The system creates a new test step configuration and returns to the list of test configurations.

14. **Optional**: To add input or output variables, re-open the step config record.

15. **Optional**: To add input variables to this step config, scroll to the Input Variables tab, then click **New**. Fill out the required fields for the new variable, then click **Submit**. Repeat until you have added all the input variables needed.
16. Optional: To control the order in which input variables appear on the New Step form, edit the values in the Order column for the Input Variables related list.

17. To add output variables to this step config, scroll to the Output Variables tab, then click New. Fill out the required fields for the new variable, then click Submit. Repeat until you have added all the output variables needed.

Step configurations
Add a predefined list of steps (template) to an automated test

Create a custom step configuration category
Create a custom step config category.

Before you begin
Role required: att_test_admin

About this task
Categories are used for filtering the step list in the Add Step dialog. For more information, see Category field example.

Procedure
1. Navigate to Automated Test Framework > Administration > Step Configuration Categories.
2. Click New.
   The system shows the Test Step Config Category form.
3. In the Name field, enter a name for your step category.
4. In the Step Environment field, enter the step environment in which steps under this category execute:
   - Server - Independent, if you want this category to contain steps that execute on the Server.
   - UI, if you want this category to contain steps that execute on browser.
   - Server - REST, if you want this category to contain steps that send Inbound REST messages to the instance.
5. In the **Display name** field, enter the category name you want to appear in the middle column of the Add Test Step dialog when this category is selected.

**Example**

![Add Test Step dialog](image)

6. Click **Submit**. The system creates a test step category and returns to the list of test step environments.

**Working with test step templates**

Test step templates contain a list of steps to be added all at once to an automated test.

**Related information**

- Add a predefined list of steps (template) to an automated test

**Create an automated test steps template**

Reduce testing time by creating a template containing a list of steps to add all at once to an automated test.

**Before you begin**

Role required: atf_test_admin

**About this task**

Many tests follow similar patterns. One common pattern, for example, is to open a form, set some field values, validate some field values, click a UI action,
open a record producer, open a catalog item, and submit the current form. If a template exists containing these steps, you can add them to a test all at once. The Automated Test Framework comes with default templates in the base system. With this procedure, you create your own templates.

Procedure

1. Navigate to **Automated Test Framework > Administration > Test Templates**. The system displays the Test Templates list.

2. Click **New**. The system displays the Test Template form.

3. In the **Name** field, enter a name for your template.

4. In the **Test Template** field, click the lock icon (🔒). The Test Template field unlocks and expands to allow editing.

5. In the **Test Template** field, enter the name of the first test step to add to this template. The system adds the test step to the Test template list.

6. Continue adding test steps – in the order that you want them to appear – until you’ve added all the steps that you want to include in the list.

   - **Note:** The test template supports tables, catalog items, and the record producer.

7. In the **Description** field, enter a description for this template.

8. Click **Submit**.

Related information

Add a predefined list of steps (template) to an automated test

Edit automated test steps template

Edit an existing test template.

Before you begin

Role required: atf_test_admin

Procedure

1. Navigate to **Automated Test Framework > Administration > Test Templates**. The system displays the **Test Templates** list.

2. Click the row for the test template you want to edit. The system displays the Test Template form.
3. In the **Test Template** field, click the lock icon (잠금 아이콘). The Test Template field unlocks and expands to allow editing.

4. **Note:** You can delete steps anywhere in the list, but you can add steps only to the end of the list. You can re-order steps in a test after you add them using the template, but you cannot re-order steps in the template itself.

Add or delete steps to the template.

- To delete a step, select that step, then click the X icon.
- To add a step, in the **Test Template** field, enter the name of the step to add.

5. Continue adding and deleting test steps until it contains the steps you want.

6. Click **Submit**.

**Related information**

Add a predefined list of steps (template) to an automated test

**Enable or disable executing Automated Test Framework tests**

Allow or prevent tests and test suites from executing on this instance.

**Before you begin**

Role required: att_test_admin

**About this task**

By default, the system property that is used to run automated tests is disabled to prevent you from accidentally running these tests on a production system. To avoid data corruption or an outage, run tests only on development, test, and other non-production instances.

**Procedure**

1. Navigate to **Automated Test Framework > Administration > Properties**.
2. Set the test execution property.
   - To enable test and test suite execution, check **Enable test/test suite execution**.
   - To disable test and test suite execution, uncheck **Enable test/test suite execution**.
3. Click **Save**.
Modify data retention policy for ATF test results

Modify the Auto Flush data retention policy, which designates how long the system retains data, and referencing data, for test and test suite results. You can change the frequency of flushing for the sys_atf_test_result or sys_atf_test_suite_result base tables. This setting controls how far back in time test result data is available.

Before you begin
Role required: atf_test_admin

About this task
The system regularly flushes data in the sys_atf_test_result and sys_atf_test_suite_result base tables, (and optionally, referencing data). By default, the system deletes test and test suite results data 30 days after creation. This task enables you to modify the Auto Flush retention policy for data stored in a specific base table (sys_atf_test_result or sys_atf_test_suite_result).

Procedure
1. Navigate to Automated Test Framework > Administration > Table Cleanup. The system displays a list of the retention policies (Auto Flushes) it maintains for automated testing results tables.
2. Select the retention policy (sys_atf_test_result or sys_atf_test_suite_result) to modify. The system displays the record for this retention policy.
3. The Tablename field displays the name of the table to which the selected Auto Flush retention policy applies. Skip this field to accept the default.

Note: Selecting another tablename in this field compromises the integrity of the Auto Flush record. Leave the tablename on existing ATF policies at the base system (default) value so it does not adversely affect ATF data retention behavior.

4. Specify how the system should determine the length of time for retention of data, and referencing data.
   a. In the Matchfield field, enter the field you want the system to use to monitor duration. For example, to specify that you want to delete data x amount of time after the system created it, leave Matchfield set to its default value of sys_created_on.
   b. In the Age in seconds field, enter the amount of time (in seconds) the system must wait before deleting the associated data and referencing data.
5. If you want to apply the policy to the specified data (for example, sys_atf_test_result), AND any data that references it, select Cascade delete (default value).
Affected referencing data is stored in the following tables: sys_atf_test_result_item, sys_atf_test_result_step, and sys_attachment (when table_name = sys_atf_test_result). If you want the policy to simply flush data in the selected table (for example, sys_atf_test_result), and skip flushing of the referencing data, then clear Cascade delete.

6. In the Conditions field, specify the filter conditions to use for selection of data (and optionally, referencing data) for this Auto Flush retention policy. The default is Retain indefinitely is false, because the Test results record also contains a Retain indefinitely check box that allows opting out of the auto flushes for specific test results.

7. Click Update.

Manage status and retention policies for automated test client runners
Modify how often active client test runners report in to the system and how long the system retains records for inactive client test runners.

Before you begin
Role required: atf_test_admin

About this task
When you start a client test runner, the system registers that runner as active, meaning that it is either running a test or is available to run a test. While the runner is active, it reports in to the system at a specified interval. If the runner does not report in at the expected time, the system marks the runner as inactive. After a period of time the system deletes the runner. This task enables you to modify the Automated Test Framework properties that control these intervals.

Procedure
1. Navigate to Automated Test Framework > Administration > Properties.
2. Navigate to the Test Runner Properties section.
3. To set the interval at which active client test runners report in to the system, enter the reporting interval in seconds in the Test runner heartbeat interval field.
4. To set the period of time a test runner can remain inactive before the system deletes it, enter the period of time in seconds in the Test runner timeout field.
5. Click Save.

Move automated tests from one instance to another
Move automated tests from one instance to another using the normal process for update sets.

Before you begin
Role required: atf_test_admin

About this task
You can move automated tests, automated test suites, and related data using update sets. For more information, see System update sets.

Compare results and execution times for different automated test and suite results
You can compare execution times for different runs of an automated test or automated test suite. You can also compare results over time for a single automated test suite.

Before you begin
Role required: atf_test_admin or atf_test_designer

Compare execution times for different runs of an automated test
Compare how long it took the system to execute each test step across different runs of the same test.

Procedure
1. Navigate to Automated Test Framework > Tests.
2. Select the row for the test whose results you want to compare.
   The system displays the Test form.
3. Navigate to the Test Results related list.
4. Check the rows for the test results you want to compare.
5. From the Actions on selected rows control, click Compare test step results.
   The system displays the Compare test result execution times bar graph.
Compare execution times for different runs of the same automated test suite

Compare how long it took the system to execute each test across different runs of the same test suite.

Procedure
1. Navigate to Automated Test Framework > Suites.
2. Select the row for the test suite whose results you want to compare. The system displays the Test Suite form.
3. Navigate to the Test Suite Results related list.
4. Check the rows for the test suite results you want to compare.
5. From the Actions on selected rows control, click Compare test results. The system displays the Compare test result execution times bar graph.

Compare results for automated test suite runs (aging report)

Compare how many tests passed versus failed across different runs of the same test suite.

Procedure
1. Navigate to Automated Test Framework > Suites.
2. Select the row for the test suite whose results you want to compare. The system displays the Test Suite form.
3. Under Related Links, click Display aging report. The system displays the Test suite aging report.

Administering REST test step configurations

Set request and response payload sizes, filter request and response headers, and create basic auth profiles.

Create a basic auth profile using the Automated Test Framework

Create basic auth profiles to specify basic authentication credentials for Send Request - Inbound test steps.

Before you begin
Role required: web_service_admin

About this task
The user name and password must be valid credentials on the instance where the tests using the profile are run.
Procedure

1. Navigate to Automated Test Framework > Tests.
2. Select a test that uses a Send Request - Inbound step.
3. Select a Send Request - Inbound step.
4. In the Basic authentication field, select the hourglass to look up the available profiles.
5. On the Basic Auth Configurations form, select New.
6. In the Name field, enter a name for the profile.
7. In the Username field, enter a user name.
8. In the Password field, enter a password.
9. Click Submit.

Filter REST request and response headers

You can add a list of REST request and response headers that are not to be saved in step-result records. You can filter headers that might contain authentication credentials or other sensitive information. The phrase "Header redacted for security" is saved instead.

To specify headers to be filtered, create a system property glide.atf.rest.log.header_blacklist with a comma-separated list of header names to be filtered. For information on adding properties, see Add a system property.

Automated Test Framework REST properties

These properties are installed with ATF REST.

ℹ️ Note: To open the System Property [sys_properties] table, enter sys_properties.list in the navigation filter.

<table>
<thead>
<tr>
<th>Property</th>

</table>

**Optimizing automatic test performance**

You can troubleshoot automatic test performance by inspecting system transaction log records and potentially shorten execution time by adjusting how often automatic tests capture screenshots.

**Managing automatic test screenshot settings**

Capturing many screenshots can impair test performance. You can control which types of screenshots the system captures to minimize this effect.

By default, the system captures a screenshot every time it executes a form test step. This information can be useful for understanding test results, but may slow down how fast the system executes the test.

You can change automatic test framework settings so that the system captures all screenshots (as it does by default), no screenshots, or just screenshots for failed test steps.

You can change these settings to affect all tests run on this instance, or to affect just the current client test runner session. To affect all tests run on this instance,
set the automatic test framework property from the automatic test framework properties page. To affect just the current client test runner session, set the screenshot mode from client test runner browser window.

**Set the system property to control when the Automated Test Framework captures screenshots.**

To control how often this instance captures screenshots for form test-steps, set the screenshot capture mode on the automatic test framework properties page.

**Before you begin**
Role required: atf_test_admin or admin

**About this task**
Setting the screenshot mode from the automatic test framework properties page affects any new client test runners started on this instance. This setting does not affect currently-running test-runners.

**Procedure**

1. Navigate to **Automated Test Framework > Administration > Properties**.
2. Set the **Enable or disable screenshot capture** property. From the drop-down menu
   - To capture screenshots for all steps, select **Enable for all steps**.
   - To capture screenshots only for failed steps, select **Enable for all failed steps**.
   - To capture no screenshots, select **Disable for all steps**.
3. Set the **Screenshot timeout** time interval, in seconds. The Client Test Run does not take a screenshot capture if the length of the attempt exceeds this value. Users should review performance settings and browser caches on affected client systems before increasing this value.
4. Click **Save**.

**Set the client test-runner property to control when the Automated Test Framework captures screenshots**

To control how often the current client test runner captures screenshots for form test-steps, set the screenshot capture mode on the client test runner browser window.

**Before you begin**
Role required: atf_test_admin or admin
About this task
Setting the screenshot mode from the client test-runner browser window affects only this client test-runner and persists until this test-runner session is closed. This setting does not affect any other running test-runners or any future test runners.

Procedure
1. From the client test-runner browser window, click the form preferences icon ( ).
2. Click the **Screenshot mode** option.
   • To capture screenshots for all steps, select **Enable for all steps**.
   • To capture screenshots only for failed steps, select **Enable for all failed steps**.
   • To capture no screenshots, select **Disable for all steps**.
3. Click **Save**.

View transaction data for automated test results
To help troubleshoot performance issues with automatic tests, you can inspect related records from the transactions log entry [syslog_transaction] table.

Before you begin
Role required: test_admin or admin

About this task
⚠️ **Note:** The system may not be able to log some transactions with short durations.

Procedure
Navigate to related transaction record in the system transaction log.
• From the **Step results record**, view transactions in the Step transactions related list.
• From the **Test Results record**, view transactions in the Test Transactions related list.

Working with scheduled test suites
You can schedule a test suite to run at a specified date and time.
To schedule a test suite, you need three components:
- a test suite record
- a schedule record specifying when you want the system to run the test suite
- a scheduled suite run record that associates the test suite to run with the schedule for running it

With this model, you can associate a schedule with many different test suites and vice-versa.

**: Note:** You can schedule only test suites, not individual tests. Scheduled tests will only run if there is an open Scheduled Client Test Runner page matching the scheduled suite’s browser conditions. Scheduled tests cannot run on a machine that is locked, powered down, or does not already have the browser open.

The watchlist on the test suite run record also allows you to specify users to receive an email when the system finishes executing the test suite run.

If the test suite contains one or more form steps (steps involving a user interface), you must ensure that a scheduled client test runner is actively running in a browser when the schedule triggers the suite run.

**: Note:** See Browser recommendations and requirements for recommendations and requirements for running the client test runner.

For step-by-step instructions on how to schedule a test suite, see *Schedule an automated test suite*.

**Designate users to receive email when system finishes running a scheduled test suite**

You can designate users to be notified when a scheduled test suite finishes executing.

**Before you begin**

Role required: atf_test_admin

**Procedure**

1. Navigate to the scheduled test suite run record.
2. Add to the record’s **watchlist** all users you want the system to notify when this scheduled test suite run completes.
Automated Test Framework scheduled test suite completed email

When the system completes executing a scheduled test suite, it sends an email to users on the Scheduled Suite Run record watchlist. This email contains information and links to further information about the Scheduled Suite Run and its results.

⚠ Note: Email functionality must be enabled in order to send an email.

Suite Stats

The Suite Stats section of the email reports the number of suites and individual tests broken down by result status: Failed (F), Error (E), Skipped (S), Canceled (C), or Passed (P). For a description of what each status means, see Test suite results record.

Test Suite Results

The Test Suite Results section of the email reports test suite results over time.

⚠ Note: By default, this report includes only suites with failed tests, but you can change this setting with the Email properties field on the Properties page. If set to default, only the failed tests within a test suite are reported.
Note: ATF reports only recent tests results on the email report. All the previous test results still exist if it's within the set retention time limit. See Table cleanup for more information on retention policy for ATF test results.

### Test Results Key

<table>
<thead>
<tr>
<th>Letter</th>
<th>Color</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>F</td>
<td>red</td>
<td>Test failed</td>
</tr>
<tr>
<td>P</td>
<td>green</td>
<td>Test passed</td>
</tr>
<tr>
<td>S</td>
<td>white</td>
<td>Test skipped</td>
</tr>
<tr>
<td>C</td>
<td>white</td>
<td>Test canceled</td>
</tr>
<tr>
<td>E</td>
<td>orange</td>
<td>Test has error</td>
</tr>
</tbody>
</table>
Each entry acts as a link to the result record for that run. If you point the mouse to any of these entries, the system displays the parent suite number, the parent suite end time, and the test result output.

**Properties affecting email content**
On the Automated Test Framework Properties form, you can set options affecting the format and content of the email.

**Automated Test Framework use case examples**
Use cases can help you construct tests for common scenarios.

**Automated Test Framework use case: test basic form operations**
This use case illustrates testing basic form operations with the Automated Test Framework.

**About this task**

**Steps in test**
**Procedure**

1. Impersonate a user with the permissions needed to perform these steps, in this example ATF.User.

**Example**

**Test step 1 - Impersonate**

2. Open a form, in this example a Catalog Task form.

**Example**

**Test step 2 - Open a new Form**

3. On the open form, set field values, including for any mandatory fields. This example sets field values for **Assigned to**, **Short description**, and **Description**.
### Example

**Test step 3 - Set Field Values**

<table>
<thead>
<tr>
<th>Execution order</th>
<th>Application</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Global</td>
</tr>
</tbody>
</table>

**Table**: Catalog Task [xc_task]

**Field values**:
- **Assigned to**: MFT User
- **Short description**: Deliver PC to lab.
- **Description**: Deliver PC to IT Lab from receiving or move PC from stockroom

4. Submit the open form.

### Example

**Test Step 4 - Submit a Form**

<table>
<thead>
<tr>
<th>Execution order</th>
<th>Application</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Global</td>
</tr>
</tbody>
</table>

**Description**: Submit the current form and confirm form submitted to server

**Assert type**: Form submitted to server
Automated Test Framework use case: reference a value from a previous step

This use case illustrates assigning a form field the value of an output variable from a previous step.

About this task

In this example, the second step references an output value from the first step.

Automated Test Framework: Pass values from one step to another example

Procedure

1. Insert a record into the incident table. This example inserts a record into the Incident table.

Example

Step 1 - Record Insert

2. Open the record just inserted. Specify the record to open by assigning to the Record field, the output variable from Step 1.
3. Validate that fields on the open record have the values you expect.

**Example**

**Step 3 - Field Values Validation**

**Related information**

Pass values from one automated test step to another
Automated Test Framework use case: test a business rule

This use case illustrates testing a business rule with the Automated Test Framework.

About this task

This example tests a business rule that sets the value of Locked out to true when active is set to false.

Automated Test Framework: Business rule example
Procedure

1. Impersonate a user with the necessary permissions. In this example, the step impersonates the admin user.

Example

Step 1 - Impersonate

2. Open a form for the table to which this business rule applies. This example opens a new User form.

Example

Step 2 - Open a New Form

3. Set values on the form that meet the requirements for submitting the form and for triggering the business rule. This examples sets values for the Active, Last name, and First name fields.
Example

**Step 3 - Set Field Values**

<table>
<thead>
<tr>
<th>Execution order</th>
<th>Application</th>
<th>Active</th>
<th>Test</th>
<th>Step config</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Global</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Description**
Set the values on the form as follows:
Active = false
Last name = Testperson
First name = Jane

**Table**
User [sys_user]

**Field values**
- Active
- Last name
- First name

4. Submit the form.

Example

**Step 4 - Submit Form**

<table>
<thead>
<tr>
<th>Execution order</th>
<th>Application</th>
<th>Active</th>
<th>Test</th>
<th>Step config</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Global</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Description**
Submit the current form and confirm form submitted to server

**Assert type**
Form submitted to server
5. Validate that the business rule ran. In this example the business rule tested sets **Locked out** to **true** if **Active** is set to **false**.

**Example**

**Step 5 - Field Values Validation**

Automated Test Framework use case: test a data policy

This use case illustrates testing a data policy with the Automated Test Framework.

**About this task**

This example tests the data policy that sets the field **Assignment Group** to **mandatory** if **impact** is **high**.
Automated Test Framework: Data policy being tested
Automated Test Framework: Data policy example

Procedure

1. Impersonate a user with the necessary permissions. In this example, the step impersonates an admin user.

Example

Step 1 - Impersonate

2. Open a form for the table to which this data policy applies. This example opens a new incident form.
Example

Step 2 - Open a New Form

3. Check that the data policy has not yet been triggered. In this example, the step checks to confirm that **Assignment group** is not mandatory.

Example

Step 3 - Field State Validation
4. If applicable, set the conditions that trigger the data policy. This example sets **Impact** to **High**.

**Example**

**Step 4 - Set Field Values**

- **Execution order**: 1
- **Application**: Global
- **Step config**: Data Policy Test Example
- **Table**: Incident (incident)
- **Field values**:
  - **impact**: 1 - High
  - **~ value~**

5. Validate that the data policy is enforced. In this example, the test confirms that the data policy set **Assignment group** to **High** after the previous step set **Impact** to **High**.

Example

**Step 5 - Field State Validation**

Automated Test Framework use case: test a script include

This use case illustrates testing a script include with the Automated Test Framework.

To test a script include with the Automated Test Framework, create a test that performs these steps:

- a step that causes the system to execute the script include. Examples:
  - Run Server Side Script test step that calls the script include.
  - Form action step script – such as open a form, submit or form, or set a field value – that invokes the script include.

- A step that validates that the script include took the expected actions. The specific test step for this validation depends on what the script include is designed to do. Examples:
- Field values validation, if the script sets a field value
- Field state validation, if the script changes a field state
- Record Query, if the script generates a new record

This example shows a test with one test step: Run Server Side Script. The script associated with this test step calls a script include that returns the value of its argument plus three. If the value returned from the script include is 8, the script include has worked as intended and the test passes.

Automated Test to test a script include
Automated test step for testing script include

```
62 //
63 // assertEqual: A function used to compare that assertion.value == assertion.value;
64 // In case of failure it throws an error and logs that the assertion by
65 // name has failed
66 //
67 // Example:
68 //
69 // var testAssertion = {};
70 // name: "my test assertion",
71 // shouldbe: "expected value"
72 // value: "actual value"
73 //
74 // assertEqual(testAssertion); // throws error, logs message to test step output
75 //
76 // function testoutput(step, stepResult, assertEqual)
77 // var input = assertEqual(s);
78 // if (input === true)
79 // return true;
80 // else
81 // return false;
82 //)
83 //)
84 //)
85 //)
86 //)
87 //)
88 //)
89 //)
```

Script include to test with Automated Test Framework

```
1 - function addThree() {
  2   return x + 3;
  3 }
```

Automated Test Framework use case: test a Service Catalog request

This use case illustrates testing a service catalog request with the Automated Test Framework.
About this task
With the Replay Request Item test step, you can test the service catalog ordering process once a request exists and has a record in the request item table. In the Rome release, you cannot create an automated test for the process by which the user creates a new request.

Automated Test Framework: Service catalog example
Procedure

1. Replay an existing service catalog request item. This test step inserts a new record in the [sc_request] table for the catalog request item RITM0010001.

Example

Service Catalog test step 1 details: Replay Request Item

This insertion triggers the Service Catalog Request workflow, which checks the price of the item, determines that it exceeds $1000.00, and therefore generates approval records for users belonging to the Catalog Request Approvals group. In this example, only one user–Eric Schroeder–belongs to this group.

2. Impersonate Eric Schroeder, the user who needs to approve this Service Catalog Request.
3. Verify that the system created an approval record for Eric Schroeder and this request. Note that for the Approval for field, you assign the output value from Step 1: Replay Request item > Request.

**Example**

**Step 3 details: Record Query for Approval record**

4. Set the state of this approval record to Approved.
The Service Catalog Request workflow sees that all required approval records have the state of **Approved** and transitions to the Approval Action which marks the request record \[\text{sc\_request}\] as **Approved**.

**Step 4: Triggered workflow marks request record as approved**

When the record in \[\text{sc\_request}\] changes to the Approved state, an associated business rule generates request items \[\text{sc\_request\_item}\] for each item in the request. In this example, the request contains only one item, so the business rule inserts one record into the \[\text{sc\_request\_item}\] table. This insertion triggers the Service Catalog Item Request workflow.
The first activity in the Service Catalog Item Request workflow generates an approval record for the head of the department in which the requesting user works. In this example, the department head is Natasha Ingram.

5. The workflow does not continue until the department head approves it, so the next test step impersonates Natasha Ingram.
Example

Step 5 - Impersonate User

6. Obtain the sys_id for the new approval record with the Record Query step. Note that Record Query creates an output variable with the sys_id of the first record returned from the query.

Example

Step 6 - Record Query test step

7. Set the approval record to Approved.
Example

**Step 7 - Approval User test step**

Note how Step 7 refers to the **First record** output variable from Step 6 to specify which record to approve. When the record is approved, the workflow transitions to the next Approval - User activity, which generates an approval record for the CIO. In this example, the CIO is Bow Ruggeri.

**Step 7 details - Service Catalog Item workflow**

8. Impersonate Bow Ruggeri.
9. Obtain the sys_id for the approval record for Bow Ruggeri.
10. Set the approval record to **Approved**.
When the record is approved, the workflow transitions to the Approval Action activity which sets the record for this item in the [sc_request_item] table to **Approved**. The workflow transitions to the Catalog Task activity labelled *Asset Mgmt. Fulfills Order*. This Catalog Task activity generates a new record in the [sc_task] table that instructs a user in the Fulfillment group to order the item.

**Step 10 - Service Catalog Item workflow**

11. Impersonate a user in the Fulfillment group, in this example ATF.User.

**Example**

**Step 11 - Impersonate User test step**

12. Obtain the sys_id for the new catalog task with the Record Query step. Note that Record Query creates an output variable with the sys_id of the first record returned from the query.
Example

Step 12 - Record Query test step

13. Mark the [sc_task] record as Closed Complete.

Example

Step 13 - Record Update test step

Note how Step 13 uses the First record output variable from Step 12 to specify which record to mark as Closed Complete.

When the record is marked Closed Complete, the workflow exits the Catalog Task activity along the In Stock exit path.
Step 13 - Service Catalog Item Request workflow

The workflow transitions to the Notification activity, then to the Catalog Task activity labelled Deploy Item to User. The Deploy Item to User Catalog Task activity inserts a new record into the [sc_task] table that instructs a user in the Deployment group to deliver the item.

14. Obtain the sys_id for the new catalog task with the Record Query step. Note that Record Query returns an output variable with the sys_id of the first record returned from the query.

Example

Step 14 - Record Query test step
15. Mark the [sc_task] record as *Closed Complete*. Note how Step 15 uses the *First record* output variable from Step 14 to specify which record to mark as *Closed Complete*.

**Example**

**Step 15 - Record Update test step**

When the record is marked *Closed Complete*, the workflow exits the Catalog Task activity, logs a message, and exits.

**Step 15 - Service Catalog Item Request workflow**

16. Verify that the request item in [sc_request_item] has the state *Closed Complete*. 
17. Verify that the request \[sc_request\] has the state Closed Complete.

**Example**

**Step 16 - Record Validation test step**
Automated Test Framework use case: Retrieve an incident using REST-Inbound

The Get Newly Created Resource via REST API Test test is provided with the Automated Test Framework, and uses the REST - Inbound and assert steps.

Before you begin
Review the REST API and the Send REST Request- Inbound- REST API Explorer configuration step information before creating this test.

Role required: atf_ws_designer

About this task
This test creates an incident record, uses a REST- Inbound step to retrieve the record, and then uses assert steps to determine whether the request was successful.

You can use the Send REST Request- Inbound REST API Explorer step to build and test the request, or you can manually create the request using the Send REST Request- Inbound step. In either case, you must specify the basic authentication information on the Send REST Request- Inbound step form.

When creating your test, start with your REST API and determine what behavior you want to validate. You can then determine what test data to create. You can use other test step configuration categories to create, update, or delete records, and then use a Send REST Inbound step to retrieve, update, or delete the test data. Conversely, you can use the Send REST Inbound step to create records, and then use other test step configuration categories to validate that the records were created correctly.

This task steps you through creating the Get Newly Created Resource via REST API Test test.

Procedure

1. Create a test.

   a. Navigate to Automated Test Framework > Tests, click New. The Test new record form is shown.

   b. Enter a test name and a description, and click Submit.

   c. Click the test created in the previous step. The Test form is shown.

2. Create test data.

   a. Click the Add Test Step button. The Add Test Step form is shown.
b. Click a test configuration category, and then click a test configuration.
   To replicate the **Get Newly Created Resource via REST API Test** test, click **Server > Record Insert**, and then **Next**.
   The test configuration form you selected is shown.

c. Fill in the information needed for the test configuration you selected.
   To replicate the **Get Newly Created Resource via REST API Test** test, on the **Record Insert** form, specify the incident table, and add a value for the Short description field, and click **Submit**.

3. Create the REST request.

   a. Click the **Add Test Step** button.
      The **Add Test Step** form is shown.

   b. Click a test configuration category, and then click a test configuration.
      To replicate the **Get Newly Created Resource via REST API Test** test, click **REST > Send REST Request - Inbound REST API Explorer**, and then **Next**.
      The **REST API Explorer** is shown.

   c. Fill in the information needed for the REST request, and click **Send**.
      To replicate the **Get Newly Created Resource via REST API Test** test, fill in the fields.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Namespace</td>
<td>now</td>
</tr>
<tr>
<td>API Name</td>
<td>Table API</td>
</tr>
<tr>
<td>API Version</td>
<td>latest</td>
</tr>
<tr>
<td>tableName</td>
<td>incident</td>
</tr>
</tbody>
</table>

When you do not specify the **Basic authentication**, the REST API Explorer uses your credentials.

The **Create Automated Test Step** is shown after you click **Send**.

d. When ready, click **Create Automated Test Step**.
   The Send REST Request - Inbound test step is created.

e. Click the Send REST Request - Inbound step, and in the **Basic authentication** field, specify a basic auth configuration.
If no configurations are available, you can create a basic auth configuration by clicking New on the Basic Auth Configurations form.

f. To replicate the Get Newly Created Resource via REST API Test test, in the Path field, click the contextual search button, and then click Record Insert > Record.

g. Click Update.

4. Create assert steps to verify the REST response.

   a. Click the Add Test Step button.
      The Add Test Step form is shown.

   b. Click a test configuration category, and then click a test configuration.
      To replicate the Get Newly Created Resource via REST API Test test, click REST > Assert Status Code, and then Next.
      The Assert Status Code form is shown.

   c. Enter the information needed for the form, and click Submit.
      To replicate the Get Newly Created Resource via REST API Test test, in the Operation field, select is and in the Status Code field, enter 200.
      To replicate the Get Newly Created Resource via REST API Test test, repeat this step to create Assert Response JSON Payload is Valid, and Assert JSON Response Payload Element test steps.

Quick start tests

Copy and customize quick start tests provided by the Now Platform® to validate that your instance works after you make any configuration changes. For example, if you apply an upgrade or develop an application.

The tests can only produce a pass result when you run them with the default demo data that’s provided with the application or feature plugin.

⚠️ Note: If your QST fails, it can be that the test doesn’t match your instance customizations. Use the Notes field for each test step to update the test to pass with your data. If you have customized the business process associated with a test, revise the test to match your customizations.

To apply a quick start test to your instance-specific data, copy the quick start test and add your custom data.

⚠️ Note: You can copy either individual quick start test or the entire quick start tests suite.
Activation

Each application or feature has its own plugin activation requirements for enabling quick start tests. See Available quick start tests by application or feature for activation information.

Managing copies

When you copy a test, Automated Test Framework populates the Copied from field with the name of the copied test. When an upgrade changes a quick start test Automated Test Framework notifies test designers about the change in a notification on the test form. Test designers can revert the copied test to the upgraded version with the Revert Copy to Base System UI action.

Tip: If a QST is updated, the previously copied versions of the QST won’t have the recent changes. Review the old copies using Copies to Review for all the tests that have an associated warning message.

Available quick start tests by application or feature

Validate that your instance still works after you make any configuration change such as apply an upgrade or develop an application. Copy and customize the ServiceNow-provided quick start tests to pass when using your instance-specific data.

DANGER: By default, the system property that is used to run automated tests is disabled to prevent you from accidentally running these tests on a production system. To avoid data corruption or an outage, run tests only on development, test, and other non-production instances. See Enable or disable executing Automated Test Framework tests.

Agile Development 2.0

Agile Development 2.0 quick start tests require activating the Agile Development 2.0 plugin (com.snc.sdlc.agile.2.0) and the Agile Development 2.0 - ATF Tests plugin (com.snc.sdlc.agile.2.0.atf).

<td>Delete a test result group rule.</td>
<td>Rome</td>
</tr>
</tbody>
</table>

To learn more about Configuration Compliance, see [Configuration Compliance](#).
Configuration Management Database (CMDB)

Configuration Management Database (CMDB) quick start tests require activating the Configuration Management (CMDB) plugin (com.snc.cmdb) and the CMDB - ATF Tests plugin (com.snc.cmdb.atf).

CMDB BSM: Dependency Views test suite
Test suite to check functionality of Dependency Views APIs.

<table>
<thead>
<tr>
<th>Test</th>
<th>Description</th>
<th>Release version</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMDB BSM: Dependency Views</td>
<td>Test functionality of Dependency Views APIs. These APIs retrieve Dependency Views map and associated map items such as context menu items, for a given CI sys_id and using itil user role.</td>
<td>New York</td>
</tr>
</tbody>
</table>

CMDB HEALTH: CI Health Dashboard test suite
Test suite to check whether CMDB CI Health Dashboard is functional at a basic level.

<table>
<thead>
<tr>
<th>Test</th>
<th>Description</th>
<th>Release version</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMDB HEALTH: Health Job Status</td>
<td>Checks whether any CMDB Health dashboard jobs, which were started 30 or more days ago, are still in progress.</td>
<td>New York</td>
</tr>
<tr>
<td>CMDB HEALTH: CMDB Health Completeness/Recommended</td>
<td>Checks whether the CI dashboard is functional for the recommended metric (included in the CMDB Health completeness KPI). This test validates:</td>
<td>New York</td>
</tr>
</tbody>
</table>
**CMDB HEALTH: CI Health Dashboard test suite**

Test suite to check whether CMDB CI Health Dashboard is functional at a basic level.

(continued)

<table>
<thead>
<tr>
<th>Test</th>
<th>Description</th>
<th>Release version</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Creation of a health inclusion rule for the recommend metric.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Creation of a recommended field that satisfies the health inclusion rule.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Validate that the health inclusion rule is correctly applied to a test record with missing data in the recommended field.</td>
<td></td>
</tr>
</tbody>
</table>

**CMDB IRE: Identification Reconciliation Engine test suite**

Test suite to check Identification and Reconciliation Engine (IRE) functionality.

<table>
<thead>
<tr>
<th>Test</th>
<th>Description</th>
<th>Release version</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMDB IRE: IRE Validation</td>
<td>Validate CI identifiers and reconciliation definitions and check indexes for CI identifiers.</td>
<td>Madrid</td>
</tr>
<tr>
<td>CMDB IRE: Reconciliation Rule</td>
<td>Check operations on a reconciliation rule, in CI Class Manager, using itil and itil_admin roles. Operations include create, edit, and delete a reconciliation rule. Also, check for active and not active setting, and derived rules.</td>
<td>Paris</td>
</tr>
</tbody>
</table>
**CMDB IRE: Identification Reconciliation Engine test suite**

Test suite to check Identification and Reconciliation Engine (IRE) functionality.

(continued)

<table>
<thead>
<tr>
<th>Test</th>
<th>Description</th>
<th>Release version</th>

<tbody>
<tr>
<td>CMDB IRE: Identification Rule</td>
<td>Check operations on an identification rule, in CI Class Manager, using itil and itil_admin roles. Operations include create, edit, and delete an identification rule. Also, check for active and not active setting, and derived rules.</td>
<td>Paris</td>
</tr>
</tbody>
</table>

**CMDB QB: Query Builder test suite**

Test suite to verify CMDB Query Builder functions such as create query, read query, and execute query using two related user roles - cmdb_query_builder and cmdb_query_builder_read.

<table>
<thead>
<tr>
<th>Test</th>
<th>Description</th>
<th>Release version</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMDB QB: Query Builder - cmdb_query_builder Role</td>
<td>Verify that cmdb_query_builder user role can save queries, and access and run all saved queries, in CMDB Query Builder.</td>
<td>New York</td>
</tr>
<tr>
<td>CMDB QB: Query Builder - cmdb_query_builder_read Role</td>
<td>Verify that cmdb_query_builder_read user role can access and run all saved queries, and cannot save any query, in CMDB Query Builder.</td>
<td>New York</td>
</tr>
</tbody>
</table>
### CMDB REL: Relationship Editor and Formatter test suite

Test suite to verify functionality of Relationship Editor and Relationship Formatter.

<table>
<thead>
<tr>
<th>Test Description</th>
<th>Release version</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMDB REL EDITOR:Relationship Editor</td>
<td>Check addition of relations to a CI and deletion of relations from a CI using itil user role.</td>
</tr>
<tr>
<td>CMDB REL FORMATTER:Relationship Formatter</td>
<td>Check accuracy of CI information, relationship types, relationships, associated records such as change tickets, and settings such as CMDB views (relationship filters), displayed for a specific CI in relationship formatter using itil user role.</td>
</tr>
</tbody>
</table>

### CMDB Workspace: Agent Workspace test suite

Test suite to verify functionality of CMDB Agent Workspace.

<table>
<thead>
<tr>
<th>Test Description</th>
<th>Release version</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMDB Workspace: Workspace Validation</td>
<td>Test adding, editing, and deleting of a list item, and editing of a filtered list, using itil and admin roles.</td>
</tr>
</tbody>
</table>

### CMDB SDK: SDK REST API test suite

Test suite to verify functionality of CMDB SDK Rest APIs.

<table>
<thead>
<tr>
<th>Test Description</th>
<th>Release version</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMDB SDK: Query CMDB Metadata</td>
<td>Test querying CMDB metadata.</td>
</tr>
</tbody>
</table>
CMDB SDK: SDK REST API test suite

Test suite to verify functionality of CMDB SDK Rest APIs.

(continued)

<table>
<thead>
<tr>
<th>Test</th>
<th>Description</th>
<th>Release version</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMDB SDK: Create a relation for a CI using REST APIs</td>
<td>Test creation of a relationship for a CI in the CMDB using the CMDB REST APIs.</td>
<td>New York</td>

<td>Create an improvement initiative from a survey.</td>
<td>Paris</td>
</tr>
</tbody>
</table>

To learn more about Continual Improvement Management, see Continual Improvement Management.

**Customer Service Management**

All Customer Service Management quick start tests require activating the Customer Service Management Demo Data plugin (com.snc.customerservice.demo). Some quick start tests also require activating the following plugins:

- Consumer Service Portal (com.glide.service-portal.consumer-portal)
- Customer Service Management for Orders (com.snc.csm.order)
- Customer Service Portal (com.glide.service-portal.customer-portal)
- Customer Service with Request Management (com.sn_cs_sm_request)
- Customer Service with Service Management (com.sn_cs_sm)
- Customer Service Household (com.snc.household)
- Business Location (com.snc.business_location)
- CSM Extension for Proxy Contacts (com.snc.csm_proxy_contacts)
- Case Playbook for Complaints (sn_complaint)
- Case Playbook for Onboarding (sn_onboarding)
- Major Issue Management (com.sn_majorissue_mgt)
- Proactive Customer Service Operations with Event Management (com.snc.proactive_cs_itom)
- Skill Determination (com.snc.skill_determination)

**CSM: Case Management test suite**

<table>
<thead>
<tr>

### Financial Management

Financial Management quick start tests require activating the Financial Management Core - ATF Tests plugin (com.snc.financial_management.atf)

<table>
<thead>
<tr>
<th>Test</th>
<th>Description</th>
<th>Release version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Verify FM Cost Allocation Flow</td>
<td>Verify the cost allocation flow in financial modeling.</td>
<td>Madrid</td>
</tr>
</tbody>
</table>

To learn more about Financial Management, see [Financial Management](#).

### GRC: Audit Management

GRC: Audit Management quick start tests require activating the GRC: Audit Management plugin (com.sn_audit) and loading the demo data.
## GRC: Audit Management test suite

<table>
<thead>
<tr>
<th>Test</th>
<th>Description</th>
<th>Release version</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRC: Create Audit Engagement and Generate Audit Task</td>
<td>Validates audit engagement creation and associates entities to generate controls and test plans. Generates audit task which is associated to a test plan.</td>
<td>Paris</td>
</tr>
<tr>
<td>GRC: Create and process a milestone</td>
<td>Create a milestone in an engagement, notice that the due date cannot be in past and the completion date cannot be in future and for a milestone in open state the percent complete is 0 which changes in accordance with the milestone state change.</td>
<td>Paris</td>
</tr>
<tr>
<td>GRC: Cost and Resource plan rollup</td>
<td>Create an audit plan and associate an engagement to it, on adding cost plan and resource plan to this engagement, notice that these costs are rolled up to the plan. Any edits to these costs in engagement reflects in the plan.</td>
<td>Paris</td>
</tr>
<tr>
<td>GRC: Create Engagement Project Manual and automatic</td>
<td>On an engagement in the validate state, once the Enable advanced planning ui-action is performed notice an engagement project gets created and when the state of an</td>
<td>Paris</td>
</tr>
</tbody>
</table>
### GRC: Audit Management test suite (continued)

<table>
<thead>
<tr>
<th>Test</th>
<th>Description</th>
<th>Release version</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>engagement associated to an audit plan having &quot;Advanced planning capabilities&quot; is changed to validate notice that an engagement project gets created automatically.</td>
<td></td>
</tr>
<tr>
<td>GRC: Auditable Unit with Detailed Risk Assessment</td>
<td>Create an Auditable unit with method as &quot;Detailed Risk Assessment&quot; and request for Assessing the Risk Assessment by adding the Assessor once the assessor responds and Marks Assessment as Complete after performing the control assessment and residual assessment, the risk assessment fields should be auto updated.</td>
<td>Paris</td>
</tr>
</tbody>
</table>

To learn more about Audit Management, see [Audit Management](#).

### GRC: Continuous Authorization and Monitoring

GRC: Continuous Authorization and Monitoring quick start tests require activating the Continuous Authorization and Monitoring plugin (com.sn_compliance) and loading the demo data.

<table>
<thead>
<tr>
<th>Test</th>
<th>Description</th>
<th>Release version</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRC: System Owner create and validate responsibilities and roles for an AB and AP</td>
<td>System Owner creates and validates responsibilities and roles for an Authorization</td>
<td>Quebec (compatible with Paris and Orlando)</td>
</tr>
<tr>
<td>Test</td>
<td>Description</td>
<td>Release version</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>Boundary and Authorization Package. Information Owners and System User are pre-populated when selecting the Authorization Boundary.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| GRC: System Owner validate App Modules visibility | Verifies that the system owner persona is able to view the following application menu:  
• Continuous Authorization & Monitoring and the following modules under that menu:  
• All Authorization Boundaries  
• All Authorization Packages  
• Information Type Library  
• Control Overlays  
• Control Objectives  
• Controls  
• All Engagements | Quebec (compatible with Paris and Orlando) |
| GRC: System Owner Request First approval & My approvals module | System Owner requests an approval. | Quebec (compatible with Paris and Orlando) |
| SO: Create and validate responsibilities and roles for an AB and AP | Verifies if a system owner can create an Authorization Boundary by completing the fields | Quebec (compatible with Paris and Orlando) |
GRC: Continuous Authorization and Monitoring Quick Start Tests test suite (continued)

<table>
<thead>
<tr>
<th>Test</th>
<th>Description</th>
<th>Release version</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>on the Authorization Boundary form. Also verify if the same SO can create an Authorization Package from the form view.</td>
<td></td>
</tr>
</tbody>
</table>

To learn more about Continuous Authorization and Monitoring, see Continuous Authorization and Monitoring.

GRC: Policy and Compliance Management

GRC: Policy and Compliance Management quick start tests require activating the Policy and Compliance Management plugin (com.sn_compliance) and loading the demo data.

<table>
<thead>
<tr>
<th>Test</th>
<th>Description</th>
<th>Release version</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRC: Create Controls</td>
<td>Validates control creation.</td>
<td>Madrid</td>

<tr>
<td>GRC: Create Policy Exception and Flow</td>
<td>Create a policy exception and navigate through its states.</td>
<td>Paris</td>
</tr>
<tr>
<td>GRC: Policy Lifecycle</td>
<td>Create a policy and navigate through its states.</td>
<td>Paris</td>
</tr>
</tbody>
</table>

To learn more about Policy and Compliance Management, see Policy and Compliance Management.

GRC: Risk Management

GRC: Risk Management quick start tests require activating the Risk Management plugin (com.sn_risk) and loading demo data.
<table>
<thead>
<tr>
<th>Test</th>
<th>Description</th>
<th>Release Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRC: Create Profile</td>
<td>Validate profile creation.</td>
<td>Madrid</td>
</tr>
<tr>
<td>GRC: Create Risk</td>
<td>Validates risk creation.</td>
<td>Madrid</td>
</tr>
<tr>
<td>GRC: Create Control</td>
<td>Validates control creation.</td>
<td>New York</td>
</tr>
<tr>
<td>GRC: Create Control Objective and Generate Controls</td>
<td>Validates control objective creation and associates profiles to generate controls.</td>
<td>New York</td>
</tr>
<tr>
<td>GRC: Create Issue</td>
<td>Validates issue creation</td>
<td>New York</td>
</tr>
<tr>
<td>GRC: Accept an Issue</td>
<td>Validates all the states of an issue till it is closed by accepting the issue.</td>
<td>New York</td>
</tr>
<tr>
<td>GRC: Remediate an Issue</td>
<td>Validates issue cannot be closed be with an open remediation task.</td>
<td>New York</td>
</tr>
<tr>
<td>GRC: ATF Flow for Indicator (Manual):</td>
<td>Create an indicator template with type manual and associate a control objective to it. Execute one of the indicators thus formed. Mark the state of the indicator task created as closed and result as failed. The associated control will become non-compliant and an issue will be generated.</td>
<td>New York</td>
</tr>
<tr>
<td>GRC: ATF flow for Indicator (Basic)</td>
<td>Create an indicator template with type basic and result as failed. Associate a control objective to it and give the supporting data. Execute one</td>
<td>New York</td>
</tr>
</tbody>
</table>
### GRC: Risk Management Quick Start Tests test suite (continued)

<table>
<thead>
<tr>
<th>Test</th>
<th>Description</th>
<th>Release Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>of the indicators thus formed. The associated control will become non-compliant and an issue will be generated.</td>
<td>GRC: ATF flow for indicator (Script) Create an indicator template with type script and enter a script and set the value of result.passed and result.value. Associate a control objective to it. Execute one of the indicators. The associated control will become non-compliant and an issue will be generated.</td>
<td>New York</td>
</tr>
</tbody>
</table>

To learn more about Risk Management, see [Risk Management](#).

### Hardware Asset Management

Hardware Asset Management quick start tests are available when you install the HAM: Hardware Asset Management application from the ServiceNow Store.

**Hardware Asset Management test suite**

<table>
<thead>
<tr>
<th>Test</th>
<th>Description</th>
<th>Release version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Asset Lifecycle Automation - Asset Disposal workflow</td>
<td>Validates asset disposal work flow.</td>
<td>Paris</td>
</tr>
<tr>
<td>Asset Lifecycle Automation-Deployment workflow</td>

<td>Verify the roster details for overlapping shifts when the escalation rule is set to <strong>Escalate to outgoing shifts</strong>.</td>
<td>Orlando</td>
</tr>
<tr>
<td>On-Call: Roster Details for overlapping shifts with the escalation rule 'Escalate to all shifts'</td>
<td>Verify the roster details for overlapping shifts when the escalation rule is set to <strong>Escalate to all shifts</strong>.</td>
<td>Orlando</td>
</tr>
<tr>
<td>On-call: Verify On-Call workbench</td>
<td>Test to verify the On-Call workbench layout.</td>
<td>Orlando</td>
</tr>
<tr>
<td>On-call: Hide or show shifts</td>
<td>Verify whether you can hide or show shifts from On-Call calendar</td>
<td>Orlando</td>
</tr>
</tbody>
</table>
To learn more about On-Call Scheduling, see On-Call Scheduling.

**Metric Intelligence**

Metric Intelligence quick start tests require activating the Metric Intelligence plugin (com.snc.sa.metric).

<table>
<thead>
<tr>
<th>Test</th>
<th>Description</th>
<th>Release version</th>
</tr>
</thead>
<tbody>
<tr>
<td>OI: Health Metrics Collection</td>
<td>An individual test that verifies the following:</td>
<td>Madrid</td>
</tr>
<tr>
<td></td>
<td>• There is at least one Metric Intelligence Metrics extension that is running.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• There are entries for the ‘Health Metrics’ in the Metric to CI table.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• For each of the Metric Intelligence Metrics extensions that are currently running, that</td>
<td></td>
</tr>
<tr>
<td></td>
<td>there is data stored in MetricBase.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>If the test initially fails, wait until the Metric Intelligence Metrics extension runs for at</td>
<td></td>
</tr>
<tr>
<td></td>
<td>least 10-15 minutes. Then try again.</td>
<td></td>
</tr>
</tbody>
</table>

To learn more about Metric Intelligence, see Metric Intelligence.

**Predictive Intelligence**

Predictive Intelligence quick start tests require activating the Predictive Intelligence [com.glide.platform_ml] plugin. In order to execute critical upgrade tests on existing machine learning solutions, you need to create a basic authorization profile named ml_atf in the Basic Auth Configurations table (sys_auth_profile_basic.list). To run the tests successfully, the user attached to the ml_atf authorization profile must have the ml_admin role.
### Predictive Intelligence: Classification and Similarity Solution Prediction test suite

<table>
<thead>
<tr>
<th>Test</th>
<th>Description</th>
<th>Release version</th>
</tr>
</thead>
<tbody>
<tr>
<td>PI: Presence of ML model artifacts persisted in glide</td>
<td>Verify all the trained ML model artifacts are persisted in glide (sys_attachments table) after model training/instance cloning so that ML prediction calls are successful.</td>
<td>New York</td>
</tr>
<tr>
<td>PI: Valid setup of ML user (sharedservice.worker) in glide</td>
<td>Validate if the ML user in glide (sharedservice.worker) is active and not logged out so that model training is successful.</td>
<td>New York</td>
</tr>
<tr>
<td>PI: Glide upgrade test for Classification solution</td>
<td>Validate that the classification model prediction on existing active models is producing the same class membership and confidence value results after a glide upgrade.</td>
<td>New York</td>
</tr>
<tr>
<td>PI: Glide upgrade test for Similarity solution</td>
<td>Validate that the similarity model prediction API calls on active models are successful after a glide upgrade.</td>
<td>New York</td>
</tr>
</tbody>
</table>

### Problem Management

Problem Management quick start tests require activating the Problem Management Best Practice — Madrid plugin (com.snc.best_practice.problem.madrid) and the Problem Management — ATF Tests plugin (com.snc.problem.atf). For all state related test, the Problem Management State Model (com.snc.best_practice.problem.madrid.state_model) plugin needs to be active.
<table>
<thead>
<tr>
<th>Test</th>

<td>Validate that the aggregated cost of all resource plans on a project or demand roll up to the total planned cost of the associated program.</td>
<td>Orlando</td>
</tr>
</tbody>
</table>
| Verify records on completion of a resource plan | Validate the changes in a resource plan on completion:  
- The state of the resource plan is updated to Completed.  
- If the completion date is earlier than the resource plan end date, the end date of the resource plan is updated with the completion date. If the completion date entered is later than the resource plan end date, the resource plan end date is retained.  
- All the requested and allocation records for the resource plan for the period after the completion date are deleted. If there are any actual hours logged against an allocation, that allocation is not deleted. For those allocation records, the allocated hours become zero and the actual hours are retained.  
- The available and allocated hours for resources are updated in the aggregate tables. | Orlando |
<p>| Verify records on completion of a resource plan with Planned Duration as allocation type: | Validate the following on completion of a resource plan with Planned Duration as allocation type: | Orlando |</p>
<table>
<thead>
<tr>
<th>Test</th>
<th>Description</th>
<th>Release version</th>
</tr>
</thead>
</table>
| Planned Duration as allocation type       | • The state of the resource plan is updated to Completed.  
• Allocations are not deleted.  
• End date of the allocation is updated to the completion date.                                                                                           |                 |
| Verify the RP replan Capability           | Validate that when a cancelled resource plan is replanned, the state of the resource plan changes to Planning.                                                                                             | Orlando         |
| Verify whether change in resource plan is reflected in corresponding cost plan | Validate that when a resource plan is updated, the corresponding cost plan is updated accordingly. For example, if the total planned cost is 500 USD, and the planned hours is 10, and you change the planned hours to 20, the total planned cost is updated to 1000 USD. | Paris           |
| Resource-Test the default population of resource plan start & end date | Validate the following on creating a user or group resource plan from the related list of a demand:  
• If a demand is created without a start date and end date, the user or group resource plan has task as demand and no start and end date.  
• If a demand is created with a start date and end date, the user resource plan has task as demand and the start date and end date as added for the demand. | Paris           |
| Validate that actual hours in operational resource plan and time card are equal | Validate that when a time card category is mapped with an operational work type, on submitting the time card for the operational resource plan associated with that work type, the actual hours in the resource plan and the time card are equal. | Quebec          |
| Verify Resource plan auto population for Operational plans | Validate that the operational resource plans associated with a time card are automatically retrieved on the time card when time is logged.                                                                       | Rome            |

<td>Click a UI Action</td>
<td></td>
</tr>
<tr>
<td>Server</td>
<td>Submit a Form</td>
<td></td>
</tr>
<tr>
<td>Reporting</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

You can select a specific test category to list only the test steps available for that test category in the middle panel. A description of the selected step appears in the right panel.
Service Catalog in Service Portal category
Validate catalog item transactions and requester flows from Service Portal.

Activation of the Automated Test Framework for Service Catalog in Service Portal
These ATF test steps require activation of the Automated Test Framework Service Catalog Service Portal (com.glide.automated_testing_impl.service_catalog_portal) plugin, which is active by default on new instances. Administrators may need to activate the plugin on instances upgraded from earlier versions.

Support for parametrized tests
Service Catalog in Service Portal step configurations support parametrized tests. For more information on parametrized tests, refer to Parameterized tests.

Open a Record Producer (SP)
Open a record producer in the Service Portal.

<table>
<thead>

**Note:** You should have access to this order guide.
Add row to multi-row variable set (SP)

Add a row to a multi-row variable set included in the current catalog item in Service Portal. You can use this step configuration only when the current catalog item contains a multi-row variable set. Use this step after the Open a Catalog Item(SP) step, Open a Record Producer(SP) step, or Open an Order Guide (SP) step. If a contextual value has been used for the Open a Catalog Item(SP) step, Open a Record Producer(SP) step, or Open an Order Guide (SP) step, set the catalog item in this step.

Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you're adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Catalog Item</td>
<td>Catalog item whose multi-row variable set requires an addition of a row. If an item is not already selected, you can either search for the item, or insert a reference to the contextual value of the item from a list of available parameters.</td>
</tr>
</tbody>
</table>
Inputs (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Multi-Row Variable Set</td>
<td>Multi-row variable set for which a row should be added.</td>
</tr>
</tbody>
</table>

Save current row of multi-row variable set (SP)

Save the current row of a multi-row variable set included in the current catalog item in Service Portal. You can use this step configuration only when the current catalog item contains a multi-row variable set. Use this step after the Add row to multi-row variable set (SP) step.

Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>

### Set Catalog Item Quantity (SP)

Set the quantity for a catalog item in Service Portal. This step is not applicable for a record producer. Use this step after using the Open a Catalog Item (SP) step, and before using the Order Catalog Item (SP) step.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Execution order</strong></td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you're adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Quantity</td>
<td>Quantity of the catalog item that you want to order.</td>
</tr>
</tbody>
</table>

### Validate Order Guide Items (SP)

Validate items included in the order guide.
**Inputs**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the Execution order values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you're adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Catalog Items</td>
<td>Catalog items that you want to validate.</td>
</tr>
</tbody>
</table>

**Note:** You should have access to these catalog items.

**Review Order Guide Summary (SP)**

Review the order guide summary in the Service Portal.
### Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step.</td>
</tr>
<tr>
<td></td>
<td>As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <strong>Execution order</strong> values.</td>

<tr>
<td>Test</td>
<td>Read-only name of the test that you're adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Catalog Items</td>
<td>Catalog items that you want to review.</td>
</tr>
<tr>
<td>Price</td>
<td>Price of the catalog item for the step to pass.</td>
</tr>
</tbody>
</table>

**Note:** You should have access to these catalog items.

### Review Item in Order Guide (SP)

Review individual items in the order guide and choose whether or not to include the item.
### Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you're adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Catalog Item</td>
<td>Catalog item that you want to review. <strong>Note:</strong> You should have access to this catalog item.</td>
</tr>
</tbody>
</table>
Inputs (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Included</td>
<td>Selected if the catalog item should be included in the order guide, otherwise unselected.</td>
</tr>
</tbody>
</table>

Add Item to Shopping Cart (SP)

Add the current catalog item to the shopping cart in Service Portal. Use this step after using the Open a Catalog Item (SP) step.

Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step.</td>
</tr>
<tr>
<td></td>
<td>As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the Execution order values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you’re adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Assert Type</td>
<td>Criteria for the test to pass.</td>
</tr>
</tbody>
</table>

**Successfully added item to Shopping Cart**

Test passes only if the catalog item is successfully added to the shopping cart.
Inputs (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cannot add item to Shopping Cart</td>
<td>Test passes only if the catalog item cannot be added to the shopping cart.</td>
</tr>
</tbody>
</table>

Outputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cart_item_id</td>
<td>The sys_id of the added catalog item.</td>
</tr>
</tbody>
</table>

Add Order Guide to Shopping Cart (SP)

Add an order guide to the shopping cart.

Input

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you're adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Assert Type</td>
<td>Criteria for the test to pass.</td>
</tr>
<tr>
<td></td>
<td><strong>Cannot add order guide to shopping cart</strong></td>
</tr>
<tr>
<td></td>
<td>Test passes only if the order guide cannot be added to the shopping cart.</td>
</tr>
<tr>
<td></td>
<td><strong>Successfully added order guide to shopping cart</strong></td>
</tr>
<tr>
<td></td>
<td>Test passes only if the order guide is successfully added to the shopping cart.</td>

</tbody>
</table>

**Order a Catalog Item (SP)**

Click **Order Now** for the current catalog item in the Service Portal. Use this step after using the Open a Catalog Item (SP) step. After this step, you cannot use any other steps on the catalog item. If the two-step checkout is false, a request is generated for the catalog item. If the two-step checkout is true, you are redirected to the cart preview page.
### Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the Execution order values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you're adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Assert type</td>
<td>Criteria for the test to pass.</td>
</tr>
<tr>
<td></td>
<td>Successfully ordered Catalog Item</td>
</tr>
<tr>
<td></td>
<td>Test passes only if the catalog item is successfully ordered.</td>
</tr>
<tr>
<td></td>
<td>Cannot order Catalog Item</td>
</tr>
<tr>
<td></td>
<td>Test passes only if the catalog item cannot be ordered.</td>

</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>The table containing the submitted order guide.</td>
</tr>
<tr>
<td>record_id</td>
<td>The sys_id of the submitted order guide.</td>
</tr>
</tbody>
</table>

Submit Record Producer (SP)

Submit the current record producer in the Service Portal. Use this step after using the Open a Record producer (SP) step. After this step, you cannot use any other steps on the record producer.

Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <code>Execution order</code> values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
</tbody>
</table>
## Inputs (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Test</td>
<td>Read-only name of the test that you're adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Assert Type</td>
<td>Criteria for the test to pass.</td>
</tr>
</tbody>
</table>

**Successfully submitted Record Producer**

Test passes only if the record producer is submitted successfully.

**Cannot submit Record Producer**

Test passes only if the record producer cannot be submitted.

## Outputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>The table containing target record of the record producer.</td>
</tr>
</tbody>
</table>

## Application Navigator category

Verify the functionality of menus and modules in the application navigator.

## Application Menu Visibility

Verifies the visibility, or lack thereof, of selected application menus in the application navigator (left navigation bar). For example, you create a test that first impersonates a user, then verifies that specified application menus (such as Self-Service and Reports) are visible, or are not visible, to that user.

## Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step.</td>
</tr>
</tbody>
</table>
### Inputs (continued)

<table>
<thead>
<tr>
<th>Field</th>

<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Component values</td>
<td>Page components to be tested and the value each page component should have for the step to succeed.</td>
</tr>
</tbody>
</table>

**Note:** The **Value** field defaults to the last retrieved field value of the selected component.

### Click Component (Custom UI)

Click a component on a custom UI page.

### Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you're adding the step to.</td>
</tr>
</tbody>
</table>
Component State Validation (Custom UI)

Validate the state of a specified component on a custom UI page.

Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the Execution order values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you're adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This</td>
</tr>
</tbody>
</table>
Open Service Portal Page
Open a portal page. Test designers must first open a page in a portal before testing UI components on the page.

Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| Execution order | Integer specifying the order in which the test executes this step.  
As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the Execution order values. |
| Active        | Option to activate this test step for use.                                                                                                   |
| Application   | Application scope in which the system runs this step.                                                                                       |
| Test          | Read-only name of the test that you're adding the step to.                                                                                   |
| Step config   | Read-only name of the step.                                                                                                                  |
| Description   | Description of the test step. This field value is automatically set based on...                                                             |
Form category

Validate the functionality of fields and UI actions on a form.

Note: Test steps that include the Form UI field give you the option to select an available UI. For any available workspace, navigation between tabs is not supported. Use the Open a New Form or Open an Existing Record step to reopen a form.

Open a New Form

Open a form to a new record in the specified table and Form UI.

Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the Execution order values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
</tbody>
</table>
### Inputs (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you’re adding the step to.</td>
</tr>
<tr>

<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Form UI</td>
<td>Option to select an available UI.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Workspaces are not supported in Internet Explorer (IE). See <a href="#">KB0683275</a> for more details.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table for the new form.</td>
</tr>
<tr>
<td>View</td>
<td>Name of the view in which you want this form to open. The testing user must have access to that view. If the name is not a valid form view, the form opens in its default view.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This field appears when <strong>Standard UI</strong> is chosen from <strong>Form UI</strong>.</td>
</tr>
</tbody>
</table>

### Open an Existing Record

Open a form to an existing record in the specified table and **Form UI**.

**Note:** Using an existing record may cause unexpected behavior for this test. See [Automated Test Framework design considerations](#) for more information.

### Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
</tbody>
</table>
### Inputs (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you're adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Form UI</td>
<td>Option to select an available UI.</td>
</tr>
<tr>

<td>Name of the table for the record you want to open.</td>
</tr>
<tr>
<td>Record</td>
<td>Record ID of the record that you want to open and name of the document that you want to open.</td>
</tr>
<tr>
<td>View</td>
<td>Name of the view in which you want this form to open. The testing user must have access to that view. If the name is not a valid form view, the form opens in its default view.</td>
</tr>
<tr>
<td>![Note:](Note: This field appears when Standard UI is chosen from Form UI.)</td>
<td></td>
</tr>
</tbody>
</table>

### Set Field Values

Set the fields on the current form to the specified values.

To run this step, your test must have already opened a form using either the **Open a New Form** or **Open an Existing Record** step. It is recommended to not run this step directly after a **Submit a Form** or **Click a UI Action** step. This is because they can redirect your test to a different page based on the navigation stack configuration on your instance or the script defined in the clicked UI action. Unless you are certain that the UI action will take you to a specific page, you should explicitly use an **Open a New Form** step after **Submit a Form** or **Click a UI Action** to ensure that the test is on the form as expected. Ensure that the test keeps passing consistently when added to a suite.
The **Field Values Validation**, **Set Field Values**, **Field State Validation**, and **UI Action Visibility** steps can appear in any order.

ℹ️ **Note:** This step waits for the form to load before setting field values.

ℹ️ **Note:** This step doesn't support reference qualifiers, neither at test design time nor at test runtime.

ℹ️ **Note:** A modal form appears either on top of another form or a list. To submit a modal form after setting the field values, your test must have already opened it on top of a form or a list.

<td>Table that contains the field whose value you want to set.</td>
</tr>
<tr>
<td>Set field value</td>
<td>Assigns a value to a field on an open form.</td>
</tr>
</tbody>
</table>

**Field Values Validation**

Validate field values on the current form.

To run this step, your test must have already opened a form using either the **Open a New Form** or **Open an Existing Record** step. It is recommended to not run this step directly after a **Submit a Form** or **Click a UI Action** step. This is because they can redirect your test to a different page based on the navigation stack configuration on your instance or the script defined in the clicked UI action. Unless you are certain that the UI action will take you to a specific page, you should explicitly use an **Open a New Form** step after **Submit a Form** or **Click a UI Action** to ensure that the test is on the form as expected. Ensure that the test keeps passing consistently when added to a suite.

The **Field Values Validation**, **Set Field Values**, **Field State Validation**, and **UI Action Visibility** steps can appear in any order.

For the **Field Values Validation** step, specify the values that you want to test using the standard conditions builder. You can test several conditions against the same field. This step passes if the overall condition is satisfied and fails if the condition is not satisfied. The **Conditions** field is case-sensitive and requires
to have the exact value as on the form. To test the values of individual fields independently of each other, include a separate Field Values Validation step for each value that you test.

**Note:** The Field Values Validation step works only with fields that belong to the record for the open form. For example, with the incident table, this step is not able to validate the Additional comments, Approval history, Comments, or Work notes fields because these UI controls are not actual fields on the incident record. These UI controls make it convenient to work with related tables. To validate these cases, use the Server test step, Record Validation, instead.

### Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. <tr>
<td>Note</td>
<td>Workspaces are not supported in Internet Explorer (IE). See KB0683275 for more details.</td>
</tr>
</tbody>
</table>

Table

Table that contains the fields whose values you want to validate.

Conditions

Fields and values to be validated. Includes only fields that are visible on the open form. This field is case-sensitive.

**Field State Validation**

Validate the state of specified fields. States validated can include mandatory, non-mandatory, read-only, non-read-only, visible, and non-visible.

You can specify a maximum time to wait for the states of the fields to match the conditions in this step.

**Inputs**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step.</td>
</tr>
<tr>
<td></td>

</tr>
<tr>
<td>Upload Attachments</td>
<td>Button to add one or more mandatory attachments to the form.</td>
</tr>
</tbody>
</table>

**Click Modal Button**

Click a button within a modal in the specified **Form UI**.

Specify your testing by selecting either the standard platform UI or workspace UI from the **Form UI** field. If you select the standard platform UI, this test step selects the button by ID on the specified modal and validates the following conditions:

- UI page was opened in a modal.
- Button is visible and enabled.

If you select an available workspace UI, this test step selects either the Confirm or Cancel action and optionally sets the field values within the modal. This step succeeds only if a modal dialog is open on the form, and if the specified button exists on that modal dialog.

Only modals opened with the following g_modal functions are supported:

- alert
- confirm
- confirmDestroy
- showFields

⚠️ Note: Click Modal Button now supports global and scoped application modals.
<table>
<thead>
<tr>

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Note</td>
<td>This field appears only if a workspace is chosen as Form UI.</td>
</tr>
</tbody>
</table>

**Assert type**
The effect on the tests on clicking the modal button.

- **Modal closed and page is reloaded or redirected**: The test passes only if the modal was closed and the page was reloaded or redirected to another page.

- **Modal closed and page is not reloaded or redirected**: The test passes only if the modal was closed and the page was not reloaded or redirected to another page.

- **Modal not closed**: The test passes only if the modal still exists and was not closed.

**Assertion timeout**
Number of seconds allowed before the assert fails. If the assert fails, the system repeats the assert until the duration of the Timeout is reached. If the validation fails after the Timeout duration has passed, the step fails.

**Click a UI Action**
Click a UI action on the current form.

When this step runs, the system performs the action normally activated by that control. The test step also validates that the current form contains the control and that the control is visible and enabled. To run this step, your test must have already opened a form using either the **Open a New Form** or **Open an Existing Record** step. It is recommended to not run this step directly after a **Submit a Form** or **Click a UI Action** step. This is because they can redirect your test to a different page based on the navigation stack configuration on your instance or the script defined in the clicked UI action. Unless you are certain that the UI action will take you to a specific page, you should explicitly use an **Open a New Form** step after **Submit a Form** or **Click a UI Action** to ensure that the test is on the form as expected. Ensure that the test keeps passing consistently when added to a suite.

In the Rome release, this step supports UI actions of type **Form context menu**.
Note: Don’t write tests that depend on the system displaying a specific page after executing a Submit a Form or Click a UI Action step. After these test steps, the system returns to the page that was open before the form was opened. The test cannot determine what that page was, so writing a test that expects a particular page can lead to unpredictable results.

Inputs

Submit a Form

Submit the current form.

To run this step, your test must have already opened a form using either the Open a New Form or Open an Existing Record step. It is recommended to not run this step directly after a Submit a Form or Click a UI Action step. This is because they can redirect your test to a different page based on the navigation stack configuration on your instance or the script defined in the clicked UI action. Unless you are certain that the UI action will take you to a specific page, you should explicitly use an Open a New Form step after Submit a Form or Click a UI Action to ensure that the test is on the form as expected. Ensure that the test keeps passing consistently when added to a suite.

ℹ️ Note: Don’t write tests that depend on the system displaying a specific page after executing a Submit a Form or Click a UI Action step. After these test steps, the system returns to the page that was open before the form was opened. The test cannot determine what that page was, so writing a test that expects a particular page can lead to unpredictable results.
Note: A modal form appears either on top of another form or a list. To submit a modal form, your test must have already opened it on top of a form or a list.

Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you're adding the step to.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
</tbody>
</table>
Inputs (continued)

<table>
<thead>
<tr>
<th>Field</th>

<tr>
<td>record</td>
<td>The sys_id of the submitted record.</td>
</tr>
</tbody>
</table>

Service Catalog category

Validate single catalog item transactions as well as requester and fulfiller flows in Service Catalog.

Activation of the Automated Test Framework for Service Catalog

These test steps require activation of the The Automated Test Framework Service Catalog (com.glide.automated_testing_impl.service_catalog) plugin, which is active by default on new instances. Administrators may need to activate the plugin on instances upgraded from earlier versions.
Support for parametrized tests

Service Catalog step configurations support parametrized tests. For more information on parametrized tests, refer to Parameterized tests.

Variable editor support

After opening a record that supports variable editor (requested item, catalog task, or incident), you can add step configurations to set variable values, or validate variable states or values. Use the step configurations in the following order to support variable editor.

1. Step configurations to order a catalog item or record producer in the Service Catalog category.
2. Open an Existing Record step configuration in the Form category.
3. Set Variable Values, Validate Variable Values, or Variable State Validation step configuration in the Service Catalog category.

Note: Custom variables and custom variable with labels are not supported for Set Variable Values, Validate Variable Values, and Variable State Validation step configurations.

Open a Catalog Item

Open a catalog item.

<table>
<thead>
<tr>
<th>Field</th>

</tbody>
</table>

Set Variable Values

Set variable values for the current catalog item or the record producer. For a catalog item, use this step after opening a catalog item page using the Open a Catalog Item step, and before using the Order Catalog Item step. For a record
producer, use this step after opening a record producer page using the Open a Record Producer step, and before using the Submit Record Producer step.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the Execution order values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you’re adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td></td>
<td>Note: Use the condition builder to set the field value. The condition builder displays an appropriate control for the field data type. For example, a reference field displays a Lookup record control.</td>
</tr>
<tr>
<td>Item</td>
<td>Catalog item or record producer for which you want to set variable values.</td>
</tr>
<tr>
<td>Variable Values</td>
<td>List of variables and the values that you want to set for them.</td>
</tr>
<tr>
<td></td>
<td>Note: You can set the value for multiple variables.</td>
</tr>
</tbody>
</table>

**Set Catalog Item Quantity**

Set the quantity for the current catalog item.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>

<td>Recurring price of the catalog item for the step to pass.</td>
</tr>
<tr>
<td>Recurring price frequency</td>
<td>Recurring price frequency of the catalog item for the step to pass.</td>
</tr>
</tbody>
</table>

Add Item to Shopping Cart

Add a catalog item to the shopping cart. Use this step after opening a catalog item page using the Open a Catalog Item step. After this step, you cannot use any other steps on the catalog item.

Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the Execution order values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you’re adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
</tbody>
</table>
Inputs (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Assert Type</td>
<td>Criteria for the test to pass.</td>
</tr>
</tbody>
</table>

**Successfully added item to Shopping Cart**

Test passes only if the catalog item is successfully added to the shopping cart.

**Cannot add item to Shopping Cart**

Test passes only if the catalog item cannot be added to the shopping cart.

Outputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cart_item_id</td>
<td>The sys_id of the added catalog item.</td>
</tr>
</tbody>
</table>

**Order Catalog Item**

Clicks **Order Now** for a catalog item. Use this step after opening a catalog item page using the Open a Catalog Item step. After this step, you cannot use any other steps on the catalog item. If the two-step checkout is false, a request is generated for the catalog item. If the two-step checkout is true, you are redirected to the cart preview page.

Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. </tbody>
</table>

### Outputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>record_id</td>
<td>The sys_id of target record of the record producer.</td>
</tr>
</tbody>
</table>

### Forms in Service Portal category

Validate the functionality of fields and UI actions in Service Portal form widgets.
# Service Portal dependency

Creating automated Service Portal steps requires knowledge of the ServiceNow data model and Service Portal form and data structures.

## Open a Form (SP)

Opens a form in a portal.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you're adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Portal</td>
<td>Portal in which the defined form opens. Service Portal is the default.</td>
</tr>
<tr>
<td>Page</td>
<td>Page to open in the defined portal. The form page is the default.</td>
</tr>
<tr>
<td>Table</td>
<td>Table containing the form to open.</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the record to open. Default is -1, which opens a new record.</td>
</tr>
</tbody>
</table>
### Field Values (SP)

Sets the values of fields in a form. To use this step, you must have already opened a form using the **Open a Form (SP)** test step.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step.</td>
</tr>
<tr>
<td></td>
<td>As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you're adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
</tbody>
</table>

**Note:** Use the condition builder to set the field value. The condition builder displays an appropriate control for the field data type. For example, a reference field displays a **Lookup record** control.

<table>
<thead>
<tr>
<th>Table</th>
<th>The table for the form on which to set field values. The value should be the table in the <strong>Open a Form (SP)</strong> step.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Field values</td>
<td>Fields for which to set values and the values to be set for those fields.</td>
</tr>
</tbody>
</table>
Field Values Validation (SP)

Validates field values on the current form based on defined conditions. To use this step, you must have already opened a form using the **Open a Form (SP)** test step.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you're adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Use the condition builder to set the field value. The condition builder displays an appropriate control for the field data type. For example, a reference field displays a <strong>Lookup record</strong> control.</td>
</tr>
<tr>
<td>Table</td>
<td>The table that contains the form on which to validate fields. The value should be the table in the <strong>Open a Form (SP)</strong> step.</td>
</tr>
<tr>
<td>Conditions</td>
<td>Conditions used to validate one or more fields on the form. If the condition evaluates to true, the step passes.</td>
</tr>
</tbody>
</table>

Field State Validation (SP)

Validates field states on a form in Service Portal.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>

<tr>
<td>Not Mandatory</td>
<td>Validates whether the fields on this form are mandatory. The test fails if the fields are mandatory.</td>
</tr>
</tbody>
</table>

**Add Attachments to Form (SP)**

Test the functionality of attaching a file to a Service Portal form widget.
To use this step, you must have already opened a form using the **Open a Form (SP)** test step or **Open Service Portal Page steps**. This step can’t be used after a **Submit Form** step or **Click a UI Action** step has been used.

### Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you’re adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Upload Attachments</td>
<td>Button to attach one or more files to the form.</td>
</tr>
</tbody>
</table>

### UI Action Visibility Validation (SP)

Determines whether a UI action on the current Service Portal form is visible. To use this step, you must have already opened a form using the **Open a Form (SP)** test step.

Service Portal only supports server UI actions. The setRedirectURL() method and client UI actions are not supported. UI action visibility can vary depending on the currently logged in or impersonated user.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>in. You can change this default order by editing the Execution order values.</td>
<td></td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you’re adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Table</td>
<td>The table for the form on which to check UI action visibility. The value should be the table in the <strong>Open a Form (SP)</strong> step.</td>
</tr>
<tr>
<td>Visible</td>
<td>Fields from the UI Actions table to be checked for visibility. Includes only form-based UI actions. The test fails if the UI action is not visible on the form for the currently logged in user.</td>
</tr>
<tr>
<td><em>Note:</em> If the list contains UI actions with the same name, check the form to determine the sys_id of the element. Then filter by sys_id in the UI Action table to select the correct element in the step.</td>
<td></td>
</tr>
<tr>
<td>Not visible</td>
<td>Fields from the UI Actions table to be checked for visibility. Includes only form-based UI actions. The test fails if the UI action is visible on the form for the currently logged in user.</td>
</tr>
<tr>
<td><em>Note:</em> If the list contains UI actions with the same name, check the form to determine the sys_id of the element. Then filter by sys_id in the UI Action table to select the correct element in the step.</td>
<td></td>
</tr>
</tbody>
</table>

**Click UI Action (SP)**

Selects a UI action on the current Service Portal form and outputs the table and sys_id of the record on which the action was selected.
To use this step, you must have already opened a form using the **Open a Form (SP)** test step. After using this step, you cannot use any other form steps.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. </tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you're adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Table</td>
<td>The table for the form on which to click a UI action. The value should be the table in the <strong>Open a Form (SP)</strong> step.</td>
</tr>
<tr>
<td>UI action</td>
<td>The UI action to click, selected from the UI Actions table. Includes only form-based UI actions.</td>
</tr>
<tr>
<td>Assert type</td>
<td>Specifies where to check for form submission after clicking the UI action:</td>
</tr>
</tbody>
</table>
### Field Description

- **--None--**: Selects the UI action without validating mandatory or other fields.

- **Form submission canceled in browser**: Checks whether the form was canceled in the browser and did not reach the server due to validation or other issues.

- **Form submitted to server**: Checks whether the form was submitted to the server.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>record_id</td>
<td>Sys_id of the record on which the action was clicked.</td>
</tr>
<tr>
<td>table</td>
<td>Table with the clicked UI action.</td>
</tr>
</tbody>
</table>

### Submit a Form (SP)

Submits the current form in a Service Portal page and outputs the table and sys_id of the submitted record.

To use this step, you must have already opened a form using the **Open a Form (SP)** test step. After using this step, the page closes. You can't use any other steps on the current page.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step.</td>
</tr>
<tr>
<td></td>
<td>As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <strong>Execution order</strong> values.</td>

<td>Sys_id of the submitted record.</td>
</tr>
<tr>
<td>table</td>
<td>Table for the submitted record.</td>
</tr>
</tbody>
</table>

**List and Related List**

Validate the functionality and visibility of records and UI actions in lists and related lists.

**Validate Related List Visibility**

Validate the visibility of the selected related lists on a form.

**Inputs**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps</td>
</tr>
</tbody>
</table>
### Inputs (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>

<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Name of the test that you're adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Name of the step.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table of the parent form where related list visibility is validated.</td>
</tr>
<tr>
<td>Visible</td>
<td>List of related lists to assert as visible.</td>
</tr>
<tr>
<td>Not visible</td>
<td>List of related lists to assert as not visible.</td>
</tr>
</tbody>
</table>

### Apply Filter to List

Apply a filter to a list to find the required record.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>

<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Name of the test that you're adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Name of the step.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>List type</td>
<td>Option to select the type of list.</td>
</tr>
</tbody>
</table>
Inputs (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>List</td>
<td></td>
</tr>
<tr>
<td>Related list</td>
<td></td>
</tr>
</tbody>
</table>

Assert Type
Specifies the assertion on executing the test step:
- **At least one matching record found**: The step succeeds if there is at least one matching record.
- **No matching record found**: The step fails if there is any matching record.
- **One matching record found**: The step succeeds if there is exactly one matching record.

Table
If the **List type** is **List**, this field is the table of the opened list.
If the **List type** is **Related list**, this field states the name of the table of the parent form where the list belongs.

Related List
The related list to apply a filter to.

Note: This field is available when **Related list** is selected from **List type**.

List filter
Filter conditions to apply to the list.

Outputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>first_record</td>
<td>The first record found in the list after applying the indicated filter.</td>
</tr>
</tbody>
</table>

Validate Record Present in List

Validate the presence of a record in a list. A valid form must be open and the list containing the record must be visible to proceed.

Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step.</td>
</tr>
<tr>
<td></td>
<td>As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps</td>
</tr>
<tr>

<td><strong>Note:</strong> This field appears when you choose Single record in the Apply to field.</td>
</tr>
</tbody>
</table>

**REST category**
Verify the functionality of REST calls.

**Send REST Request - Inbound - REST API Explorer**
This test step begins with the REST API Explorer. Use the REST API Explorer to create and specify the HTTP method, path, query parameters, request headers, and body of a REST request, and then send the REST request to the current instance.
When you have tested the request, the **Create Automated Test Step** button appears. Click **Create Automated Test Step** to create the test step. This button does not appear until after the request has been sent. You cannot create a test step when the request payload is larger than the maximum request payload size property.

This test step creates the same test record as the **Send REST Request - Inbound** test step. After the test step is created, you cannot go back and use the REST API Explorer to update the test. All changes must be made on the **Send REST Request - Inbound** test step form.

No HTTP response validation is performed as part of this step. The step fails if the response payload size is too big, the request parameters are invalid, or the request could not be sent. Use the assert steps to validate the response.

You cannot use this step to send a request to another instance or third party/remote address.

These inputs are for the REST API Explorer. The fields you see depend upon the API selected. For more information on using REST APIs on your instance, see **REST API**.

**Inputs**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Namespace</td>
<td>Namespace for the request. Select from the list.</td>
</tr>
<tr>
<td>API Name</td>
<td>API to be used. Select from the list.</td>
</tr>
<tr>
<td>API Version</td>
<td>API version to be used. Select the version available on your instance from the list.</td>
</tr>
<tr>
<td>Path parameters</td>
<td>The part of the path after the API name. Path parameters are generally name-value pairs where the allowable values are in a list.</td>
</tr>
<tr>
<td>Query parameters</td>
<td>Name-value pairs of query parameters added to the URI after the path.</td>
</tr>
<tr>
<td>Request headers</td>
<td>Name-value pairs contained in the request header. The authentication</td>
</tr>
</tbody>
</table>
**Send REST Request - Inbound**

Create a test step to send a REST request to the current instance. Specify the HTTP method, path, query parameters, request headers, and body of a REST request.

No HTTP response validation is performed as part of this step. The step fails if the response payload size is too big, the request parameters are invalid, or the request could not be sent. Use the assert steps to validate the response.

You cannot use this step to send a request to another instance or third party/remote address.

For more information on using REST APIs, see the [REST API](#).

<table>

<td>The body of the request.</td>
</tr>
</tbody>
</table>

### Assert Status Code

Assert that the HTTP response status code has the specified relationship to the specified value. You specify a numeric value of the status code and the relationship.

Assert steps must immediately follow a **Send REST Request - Inbound** step. You can have multiple REST assert steps following a **Send REST Request - Inbound** step, but the assert steps cannot be separated from the **Send REST Request - Inbound** step by steps from other test categories.
<table>

<td></td>
<td>• greater than or is</td>
</tr>
<tr>
<td>Status code</td>
<td>Status code to be tested against the response code.</td>
</tr>
</tbody>
</table>
Assert Status Code Name

Assert that the HTTP response status code name has the specified relationship to the specified value. You specify a value of the status code name, and the relationship.

Assert steps must immediately follow a **Send REST Request - Inbound** step. You can have multiple REST assert steps following a **Send REST Request - Inbound** step, but the assert steps cannot be separated from the **Send REST Request - Inbound** step by steps from other test categories.

## Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step.</td>
</tr>
<tr>
<td></td>
<td>As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you’re adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Operation</td>
<td>Comparison to be performed between values:</td>
</tr>
</tbody>
</table>
### Inputs (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• contains</td>
<td></td>
</tr>
<tr>
<td>• does not contain</td>
<td></td>
</tr>
<tr>
<td>• is</td>
<td></td>
</tr>
<tr>

<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Operation</td>
<td>Comparison to be performed between Response time entered and actual response time:</td>
</tr>
<tr>
<td></td>
<td>• less than</td>
</tr>
<tr>
<td></td>
<td>• greater than</td>
</tr>
<tr>
<td>Response time (ms)</td>
<td>Time in milliseconds to be compared to the actual response time.</td>
</tr>
</tbody>
</table>

### Assert Response Header

Assert the HTTP response header exists, or the header has the specified relationship to the specified value.

Assert steps must immediately follow a **Send REST Request - Inbound** step. You can have multiple REST assert steps following a **Send REST Request - Inbound** step, but the assert steps cannot be separated from the **Send REST Request - Inbound** step by steps from other test categories.
Inputs (continued)

<table>
<thead>
<tr>
<th>Field</th>

<tr>
<td>Test</td>
<td>Read-only name of the test that you're adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Element path</td>
<td>XML path to the element to be evaluated. For example, /result/short_description for</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&quot;result&quot;: {</td>
</tr>
<tr>
<td></td>
<td>&quot;number&quot;: &quot;INC0020001&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;short_description&quot;: &quot;test&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>Operation</td>
<td>Comparison to be performed between values:</td>
</tr>
</tbody>
</table>
Inputs (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• contains</td>
</tr>
<tr>
<td></td>
<td>• does not contain</td>
</tr>
<tr>
<td></td>
<td>• is</td>
</tr>
<tr>
<td></td>
<td>• is not</td>
</tr>
<tr>
<td></td>
<td>• is not empty</td>
</tr>
</tbody>
</table>

Value

Element value to be used in the test. Not shown if the Operation is is not empty.

Assert JSON Response Payload Element

Assert the JSON response payload element exists, or has the specified relationship to the specified value.

Assert steps must immediately follow a Send REST Request - Inbound step. You can have multiple REST assert steps following a Send REST Request - Inbound step, but the assert steps cannot be separated from the Send REST Request - Inbound step by steps from other test categories.

Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the Execution order values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>

<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you're adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
</tbody>
</table>
| Element path| SNC path to the element to be evaluated. For example, /result/short_description for 

```json
{
  "result": {
    "number": "INC0020001",
    "short_description": "test"
  }
}
```

See Importing JSON files for more information. |
| Operation   | Comparison to be performed between values: |
|             | • contains |
|             | • does not contain |
|             | • is |
|             | • is not |
|             | • is not empty |
| Value       | Element value to be used in the test. Not shown if the Operation is is not empty. |
Assert Response Payload

Assert the HTTP response payload has the specified relationship to the specified value. You specify the value and the relationship.

Assert steps must immediately follow a Send REST Request - Inbound step. You can have multiple REST assert steps following a Send REST Request - Inbound step, but the assert steps cannot be separated from the Send REST Request - Inbound step by steps from other test categories.

ℹ️  Note: The entire payload is used to look for a match. A large payload can affect performance.

Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step.</td>
</tr>
<tr>
<td></td>
<td>As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the Execution order values.</td>

</tbody>
</table>
Inputs (continued)
Field

Description

• contains
• does not contain
• is
• is not
• is not empty
Response body

The value of the response body to be
used in the test.
Must contain the name and value
to be compared as it appears in the
response payload. Must not contain
any curly braces.
Not shown if the Operation is is not
empty.

To check the short description in the response payload
{"result":{"number":"INC0010040","short_description":"Test ATF Incident"}}

the Response body should contain
"short_description":"Test ATF Incident"

These formats are incorrect and the step fails.
• {"short_description":"Test ATF Incident"}
• "{"short_description":"Test ATF Incident"}"
• short_description: Test ATF Incident
• short_description:"Test ATF Incident"
Email category
Use Automated Test Framework (ATF) to test email notifications, outbound email
flows, and inbound email responses.
Validate Outbound Email
Verify that a certain outbound email exists by searching for it in the Email
[sys_email] table.

Use this step to test any email-generating script that isn’t captured in the Validate Outbound Email Generated by Flow or Validate Outbound Email Generated by Notification test steps.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution</td>
<td>Integer specifying the order in which the test executes this step.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Test</td>
<td>Name of the test that you’re adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Name of the step.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Conditions</td>
<td>Conditions used to filter outbound emails.</td>
</tr>
<tr>
<td>Table</td>
<td>Table to be queried.</td>
</tr>
</tbody>
</table>

Note: During testing, this step may take longer than expected to execute. The step times out after two minutes by default.

Validate Outbound Email Generated by Flow

Verify that a certain outbound email exists by searching for it in the Email table. Use this step to test that a flow is triggered as expected.

Note: This step searches only for emails that are created by a flow Send Email action. To find an email that was sent after a notification was triggered in a flow, use the Validate Outbound Email Generated by Notification step instead. To find an email that was created in any other flow action, such as a custom scripted action, use the Validate Outbound Email step instead.
Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
<tr>

<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Test</td>
<td>Name of the test that you’re adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Name of the step.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Source Flow</td>
<td>Flow that the outbound email was created from.</td>
</tr>
<tr>
<td>Conditions</td>
<td>Conditions used to filter outbound emails. For example, to find an email that was sent to <a href="mailto:user@example.com">user@example.com</a>, set the condition to [Recipients] [is] [<a href="mailto:user@example.com">user@example.com</a>].</td>
</tr>
<tr>
<td>Table</td>
<td>Table to be queried. By default, this step queries only the Email [sys_email] table.</td>
</tr>
</tbody>
</table>

⚠ **Note:** During testing, this step may take longer than expected to execute. The step times out after two minutes by default.

**Validate Outbound Email Generated by Notification**

Verify that a certain outbound email exists by searching for it in the Email [sys_email] table. Use this step to test that an email notification is triggered as expected.

Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps</td>
</tr>
</tbody>
</table>
### Inputs (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them. You can change this default order by editing the <strong>Execution order</strong> values.</td>

<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
</tbody>
</table>
Inputs (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Test</td>
<td>Name of the test that you’re adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Name of the step.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>From</td>
<td>Address of the email sender. You can manually enter an email address or reference an email address from a user record. If you manually enter an email address, the system matches the address to an existing user record during testing.</td>
</tr>
<tr>
<td>To</td>
<td>Address of the email recipient. You can manually enter an email address or reference an email address from a user record. If you manually enter an email address, the system matches the address to an existing user record during testing.</td>
</tr>
<tr>
<td>Subject</td>
<td>Subject of the email. You can enter text or reference a string output from a previous test step.</td>
</tr>
<tr>
<td>Body</td>
<td>Content of the message body. You can enter text or reference a string output from a previous test step.</td>
</tr>
</tbody>
</table>

Output

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>output_email_record</td>
<td>Record in the Email [sys_email] table.</td>
</tr>
<tr>
<td></td>
<td>The <strong>Receive type</strong> is <strong>New</strong> and the <strong>Type</strong> is <strong>send-ready</strong>. For more information on what these fields mean, see <em>System email log and mailboxes</em>.</td>
</tr>
</tbody>
</table>

Generate Inbound Reply email

Create a reply email record to test how the system handles a user response to an email notification.

Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
Inputs (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Test</td>
<td>Name of the test that you’re adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Name of the step.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Target Table</td>
<td>Table of the target record.</td>
</tr>
<tr>
<td>Target Record</td>
<td>Record that the reply email updates. Selecting a target record also applies a watermark to the reply email.</td>
</tr>
<tr>
<td>From</td>
<td>Address of the email sender. You can manually enter an email address or reference an email address from a user record. If you manually enter an email address, the system matches the address to an existing user record during testing.</td>
</tr>
<tr>
<td>To</td>
<td>Address of the email recipient. You can manually enter an email address or reference an email address from a user record. If you manually enter an email address, the system matches the address to an existing user record during testing.</td>
</tr>
<tr>
<td>Subject</td>
<td>Subject of the email. You can enter text or reference a string output from a previous test step.</td>
</tr>
<tr>
<td>Body</td>
<td>Content of the message body. You can enter text or reference a string output from a previous test step.</td>
</tr>
</tbody>
</table>

Output

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| output_reply_email_record | Record in the Email [sys_email] table.  
The **Receive type** is **Reply** and the **Type** is **send-ready**. For more information on what these fields mean, see **System email log and mailboxes**. |
Generate Random String

Generate a string of random alphanumeric characters that you can use as test data for another step.

**Inputs**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Test</td>
<td>Name of the test that you're adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Name of the step.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Length</td>
<td>Number of characters in the generated string. The maximum length is 10,000 characters. If you leave the field blank, the string length is 10 characters by default.</td>
</tr>
</tbody>
</table>

**Output**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>random_string</td>
<td>String of random alphanumeric characters.</td>
</tr>
</tbody>
</table>

**Server category**

Perform server-side operations. For example, query and update a record, impersonate a user, or run a server-side script.

**Create a User**

Create a user with specified roles and groups for the test. The user record gets rolled back after the test completes.
**Inputs**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Test</td>
<td>Name of the test that you're adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Name of the step.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>First name</td>
<td>First name of the user.</td>
</tr>
<tr>
<td>Last name</td>
<td>Last name of the user.</td>
</tr>
<tr>
<td>Roles</td>
<td>Assigned roles of the user.</td>
</tr>
<tr>
<td>Groups</td>
<td>Assigned groups of the user.</td>
</tr>
<tr>
<td>Impersonate this user</td>
<td>Option to impersonate the new user.</td>
</tr>
</tbody>
</table>

**Outputs**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user</td>
<td>The user ID of the user impersonated.</td>
</tr>
</tbody>
</table>

**Impersonate**

Impersonate the specified user for the test.

**Impersonate** specifies a user for executing subsequent steps in this test. It works for both server-side and browser-side steps and stays in effect until changed with another **Impersonate** step or until the test ends. The impersonation automatically ends when the test is over.
Note:

- Do not impersonate a user with the test author role. Doing so can lead to conflicts that interfere with executing the test.
- Tests which involve impersonated users which no longer exist fail.

**Tip:** It is recommended to create a new user to avoid data dependencies. See Create a User, for more information.

- Do not rely on user IDs being consistent across different instances. The system dynamically assigns users IDs, so the ID for a particular user often differs from one instance to the next.
- When exporting and importing automated tests, keep in mind that update sets do not update the user field.
- Tests can impersonate users with the snc_external role, which allows testing users who do not have login access. See Explicit Roles for requirements of the snc_external role.

### Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| Execution order | Integer specifying the order in which the test executes this step.  
As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the Execution order values. |
| Active      | Option to activate this test step for use.                                 |
| Application | Application scope in which the system runs this step.                      |
| Test        | Read-only name of the test that you're adding the step to.                  |
| User        | The user ID for the test to impersonate.                                   |

### Outputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user</td>
<td>The user ID of the user impersonated.</td>
</tr>
</tbody>
</table>
Search for a Catalog Item

Searches for a catalog item or record producer in the specified catalog and category. You can perform this step both in Platform and Service Portal.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you’re adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Search in Portal only</td>
<td>Selected if the search is restricted to the Service Portal only. Otherwise, not selected.</td>
</tr>
<tr>
<td>Search term</td>
<td>Term used to search for a catalog item.</td>
</tr>
<tr>
<td>Catalog</td>
<td>Catalog in which to search for the catalog item.</td>
</tr>
<tr>
<td>Category</td>
<td>Category in which to search for the catalog item.</td>
</tr>
<tr>
<td>Assert item</td>
<td>Catalog items that should be available in the search results.</td>
</tr>
<tr>
<td>Assert Type</td>
<td>Specifies how searching the catalog item affects the test:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Assert Item present in search result:</strong> Test passes only if the assert item is present in the search result.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Assert Item not present in search result:</strong> Test passes only if the assert item is not present in the search result.</td>
</tr>
</tbody>
</table>
Outputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>catalog_item_id</td>
<td>The sys_id of the first catalog item found that the user can view.</td>
</tr>
</tbody>
</table>

Record Query

Query the database to verify that a record exists matching the conditions set in this step.

Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step.</td>
</tr>
<tr>
<td></td>
<td>As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the Execution order values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you're adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Enforce security</td>
<td>Selected to enforce ACLs. Otherwise, not selected.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
</tbody>
</table>
### Inputs (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong></td>
<td>Use the condition builder to set the field value. The condition builder</td>
</tr>
<tr>
<td></td>
<td>displays an appropriate control for the field data type. For example, a</td>
</tr>
<tr>
<td></td>
<td>reference field displays a <strong>Lookup record</strong> control.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Assert type</th>
<th>Specifies how querying the record affects the test:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>There is at least one record matching the query</strong>: The test fails if</td>
</tr>
<tr>
<td></td>
<td>there are no records matching the query.</td>
</tr>
<tr>
<td></td>
<td>• <strong>No records match the query</strong>: The test fails if any records match the</td>
</tr>
<tr>
<td></td>
<td>query.</td>
</tr>
</tbody>
</table>

| Table       | The table to be queried.                                                    |
| Conditions  | Conditions used to run the query.                                           |

### Outputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>The table queried.</td>
</tr>
<tr>
<td>first_record</td>
<td>The first record resulting</td>
</tr>
<tr>
<td></td>
<td>from the query.</td>
</tr>
</tbody>
</table>

*Note:* If you don’t update your record query test step, the original record query test step still functions the same way as before, irrespective of it being termed as *(Deprecated)*.

### Record Insert

Inserts a record into a table with the field values you specify.

### Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution</td>
<td>Integer specifying the order in which the test executes this step.</td>
</tr>
<tr>
<td>order</td>
<td>As you create steps, the system automatically assigns each step an</td>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you're adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Use the condition builder to set the field value. The condition builder displays an appropriate control for the field data type. For example, a reference field displays a <em>Lookup record</em> control.</td>
</tr>
<tr>
<td>Assert type</td>
<td>Specifies how inserting the record affects the test:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Record successfully inserted:</strong> Test fails if the record was not successfully inserted.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Record was not inserted:</strong> Test fails if the record was successfully inserted.</td>
</tr>
<tr>
<td>Enforce security</td>
<td>Selected to enforce ACLs and the read-only role. Otherwise, not selected.</td>
</tr>
<tr>
<td>Table</td>
<td>The table into which the record should be inserted.</td>
</tr>
<tr>
<td>Conditions</td>
<td>Specific field values to be set when the test runs this step.</td>
</tr>
</tbody>
</table>

### Outputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>The table to which the new record belongs.</td>
</tr>
<tr>
<td>record_id</td>
<td>The sys_id of the new record.</td>
</tr>
</tbody>
</table>

### Record Update

Changes field values on a record on the server.
Note: To ensure that the changes were applied, follow this step with a **Record Validation** step.

### Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you’re adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Assert type</td>
<td>Specifies how updating the record affects the test:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Record successfully updated</strong>: Test fails if the record was not successfully updated.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Record was not updated</strong>: Test fails if the record was successfully updated.</td>
</tr>
<tr>
<td>Enforce security</td>
<td>Selected to enforce ACLs and the read-only role. Otherwise, not selected.</td>
</tr>
<tr>
<td>Table</td>
<td>The table containing the record to be updated.</td>
</tr>
<tr>
<td>Record</td>
<td>ID of the record to be updated.</td>
</tr>
<tr>
<td>Field values</td>
<td>Fields for which you want to set values and the values you want to set for those fields.</td>
</tr>
</tbody>
</table>
Inputs (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong></td>
<td>Use the condition builder to set the field value. The condition builder displays an appropriate control for the field data type. For example, a reference field displays a <strong>Lookup record</strong> control.</td>
</tr>
</tbody>
</table>

| **Note:** | Record Update step succeeds even if a field on the record is blocked by ACL. Use the **Record Validation** step after Record Update to check whether a particular field was modified, or use the **Form steps** to evaluate ACL conditions for individual fields on a record. |

**Record Delete**

Deletes a specified record in a table.

**Inputs**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you're adding the step to.</td>
</tr>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Assert type</td>
<td>Specifies how updating the record affects the test:</td>
</tr>
</tbody>
</table>
### Record Validation

 Validates that a record meets the specified conditions on the server side.

 For the **Record Validation** step, specify the values you want to test using the standard conditions builder. You can apply several conditions to the same field. This step passes if the overall condition is satisfied and fails if it is not. If you need to test the values of individual fields independently of each other, include a separate **Record Validation** step for each value to be tested.

### Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Number of seconds allowed before the step fails. If the validation fails, the system repeats the step until it reaches the duration of the timeout. If the validation fails after the timeout duration has passed, the step fails.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you’re adding the step to.</td>
</tr>
</tbody>
</table>
**Inputs (continued)**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Use the condition builder to set the field value. The condition builder displays an appropriate control for the field data type. For example, a reference field displays a <code>Lookup record</code> control.</td>
</tr>
<tr>
<td>Assert type</td>
<td>Specifies how validating the record affects the test:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Record successfully validated:</strong> The test fails if the record does not match the conditions.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Record not found:</strong> Test fails if the record is found.</td>
</tr>
<tr>
<td>Table</td>
<td>The table that contains the field to be validated.</td>
</tr>
<tr>
<td>Record</td>
<td>The record that contains the field to be validated.</td>
</tr>
<tr>
<td>Field values</td>
<td>Specific fields to be validated when the test runs this step.</td>
</tr>
</tbody>
</table>

**Run Server Side Script**

Executes a script on the server.

**Inputs**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <code>Execution order</code> values.</td>
</tr>
<tr>
<td>Active</td>
<td>Option to activate this test step for use.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this step.</td>
</tr>
<tr>
<td>Test</td>
<td>Read-only name of the test that you’re adding the step to.</td>
</tr>
</tbody>
</table>
Inputs (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Step config</td>
<td>Read-only name of the step.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the test step. This field value is automatically set based on the field values of the test step. This field appears after the test step is submitted.</td>
</tr>
<tr>
<td>Notes</td>
<td>Notes about the test step.</td>
</tr>
<tr>
<td>Jasmine version</td>
<td>The version of the Jasmine testing framework to use for running the server-side script. Any new scripts you create use Jasmine version 3.1. Your existing scripts can continue to use Jasmine version 1.3, or you can upgrade them to Jasmine version 3.1.</td>
</tr>
<tr>
<td>Test script</td>
<td>The javascript for the server to execute. Supports the Jasmine testing framework.</td>
</tr>
<tr>
<td></td>
<td>Note: steps(SYS_ID) can be defined as a function to retrieve Output variable data from a step that executed earlier in the test.</td>
</tr>
</tbody>
</table>

Outputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>record_id</td>
<td>The sys_id output by the server-side script.</td>
</tr>
<tr>
<td>table</td>
<td>The table output by the server-side script.</td>
</tr>
</tbody>
</table>

Note: If the script creates data, the system rolls back that data after all steps in the test finish.

• Test script

```javascript
// Test step 1 - add data
var now_GR = new GlideRecord('sc_task');
// this sample step's Step config has Output variables named table and record_id
outputs.table = 'sc_task';
outputs.record_id = gr.insert();
// Test step 2 - access added data and validate
// check that the record exists (or that business logic changed it)
var now_GR = new GlideRecord("sc_task");
gr.get(steps(PREVIOUS_STEP_SYS_ID).record_id);
assertEqual({name: "task gr exists", shouldbe: true, value: gr.isValidRecord()});
```
stepResult.setOutputMessage: Log a message to step results after step executes.  
Can only be called once or will overwrite previous message

• Create a suite of test scripts

```javascript
var now_GR = new GlideRecord('sc_task');
gr.setValue('short_description', 'verify task can be inserted');
var grSysId = gr.insert();
var justCreatedGR = new GlideRecord('sc_task');
if (justCreatedGR.get(grSysId)) {
  stepResult.setOutputMessage("Successfully inserted task record");
  return true; // pass the step
} else {
  stepResult.setOutputMessage("Failed to insert task record");
  return false; // fail the step
}
```

• Jasmine test

```javascript
describe('my suite of script tests', function() {
  it('should meet expectations', function() {
    expect(true).not.toBe(false);
  });
});
// make sure to uncomment jasmine.getEnv().execute(); outside the function body
```

assertEqual: A function used to compare that assertion.shouldbe == assertion.value;  
in case of failure it throws an Error and logs that the assertion by name has failed

**Note:** describe is only supported in Global scope. Use describe to create a suite of test scripts and it to define test expectations

• Logs message to test step output

```javascript
var testAssertion = {
  name: "my test assertion",
  shouldbe: "expected value"
  value: "actual value",
};
assertEqual(testAssertion); // throws Error, logs message to test step output
```

• See Step Execution Scripts for Run Server Side script example.

**Replay Request Item**

Get the item and requester from an existing request item, add the item to a new cart for that user, and place an order.
## Inputs

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution order</td>
<td>Integer specifying the order in which the test executes this step. As you create steps, the system automatically assigns each step an incremental value. This value causes the test to execute steps in the order that you created them in. You can change this default order by editing the <strong>Execution order</strong> values.</td>
</tr>
<tr>
<td>Active</td>

**Automated Test Framework reference**

Reference information for the Automated Test Framework.
Tables excluded from rollback after running an automated test

The Automated Test Framework tracks data created by running tests and rolls back changes after testing. The system excludes certain tables from being tracked during testing.

The system excludes certain tables from being tracked or rolled back:

- The History [sys_history_line] table
- The ECC Queue table [ecc_queue].
- The Email [sys_email] Email Log [sys_email_log] tables
- The Execution Tracker [sys_execution_tracker] tables
- The Progress Worker [sys_progress_worker] table
- The Schema Change [sys_schema_change]
- The Upgrade History [sys_upgrade_history] and Upgrade History Log [sys_upgrade_history_log] tables
- The Mutex [sys_mutex] table
- The Plugin Log [sys_plugin_log] table
- The Status [sys_status] table
- The Number Counter [sys_number_counter] table
- The AMB Channel Presence [sys_amb_channel_presence] table
- Any table that extends an excluded table.
- Any table starting with the following prefixes are also excluded:
  - syslog
  - sys_amb_message
  - sys_cluster
  - cmdb_metric
  - ts_
  - v_
  - sys_delete_recovery

If your test run changes (inserts/updates/deletes) any record on these excluded tables, the system does not roll back the change after testing.
**Tests**

The Tests module opens the Test table. From here, you can add, edit, and run tests. By opening an individual test record, you can view and edit the steps comprising that test.

**Related information**

Building and running automated test suites

**Test record form**

In the Test record form, you view and edit values of fields for the test record.

**Fields**

<table>
<thead>
<tr>
<th>Field / UI Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Test name.</td>
</tr>
<tr>
<td>Description</td>
<td>Test description.</td>
</tr>
<tr>
<td>Active</td>
<td>If this test is active, true. Otherwise, false.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this test or test suite.</td>
</tr>
<tr>
<td>Test steps related list</td>
<td>The steps that this test executes.</td>
</tr>
<tr>
<td>Test results related list</td>
<td>The results from individual executions of this test.</td>
</tr>
</tbody>
</table>

**UI Actions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Update</td>
<td>Click to update the test record.</td>
</tr>
<tr>
<td>Run test</td>
<td>Click to run test.</td>
</tr>
<tr>
<td>Copy test</td>
<td>Click to copy test.</td>
</tr>
<tr>
<td>Delete</td>
<td>Click to delete this test.</td>
</tr>
</tbody>
</table>

**Suites**

The Suites module opens the Test Suites table. You can create, edit, and run test suites from this table.

<td></td>
</tr>
<tr>
<td>Test Suite Schedules</td>
<td>Any test suite schedules that include this test suite.</td>
</tr>
<tr>
<td>Schedules (related list)</td>
<td></td>
</tr>
</tbody>
</table>

Test results

Each time you run a test, the automated test framework creates a record of the test results. Use the Test Results module to view details about the results of individual tests and individual steps within a test. If the test generated screenshots, they appear as attachments on the test results record.

Each Test Results record displays detailed results information about one test execution, and contains links to detailed step results and test logs. Step results records display information about one step in a test result, while test log (test
results item) records contain detailed console logging and test execution information.

By default, the system deletes test and test suite results data 30 days after creation. You can modify this default retention policy as needed in the Table Cleanup module.

**Related information**

- Modify data retention policy for ATF test results
- Table Cleanup module

**Test results record**

A Test Results record contains detailed results information about one test execution. Client Error Details and Failure Details sections appear when a test fails due to error conditions, and include detailed error information you can use for troubleshooting purposes.

<table>

- Allow client errors from step results

**Test logs record**
The Test Results Item (test log) record contains console logging and test execution information.

During test execution, any information reported to the environment is recorded in the Test Log (sys_atf_test_result_item) table. This information can include browser console logging, results, and error messages recorded by step environments. You access specific test logs from the Test Log related list in the Test Results form.

<table>
<thead>
<tr>

<td>User canceled the test or suite.</td>
</tr>
</tbody>
</table>

**Type**

Type of test log:
- Step Result
- Client Log
- Client Error

**Note:** If a Client Error, you can optionally add it as an ignored or warning entry in the Allowed Client Errors. Doing so prevents the allowed client errors from affecting ATF test executions when they recur in future test runs. For more details, refer to Allowed client errors.

**Output**

Output generated for the test log.

</tbody>
</table>

**Related information**

**Test results**

**Test suite results examples**

Examples of relationship terms and how aggregated results roll up for test suites.
Example: Base test suite result

The base test suite is the top-level test suite in the hierarchy. For example, if you are viewing the test suite results record for (A) Test Suite 1.3.1, the base test suite result field links to the test suite results record for (B) Test Suite 1.

Example: Parent test suite results

The parent test suite is the test suite immediately above the one you are currently viewing. For example, if you are viewing the test suite results record for (A) Test Suite 1.3.1, the parent field links to the test suite results record for (B) Test Suite 1.3.
Rolled up counts for test suites results

You can view rolled up counts for a test suite for four metrics: test successes, failures, errors, and skips. Each of these sum data from all tests in the test suite plus all tests in the test suite’s descendents.

For example, if you are viewing the test suite results record for (A) Test Suite 1.3.1, the Rolled up test success count field shows the total number of successes counting results from all the tests represented by boxes labeled A.

If you are viewing the test suite results record for (B) Test Suite 1.3.1, the Rolled up test success count field shows the total number of successes counting results from all the tests represented by boxes labeled B.
Child Test Suites Results

If you are viewing the test suite results record for (A) Test Suite 1, the Child Test Suites Results related list shows result records for Test Suite 1.3 (B).
All Test Suites Results

If you are viewing the test suite results record for (A) Test Suite 1, the All Suites Results related list shows result records for all Test Suites represented by boxes labeled A.

If you are viewing the test suite results record for (B) Test Suite 1.3, the All Suites Results related list shows result records for all Test Suite 1.3.1 only (represented by the box labeled B)
Suite schedules

Open the Suites Schedules table. You can drill down to see details about the results of individual schedules or create a new schedule.

</tr>
</tbody>
</table>

### Active manual test runners

View the client test runners table filtered to show only those runners available to run manually-started tests.

When you start a manual client test runner, the system registers that runner in the Test Runners table as active.

The data in this table is transient. While the runner is active, it reports in to the system at a specified interval. If the runner does not report in at the expected time, the system marks the runner as inactive. After a period of time the system deletes the runner. You can modify these intervals on the Automated Test Framework properties page.
### Example Active Manual Client Runner Test table

![Example Active Manual Client Runner Test table](image)

### Fields on the Client Runner Test table

<table>
<thead>
<tr>
<th>Field / UI Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>Whether this test runner is for manual or scheduled tests. In the Active Manual Test Runners module, Type is always <strong>Manual</strong>.</td>
</tr>
<tr>
<td><strong>User</strong></td>
<td>The user logged into the browser session.</td>
</tr>
<tr>
<td><strong>Browser name</strong></td>
<td>The browser name.</td>
</tr>
<tr>
<td><strong>Browser version</strong></td>
<td>The browser version.</td>
</tr>
<tr>
<td><strong>OS name</strong></td>
<td>The name of the operating system running the browser.</td>
</tr>
<tr>
<td><strong>OS version</strong></td>
<td>The version of the operating system running the browser.</td>
</tr>
<tr>
<td><strong>Status</strong></td>
<td>Whether this runner is currently online or offline. In the Active Manual Test Runners module, Status is always <strong>Online</strong>.</td>
</tr>
<tr>
<td><strong>Last checkin</strong></td>
<td>The time/date this runner most recently reported in to the system.</td>
</tr>
<tr>
<td><strong>Status reason</strong></td>
<td>If the Status is Offline, the reason why. In the Active Manual Test Runners module, Status reason is always empty.</td>
</tr>
</tbody>
</table>

### Active scheduled test runners

View the client test runners table filtered to show only those runners available to run tests to be started by a schedule.
When you start a **scheduled client test runner**, the system registers that runner in the Active Scheduled Test Runners table.

The Active Scheduled Test Runner module is useful when you create a scheduled suite run. For scheduled suite runs, you can specify the browser to use. To determine the name and version of a browser you want to use, start a scheduled test runner with that browser, then inspect that runner’s record in the Active Scheduled Test Runners module.

The data in this table is transient. While the runner is active, it reports in to the system at a specified interval. If the runner does not report in at the expected time, the system marks the runner as inactive. After a period of time the system deletes the runner.

You can modify these intervals on the Automated Test Framework properties page.

### Example Scheduled Client Runner Test table

<table>
<thead>
<tr>

<td>If the Status is Offline, the reason why. In the Active Scheduled Test Runners module, Status reason is always empty.</td>
</tr>
</tbody>
</table>

**Waiting/running test runs**

The Waiting/Running Test Run module opens a list of records showing the tests waiting to be run.

⚠️ **Note:** To prevent conflicts, the system allows only one test to run at a given time. This is true even if you have multiple client test runner windows open. If you submit tests to run when another test is already running, the system holds the new tests in a queue to run later. If a test remains in the queue for more than ten minutes, the system cancels the test.

You can cancel execution of a waiting automated test.

**Waiting/running suite runs**

The Waiting/Running Suite Runs module opens a list of records showing the test suites waiting to be run.

**Allowed client error records**

Review the list of existing Allowed Client Error [sys_atf_whitelist] records to see which client errors produce warnings and which are ignored. Modify existing Allowed Client Error records as needed or create new ones.

**Allowed Client Error form**

### Step configurations

Step configuration records define how each type of step behaves.

### Automated Test Framework Step Config record

The step config record controls how a test step of this type behaves.

#### Fields

<table>
<thead>
<tr>
<th>Field / Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name for this test step configuration.</td>
</tr>
<tr>
<td>Active</td>
<td><strong>True</strong> if this step configuration is active. Otherwise, <strong>false</strong>.</td>
</tr>
<tr>
<td>Step Environment</td>
<td>The <strong>step environment</strong> in which a step with this configuration can run.</td>
</tr>
<tr>
<td>Category</td>
<td>The <strong>category</strong> assigned to a step with this configuration.</td>
</tr>
<tr>
<td>Application</td>
<td>The application scope in which the system runs steps with this configuration.</td>
</tr>
<tr>
<td>Batch order constraint</td>
<td>Constrains where a step with this configuration can appear in a test:</td>
</tr>
<tr>
<td>Field / Element</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>• <strong>None</strong>: A step based on this configuration can appear at any point in a test.</td>
<td></td>
</tr>
<tr>
<td>• <strong>Start Batch Execution</strong>: If a test includes this a step based on this configuration, it must be the first step in the test.</td>
<td></td>
</tr>
<tr>
<td>• <strong>Run in the middle of an execution</strong>: If a test includes a step based on this configuration, it cannot be the first or last step.</td>
<td></td>
</tr>
<tr>
<td>• <strong>Stop Execution</strong>: If a test includes a step based on this configuration, it must be the last step in the test.</td>
<td></td>
</tr>
<tr>
<td>Class type</td>
<td>For custom step configurations, this field is always <strong>Script</strong>.</td>
</tr>
<tr>
<td>Order</td>
<td>An integer specifying where steps with this configuration appear in the step list on the Add Test Step dialog. For more information, see the example using the Order field.</td>
</tr>
<tr>
<td>Template reminder</td>
<td>The instructions that appear when a step with this configuration is included in a test as part of a template. For more information, see the example of using the Template reminder field.</td>
</tr>
<tr>
<td>HTML description</td>
<td>The text that appears when the cursor highlights a step with this configuration on the Create New Step dialog. For more information, see the example using the HTML description field.</td>
</tr>
<tr>
<td>Description generation script</td>
<td>Generates the text that describes a step when a test includes it. For more information, see the example using the description generation script.</td>
</tr>
<tr>
<td>Step execution script</td>
<td>Script (javascript) that runs when a step with this config runs.</td>
</tr>
<tr>
<td>Input Variables related list</td>
<td>The variables that act as inputs for a step with this config.</td>
</tr>
<tr>
<td>Output variables related list</td>
<td>The variables that act as outputs for a step with this config.</td>
</tr>
</tbody>
</table>
Examples of step config field values

Examples of where the system displays values assigned to some of the step config fields.

Order field example

The steps in the middle column are sorted according to the values of the Order field.

Category field example

The labels in the left column show the categories for available steps. You can filter the list in the middle column, by selecting a category in the left column.
Template reminder example

Here is a portion of the new record form for a test step config for Example Custom Step.
When you add a template to a test, the system generates a set of instructions for completing the template steps and saves them in the test Description field. The text in the step config's **Template reminder field** appears as the instructions for the corresponding step.
HTML description example
Here is a portion of the new record form for a custom step named Example Custom Step.
Here is how the step appears in the Add Test Step dialog.
Description generation script example

Here is a portion of the new record form for a custom step named **Example Custom Step**.

```javascript
function generateDescription()
{
  // the global variable 'step' represents the current glide record
  var description = "This is the generated description for the example step;"
  return description;
}
```

When a step of this type is included in a test, the generated description appears in the Test Steps related list.
**Step execution scripts**

In a step configuration record, the step execution script field determines what a step with this configuration does when it runs.

**Step inputs**

The input variables to a step are determined by the inputs related list in the step configuration record. The `inputs` parameter to `executeScript()` gives the script access to these variables. For example, if the inputs related list contains two records, `var1` and `var2`, the script can reference `var1` with the expression `inputs.var1` and can reference `var2` with `inputs.var2`.

**Step outputs**

The output variables to a step are determined by the outputs related list in the step configuration record. The `outputs` parameter to `executeScript()` gives the script access to these variables. For example, if the outputs related list contains two records, `out1` and `out2`, the script can reference `out1` with the expression `outputs.out1` and can reference `out2` with `outputs.out2`.

**Step result**

The `stepResult` parameter provides access to an API that controls whether the step passes or fails. It also determines the message the step writes to the log.

The method `stepResult.setSuccess()` causes the step to succeed. The method `stepResult.setFailed()` causes the step to fail.

The method `stepResult.setOutputMessage()` sets the message to write to the log when the step succeeds or fails. It takes one parameter: the string to write to the log. If the script calls `stepResult.setOutputMessage()` more than once, the most recent value set overwrites any previous value.

**Example: Record Query step execution script**

```javascript
(function executeStep(inputs, outputs, stepResult) {
    if (gs.nil(inputs.table)) {
        stepResult.setOutputMessage(gs.getMessage("The '{0}' input variable was not specified", 'table'));
        stepResult.setFailed();
    }
    return;
})
```
```
var query = new GlideRecord(inputs.table);
query.addEncodedQuery(inputs.field_values);
query.query();
if (!query.next()) {
    stepResult.setOutputMessage(gs.getMessage("No records matching query:
    {0}",
    inputs.field_values));
    stepResult.setFailed();
} else {
    stepResult.setSuccess();
    outputs.table = inputs.table;
    outputs.first_record = query.getUniqueValue();
    stepResult.setOutputMessage(gs.getMessage("Found {0} {1} records matching
query:
    {2}",
    [query.getRowCount(),
    inputs.table,
    inputs.field_values]));
}
(inputs, outputs, stepResult));
```

Example: Custom scripted step configs

```
(function executeStep(inputs, outputs, stepResult, timeout) {
    // Waits up to the timeout for some asynchronous logic to finish
    // This script checks for completion once a second for up to 60 seconds
    var counter = 1;
    // Try for up to 60 seconds
    while (counter <= timeout) {
        // If the asynchronous logic is finished, return "true" to pass the step
        // isMyAsyncLogicFinished() can be replaced with any asynchronous event that needs to be
tested
        if (isMyAsyncLogicFinished()) {
            stepResult.setOutputMessage("Success!");
            stepResult.setSuccess();
            return;
        }
        // Wait one second, and log the total number of seconds waited
        gs.info("Waited " + counter + " seconds for asynchronous logic to finish");
        sn_atf.AutomatedTestingFramework.waitOneSecond();
        counter++;
    }

```

Note: The above example can also be used for Run Server Side script by replacing `stepResult.setSuccess()` and `stepResult.setFailed()` with `return true` and `return false`.

Step description generation script

In a step configuration record, the step description generation script field determines the step description that the system generates when a step of this type is added to a test.

For an example showing how where the description generated by this script appears, see Description generation script example.

Step

The `step` parameter to `generateDescription()` gives the script access to the step object, which in turn gives access to the input variables as defined in the step configuration record. (Input variables are defined in a related list.)

For example, if – in a step config record – the inputs related list contains two records: `var1` and `var2`, the script can reference `var1` with the expression `step.inputs.var1` and can reference `var2` with `step.inputs.var2`.

Example: Record Query description generation script

```javascript
(function generateDescription(step) {
    var td = GlideTableDescriptor.get(step.inputs.table);
    if (!td) {
        gs.log("Invalid table name in test step: " + step.inputs.table);
        return gs.getMessage("Set field values");
    }
    var descriptionGenerator = new ATFStepDescriptionGenerator();
    var description = gs.getMessage("There should be at least one record in '{0}' matching " +
        "a query of\n\n{1},
    [step.inputs.table.getDisplayValue(),
```
Add output variables to scripted steps

Execute the following steps to add additional outputs in Run Server Side Script and Custom Scripted StepConfig test steps.

Adding outputs in Run Server Side Script test step

Modify the test scripts of Run Server Side Script test step to create additional outputs of your choice.

Before you begin
Role required: admin or atf_test_admin

Procedure
1. Navigate to Automated Test Framework (ATF) > Administration > Step Configurations.
2. Search and select Run Server Side Script.
The read-only Test Step Config form shows up.

⚠ Note: Although the form is read-only, new output variables can be created.

3. Scroll down to the Output Variables related list.
The list of default output variables shows up.

4. Click New to create a new output variable.

<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Type of output variable</td>
</tr>
<tr>
<td>Application</td>
<td>Scope of the user</td>
</tr>
<tr>
<td>Label</td>
<td>User-facing name of the output variable</td>
</tr>
<tr>
<td>Column name</td>
<td>Variable name used in the script</td>
</tr>
<tr>
<td>Max length</td>
<td>Length of the data type.</td>
</tr>
</tbody>
</table>
The new output variable gets added to the Output Variable related list.

6. Select the test where you want to implement the new output variable.

7. Click Add Test Step.

9. Follow the instructions to change outputs mentioned in the Test script.

```plaintext
outputs.<column_name> = "<desired value>";
```

10. Click Submit.

   The newly created output variables are now ready to be used in any subsequent steps of the test.

Adding outputs in Custom Scripted StepConfig test step

Copy the Custom Scripted StepConfig test step and customize the copied version by adding additional outputs.

Before you begin

Role required: admin or atf_test_admin
Procedure

1. Navigate to **Automated Test Framework (ATF) > Administration > Step Configurations**.

2. Search and select Custom Scripted StepConfig. The read-only Test Step Config form shows up.

   **Note:** Since the form is read-only, you must copy the test step to customize it to add more output variables.

3. Click **Copy** to have a copied version of the test step.

   **Note:** The copied version is no longer read-only.

4. Add additional output variables in the copied version by implementing the following steps:

   a. Click **New** under Output Variables related list

   b. Modify **Step execution script** to add more output variables

   **Note:** See Adding outputs in Run Server Side Script test step to add more output variables.

   **Note:** You can use these steps to customize the test step only in the copied version.

5. Reuse the copied version of the test step in any test whenever required.
Test templates
The Test Templates module opens a list of available templates. From this module, you create, view, and edit test templates.

To view or edit a test template, click the row for the template you want. For more information, see Edit automated test steps template.

For information how to add a new template, see Create an automated test steps template. For information on how to use a template when creating a test, see Add a predefined list of steps (template) to an automated test.

Automated Test Template record
The Test Template record contains information about one test template.

Fields
<table>
<thead>
<tr>
<th>Field / Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name of this test template.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope in which the system runs this test or test suite.</td>
</tr>
<tr>
<td>Test Template</td>
<td>The tests to include in this template.</td>
</tr>
<tr>
<td>Description</td>
<td>(Optional) Enter a description to identify the purpose of this test template.</td>
</tr>
</tbody>
</table>

Step configuration categories
The Step Configuration Categories module opens a list of records specifying the step categories on the Add Step dialog. From this module, you can add, delete, and edit these categories.

Categories are used for filtering the step list in the Add Step dialog. For more information, see Category field example.

Test step config category form
On the Test Step Config Category form, you specify a retention policy for a set of records on a given test results table.
Fields

<table>
<thead>
<tr>
<th>Field / Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name for this step config category.</td>
</tr>
<tr>
<td>Step Environment</td>
<td>The step environment for this step config category.</td>
</tr>
<tr>
<td>Display name</td>
<td>The category name that appears in the middle column of the Add Test Step dialog when this category is selected. See an example in Step Config Category Display name.</td>
</tr>
<tr>
<td>Application scope</td>
<td>The application scope to which this policy applies.</td>
</tr>
</tbody>
</table>

Table cleanup

The Table Cleanup module opens a list of records specifying the retention policies for test result and test suite result tables and the records within them. From this module, you can view and modify these policies.

By default, the system deletes system records related to test results and test suite results 30 days after creation. To modify the retention policies for a table and its records, click the table for which you want to modify policies. For more information, see Modify data retention policy for ATF test results.

ℹ️ Note: Table cleanup policies are platform-specific policies. See Table cleaner for more information.

Autoflush form

On the Auto Flush form, you specify a retention policy for a set of records on a given test results table.

Fields

<table>
<thead>
<tr>
<th>Field / Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tablename</td>
<td>The table containing the records to which the policy applies.</td>
</tr>
<tr>
<td>Matchfield</td>
<td>The field for which the system monitors duration.</td>
</tr>
<tr>
<td>Age in seconds</td>
<td>The amount of time (in seconds) the system wait before deleting the records.</td>
</tr>
<tr>
<td>Active</td>
<td>True if this policy is active. Otherwise, false.</td>
</tr>
</tbody>
</table>
### Fields (continued)

<table>
<thead>
<tr>
<th>Field / Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application scope</td>
<td>The application scope to which this policy applies.</td>
</tr>
<tr>
<td>Cascade delete</td>
<td>If checked, the system deletes all matching records plus any records referring to them. If unchecked, the system deletes matching records, but not records referring to them.</td>
</tr>
<tr>
<td>Conditions</td>
<td>The filter conditions defining the records in this table to which the policy applies.</td>
</tr>
</tbody>
</table>

**Note:** Table cleanup policies are platform-specific policies. See Table cleaner for more information.

### Step environments

A test step environment specifies where the step executes (for example, server versus browser). In this release, custom step configs can use only the Server-Independent environment.

In this release, you cannot add custom test step environments.

### ServiceNow application repository

After you develop and test a custom application, you can make the application available to company instances by publishing it to the ServiceNow application repository.

The ServiceNow application repository is a central repository for all scoped applications that are published by all ServiceNow customers. The application repository allows ServiceNow customers to upload and distribute applications between their instances. When you access the application repository, you can see and manage only the applications that are published by your own organization. You can't see or manage applications that are published by other organizations.

After you have designed, developed, and successfully tested a custom application, you can publish your application to the ServiceNow application repository to share it to other instances in your company.

### Entitlements

An entitlement refers to permission given to an instance to install a scoped application from the application repository. An instance must be entitled to an application in order for you to be able to install the application on the instance.
By default, after you publish an application to the application repository, all your company instances are entitled to the application automatically. To limit which company instances are entitled to the application, access the application repository by going to https://apprepo.service-now.com, and then change the entitlement type for the application. You can also entitle an instance again if the application entitlement has already been removed. For more information, see Manage application entitlements from the application repository.

**Using the application repository**

You can access the application repository by going to https://apprepo.service-now.com.

After you publish an application to the application repository, you can:

- Install an application from the application repository
- Manage application entitlements from the application repository
- Delete an application from the application repository
- Release a scope from the application repository
- View scopes that are available to your company
- View keys that are available to your company

**Manage applications**

Learn how to manage the applications you publish to the ServiceNow application repository.

After you have designed, developed, and successfully tested a custom application, you can publish your application to the ServiceNow application repository to share it to other instances in your company. You can see, manage and customize only the applications that are published by your own organization or scoped applications that are installed via plugins using the ServiceNow Application Repository. You can't see or manage, or customize applications that are published by other organizations.

**Manage application entitlements from the application repository**

Add or remove application entitlements to limit which instances the application can be installed on.

**Before you begin**

You can manage only the applications that you've published to the application repository. For more information, see Publish an application to the application repository.

Role required: none
About this task
By default, after you publish an application to the application repository, all your company instances are entitled to the application automatically. To limit which company instances are entitled to the application, access the application repository by going to https://apprepo.service-now.com, and then change the entitlement type for the application. You can also entitle an instance again if the application entitlement has already been removed.

Procedure
2. Log in using your HI credentials.
3. Next to the application listing, click Select Action and then click Manage Entitlements.
4. Choose an entitlement type for your application.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Remove all existing entitlements</td>
<td>None of your company instances can install the application.</td>
</tr>
<tr>
<td>Entitle all instances</td>
<td>Any of your company instances can install the application. This option is selected by default when you publish an application to the application repository.</td>
</tr>
<tr>
<td>Entitle selected instances</td>
<td>Only instances that you select can install the application. Pick which instances to entitle by moving instances from the Available Instances list to the Selected Instances list.</td>
</tr>
</tbody>
</table>

5. Click OK.

Release a scope from the application repository
Release a scope from the application repository so that the scope can be used to create new scoped applications.

Before you begin
You can release an application scope only if the scope isn’t being used by any application. If your scope is being used by an application, follow the steps in Delete an application from the application repository before releasing the scope.
Role required: customer_admin on HI

**About this task**
The application repository stores the scopes of all your custom applications. You cannot create a new application using a scope that is being stored in the application repository. To *release* a scope means to remove the scope from the application repository so that you can create new applications using the scope.

**Procedure**

1. Go to [https://apprepo.service-now.com](https://apprepo.service-now.com).
2. Log in using your HI credentials.
3. Open the Scopes tab.
4. Next to the scope listing, click the trash icon (🗑).

**Publish an application to the application repository**

Publish a custom application to the application repository so that it can be installed on other instances in your organization.

**Before you begin**
To allow a developer to publish an application to the application repository, delegate the Publish to App Repo permission to the developer. For more information, see [Delegate development and deployment permissions to personnel](#).

Role required: admin, or delegated_developer with Publish To App Repo permission enabled

**Procedure**

1. Navigate to *System Applications > My Company Applications*.
2. Open the In Development tab.
3. Open the application record that you want to publish to the application repository.
4. Click the *Publish to My Application Repository* related link.
5. Click *Submit*.

**What to do next**
Install the application on company instances so that your organization can start using it. For more information, see [Install an application from the application repository](#).
By default, after you publish an application to the application repository, all your company instances are entitled to the application automatically. To limit which company instances are entitled to the application, access the application repository by going to https://apprepo.service-now.com, and then change the entitlement type for the application.

Note:
The Can Edit Application in Studio property defaults to true for new applications, but you can set it false before publishing.

In Studio, when an application customization has the Can Edit Application in Studio property set to false, the user sees this warning:

For more information, see Manage application entitlements from the application repository and Access ServiceNow Studio.

Install an application from the application repository
Install your application on an instance so that employees can start using the application that you developed.

Before you begin
• Publish an application to the application repository.

• Check the entitlement type of the application to ensure that your instance is entitled to the application. For more information, see Manage application entitlements from the application repository.

Role required: admin
Procedure

2. Find the application.
3. Next to the application listing, select a version to install.
4. Click Install.

Delete an application from the application repository

Delete an application from the application repository so that it’s no longer available to your company instances.

Before you begin

• Publish an application to the application repository
• You can delete an application only if the application is not installed on any of your company instances. Uninstall the application on all your instances before deleting it from the application repository.

Role required: customer_admin on HI

Procedure

2. Log in using your HI credentials.
3. Next to the application listing, click Select Action and then click Flag for Deletion.
4. On the confirmation window, click Yes.
   After you flag an application for deletion, the application is deleted automatically after 90 days.
5. To delete the application immediately:
   a. Open the Flagged Apps tab.
   b. Next to the application listing, click Select Action and then click Delete Immediately.
Using MID Server with source control

The ServiceNow® MID Server enables communication and the movement of data between a ServiceNow instance and external applications, data sources, and services.

How bundle files work with MID Server

The .bundle file helps source control function with a MID Server. A bundle file is the way Git packages a local repository in a single file. This makes sharing or moving the repository simpler and more streamlined. The file is then sent to the MID Server, which passes it on to the remote repository.

The outgoing.bundle (commit operations) and incoming.bundle (apply remote changes) are attached to the MID Server attachment table [ecc_agent_attachment] for any request that goes to the MID Server. The outgoing.bundle is created on the instance while the incoming.bundle is created on the MID Server.

After an operation completes successfully, the bundle file is “promoted” into a golden.bundle that is attached to the Repository configuration table [sys_repo_config]. There is one golden bundle per repository and it’s used to initialize the repository on a node that has not performed any Source Control operations yet.

The Auto Flush tool [sys_auto_flush] is a “table cleaner” that removes any ecc_agent_attachment record older than 30 days by default. This action removes the corresponding attachment as well, as they are not necessary after the cleanup operation.

⚠️ Note: If you want to customize the cleanup operation for bundle files, it is best to create and configure an additional auto-flush tool rather than changing any of the default settings.

The bundle files are kept on the MID Server and then saved to the Import directory on the MID Server.

On the MID Server, the bundle file is saved in the Import folder. This folder is under the user directory defined by the system property (user.dir), which users can configure. The bundle file is removed as part of the system flushing at the end of every operation.

Working with the MID Server

- Avoid conflicts with Discovery and create files for the system attachment [sys_attachment] table: MID Server
- Learn about system properties restrictions: Configure attachment system properties
Manage customizations to applications

You can manage your company's customizations for applications that belong to other organizations or a scoped ServiceNow plugin. You cannot change the actual applications that belong to other organizations (purchased from the Store) or the global plugins provided in the ServiceNow base system. But you can create and manage your company's customizations for store applications or scoped applications that are installed via plugins, using the ServiceNow Application Repository.

Before you begin
Role required: admin

The entitlements of your company's application-customizations are controlled solely by the entitlements of the respective store or vendor-released application. There are no separate entitlements for application-customizations, so you can't customize instances that don't have an entitlement to a base store application.

The development instance that you are using to create application-customizations should have its respective store or plugin application entitled and installed.

About this task
To customize an application

There are two ways to create application-customizations:

• In ServiceNow Studio, open the Store application or the application installed via plugin. To learn more, see Access ServiceNow Studio.

Or

1. Navigate to System Applications> All.
2. Search for the installed application you want to customize.

   Note: You can open the application in either Studio or select it as the current working application in the Store application record.

a. On the stack menu, click Edit in Studio to open this application in Studio.
Or

b. Click the name of the application to open its table record. In the Related Links section of the record, select **Switch to this Application** to make it the current working application in the Application picker.

**Related information**

*Manage application entitlements from the application repository*

**Publish customizations to an application repository**

After you have designed, developed, and successfully tested your customizations to a store application or a scoped plugin, you can publish it to the ServiceNow application repository to share it to other instances in your company.

**Before you begin**

Role required: admin, or delegated_developer with Publish To App Repo permission enabled

To enable a developer to publish an application to the application repository, delegate the Publish to App Repo permission to the developer. For more information, see *Delegate development and deployment permissions to personnel*.

**Procedure**

1. Navigate to **System Applications > All Available Applications > All**.
2. Find the application by typing its name in the Filter Navigation box.

![Filter navigator](image)

3. Open the application record for which you want to publish the customization to the application repository.

4. Click the **Publish Customizations to My App Repo** related link or in ServiceNow Studio, use the **FilePublish** menu item.

5. Click **Submit**.

**Install customizations from an application repository**

Install your customization to a store application on an instance.
Before you begin
Role required: admin

Publish a customization of a store application to the application repository. Check the entitlement type of the application to ensure that your instance is entitled to the application.

Procedure
1. Navigate to System Applications > All Available Applications > All.
2. Find the application.
3. Select a customization version to install.

Note: For scoped applications installed via plugins, the base system version is the ServiceNow release version that you are currently using (Paris, Quebec, Rome, and so on).

4. Click Install.

ServiceNow CLI
The ServiceNow CLI is a command-line interface that lets you perform instance operations from your local system. You can extend the CLI to include new commands that meet your application’s needs.

Benefits
The ServiceNow CLI lets you:
• Perform basic CRUD operations on records in your instance.
• Develop custom components and deploy them to your instance to personalize a UI.
• Create custom commands that enable you to manage custom applications from the command line.
• Use the ServiceNow CLI in scripts to simplify setup tasks and operational activities.

Architecture
Commands are stored in a table on the instance you are connected to. When the ServiceNow CLI connects to the instance, it receives all the available commands supported by that instance.

Commands map to a REST endpoint that executes asynchronously. For more information, see Create a custom command in ServiceNow CLI.

Activating ServiceNow CLI
Install ServiceNow CLI by requesting it from the ServiceNow Store. Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store. For cumulative release notes information for all released apps, see the ServiceNow Store version history release notes.

Configuration file
The ServiceNow CLI stores profile information in a config.json file which, by default, is stored in your home directory at the following path:

• Linux and Mac: ~/.snc/config.json
• Windows: %USERPROFILE%\.snc\config.json

The CLI uses this file to determine what information to use to connect to an instance, and what settings to use to generate output. By default, the

© 2021 ServiceNow, Inc. All rights reserved. ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
ServiceNow CLI uses the settings found in the default profile to connect to an instance. To use alternate settings, you can create and reference additional named profiles. For more information, see Configure and manage your ServiceNow CLI connection profiles.

The following example shows a configuration file with a default profile and a named profile. Each profile can use different credentials and specify different hosts and output formats.

```json
{
  "profiles":{
    "default":{
      "host":"https://myinstance.service-now.com",
      "loginmethod":"basic",
      "username":"admin",
      "output":"json",
      "hostversion":"Paris",
      "appversion":"1.0"
    },
    "user1":{
      "host":"https://otherinstance.service-now.com",
      "loginmethod":"basic",
      "username":"user1",
      "output":"yaml",
      "hostversion":"Paris",
      "appversion":"1.0"
    }
  }
}
```

⚠️ Note: Sensitive credential information is only stored in the OS keychain, not in the configuration file.

**Command structure**

ServiceNow CLI commands follow this structure:

1. The base call to the `snc` program.
2. The top-level command group followed by any child command groups.
3. The command that specifies which operation to perform.
4. General CLI arguments required by the operation. You can specify arguments in any order.

```sh
$ snc <command-group> <command> [arguments]
```
Arguments can take various types of input values, such as numbers, strings, and JSON objects. The types supported depend on the command you specify.

**Argument values**
Many argument values in the ServiceNow CLI are simple string or numeric values, such as the table and table name in the following example.

```bash
$snc record create --table incident --data "{short_description: 'New Incident'}"
```

You can surround strings that do not contain any space characters with quotation marks or not. However, you must use quotation marks around strings that include one or more space characters.

**Output formats**
The ServiceNow CLI supports four output formats:

- **json**: The output is formatted as JSON. This is the default.

```
{
  "default": {
    "appversion": "1.0.8",
    "host": "https://myinstance.service-now.com",
    "hostversion": "Paris",
    "loginmethod": "basic",
    "output": "json",
    "username": "admin"
  },
  "user1": {
    "appversion": "1.0.8",
    "host": "https://otherinstance.service-now.com",
    "hostversion": "Paris",
    "loginmethod": "basic",
    "output": "yaml",
    "username": "admin"
  }
}
```

- **yaml**: The output is formatted as YAML. Use YAML to handle the output with services and tools that emit or consume YAML-formatted strings.

```
default:
  appversion: 1.0.8
  host: https://myinstance.service-now.com
  hostversion: Paris
  loginmethod: basic
```

© 2021 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
output: json
username: admin

user1:
  appversion: 1.0.8
  host: https://otherinstance.service-now.com
  hostversion: Paris
  loginmethod: basic
  output: yaml
  username: admin

- **text**: The output is formatted as multiple lines of tab-separated string values. Use this output with traditional UNIX text tools such as grep, sed, and awk, and the text processing performed by PowerShell.

<table>
<thead>
<tr>
<th>NAME</th>
<th>HOST</th>
<th>HOSTVERSION</th>
<th>APP VERSION</th>
<th>LOGIN METHOD</th>
<th>USERNAME</th>
<th>OUTPUT</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>myinstance</td>
<td>Paris</td>
<td>1.0.8</td>
<td>basic</td>
<td>admin</td>
<td>json</td>
</tr>
<tr>
<td>user1</td>
<td>otherinstance</td>
<td>Paris</td>
<td>1.0.8</td>
<td>basic</td>
<td>admin</td>
<td>yaml</td>
</tr>
</tbody>
</table>

- **table**: The output is formatted as a table which presents the information in a human-readable format.

- **none**: The CLI does not print the output to the console. Success, error, and progress messages still display.

You can specify command output in two ways:

**Use the `output` option in a named profile in the configuration file**

The following example sets the default output format to text.

```
{
  "profiles": {
    "default": {"output": "text"}
  }
}
```

**Use the `--output` argument on the command line**

The following example sets the output of a single command to JSON. This option on the command overrides any currently set value in the configuration file.

```
$ snc record query --table incident --query 'active=true' --output json
```
Install the ServiceNow CLI

Install the ServiceNow CLI on a Mac, Windows, or Linux machine.

**Before you begin**
The latest version of the ServiceNow CLI is 1.0.0. To find your installed version and see if you must update, run `snc version`.

Installing the ServiceNow CLI requires:

- Admin rights to install software on your machine.
- Software to extract or unzip the downloaded package.

Available for the following operating systems:

- Mac
- Windows
- Linux

**Install the ServiceNow CLI on Mac**
Install ServiceNow CLI on a Mac OS using the installer.

**Before you begin**
You must have an Apple-supported version of 64-bit Mac OS.

**Procedure**
1. In your browser, download the installer bundle from the ServiceNow Store.
2. Extract the OS-specific installers.
3. Open the `snc-1.0.0-osx-installer` file.
4. Follow the on-screen instructions.
   - When prompted, ensure the **Add to PATH** option is selected. This option requires root account access.
5. To verify that the installation succeeded, use the following commands.

```bash
$ which snc
/usr/local/bin/snc

$ snc version
{
  "extensions": {},
```

© 2021 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
Install the ServiceNow CLI on Windows

Install ServiceNow CLI on a Windows OS using the installer.

Before you begin
You must have a 64-bit version of Windows 10 or later.

Procedure
1. In your browser, download the installer bundle from the ServiceNow Store.
2. Extract the OS-specific installers.
3. Open the snc-1.0.0-windows-x64-installer.exe file.
4. Follow the on-screen instructions. By default, the CLI installs to C:\Program Files\ServiceNow CLI.
5. To confirm the installation, check the version in the command line using the following command.

   ```
   C:\>snc version

   {
     "extensions": {},
     "snc": "1.0.0"
   }
   ```

   If Windows is unable to find the program, close and reopen the command prompt window to refresh the path.

Install the ServiceNow CLI on Linux

Install ServiceNow CLI on a Linux machine using the installer.

Before you begin
You must have a 64-bit version of a recent distribution of CentOS or Ubuntu.

Procedure
1. In your browser, download the installer bundle from the ServiceNow Store.
2. Extract the OS-specific installers.
3. Open the snc-1.0.0-linux-x64-installer.run file.
4. Follow the on-screen instructions.
a. When prompted, ensure the **Add to PATH** option is selected. This option requires root account access.

5. To verify that the installation succeeded, use the following commands.

```bash
$ which snc
~/ServiceNow CLI/bin/snc

$ snc version
{
  "extensions": {},
  "snc": "1.0.0"
}
```

**Configure and manage your ServiceNow CLI connection profiles**

Create a connection profile to connect with your instance, view connection profiles, refresh your connection and available commands, or delete profiles you no longer need.

**About this task**
The ServiceNow CLI stores profile information in a `config.json` file which, by default, is stored in your home directory at the following path:

- **Linux and Mac:** `~/.snc/config.json`
- **Windows:** `%USERPROFILE%\snc\config.json`

The CLI uses this file to determine what information to use to connect to an instance, and what settings to use to generate output. By default, the ServiceNow CLI uses the settings found in the *default* profile to connect to an instance. To use alternate settings, you can create and reference additional named profiles. For more information, see Configure and manage your ServiceNow CLI connection profiles.

The following example shows a configuration file with a default profile and a named profile. Each profile can use different credentials and specify different hosts and output formats.

```json
{
  "profiles": {
    "default": {
      "host": "https://myinstance.service-now.com",
      "loginmethod": "basic",
      "username": "admin",
```
Create a default profile

Create a connection profile that the ServiceNow CLI uses by default. You must create a default profile to set up the CLI's initial connection with an instance.

About this task

By default, the information in this profile is used when you run a command that does not explicitly specify a profile to use.

ℹ️ Note: Sensitive credential information is only stored in the OS keychain, not in the configuration file.

Procedure

1. Open your system's command-line tool and execute this command.

```bash
$ snc configure profile set
```

2. The CLI prompts you for the following information. Enter the requested values. When prompting for information, the CLI displays current values in brackets []). To keep an existing value, press the Enter key.

<table>
<thead>
<tr>
<th>Requested information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>The host name of the instance to connect to. Supports both the full URL (<a href="https://my-instance.service-now.com">https://my-instance.service-now.com</a>) or just the host name (my-instance).</td>
</tr>
<tr>
<td>Login method</td>
<td>The login method to use to connect to the instance. Supports Basic, OAuth, and OAuth + MFA.</td>
</tr>
</tbody>
</table>
### Requested information

<table>
<thead>
<tr>
<th>Requested information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Username</td>
<td>The user name to use to connect to the instance.</td>
</tr>
<tr>
<td>Password</td>
<td>The password to use to connect to the instance.</td>
</tr>
<tr>
<td>Client id</td>
<td>The client ID to use to connect to the instance when the login method is OAuth or OAuth + MFA.</td>
</tr>
<tr>
<td>Client secret</td>
<td>The client secret to use to connect to the instance when the login method is OAuth or OAuth + MFA.</td>
</tr>
<tr>
<td>Authentication code</td>
<td>The authentication code to use to connect to the instance when the login method is OAuth + MFA.</td>
</tr>
<tr>
<td>Default output format</td>
<td>Specifies how to format the command results. Options are json, yaml, text, and table.</td>
</tr>
</tbody>
</table>

### Example

```bash
$ snc configure profile set

Host:
https://myinstance.service-now.com

Login Method (Basic, OAuth, OAuth + MFA):
Basic

Username:
myusername

Password:
mypassword
```

3. Run any command using the values specified in your default profile by omitting the `--profile` attribute from your command.

### Example

```bash
$ snc record create
```

The command creates a record in the instance specified in the default profile with the specified connection options.
Create a named profile

Create a named connection profile to use with specific commands. This allows you to specify a different instance or connection protocol for a specific command.

Before you begin

A default profile must first exist to communicate with an instance.

About this task

Note: Sensitive credential information is only stored in the OS keychain, not in the configuration file.

Procedure

1. Open your system's command-line tool and execute this command. Specify the name of the named profile in the profile-name argument.

   `$ snc configure profile set [--profile profile-name]

2. The CLI prompts you for the following information. Enter the requested values. When prompting for information, the CLI displays current values in brackets [ ]. To keep an existing value, press the Enter key.

<table>
<thead>
<tr>
<th>Requested information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>The host name of the instance to connect to. Supports both the full URL (<a href="https://my-instance.service-now.com">https://my-instance.service-now.com</a>) or just the host name (my-instance).</td>
</tr>
<tr>
<td>Login method</td>
<td>The login method to use to connect to the instance. Supports Basic, OAuth, and OAuth + MFA.</td>
</tr>
<tr>
<td>Username</td>
<td>The user name to use to connect to the instance.</td>
</tr>
<tr>
<td>Password</td>
<td>The password to use to connect to the instance.</td>
</tr>
<tr>
<td>Client id</td>
<td>The client ID to use to connect to the instance when the login method is OAuth or OAuth + MFA.</td>
</tr>
<tr>
<td>Client secret</td>
<td>The client secret to use to connect to the instance when the login method is OAuth or OAuth + MFA.</td>
</tr>
</tbody>
</table>
### Requested information

<table>
<thead>
<tr>
<th>Requested information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authentication code</td>
<td>The authentication code to use to connect to the instance when the login method is OAuth + MFA.</td>
</tr>
<tr>
<td>Default output format</td>
<td>Specifies how to format the command results. Options are json, yaml, text, and table.</td>
</tr>
</tbody>
</table>

**Example**

```
$ snc configure profile set --profile user1
```

**Host:**
```
https://mytestinstance.service-now.com
```

**Login Method (Basic, OAuth, OAuth + MFA):**
```
Basic
```

**Username:**
```
myusername
```

**Password:**
```
mypassword
```

3. Run any command using the values specified in your named profile by adding the `--profile <profile-name>` attribute to your command.

**Example**

```
$ snc record create --profile user1
```

The command creates a record in the instance specified in the `user1` profile with the specified connection options.

### View profiles

View all connection profiles set in the configuration file, or view information about a specific profile.

### Before you begin

A default profile must first exist to communicate with an instance.

### About this task

For each profile, the CLI displays host information, version details, user name, login method, and preferred output format. It does not display sensitive information such as passwords or client IDs.
**Procedure**

Open your system’s command-line tool and execute this command. Include the `[--profile profile-name]` argument to view the connection information for a single profile. Otherwise, the CLI lists information for all profiles.

```
$ snc configure profile list [--profile profile-name]
```

**Example**

This command displays all configured profiles.

```
$ snc configure profile list
```

The CLI provides the following output.

```
{
  "profiles":{
    "default":{
      "host":"https://myinstance.service-now.com",
      "loginmethod":"basic",
      "username":"admin",
      "output":"json",
      "hostversion":"Paris",
      "appversion":"1.0"
    }
  }
}
```

**Remove a profile**

Remove a named connection profile that you no longer need from the configuration file.

**Before you begin**

A default profile must first exist to communicate with an instance.

**About this task**

You cannot remove the default connection profile using this command. To remove the default connection profile, edit the configuration file manually.

**Procedure**

Open your system’s command-line tool and execute this command. Specify the name of the named profile in the `profile-name` argument.

```
$ snc configure profile remove [--profile profile-name]
```
Results
The CLI removes the specified profile from the configuration file.

Refresh your connection
Update the available commands from the instance for the given profile. Refresh your connection after modifying any of the commands on the corresponding instance in order to keep the CLI up-to-date.

Before you begin
A default profile must first exist to communicate with an instance.

Procedure
Open your system's command-line tool and execute this command.
Include the [--profile profile-name] argument to refresh connection information from a named profile. If you do not include the argument, the CLI refreshes the default profile.

$ snc configure profile refresh [--profile profile-name]

Results
The CLI connects to the instance in the designated connection profile and updates any commands that may have changed.

Get help with ServiceNow CLI
See available commands, command options, and examples, or generate debug logging output.

Before you begin
• Install the ServiceNow CLI
• Configure and manage your ServiceNow CLI connection profiles

About this task
In addition to the debug logging output option, the CLI logs all command executions to a log file at the following locations:

• Linux and Mac: ~/.snc/.logs.
• Windows: %USERPROFILE%\snc\logs.
Procedure

1. To see the available commands and arguments, open your system’s command-line tool and enter the command you need help with, followed by the --help argument.

Example

The following example displays help for the available top-level commands.

```
$ snc --help
```

Example

The following example displays the available profile-specific commands.

```
$ snc configure profile --help
```

The CLI displays help for the requested command divided into eight sections:

**Name**

The name of the command.

<table>
<thead>
<tr>
<th>Name</th>
<th>set</th>
</tr>
</thead>
</table>

**Description**

The description of what the command does and its return values.

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configure connection profiles. This command is interactive and will prompt you for each configuration value.</td>
</tr>
</tbody>
</table>

**Synopsis**

The basic syntax for using the command and its options.

```
Synopsis
snc configure profile set [arguments]
```

**Available commands**

The commands available under the current command group.

<table>
<thead>
<tr>
<th>Available Commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>list : Lists the configured connection profiles.</td>
</tr>
<tr>
<td>refresh : Updates the available commands from the instance for the given profile.</td>
</tr>
<tr>
<td>remove : Removes the specified connection profile.</td>
</tr>
</tbody>
</table>
set : Configures connection profiles in order to communicate with an instance.

Command groups
The command groups available under the current command group.

Command Groups
  profile : Set, view, and remove connection profiles.

Arguments
A description of each of the arguments the command accepts.

Arguments
  -p, --profile string : Use a specific connection profile when executing a command.

Global arguments
The global arguments that the command accepts.

Global Arguments
  -d, --debug Print logs to console.
  -h, --help Display detailed help information.
  -o, --output string Set the format for printing command output.

Examples
Examples of the requested command.

Examples
  Create a new profile to save as the default:
  $ snc configure profile set
  Host:
  Login method:
  Username:
  Password:
  Client id:
  Client secret:

2. To generate debug logging output, open your system's command-line tool and enter the command you want to debug, followed by the --debug argument.

Example
The following example generates debug logging output when trying to perform the operation.
$ snc record delete --table incident --sysid 552c48888c033300964f4932b03eb092 --debug

The CLI generates debug logging output when executing the command.

**Perform record operations using ServiceNow CLI**

Create, read, update, delete, and query records in your instance using the ServiceNow CLI command-line tool.

**Before you begin**

- Install the ServiceNow CLI
- Configure and manage your ServiceNow CLI connection profiles

⚠️ **Note:** To perform record operations, install the CLI Metadata application from the ServiceNow Store on the instance you want to connect to.

**Create a record**

Inserts a single record in a specified table.

**About this task**

⚠️ **Note:** You cannot insert multiple records using this command.

**Procedure**

Open your system’s command-line tool and execute this command.

```
$ snc record create [--table table --data data]
```

Pass in values for these arguments.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>Required. Name of the table in which to save the record.</td>
</tr>
<tr>
<td>data</td>
<td>Required. Field name and the associated value for each field to define in the specified record in JSON string format.</td>
</tr>
</tbody>
</table>

**Results**

The system creates a record in the designated table and returns field-value pairs of the new record.

**Example:**

```
$ snc record create --table incident, --data "{"short_description": 'Unable to open file', 'impact':'3'}"
```
The system returns the record in JSON format.

```json
{
    "result": {
        "active": "true",
        "activity_due": "",
        "additional_assignee_list": "",
        "approval": "not requested",
        "approval_history": "",
        "approval_set": "",
        "assigned_to": "",
        "assignment_group": "",
        "business_duration": "",
        "business_service": "",
        "business_stc": "",
        "calendar_duration": "",
        "calendar_stc": "",
        "caller_id": "",
        "category": "inquiry",
        "caused_by": "",
        "child_incidents": "0",
        "close_code": "",
        "close_notes": "",
        "closed_at": "",
        "closed_by": "",
        "cmdb_ci": "",
        "comments": "",
        "comments_and_work_notes": "",
        "company": "",
        "contact_type": "",
        "contract": "",
        "correlation_display": "",
        "correlation_id": "",
        "delivery_plan": "",
        "delivery_task": "",
        "description": "",
        "due_date": "",
        "escalation": "0",
        "expected_start": "",
        "follow_up": "",
        "group_list": "",
        "hold_reason": "",
        "impact": "3",
        "incident_state": "1",
    }
}
```
Delete a record

Deletes the specified record from the specified table.

Procedure

Open your system's command-line tool and execute this command.

```bash
$ snc record delete [--table table --sysid sys_id]
```

Pass in values for these arguments.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>Required. Name of the table in which to delete the record.</td>
</tr>
<tr>
<td>sysid</td>
<td>Required. Sys_id of the record to delete.</td>
</tr>
</tbody>
</table>

Example:

```bash
$ snc record delete --table incident --sysid 552c48888c033300964f4932b03eb092
```

Get a record

Retrieves a single record based on the specified sys_id from the specified table.

Procedure

Open your system's command-line tool and execute this command.

```bash
$ snc record get [--table table --sysid sys_id]
```

Pass in values for these arguments.
Parameter | Description
---|---
table | Required. Name of the table from which to retrieve the record.
sysid | Required. Sys_id of the record to retrieve.

Example:

```
$ snc record get --table incident --sysid 552c48888c033300964f4932b03eb092
```

The system returns the record in JSON format.

```json
{
  "result": {
    "active": "true",
    "activity_due": "",
    "additional_assignee_list": "",
    "approval": "not requested",
    "approval_history": "",
    "approval_set": "",
    "assigned_to": "",

Query records
Retrieves multiple records from a specified table.

Procedure
Open your system's command-line tool and execute this command.

```
$ snc record query [--displayvalue displayValue --fields fields --limit limit --offset offset --query query --table table]
```

Pass in values for these arguments.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>displayValue</td>
<td>Include <code>--displayvalue displayValue</code> to retrieve the display value from the database for reference and choice fields. Do not include this parameter to retrieve the actual values.</td>
</tr>
<tr>
<td>fields</td>
<td>Comma-separated list of field names to return from the database.</td>
</tr>
<tr>
<td>limit</td>
<td>Maximum number of records to return.</td>
</tr>
<tr>
<td>offset</td>
<td>Starting record index for which to begin retrieving records. Use this value to paginate record retrieval.</td>
</tr>
<tr>
<td>query</td>
<td>Required. Encoded query used to filter the result set in the following format: <code>--query '&lt;column_name&gt;&lt;operator&gt;&lt;value&gt;'</code>.</td>
</tr>
<tr>
<td>table</td>
<td>Required. Name of the table in which to query the records.</td>
</tr>
</tbody>
</table>

**Example:**

```bash
$ snc record query --displayvalue --fields short_description,state --query '123TEXTQUERY321=email' --table incident
```

The CLI returns any records that match the query.

```json
{
   "result": [
      {
         "short_description": "Unable to connect to email",
         "state": "Closed"
      }
   ]
}
```

**Update a record**

Updates the specified record with the given data attributes.

**Procedure**

Open your system's command-line tool and execute this command.

```bash
$ snc record update [--sysid sys_id --table table --data data]
```

Pass in values for these arguments.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>Required. Name of the table in which to save the record.</td>
</tr>
<tr>
<td>sysid</td>
<td>Required. Sys_id of the record to update.</td>
</tr>
<tr>
<td>data</td>
<td>Required. Field name and the associated value for each field to define in the specified record in JSON string format.</td>
</tr>
</tbody>
</table>

**Example:**

```
$ snc record update --sysid 9ef81de2db0d6090d7055268dc961978 --table incident --data
"{ 'short_description': 'Email servers down', 'urgency': '1' }"
```

The system returns field-value pairs for the updated record.

```
{
  "result": {
    "active": "true",
    "activity_due": "",
    "additional_assignee_list": "",
    "approval": "not requested",
    "approval_history": "",
    "approval_set": "",
    "assigned_to": "",
    "assignment_group": {
      "link": "https://my-instance.service-now.com/api/now/table/sys_user_group/287ebd7da9fe198100f92cc8d1d2154e",
      "value": "287ebd7da9fe198100f92cc8d1d2154e"
    },
    "business_duration": "",
    "business_service": "",
    "business_stc": "",
    "calendar_duration": "",
    "calendar_stc": "",
    "caller_id": "",
    "category": "inquiry",
    "caused_by": "",
    "child_incidents": "0",
    "close_code": "",
    "close_notes": "",
    "closed_at": "",
    "closed_by": "",
    "cmdb_ci": ""
  }
}
```
Create a custom command in ServiceNow CLI

Manage your custom application from the command line by creating custom commands in the ServiceNow CLI.

Before you begin
Role required: admin

About this task
A ServiceNow CLI command maps to a scripted REST endpoint in the End Point [sn_cli_metadata_end_point] table. You can define a scripted REST endpoint to
perform a function in your custom application, or use any existing REST endpoint. Then map a CLI command to execute the REST call.

**Procedure**

1. Make a REST endpoint available to a ServiceNow CLI command.

   **a.** Navigate to **Command Line Interface (CLI) > End Points**.

   **b.** Select **New** and complete the form.

<table>
<thead>
<tr>
<th><strong>Field</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Resource Path</td>
<td>Required. Path to the endpoint on the instance to map a command to. Can be the path to an inbound REST API, or a scripted REST API. For example, <code>api/now/table/{table}/{sysid}</code>. For more information, see Available REST APIs and Scripted REST APIs.</td>
</tr>
<tr>
<td>HTTP Method</td>
<td>Required. HTTP method to use when the user runs the associated command.</td>
</tr>
<tr>
<td>Application</td>
<td>Read-only application scope for the endpoint.</td>
</tr>
</tbody>
</table>

2. Optional: Create a command group. Alternatively, you can add your new command to an existing command group.

   **a.** Navigate to **Command Line Interface (CLI) > Command Groups**.

   **b.** Select **New** and complete the form.

<table>
<thead>
<tr>
<th><strong>Field</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Required. Name of the command group.</td>
</tr>
<tr>
<td>Parent Group</td>
<td>Parent command group.</td>
</tr>
<tr>
<td>Reference Group</td>
<td>Command group to reference. For example, you can create a new command group as an alias for an existing command group. When the user calls a referenced command using the new command group, the original command executes. This enables you to create a command group specific to your custom application that includes both new and existing commands.</td>
</tr>
</tbody>
</table>
### Field | Description
--- | ---
Short Description | Required. Short description for the command group.
Description | Description of the command group used as help text when the user runs the \texttt{--help} command on the command group.
Application | Read-only application scope for the command group.
Active | When selected, the command group is active.

3. Create a command.

**a.** Navigate to **Command Line Interface (CLI) > Commands**.

**b.** Select **New** and complete the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Required. Name of the command.</td>
</tr>
<tr>
<td>Command Group</td>
<td>Required. Command group that the command is a part of.</td>
</tr>
</tbody>
</table>
| Reference Command | Command to reference. For example, you can create a new command as an alias for an existing command. When the user calls the new command, the original command executes. This enables you to create a command specific to your custom application that executes existing functionality.  

\[ \textbf{Note:} \text{ A command cannot reference a command that references another command, or reference a descendant command, an ancestor command, or a callback command.} \]| |
<p>| API Endpoint | Required. API call to execute when the user runs the command. |
| Short Description | Required. Short description of the command. |
| Application | Read-only application scope for the command. |
| Active | When selected, the command is active. |</p>
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is Callback Command</td>
<td>When true, designates the command as a callback command. Select this option to hide the command from the CLI client and prevent users from calling it from the command line. Use this field with the <strong>Callback</strong> section of a primary command. The callback command executes when the primary command is complete.</td>
</tr>
</tbody>
</table>

**Help Text**

<table>
<thead>
<tr>
<th>Description</th>
<th>Description of the command used as help text when the user runs the <code>--help</code> command.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Examples</td>
<td>Examples of the command used as help text when the user runs the <code>--help</code> command.</td>
</tr>
</tbody>
</table>

**Expressions**

<table>
<thead>
<tr>
<th>Success Expression</th>
<th>Expression used to evaluate the response from the server and determine if the command succeeded. For example, <code>result.code = 1</code>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Failure Expression</td>
<td>Expression used to evaluate the response from the server and determine if the command failed.</td>
</tr>
</tbody>
</table>

**Messages**

<table>
<thead>
<tr>
<th>Success Message</th>
<th>Message displayed on the CLI client when the command is successful.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Progress Message</td>
<td>Message displayed on the CLI client when the command is in progress.</td>
</tr>
<tr>
<td>Failure Message</td>
<td>Message displayed on the CLI client when the command fails.</td>
</tr>
</tbody>
</table>

**Callback**

<table>
<thead>
<tr>
<th>Callback Expression</th>
<th>Expression used to determine whether to execute the callback command. For example, you can write an expression that checks on a long-running process. If the expression produces a certain result, the callback executes.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Callback Command</td>
<td>Command to execute when the <strong>Callback Expression</strong> is satisfied. Must be a command with the <strong>Is Callback Command</strong> field selected.</td>
</tr>
</tbody>
</table>
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Callback Interval</td>
<td>The interval between callback command executions.</td>
</tr>
<tr>
<td></td>
<td>Unit: Milliseconds</td>
</tr>
<tr>
<td></td>
<td>Default: 1,000</td>
</tr>
<tr>
<td>Max Retries</td>
<td>Maximum number of times the callback command executes.</td>
</tr>
<tr>
<td></td>
<td>Default: 10</td>
</tr>
</tbody>
</table>

#### c. In the Command Arguments related lists, create any command arguments needed for the command.

Create a command argument to allow users to set options when running a command.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Required. Name of the command argument, for example data.</td>
</tr>
<tr>
<td>Short Name</td>
<td>Short name of the command argument, for example d.</td>
</tr>
<tr>
<td>Data Type</td>
<td>Required. Type of data expected for the command argument. Options include:</td>
</tr>
<tr>
<td></td>
<td>• String: Allows users to enter a string as input.</td>
</tr>
<tr>
<td></td>
<td>• Integer: Allows users to enter a number as input.</td>
</tr>
<tr>
<td></td>
<td>• Boolean: Allows users to enter true or false as input.</td>
</tr>
<tr>
<td></td>
<td>• File Input: Allows users to upload a file as input. Map this argument to a</td>
</tr>
<tr>
<td></td>
<td>Body Parameter Type in the API Endpoint Arguments related list in the next</td>
</tr>
<tr>
<td></td>
<td>step. Users can pass plain text, YAML, JSON, or another file type accepted</td>
</tr>
<tr>
<td></td>
<td>by the REST API. When the user submits a YAML file, the CLI client converts</td>
</tr>
<tr>
<td></td>
<td>to file to JSON format by default. Use the Skip Pre-processing field to</td>
</tr>
<tr>
<td></td>
<td>disable this behavior.</td>
</tr>
<tr>
<td></td>
<td>• Password: Allows users to securely enter a password as input.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> For File Input data types, the file size limit is 10 MB by default. However, you change this limit using the glide.rest.scripted.max_inbound_content_length_mb system property.</td>
</tr>
<tr>
<td>Skip Pre-processing</td>
<td>Set this flag to prevent the CLI client from converting YAML files into JSON format before sending them in the request. When <strong>Data Type</strong> is set to <strong>File Input</strong> and the user submits a YAML file, the CLI client converts the file to JSON before executing the command by default.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Only applies when <strong>Data Type</strong> is set to <strong>File Input</strong>.</td>
</tr>
<tr>
<td>Default Value</td>
<td>Default value to use when the user does not pass a value.</td>
</tr>
<tr>
<td>Short Description</td>
<td>Required. Short description of the command argument. Used as help text when the user runs the <strong>--help</strong> command.</td>
</tr>
<tr>
<td>Application</td>
<td>Read-only application scope for the argument.</td>
</tr>
<tr>
<td>Command</td>
<td>Required. Command that the argument applies to.</td>
</tr>
<tr>
<td>Mandatory</td>
<td>When selected, the user must provide a value for the argument when running the associated command.</td>
</tr>
<tr>
<td>Prompt</td>
<td>Prompt to request information from the user. The CLI prompts for information when the user does not include a required argument in a command.</td>
</tr>
<tr>
<td>Visibility Expression</td>
<td>Expression used to determine whether the CLI should prompt for the argument. Typically used to display an argument based on the value provided to a previous argument.</td>
</tr>
<tr>
<td>Order</td>
<td>Order in which to prompt for the argument.</td>
</tr>
</tbody>
</table>

d. In the API Endpoint Arguments related lists, create any API endpoint arguments needed for the command.

Map command arguments from the Command Arguments related list to parameters in your REST endpoint.
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Required. Name of the argument.</td>
</tr>
<tr>
<td>Value</td>
<td>Required. The value from the command that you want to pass to the REST endpoint. You can pass a static value, or an expression such as {flags.table}. Use the flags global variable to access the command arguments.</td>
</tr>
<tr>
<td>Parameter Type</td>
<td>Required. The type of parameter in the REST endpoint that you want to pass the Value to. For example, if you select Body, the CLI passes the value of the Value field to the REST endpoint body. Options include:</td>
</tr>
<tr>
<td></td>
<td>• Body</td>
</tr>
<tr>
<td></td>
<td>• Header</td>
</tr>
<tr>
<td></td>
<td>• Path</td>
</tr>
<tr>
<td></td>
<td>• Query</td>
</tr>
<tr>
<td>Application</td>
<td>Read-only application scope for the argument.</td>
</tr>
<tr>
<td>Command</td>
<td>Required. Command that the argument applies to.</td>
</tr>
</tbody>
</table>

**e. In the Return Values related lists, create any return values needed for the command.**

Create return values to only return certain keys from the response.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Path</td>
<td>Required. Expression representing the path to the key that you want to return.</td>
</tr>
<tr>
<td>Expression</td>
<td></td>
</tr>
<tr>
<td>Alias</td>
<td>Variable name to assign the return value to.</td>
</tr>
<tr>
<td>Application</td>
<td>Read-only application scope for the command.</td>
</tr>
<tr>
<td>Command</td>
<td>Required. Command that the return value applies to.</td>
</tr>
</tbody>
</table>

**Results**

When the user runs the ServiceNow CLI command, the system executes the associated REST API call and returns the result to the ServiceNow CLI.
Manage ServiceNow CLI extensions

Add extensions to the ServiceNow CLI to load additional functionality and commands, update existing extensions, or remove extensions you no longer need.

Procedure

1. Find available extensions.
   a. Open your system’s command-line tool and execute this command.

   $ snc extension list-available --o table

   The system lists available extensions and associated details.

<table>
<thead>
<tr>
<th>NAME</th>
<th>DESCRIPTION</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>ui-component</td>
<td>Build and deploy Now Experience Components</td>
<td>19.0.0-alpha.15</td>
</tr>
<tr>
<td>false</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

2. Install an extension.
   a. Open your system’s command-line tool and execute this command.

   $ snc extension add --name <extension-name>

   a. Open your system’s command-line tool and execute this command.

   $ snc extension update --name <extension-name>

4. Optional: Remove an extension.
   a. Open your system’s command-line tool and execute this command.

   $ snc extension remove --name <extension-name>

Creating custom components using the ui-component extension

Develop custom components using the Now® Experience UI Framework and the ui-component extension.

Components are reusable building blocks that you use to create a custom user interface. The Now® Experience Design System comes with a set of customizable components that you can drag into your custom UI. Develop
your own components if you can't find what you need in the Now® Experience Design System library.

To see the Now® Experience Design System library, visit the ServiceNow® Developer Site.

**Benefits of creating custom components**

Developing custom components lets you:

- Personalize a UI according to your agent, customer, and company needs.
- Make your employees more effective and reduce context switching with quick access to important data and information.
- Accommodate your company's unique omni-channel environment using APIs to consolidate your data.

For example, you might want to create a component that displays the cases associated with an SLA, or that tracks the active chats in a particular queue. You can use the Now® Experience UI Framework and the ui-component extension to develop the component you need, and access data from your platform using the Http Effect API. You can also query platform data using GraphQL by creating a custom schema. For more information, see Scripted GraphQL.

**What to know before you begin**

Before you start designing and building your component, make sure you have:

- Some general knowledge of web component concepts, development, and design.
- JavaScript knowledge to define the component behavior.
- Knowledge of Node Package Manager (npm).
- The most recent version of Node.js installed on your local machine. For more information, see, Node.js.
- The ServiceNow CLI installed on your machine.

**Now® Experience UI Framework**

The Now® Experience UI Framework is a JavaScript framework that lets you extend your apps and build web components that are reusable throughout your applications. Using the Now® Experience UI Framework lets you:
• Create a single component to use in multiple places across your applications.
• Encapsulate the component's scope to prevent conflicts with other code.
• Add properties, slots, and actions to your component, allowing users to customize the component every time they use it in a Workspace.

For more information, see the ServiceNow® Developer Site.

ui-component extension and development flow
The ui-component extension is an extension to the ServiceNow CLI that lets you develop custom components using the Now® Experience UI Framework. With the ui-component extension, you can:

• Create the set of files required to develop a component, or project scaffolding.
• Start a local development server to test your component.
• Build a component project and deploy it to a ServiceNow instance.

Application scope
When you deploy a Now® Experience UI Framework component, it deploys into a scoped application on the instance. You can provide an application scope for the component to use as a namespace identifier. Use the namespace identifier guidelines for application development on the instance. For more information, see Application scope.

When reserving an application scope, follow these requirements:

• Maximum: 18 characters.
• Case: snake case.
• Format: x_customerprefix_componentname, where:
  ◦ customerprefix is the value in the glide.appcreator.company.code system property on your instance.
  ◦ componentName is the value provided in the component's name parameter when you created the project.

If you do not provide an application scope when creating your component project, the Now CLI creates one for you.

Alternatively, you can add a value to the scopeName parameter in the now-ui.json file. For more information, see Change a component’s application scope.
Reference guide

To see the Now CLI reference guide, visit the Developer Site.

Set up your environment

Prepare your local environment by installing the Node.js JavaScript runtime environment, Node package manager (npm), and the ui-component extension. These tools enable you to develop and build components locally and deploy them to your instance.

Before you begin

The ui-component extension only supports these operating systems.

- Windows 10
- MacOS Yosemite and later
- Linux CentOS v7.5

Procedure

1. Install Node.js version 12.16.1 or greater. npm automatically installs as part of the Node.js package.
   Node.js is a JavaScript runtime environment that enables you to execute JavaScript locally. npm is the default JavaScript package manager for Node.js. For more information, see Node.js and npmjs.com.

2. Add the ui-component extension to the ServiceNow CLI.

   a. Open your system’s command-line tool and execute this command.

   ```
   $ snc extension add --name ui-component
   ```

3. Verify the installation by running an extension command with the **--help** argument.

   ```
   $ snc ui-component --help
   ```
   The CLI displays a list of available commands. See Get help with ServiceNow CLI.

What to do next

Set up your project.

Related information

- Creating custom components using the ui-component extension
- ServiceNow CLI
Set up your project

Create the component project and the set of files required to develop a component. You can connect to your instance and create an application scope for your component, or you can reserve a scope to verify later.

Before you begin
Set up your environment.

Procedure

1. Create a folder for your project and point your system's command-line tool to the folder.
2. Create the component project and all the files required to build a component.

a. From the folder you created, execute this command.

```bash
$ snc ui-component project [--name name --description description --scope scope --offline]
```

Pass in values for these arguments.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Required. The project name. Must be a valid and unique npm package name.</td>
</tr>
<tr>
<td>description</td>
<td>The project description to be available in the npm registry and the plugins list in your instance.</td>
</tr>
</tbody>
</table>
| scope        | Suggested application scope to assign to this project and its components. If provided, the instance validates the name. Use the namespace identifier guidelines for application development on the instance. For more information, see Application scope. Maximum: 18 characters. Case: snake case. Default: x_customerprefix_componentname, where: 
  - customerprefix is the value in the glide.appcreator.company.code system property on your instance.
  - componentname is the value provided in the component's name parameter when you created the project. |
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Alternatively, you can add a value to the <code>scopeName</code> parameter in the <code>now-ui.json</code> file. For more information, see <a href="#">Change a component’s application scope</a>.</td>
</tr>
</tbody>
</table>
| offline | When true, creates and scaffolds a component while disconnected from your instance. Skips validation of the given scope name.  
|        | Default: false.                                                               |

**Example**

```bash
$ snc ui-component project --name @myorg/movie-quotes --description 'A web component that prints movie quotes.'
```

**Example**

```bash
$ snc ui-component project --name @myorg/hello-world --scope x_myorg_helloWorld --offline
```

3. Run the following command to install the npm dependencies.

```bash
npm install
```

**What to do next**

 Develop a component.

**Related information**

[Creating custom components using the ui-component extension](#)

**Use a proxy server with ui-component extension**

Use a proxy server with the Now CLI to define a separate data source for your component. When using a proxy server, the instance forwards Now CLI requests to the proxy server.

**Before you begin**

 Set up your environment.

**Procedure**

1. In your component directory, open the `now-cli.json` file.
2. Update the proxy object.
Update the following parameters with your proxy information.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>development.proxy.headers</td>
<td>Headers to append to your proxied request.</td>
</tr>
<tr>
<td>development.proxy.headers.Authorization</td>
<td>Authentication header to add to the proxied request. Enter your Base 64-encoded username:password here.</td>
</tr>
<tr>
<td>development.proxy.origin</td>
<td>Host to open a proxy with (your instance host address).</td>
</tr>
<tr>
<td>development.proxy.port</td>
<td>The port the proxy runs on.</td>
</tr>
<tr>
<td>development.proxy.proxies</td>
<td>URL glob patterns to pass to the proxy server.</td>
</tr>
</tbody>
</table>

3. Save the file.

**What to do next**

Develop a component.

**Related information**

Creating custom components using the ui-component extension

**Develop a component**

Add your component code and test it using a local development server.

**Before you begin**

- Set up your environment
- Set up your project
About this task
For a tutorial on developing a counter component, visit the Developer Site.

Procedure
1. In your project directory, navigate to src/<component-name>/index.js. This is the primary code file for a component.
2. Add your component code.

Example
This example shows a sample Hello World component.

```javascript
import {createCustomElement} from '@servicenow/ui-core';
import snabbdom from '@servicenow/ui-renderer-snabbdom';
import styles from './styles.scss';

const view = (state, {updateState}) => {
  return (
    <div>Hello World!</div>
  );
};

createCustomElement('hello-world', {
  renderer: {type: snabbdom},
  view,
  styles
});
```

To develop a component for Virtual Agent, add specific properties and actions to interact with the Virtual Agent client interface. The properties required depend on the type of component you are creating. For more information, see Develop a component for Virtual Agent for more information.

3. Optionally add inner components.
An inner component is a component included in another component. For example, a card component might include a separate button component. The button component becomes an inner component that you must import, install, and define in the card component project.

   a. Install the inner component package by executing the install command using your system's command-line tool:

```
  npm install @servicenow/<now-inner-button>
```

   b. Add an import statement to the top of your `index.js` file:
c. Use the inner component in your `index.js` file:

```javascript
<now-inner-button label="Click Me" />
```

d. List the inner component in the `components.[component-name].innerComponents` array in the `now-ui.json` configuration file.

**Example**

```json
{
  "components": {
    "now-chart-timeseries": {
      "innerComponents": [
        "now-inner-button"
      ]
    }
  }
}
```

4. Run the development server command to view your component in a test browser.

```
$ snc ui-component develop [--entry entry --open --port port --host host]
```

Pass in values for these arguments.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| entry | Path to the test module in your component project.  
Default: `example/index.js`. |
| open | Opens the default browser and navigates to the test page.  
Default: false. |
| port | Port where the development server runs.  
Default: 8081. |
| host | Host address to use if you want your local development server to be accessible externally by others. Typically set to `0.0.0.0`. |

**Example**

```
$ snc ui-component develop --entry example/hello.js --open --port 3000
```
What to do next
Deploy a component to an instance.

Related information

Creating custom components using the ui-component extension

Develop a component for Virtual Agent
Create a custom Virtual Agent component to gather input or display information in the Virtual Agent client interface.

Types of Virtual Agent components
To develop a component for Virtual Agent, add specific properties and actions to interact with the Virtual Agent client interface. The properties required depend on the type of component you are creating.

Response component
A response component only provides information to the user, and does not gather input or handle user interaction. For example, a card control that does not require user input and is only in the conversation once.

Add a property to your response component to handle the data sent by the Virtual Agent server.

### Output component properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlData</td>
<td>Initial data that the Virtual Agent server sends to your component as the topic runs. Data type: JSON Object</td>
</tr>
</tbody>
</table>

Input component
An input component displays information and/or gathers user input. It includes the same property as the output component to handle data sent by the server, but has more possible states and requires user interaction.

### Input component properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlData</td>
<td>Initial data that the Virtual Agent server sends to your component as the topic runs. Data type: JSON Object</td>
</tr>
<tr>
<td>responseValue</td>
<td>Data sent to the component from the user's response, either from the client directly, or from the server if there is a refresh. Only use in components that require user input. Data type: JSON Object</td>
</tr>
<tr>
<td>forceCloseControl</td>
<td>Flag that indicates whether the component can accept input. When true, the control closes and the user cannot interact with it. Monitor changes on the client to update this value. Only use in components that require user input. Data type: Boolean</td>
</tr>
</tbody>
</table>

Use this action to emit data from user interaction.

### Input component actions

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA_CONTROL#VALUE_SENT</td>
<td>Response data from the client to send to the server. Only use in components that require user input. Data type: JSON Object</td>
</tr>
</tbody>
</table>

### Input component states

Because they accept data, input components must handle multiple states. The state flow is generally as follows:

1. Virtual Agent shows the custom component in the waiting for input state.
2. The user interacts with the component to provide input.
3. The component closes and sends the responseValue property to the server.
4. The server runs the server-side logic and sends the component with the user's
input back to the client.
Waiting for Input
The initial state of a component waiting for user interaction. The
controlData property is set, but the forceControlClosed property is
false. This example shows a slider component in the waiting for input
state.

In this example, if the user has not provided a responseValue and the
control is not closed, the slider and the input button display.
const {controlClosed, sliderVal, sliderMin, sliderMax} = state;
return (<div class={{"slider-chat": true}}>
{responseValue ? null :

<Fragment>

<div class={{"slider-label": true}}>{label}</div>
{controlClosed ? null : <Fragment>
<div class={{"slider-container": true}}>
<input on-change={onSliderChange} type="range"
min={sliderMin} max={sliderMax} value={sliderVal} class={{"slider":
true}} />
<div class={{"slider-value": true}}>
{unitIcon &&
<div class={{"unit-icon": true}}><img
src={unitIcon} /></div>
}
{sliderVal} {unitName}
</div>
<div class={{"button-container":true}}>

998


Handling Input

In the previous example, the slider uses a now-button component, which the user clicks to confirm input and send it to the server. When the user clicks the button, the `VA_CONTROL#VALUE_SENT` action fires with the `responseValue` payload.

```javascript
'NOW_BUTTON#CLICKED': (data) => {
    const {updateState, dispatch, state: {sliderVal}} = data;
    updateState({controlClosed: true});
    dispatch('VA_CONTROL#VALUE_SENT', {
        value: {
            sliderVal
        }
    });
}
```

Closed

A component that is closed can no longer accept user input. Components are generally closed because:

- The user responded to the component. The component closes and the conversation continues.
- The user ended the chat. The server does not wait for a response.

For example, the slider component only renders the original prompt when in the closed state.

How many penguins do you want to buy?

Sending response

After the user responds, the control is rendered again on the user's side of the conversation with the value of the `responseValue` property.
For example, the slider control uses this snippet to render the response.

```javascript
{responseValue && <div className="response-container slider-value">
  {unitIcon &&
    <div className="unit-icon"><img src={unitIcon} /></div>
  }
  {returnVal} {unitName}
</div>}
```

Adding the component to Virtual Agent Designer

After developing the component and deploying it to your instance, add it to Virtual Agent Designer using a custom control and definition. For more information, see Virtual Agent custom controls.

Add properties to communicate with Virtual Agent

To develop a component for Virtual Agent, add specific properties and actions to interact with the Virtual Agent client interface. The properties required depend on the type of component you are creating.

Before you begin

- Set up your environment
- Set up your project
- Develop a component
Procedure

1. In your component code, add the Virtual Agent properties to interact with the Virtual Agent client interface.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlData</td>
<td>Initial data that the Virtual Agent server sends to your component as the topic runs. Data type: JSON Object</td>
</tr>
<tr>
<td>responseValue</td>
<td>Data sent to the component from the user's response, either from the client directly, or from the server if there is a refresh. Only use in components that require user input. Data type: JSON Object</td>
</tr>
<tr>
<td>forceCloseControl</td>
<td>Flag that indicates whether the component can accept input. When true, the control closes and the user cannot interact with it. Monitor changes on the client to update this value. Only use in components that require user input. Data type: Boolean</td>
</tr>
</tbody>
</table>

2. If creating an input component, use the VA_CONTROL#VALUE_SENT action to send user values to the server.

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VA_CONTROL#VALUE_SENT</td>
<td>Data from the client to send to the server. Only use in components that require user input. Data type: JSON Object</td>
</tr>
</tbody>
</table>

What to do next
Test a component for Virtual Agent and Deploy a component to an instance.

Related information
Creating custom components using the ui-component extension

Test a component for Virtual Agent
Test your Virtual Agent custom component before deploying it to your instance.
Before you begin

- Set up your environment
- Set up your project
- Develop a component
- Add properties to communicate with Virtual Agent

About this task
Virtual Agent components must be tested within the Virtual Agent client chat to ensure that the component responds correctly to user input. You can set properties in your component project to test your component in a mock Virtual Agent test client tool.

Procedure

1. Add a dependency on the test client tool to your component project.
   a. Open the `<component-name>/package.json` file in your component project.
   b. Add `"@servicenow/ci-sdk": "1.0.8"` and `"@servicenow/library-translate": "^18.0.0"` to the `devDependencies` object.

   Example
   Here is an example `package.json` file with the correct dependencies.

   ```json
   "dependencies": {
     "@servicenow/ui-renderer-snabbdom": "rome",
     "@servicenow/library-translate": "^18.0.0",
     "@servicenow/now-button": "rome",
     "@servicenow/now-dropdown": "rome",
     "@servicenow/sass-generic": "rome",
     "@servicenow/cli-archetype": "rome",
     "@servicenow/sdk-ci": "1.0.8"
   }
   ```

2. Add sample properties to use as the initial state of the component in your test.
   a. Add a `<component-name>/example/sampleProps.json` file with initial properties to render in your test.

   Example
   Here is an example `sampleProps.json` file with initial properties set for a slider component.

   ```json
   {
     "label": "How many penguins do you want to buy?",
     "defaultValue": 10,
   }
   ```
3. Update the `example.js` file to open the component through the test client tool using the sample properties that you created.

   a. Open the `<component-name>/example/element.js` file in your component project.

   b. Add statements to import `@servicenow/ci-sdk` and the sample properties file you created.

   c. Add the following statement, replacing `<component-name>` with your component's name to create the test tool with initial data from your sample properties.

   ```javascript
   const el = document.createElement('tool-ci-custom-control-tester');
   el.componentTagName = `<component-name>`;
   el.initialExampleData = sampleProps;
   document.body.appendChild(el);
   ```

**Example**

Here is an example `example.js` file that opens the component using the test client tool.

```javascript
import '../src/now-chat-control-slider';
import '@servicenow/sdk-ci';
import sampleProps from './sampleProps.json';

const el = document.createElement('tool-ci-custom-control-tester');
el.componentTagName = `<component-name>`;
el.initialExampleData = sampleProps;
document.body.appendChild(el);
```

4. Run the development server command to view your component in a test browser.

   `$ snc ui-component develop [--entry entry --open --port port --host host]`

Pass in values for these parameters.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| entry | Path to the test module in your component project.  
Default: example/index.js. |
| open | Opens the default browser and navigates to the test page.  
Default: false. |
| port | Port where the development server runs.  
Default: 8081. |
| host | Host address to use if you want your local development server to be accessible externally by others. Typically set to 0.0.0.0 |

**Example**

```
$ snc ui-component develop --entry example/hello.js --open --port 3000
```
The component opens in the test client tool. You can see the initial data provided in the **Custom Control JSON Input Data** field and the component’s output in the **Custom Control Return Data** field.

**What to do next**
If your component is working as expected, deploy it to your instance. See [Deploy a component to an instance](#).

After developing the component and deploying it to your instance, add it to Virtual Agent Designer using a custom control and definition. For more information, see [Virtual Agent custom controls](#).

**Related information**
- [Creating custom components using the ui-component extension](#)

**Add a component to Agent Workspace**
Use custom components to create a custom Workspace interface to fulfill the specific need of your company’s agents.
Communicating with customers through multiple channels can be time consuming. To be efficient in these omni-channel interactions, your agents need a single view of customer information to reduce context switching between multiple tools. By developing custom components for Workspace, your team can bring communications from multiple channels into one interface.

Adding components to a Workspace

Once deployed to your instance, you can add components to Workspace in these ways.

Add a component to a Workspace modal

Use a UI action to launch a custom Now component in a modal so an agent doesn’t have to navigate to a different screen to accomplish a task. For more information, see Render a Now component in a modal.

Add a component to a Workspace landing page using UI Builder

Use the UI Builder to create custom landing pages for your agents. UI Builder is a drag-and-drop tool that lets you visually arrange workspace components. For more information, see Creating custom landing pages for workspaces.

Configure properties in the now-ui.json file to use deployed components in the UI Builder. See Add a component to UI Builder.

Add a component to a Workspace record view

You can add custom or standard components to the component area in the Workspace record view. For more information, see Setting up Record View in workspace.

Add a component to UI Builder

Set properties in a configuration file to add your component to the UI Builder in your instance.

Before you begin

- Set up your environment
- Set up your project
- Develop a component
Procedure

1. In your project directory, open `now-ui.json`.

2. Add the `components.[component-name].uiBuilder` object to the file. This object adds the component to the UI Builder. This object includes these key-value pairs:

<table>
<thead>
<tr>
<th>Key</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>components.[component-name].uiBuilder</td>
<td>Object</td>
<td>Object that adds the component to UI Builder.</td>
</tr>
<tr>
<td>components.[component-name].uiBuilder.label</td>
<td>String</td>
<td>Required. The display name of the component in UI Builder.</td>
</tr>
<tr>
<td>components.[component-name].uiBuilder.icon</td>
<td>String</td>
<td>Required. The name of the icon that appears in UI Builder.</td>
</tr>
<tr>
<td>components.[component-name].uiBuilder.description</td>
<td>String</td>
<td>Required. A short description of the functionality of the component.</td>
</tr>
</tbody>
</table>

Example

```
{
    "components": {
        "card": {
            "uiBuilder": {
                "label": "Card",
                "icon": "chat-fill",
                "description": "A visual card format for a record.",
                "associatedTypes": ["global.core"]
            }
        }
    }
}
```

3. If your component includes properties, add the `components.[component-name].properties` array to the file. This adds the properties as configuration options for the component in UI Builder. This object includes these key-value pairs:
<table>
<thead>
<tr>
<th>Key</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>components. [component-name].properties</td>
<td>Array &lt;Object&gt;</td>
<td>An array of objects that includes all the properties of the component and all relevant information about those properties.</td>
</tr>
<tr>
<td>components. [component-name].properties[].name</td>
<td>String</td>
<td>Name of the property in your component's code.</td>
</tr>
<tr>
<td>components. [component-name].properties[].label</td>
<td>String</td>
<td>Display name of the property to display in UI Builder, if applicable.</td>
</tr>
<tr>
<td>components. [component-name].properties[].description</td>
<td>String</td>
<td>A short description of what the property does or how to use it.</td>
</tr>
<tr>
<td>components. [component-name].properties[].readOnly</td>
<td>Boolean</td>
<td>When true, prevents a user from configuring the property in UI Builder. Default: false.</td>
</tr>
<tr>
<td>components. [component-name].properties[].required</td>
<td>Boolean</td>
<td>When true, the user must configure the property. Default: false.</td>
</tr>
<tr>
<td>components. [component-name].properties[].defaultValue</td>
<td>String</td>
<td>The default value when the user does not provide one.</td>
</tr>
<tr>
<td>components. [component-name].properties[].associatedTypes</td>
<td>Array</td>
<td>Describes where in the UI Builder toolbox the component appears. Value must be &quot;global.core&quot;.</td>
</tr>
<tr>
<td>components. [component-name].properties[].typeMetadata</td>
<td>Object</td>
<td>Extra configuration data that some data types require, such as reference properties and choice lists.</td>
</tr>
</tbody>
</table>
Example

```json
{
    "components": {
        "properties": [
            {
                "name": "backgroundColor",
                "label": "Background Color",
                "description": "Background Color",
                "readOnly": false,
                "required": false,
                "defaultValue": "lightgray"
            },
            {
                "name": "cardType",
                "label": "Type of card",
                "description": "Type of card",
                "readOnly": false,
                "required": false,
                "defaultValue": ""
            }
        ]
    }
}
```

4. Save the file.

What to do next
Deploy a component to an instance.

Related information
Creating custom components using the ui-component extension

Deploy a component to an instance
Deploy your component to display in your instance as an application plugin.

Before you begin
- Set up your environment
- Set up your project
- Develop a component

Procedure
Deploy the component to your instance.
a. Open your system's command-line tool and execute this command.

```bash
$ snc ui-component deploy [--open --force]
```

Pass in values for these arguments.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>open</td>
<td>When true, opens the default browser and navigates to UI Builder in your instance. Default: false</td>
</tr>
<tr>
<td>force</td>
<td>Deploys component changes and overwrites any existing component records. Default: false.</td>
</tr>
</tbody>
</table>

**Example**

```bash
$ snc ui-component deploy --open
```

**What to do next**

Navigate to your instance and add your component to a modal or a landing page in Agent Workspace, or to Virtual Agent. For Agent Workspace, see rendering a Now component in a modal or creating custom landing pages for workspaces. For Virtual Agent, see Virtual Agent custom controls.

**Related information**

- Creating custom components using the ui-component extension

**Change a component’s application scope**

Change a component’s application scope if you encounter scope issues when deploying your component to an instance. For example, you may have set an application scope that is already in use or invalid while creating a component in offline mode.

**Before you begin**

- Set up your environment
- Set up your project
About this task

Procedure

1. In your project directory, open now-ui.json.

2. Update the `scopeName` key with the desired scope name.

   Use the namespace identifier guidelines for application development on the instance. For more information, see Application scope.

   When reserving an application scope, follow these requirements:
   
   - Maximum: 18 characters.
   - Case: snake case.

Example

```json
"scopeName": "x_customerprefix_componentname"
```

3. Deploy your component. See Deploy a component to an instance.

Creating custom components using the ui-component extension

ServiceNow CLI available commands

Commands and command arguments available to the base system ServiceNow CLI.

Global command arguments

Use command arguments to set options for any CLI commands.

---help

Provides help information for the specified command, which includes the description, supported arguments, and examples. For more information, see Get help with ServiceNow CLI.

```bash
$ snc --help
```

---debug

Provides debug logging output when executing a command. For more information, see Get help with ServiceNow CLI.

```bash
$ snc record delete --table incident --sysid 552c48888c03330964f4932b03eb092 --debug
```
Specifies the named profile to use for a command. For more information, see Configure and manage your ServiceNow CLI connection profiles.

```bash
$ snc configure profile set --profile <profilename>
```

**--output**

Specifies the output format to use for a command. The ServiceNow CLI supports the following output formats.

- **json**: The output is formatted as JSON. This is the default.

```json
{
  "default": {
    "appversion": "1.0.8",
    "host": "https://myinstance.service-now.com",
    "hostversion": "Paris",
    "loginmethod": "basic",
    "output": "json",
    "username": "admin"
  },
  "user1": {
    "appversion": "1.0.8",
    "host": "https://otherinstance.service-now.com",
    "hostversion": "Paris",
    "loginmethod": "basic",
    "output": "yaml",
    "username": "admin"
  }
}
```

- **yaml**: The output is formatted as YAML. Use YAML to handle the output with services and tools that emit or consume YAML-formatted strings.

```
default:
  appversion: 1.0.8
  host: https://myinstance.service-now.com
  hostversion: Paris
  loginmethod: basic
  output: json
  username: admin
user1:
  appversion: 1.0.8
  host: https://otherinstance.service-now.com
```

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
• **text**: The output is formatted as multiple lines of tab-separated string values. Use this output with traditional UNIX text tools such as grep, sed, and awk, and the text processing performed by PowerShell.

```text
<table>
<thead>
<tr>
<th>default</th>
<th><a href="https://myinstance.service-now.com">https://myinstance.service-now.com</a></th>
<th>Paris</th>
<th>1.0.8</th>
<th>basic</th>
</tr>
</thead>
<tbody>
<tr>
<td>admin</td>
<td>json</td>
<td>admin</td>
<td>json</td>
<td></td>
</tr>
<tr>
<td>user1</td>
<td><a href="https://otherinstance.service-now.com">https://otherinstance.service-now.com</a></td>
<td>Paris</td>
<td>1.0.8</td>
<td>basic</td>
</tr>
<tr>
<td>admin</td>
<td>yaml</td>
<td>admin</td>
<td>yaml</td>
<td></td>
</tr>
</tbody>
</table>
```

• **table**: The output is formatted as a table which presents the information in a human-readable format.

```plaintext
NAME    HOST            HOST       VERSION APP VERSION LOGIN METHOD USERNAME OUTPUT
--------- ---------------- -------------------------- -------------------------- --------------- --------------- --------------- --------------- ---------------
---------- ---------------- -------------------------- -------------------------- --------------- --------------- --------------- ---------------
default  myinstance  Paris   1.0.8   basic   admin   json
user1     otherinstance  Paris   1.0.8   basic   admin   yaml
```

• **none**: The CLI does not print the output to the console. Success, error, and progress messages still display.

```bash
$ snc record query --table incident --query 'active=true' --output json
```

---

**--no-interactive**

Prevents the CLI from prompting the user for argument values. If the user does not pass a value for a required argument, the system uses the default value. If no default value is defined, the system throws an error.

---

**--no-verbose**

The command executes silently without messages. Use this argument in automated testing scenarios.

### Configure profile

Create a connection profile to connect with your instance, view connection profiles, refresh your connection and available commands, or delete profiles you no longer need. For more information about configuring your profile, see Configure and manage your ServiceNow CLI connection profiles.
Set up a default profile

Create a connection profile that the ServiceNow CLI uses by default. You must create a default profile to set up the CLI's initial connection with an instance.

```
$ snc configure profile set
```

The system prompts you for the following information:

<table>
<thead>
<tr>
<th>Requested information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>The host name of the instance to connect to. Supports both the full URL (<a href="https://my-instance.service-now.com">https://my-instance.service-now.com</a>) or just the host name (my-instance).</td>
</tr>
<tr>
<td>Login method</td>
<td>The login method to use to connect to the instance. Supports Basic, OAuth, and OAuth + MFA.</td>
</tr>
<tr>
<td>Username</td>
<td>The user name to use to connect to the instance.</td>
</tr>
<tr>
<td>Password</td>
<td>The password to use to connect to the instance.</td>
</tr>
<tr>
<td>Client id</td>
<td>The client ID to use to connect to the instance when the login method is OAuth or OAuth + MFA.</td>
</tr>
<tr>
<td>Client secret</td>
<td>The client secret to use to connect to the instance when the login method is OAuth or OAuth + MFA.</td>
</tr>
<tr>
<td>Authentication code</td>
<td>The authentication code to use to connect to the instance when the login method is OAuth + MFA.</td>
</tr>
<tr>
<td>Default output format</td>
<td>Specifies how to format the command results. Options are json, yaml, text, and table.</td>
</tr>
</tbody>
</table>

Set up a named profile

Create a named connection profile to use with specific commands. This allows you to specify a different instance or connection protocol for a specific command.
$ snc configure profile set [--profile profile-name]

The system prompts you for the following information:

<table>
<thead>
<tr>
<th>Requested Information</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>The host name of the instance to connect to. Supports both the full URL (<a href="https://my-instance.service-now.com">https://my-instance.service-now.com</a>) or just the host name (my-instance).</td>
</tr>
<tr>
<td>Login method</td>
<td>The login method to use to connect to the instance. Supports Basic, OAuth, and OAuth + MFA.</td>
</tr>
<tr>
<td>Username</td>
<td>The user name to use to connect to the instance.</td>
</tr>
<tr>
<td>Password</td>
<td>The password to use to connect to the instance.</td>
</tr>
<tr>
<td>Client id</td>
<td>The client ID to use to connect to the instance when the login method is OAuth or OAuth + MFA.</td>
</tr>
<tr>
<td>Client secret</td>
<td>The client secret to use to connect to the instance when the login method is OAuth or OAuth + MFA.</td>
</tr>
<tr>
<td>Authentication code</td>
<td>The authentication code to use to connect to the instance when the login method is OAuth + MFA.</td>
</tr>
<tr>
<td>Default output format</td>
<td>Specifies how to format the command results. Options are json, yaml, text, and table.</td>
</tr>
</tbody>
</table>

View profiles

View all connection profiles set in the configuration file, or view information about a specific profile.

$ snc configure profile list [--profile profile-name]

Remove a profile

Remove a named connection profile that you no longer need from the configuration file.

© 2021 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
$ snc configure profile remove [--profile profile-name]

**Refresh a profile**

Update the available commands from the instance for the given profile. Refresh your connection after modifying any of the commands on the corresponding instance in order to keep the CLI up-to-date.

$ snc configure profile refresh [--profile profile-name]

**Perform record operations**

Create, read, update, delete, and query records in your instance using the ServiceNow CLI command-line tool. For more information about performing record operations, see [Perform record operations using ServiceNow CLI](#).

**Create a record**

Inserts a single record in a specified table.

$ snc record create [--table table --data data]

Pass in values for these arguments.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>Required. Name of the table in which to save the record.</td>
</tr>
<tr>
<td>data</td>
<td>Required. Field name and the associated value for each field to define in the specified record in JSON string format.</td>
</tr>
</tbody>
</table>

**Delete a record**

Deletes the specified record from the specified table.

$ snc record delete [--table table --sysid sys_id]

Pass in values for these arguments.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>Required. Name of the table in which to delete the record.</td>
</tr>
<tr>
<td>sysid</td>
<td>Required. Sys_id of the record to delete.</td>
</tr>
</tbody>
</table>
Get a record

Retrieves a single record based on the specified sys_id from the specified table.

$ snc record get [--table table --sysid sys_id]

Pass in values for these arguments.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>Required. Name of the table from which to retrieve the record.</td>
</tr>
<tr>
<td>sysid</td>
<td>Required. Sys_id of the record to retrieve.</td>
</tr>
</tbody>
</table>

Query records

Retrieves multiple records from a specified table.

$ snc record query [--displayvalue displayValue --fields fields --limit limit --offset offset --query query --table table]

Pass in values for these arguments.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>displayValue</td>
<td>Include --displayvalue displayValue to retrieve the display value from the database for reference and choice fields. Do not include this parameter to retrieve the actual values.</td>
</tr>
<tr>
<td>fields</td>
<td>Comma-separated list of field names to return from the database.</td>
</tr>
<tr>
<td>limit</td>
<td>Maximum number of records to return.</td>
</tr>
<tr>
<td>offset</td>
<td>Starting record index for which to begin retrieving records. Use this value to paginate record retrieval.</td>
</tr>
<tr>
<td>query</td>
<td>Required. Encoded query used to filter the result set in the following format: --query '&lt;column_name&gt;&lt;operator&gt;&lt;value&gt;'.</td>
</tr>
<tr>
<td>table</td>
<td>Required. Name of the table in which to query the records.</td>
</tr>
</tbody>
</table>

Update a record
Updates the specified record with the given data attributes.

```bash
$snc record update [--sysid sys_id --table table --data data]
```

Pass in values for these arguments.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>Required. Name of the table in which to save the record.</td>
</tr>
<tr>
<td>sysid</td>
<td>Required. Sys_id of the record to update.</td>
</tr>
<tr>
<td>data</td>
<td>Required. Field name and the associated value for each field to define in the specified record in JSON string format.</td>
</tr>
</tbody>
</table>

**Work with extensions**

Add extensions to the ServiceNow CLI to load additional functionality and commands, update existing extensions, or remove extensions you no longer need. For more information, see Manage ServiceNow CLI extensions.

**Find available extensions**

```bash
$snc extension list-available -o table
```

**Install an extension**

```bash
$snc extension add --name <extension-name>
```

**Update an extension**

```bash
$snc extension update --name <extension-name>
```

**Remove an extension**

```bash
$snc extension remove --name <extension-name>
```

**Use the ui-component extension**

**Add the ui-component extension**

Add the ui-component extension to the ServiceNow CLI.

```bash
$snc extension add --name ui-component
```

**Set up your project**

Create the component project and the set of files required to develop a component. You can connect to your instance and
create an application scope for your component, or you can reserve a scope to verify later.

```
$ snc ui-component project [--name name --description description --scope scope --offline]
```

Pass in values for these arguments.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Required. The project name. Must be a valid and unique npm package name.</td>
</tr>
<tr>
<td>description</td>
<td>The project description to be available in the npm registry and the plugins list in your instance.</td>
</tr>
</tbody>
</table>
| scope   | Suggested application scope to assign to this project and its components. If provided, the instance validates the name. Use the namespace identifier guidelines for application development on the instance. For more information, see Application scope. Maximum: 18 characters. Case: snake case. Default: $customerprefix$componentname, where:
  - $customerprefix$ is the value in the glide.appcreator.company.code system property on your instance.
  - $componentname$ is the value provided in the component's name parameter when you created the project. Alternatively, you can add a value to the scopeName parameter in the now-ui.json file. For more information, see Change a component's application scope. |
| offline | When true, creates and scaffolds a component while disconnected from your instance. Skips validation of the given scope name. Default: false. |

Run the development server
Add your component code and test it using a local development server.

$ snc ui-component develop [--entry entry --open --port port --host host]

Pass in values for these arguments.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>entry</td>
<td>Path to the test module in your component project. Default: example/index.js.</td>
</tr>
<tr>
<td>open</td>
<td>Opens the default browser and navigates to the test page. Default: false.</td>
</tr>
<tr>
<td>port</td>
<td>Port where the development server runs. Default: 8081.</td>
</tr>
<tr>
<td>host</td>
<td>Host address to use if you want your local development server to be accessible externally by others. Typically set to 0.0.0.0.</td>
</tr>
</tbody>
</table>

Deploy a component to an instance

Deploy your component to display in your instance as an application plugin.

$ snc ui-component deploy [--open --force]

Pass in values for these arguments.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>open</td>
<td>When true, opens the default browser and navigates to UI Builder in your instance. Default: false</td>
</tr>
<tr>
<td>force</td>
<td>Deploys component changes and overwrites any existing component records. Default: false.</td>
</tr>
</tbody>
</table>

Commands installed with CMDB Application CLI and API

Commands and command groups available to the ServiceNow CLI when the app-cmdb-api-cli plugin is installed.
Request apps on the Store

Visit the ServiceNow Store website to view all the available apps and for information about submitting requests to the store. For cumulative release notes information for all released apps, see the ServiceNow Store version history release notes.

To script critical operations which support automation across the enterprise, you can leverage APIs or run command line operations that the CMDB Application CLI and API store app provide instead of using the user interface. The CMDB Application CLI and API store app provides a robust framework which consolidates all the APIs that are related to application services and the command lines that let you access the interface to those APIs.

CMDB Application CLI and API commands enable the following tasks:

• Registering and creating an application service and establishing upstream relationships
• Getting details of a given application service and its upstream relationships
• Connecting higher level constructs such as business applications and business service offerings
• Populating an application service with a given population type
• Changing the state of an application service

For the REST API solution, see SG Services API.

Convert Application Service

Converts a manual or empty type application service to a calculated application service. During conversion, the application service record moves into the [cmdb_ci_service_calculated] table with the newly assigned class.

Command group:
• Parent group: service-graph
• Child group: app-service

Roles required

app_service_admin

If using a service mapping related service, the user must have the required roles for that service mapping related service.

Command structure
snc service-graph app-service convert --data '{JSON}'

**Arguments**

This command passes a JSON object using the `data` parameter.

The following properties for identifying a CI take precedence as follows:

1. **sys_id** – If `sys_id`, the system only uses the `sys_id` and ignores any additional values.
2. **number** – If provided without the `sys_id`, the system only uses the number and ignores any additional values.
3. **<IRE field name>** – The system only uses these values if the `sys_id` or `number` are not provided.

**JSON object properties**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;IRE field name&gt;</td>
<td>One or more IRE fields identifying the application service. For example, name or version.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>levels</td>
<td>Number of levels to include in the conversion.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>number</td>
<td>Unique number that identifies the application service.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the application service.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

**Example**

```
snc service-graph app-service convert --data '{"name":"Test Register","environment":"Test","version":"1.0","levels":8}'
```

**Return value**

```
{
  "result": {
    "status": "success"
  }
}
```
Create Application Service Relationship

Constructs upstream relations such as business applications, business service offerings, and other application services. Running this command creates a relationship, taking input with a single parent and a corresponding child object.

Command group:
- Parent group: service-graph
- Child group: app-service

Roles required
app_service_admin

If using a service mapping related service, the user must have the required roles for that service mapping related service.

Command structure

```
snc service-graph app-service create-relationship --data '{JSON}'
```

Arguments

This command passes a JSON object using the `data` parameter.

The following properties for identifying a CI take precedence as follows:

1. sys_id – If sys_id, the system only uses the sys_id and ignores any additional values.
2. number – If provided without the sys_id, the system only uses the number and ignores any additional values.
3. <IRE field name> – The system only uses these values if the sys_id or number are not provided.

JSON object properties

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>child</td>
<td>Information identifying the child application service with which to create a relationship. The child is located in the Application Service [cmdb_ci_service_auto] table. A dynamic CI group can be added as a child but cannot be parent. Data type: Object</td>
</tr>
</tbody>
</table>
### JSON object properties (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;child&quot;: {&lt;IRE field name&gt;: &quot;String&quot;, number: &quot;String&quot;, sys_id: &quot;String&quot; }</td>
<td>One or more IRE fields identifying the child application service. For example, name or version. Data type: String</td>
</tr>
<tr>
<td>child.&lt;IRE field name&gt;</td>
<td>One or more IRE fields identifying the child application service. For example, name or version. Data type: String</td>
</tr>
<tr>
<td>child.number</td>
<td>Unique number that identifies the child application service. Data type: String</td>
</tr>
<tr>
<td>child.sys_id</td>
<td>Sys_id of the child application service listed in the Application Service [cmdb_ci_service_auto]. Data type: String</td>
</tr>
<tr>
<td>parent</td>
<td>Details identifying the parent application service with which to create a relationship. Data type: Object</td>
</tr>
<tr>
<td>&quot;parent&quot;: {&lt;IRE field name&gt;: &quot;String&quot;, number: &quot;String&quot;, sys_id: &quot;String&quot;, class_name: &quot;String&quot; }</td>
<td>One or more IRE fields identifying the application service. For example, name or version. Data type: String</td>
</tr>
<tr>
<td>parent.&lt;IRE field name&gt;</td>
<td>One or more IRE fields identifying the application service. For example, name or version. Data type: String</td>
</tr>
<tr>
<td>parent.number</td>
<td>Unique number that identifies the application service. Data type: String</td>
</tr>
</tbody>
</table>
JSON object properties (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>parent.sys_id</td>
<td>Sys_id of the application service listed in the Application Service [cmdb_ci_service_auto]. Data type: String</td>
</tr>
</tbody>
</table>
| parent.class_name     | Name of the class that contains the application service. The parent class name should be from one of the following tables:  
  • cmdb_ci_service_auto  
  • cmdb_ci_service_discovered  
  • cmdb_ci_service_by_tags  
  • cmdb_ci_service_calculated  
  • service_offering  
  • cmdb_ci_business_app  
  Default: cmdb_ci_service_auto  
  Data type: String |

Example

snc service-graph app-service create-relationship --data
'
  "child":{"name":"wdfsdf","environment":"Test","version":"1.0"},"parent":{
  "sys_id":"abcdefg","name":"business App1","class_name":"service_offering"}}'

Return value

```json
{
  "result": {
    "status": "success"
  }
}
```

Delete Application Service

Deletes an application service.

Command group:
• Parent group: service-graph
• Child group: app-service

Roles required
app_service_admin

If using a service mapping related service, the user must have the required roles for that service mapping related service.

Command structure
```
snc service-graph app-service delete --data '{JSON}'
```

Arguments
This command passes a JSON object using the `data` parameter.
The following properties for identifying a CI take precedence as follows:
1. `sys_id` – If `sys_id`, the system only uses the `sys_id` and ignores any additional values.
2. `number` – If provided without the `sys_id`, the system only uses the number and ignores any additional values.
3. `<IRE field name>` – The system only uses these values if the `sys_id` or `number` are not provided.

JSON object properties

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;IRE field name&gt;</code></td>
<td>One or more IRE fields identifying the application service. For example, name or version. Data type: String</td>
</tr>
<tr>
<td><code>number</code></td>
<td>Unique number that identifies the application service. Data type: String</td>
</tr>
<tr>
<td><code>sys_id</code></td>
<td>Sys_id of the application service listed in the Application Service [cmdb_ci_service_auto] table. Data type: String</td>
</tr>
</tbody>
</table>

Example
snc service-graph app-service delete --data '{"name":"Test Register","environment":"Test","version":"1.0"}'

Return value

```json
{
    "result": {
        "status": "success"
    }
}
```

Delete Application Service Relationship

Deletes an application service upstream relationship.

Command group:
- Parent group: service-graph
- Child group: app-service

Roles required

app_service_admin

If using a service mapping related service, the user must have the required roles for that service mapping related service.

Command structure

```
snc service-graph app-service delete-relationship --data '{JSON}'
```

Arguments

This command passes a JSON object using the `data` parameter.

The following properties for identifying a CI take precedence as follows:

1. `sys_id` – If `sys_id`, the system only uses the `sys_id` and ignores any additional values.
2. `number` – If provided without the `sys_id`, the system only uses the `number` and ignores any additional values.
3. `<IRE field name>` – The system only uses these values if the `sys_id` or `number` are not provided.
## JSON object properties

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Data type:</th>
</tr>
</thead>
<tbody>
<tr>
<td>child</td>
<td>Information describing the child relationship to be deleted from the service application.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>child.&lt;IRE field name&gt;</td>
<td>One or more IRE fields identifying the child application service. For example, name or version.</td>
<td>String</td>
</tr>
<tr>
<td>child.number</td>
<td>Unique number that identifies the child application service.</td>
<td>String</td>
</tr>
<tr>
<td>child.sys_id</td>
<td>Sys_id of the child application service listed in the Application Service [cmdb_ci_service_auto].</td>
<td>String</td>
</tr>
<tr>
<td>parent</td>
<td>Details identifying the parent application service from which to remove a relationship.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>parent.&lt;IRE field name&gt;</td>
<td>One or more IRE fields identifying the application service. For example, name or version.</td>
<td>String</td>
</tr>
</tbody>
</table>
### JSON object properties (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>parent.number</td>
<td>Unique number that identifies the application service.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>parent.sys_id</td>
<td>Sys_id of the application service listed in the Application Service [cmdb_ci_service_auto] table.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>parent.class_name</td>
<td>Name of the class that contains the application service.</td>
</tr>
<tr>
<td></td>
<td>The parent class name should be from one of the following tables:</td>
</tr>
<tr>
<td></td>
<td>• cmdb_ci_service_auto</td>
</tr>
<tr>
<td></td>
<td>• cmdb_ci_service_discovered</td>
</tr>
<tr>
<td></td>
<td>• cmdb_ci_service_by_tags</td>
</tr>
<tr>
<td></td>
<td>• cmdb_ci_service_calculated</td>
</tr>
<tr>
<td></td>
<td>• service_offering</td>
</tr>
<tr>
<td></td>
<td>• cmdb_ci_business_app</td>
</tr>
<tr>
<td></td>
<td>Default: cmdb_ci_service_auto</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

### Example

```bash
snc service-graph app-service delete-relationship --data
'"child":{"name":"Test Register","environment":"Test","version":"1.0"},"parent":{"name":"business Service Offering1","class_name":"service_offering"}"
```

### Return value

```json
{
  "result": {
    "status": "success"
  }
}
```
Find Application Service
Finds the details of a given application service and its upstream relationships.

Command group:
- Parent group: service-graph
- Child group: app-service

Roles required
- app_service_admin – This role provides unlimited viewing of application services.
- app_service_user – This role only provides viewing application services in Operational status.

If using a service mapping related service, the user must have the required roles for that service mapping related service.

Command structure
```
snc service-graph app-service find --data '{JSON}'
```

Arguments
This command passes a JSON object using the `data` parameter.
The following properties for identifying a CI take precedence as follows:
1. sys_id – If sys_id, the system only uses the sys_id and ignores any additional values.
2. number – If provided without the sys_id, the system only uses the number and ignores any additional values.
3. `<IRE field name>` – The system only uses these values if the sys_id or number are not provided.

JSON object properties

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;IRE field name&gt;</code></td>
<td>One or more IRE fields identifying the application service. For example, name or version. Data type: String</td>
</tr>
<tr>
<td>number</td>
<td>Unique number that identifies the application service. Data type: String</td>
</tr>
</tbody>
</table>
JSON object properties (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| sys_id   | Sys_id of the application service listed in the Application Service [cmdb_ci_service_auto] table.  
Data type: String                               |

**Example**

```bash
snc service-graph app-service find --data '{"name" : "Test App Service1"}'
```

**Return value**

```json
{
  "result": {
    "aliases": null,
    "asset": null,
    "asset_tag": null,
    "assigned": "",
    "assigned_to": null,
    "assignment_group": null,
    "attestation_score": null,
    "attested": "0",

```
Populate Application Service

Populates an application service with a service population method.

Command group:

- Parent group: service-graph
- Child group: app-service

Roles required

- app_service_admin

If using a service mapping related service, the user must have the required roles for that service mapping related service.

Command structure

```
snc service-graph app-service populate --data '{JSON}'
```

Arguments

This command passes a JSON object using the data parameter. The following properties for identifying a CI take precedence as follows:
1. `sys_id` – If `sys_id`, the system only uses the `sys_id` and ignores any additional values.

2. `number` – If provided without the `sys_id`, the system only uses the number and ignores any additional values.

3. `<IRE field name>` – The system only uses these values if the `sys_id` or `number` are not provided.

### JSON object properties

## Register Application Service

Creates an application service, tags and constructs upstream relationships such as business applications, business service offerings, and other application services.

**Command group:**
- Parent group: `service-graph`
- Child group: `app-service`

### Example

```bash
snc service-graph app-service populate --data '{"name":"Test Register","environment":"Test","version":"1.0","population_method":{"group_id":"String","type":"cmdb_group"}}'
```

### Return value

```json
{
  "result": {
    "status": "success"
  }
}
```
Roles required

app_service_admin

If using a service mapping related service, the user must have the required roles for that service mapping related service.

Command structure

```
snc service-graph app-service register --data '{JSON}'
```

Arguments

This command passes a JSON object using the `data` parameter.

The following properties for identifying a CI take precedence as follows:

1. `sys_id` – If `sys_id`, the system only uses the `sys_id` and ignores any additional values.
2. `number` – If provided without the `sys_id`, the system only uses the number and ignores any additional values.
3. `<IRE field name>` – The system only uses these values if the `sys_id` or `number` are not provided.

JSON object properties

Example

```
snc service-graph app-service register --data '{"name": "Test Register", "environment": "Test", "version": "1.0", "number": "SNSVC0001014", "relationships": {"business_application": [{"sys_id": "0250a9400697410f87713b656474250"}, {"number": "APM0001002"}, {"name": "Test Biz App1"}], "business_service_offering": [{"sys_id": "ed32e9800697410f87713b656474259"}], "technical_service_offering": [{"sys_id": "80e12d600697410f87713b65647421c"}, {"number": "BSN0001005"}, {"name": "Tech Service Offering2"}], "parent_app_service": [{"sys_id": "a2f061800697410f87713b656474255"}], "tags": [{"key": "key1", "value": "value1"}, {"key": "key2", "value": "value2"}]}}'
```

Return value

```
{
  "result": {
    "app_service": {
      "sys_id": "99b2a5400697410f87713b6564742ad",
      "name": "Test Register",
      "number": "SNSVC0001014"
    },
    "message": "Service registered successfully",
    "status": "INSERT"
  }
}
```

Update Application Service

Updates an existing application service provided and creates tags for the given application service.
Command group:
- Parent group: service-graph
- Child group: app-service

Roles required

app_service_admin

If using a service mapping related service, the user must have the required roles for that service mapping related service.

Command structure

`snc service-graph app-service update --data '{JSON}'`

Arguments

This command passes a JSON object using the `data` parameter. The following properties for identifying a CI take precedence as follows:

1. sys_id – If sys_id, the system only uses the sys_id and ignores any additional values.
2. number – If provided without the sys_id, the system only uses the number and ignores any additional values.
3. `<IRE field name>` – The system only uses these values if the sys_id or number are not provided.

JSON object properties

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;fields or tags to update&gt;</td>
<td>Use key-value pairs to identify each field or tag to be updated. Only basic information can be updated, no upstream relationships can be updated. Data type: String</td>
</tr>
<tr>
<td>&lt;IRE field name&gt;</td>
<td>One or more IRE fields identifying the application service. For example, name or version. Data type: String</td>
</tr>
<tr>

Example

```
snc service-graph app-service update-state --data '{"name":"Test Register","environment":"Test","version":"1.0"}'
```

Return value

```
{
    "result": {
        "status": "success"
    }
}
```

ServiceNow Extensions for Visual Studio Code

Edit your ServiceNow applications in Visual Studio Code with the help of the ServiceNow Extensions for VS Code.

The ServiceNow Extensions for the VS Code editor enables you to edit applications within your ServiceNow instance.
Advantages of using Visual Studio Code

**Edit your applications offline**

Use Visual Studio Code to download and edit a local copy of your application. You can edit the application offline, and then synchronize again when your instance is available.

**Use Visual Studio Code JavaScript features to reduce development time and improve code quality.**

Visual Studio Code IntelliSense includes editing features such as code completion, code suggestions, and quick information. Use these tools to complete your coding tasks quickly and reduce errors. For more details on using IntelliSense in your applications, see [IntelliSense in VS Code](#). The extension also supports Linting using ESLint. The same standard ESLint rules used in the ServiceNow instance are available.

**Functions of ServiceNow Extensions for VS Code**

The ServiceNow Extensions for VS Code extension includes tools for developing on the Now Platform.

The extension adds several functions to your Visual Studio Code (VS Code) implementation. You access these functions through the command palette.
## Available functions in the ServiceNow extension for VS Code

<table>
<thead>
<tr>
<th>Functionality</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Setup Now Workspace</td>
<td>Create the project folder to work with ServiceNow applications. For details on creating this workspace, see Set up a workspace in VS Code.</td>
</tr>
<tr>
<td>Activate Now Extension</td>
<td>Activates the ServiceNow extension. See Activate ServiceNow Extensions for VS Code.</td>
</tr>
<tr>
<td>Create Now Project</td>
<td>Import existing ServiceNow applications to a Visual Studio Code project. See Create a project in VS Code.</td>
</tr>
<tr>
<td>Sync Current Project</td>
<td>During development, synchronize all files between VS Code and the instance. See Synchronize the current project between a Visual Studio Code workspace and a ServiceNow instance.</td>
</tr>
<tr>
<td>Sync Current File</td>
<td>Synchronize the current file you are working on. See Sync the current file between a Visual Studio Code</td>
</tr>

Install ServiceNow Extensions for VS Code

Download and install ServiceNow extensions to begin editing your applications in VS Code.

Before you begin
Role required: none
In order to install ServiceNow Extensions for Visual Studio Code, you must have VS Code version 1.38.0 or later installed.

Procedure

1. Open VS Code and navigate to the Extensions tab by clicking the Extensions tab icon (️) or pressing Control+Shift+X on Windows or Command+Shift+X on MacOS.
3. Select ServiceNow Extensions for VS Code in the search results and click Install to proceed with installation.
5. Navigate to View > Command Palette in Visual Studio Code. You can also use a keyboard shortcut (Control+Shift+P on Windows and Command+Shift+P on MacOS) to open the command palette.
6. Choose Developer: Reload Window from the list.

What to do next
Once you reload VS Code activate the ServiceNow extension.

Activate ServiceNow Extensions for VS Code

Activate the ServiceNow Extensions for VS Code to be able to edit applications within your ServiceNow instance.
Before you begin
Install ServiceNow Extensions for VS Code to activate the extension and begin editing your applications in VS code.

About this task
Activating the extension is the first step you must perform after installation of the extension to access its functionalities.

Procedure
1. Navigate to View > Command Palette to open the command palette. You can also use a keyboard shortcut, Control+Shift+P on Windows or Command+Shift+P on MacOS, to open the command palette.
2. Choose Now: Activate Now Extension from the list.

The Setup Workspace link appears at the bottom of the VS Code IDE. After the extension is activated, Set up your workspace in VS Code to begin editing ServiceNow applications.

Set up a workspace in VS Code
Using the ServiceNow Extensions for VS Code, create a project work folder to use as a workspace for ServiceNow applications.

Before you begin
Activate the workspace to access the functionalities of ServiceNow Extensions for VS Code. Role required: admin
Procedure

1. Click the **Setup Workspace** on the status bar at the bottom of the VS Code IDE.
   You can also use a keyboard shortcut, Control+Shift+P on Windows or Command+Shift+P on MacOS, to open the command palette and choose **Now: Setup Now Workspace** from the list.

   ![Setup Now Workspace command](image)

2. Do any of the following actions:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
   | To set up a workspace from a new folder | a. Click **New Folder**.  
b. Enter a name for the folder in the **Name of new Folder** window.  
c. Click **Create**. |

   The workspace is created from the selected folder.

**What to do next**
Create a project in your workspace. You can create multiple projects of different project types within a workspace.
Create a project in VS Code

ServiceNow applications are contained within a project in the VS Code IDE. Import an application from your ServiceNow instance with the help of ServiceNow Extensions for VS Code.

Before you begin
Setup your workspace to create a project and start editing your ServiceNow applications.

Procedure
1. Click **Create Project** in the status bar on the bottom of the VS Code IDE.

You can also use a keyboard shortcut, Control+Shift+P on Windows or Command+Shift+P on MacOS, to open the command palette and choose **Now: Create Now Project** from the list.

The **Create Project** wizard opens.

2. Enter the URL of the ServiceNow instance and press Enter to confirm.
   Include the complete URL for your instance, for example, [https://example.service-now.com](https://example.service-now.com)

3. When prompted, select the Authentication type.
• To create a basic application, choose **Basic** and fill in the following fields, when prompted.

### Basic application

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Name</td>
<td>Enter the User name of the ServiceNow instance URL.</td>
</tr>
<tr>
<td>Password</td>
<td>Enter the password of the ServiceNow instance URL.</td>
</tr>
</tbody>
</table>

### Project type

• To create an OAuth application, choose **OAuth** application and fill in the following fields, when prompted.

### OAuth application

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Name</td>
<td>Enter the Username of the ServiceNow instance URL.</td>
</tr>
<tr>
<td>Password</td>
<td>Enter the password of the ServiceNow instance URL.</td>
</tr>
<tr>
<td>Client ID</td>
<td>Client ID is automatically generated by ServiceNow OAuth server.</td>
</tr>
<tr>
<td>Client secret</td>
<td>Client secret for the OAuth application.</td>
</tr>
</tbody>
</table>

4. Select the project type when prompted.
Note: You can enable the Packages and Plugins project types by enabling them from the Settings. Navigate to Preferences > Settings > Extensions > Now > Project Settings to enable them.

5. Select Import Existing.

Import an application into Visual Studio Code

After you create a project, import an application from your instance into the project to begin editing.

Procedure

1. Visual Studio Code displays the list of applications available in your instance for the selected application type. Select an application.

2. At the Configure file types prompt, click OK to select all file types.

By default, Visual Studio Code imports all the file types of your application. You can modify the selection of the file types while editing the application, by choosing Now: Configure File Types from the command palette and choosing the file types from the list.
Your ServiceNow application is imported into your workspace.

**Note:** Even if your application exists on your instance, you must create a project for it in Visual Studio Code.

You can switch applications within the workspace by clicking the name of the application, for example, EmployeeApp in this case, in the status bar at the bottom of the VS code IDE or choosing **Now: Select Application** from the command palette and selecting the application name from the list. Similarly, you can modify the update set by clicking the current update set icon, for example, EmployeeApp in this case, in the status bar at the bottom of the VS code IDE or by choosing **Now: Select Update Set** from the command pallet and selecting the name of the updateset.

**Synchronization between Visual Studio Code and a ServiceNow instance**

You can synchronize your applications between Visual Studio Code and your ServiceNow instance.

**Synchronization**

Changes made to your applications in Visual Studio Code are stored on your local file system only until you synchronise with your instance.

Synchronization accounts for the following changes:

- File modifications on the instance or in the local file system
- File creation on the instance or in the local file system
- File deletion on the instance or in the local file system

You can sync your currently selected record or all records in the current application.

**Sync the current file between a Visual Studio Code workspace and a ServiceNow instance**

Identify conflicting files and merge or overwrite the changes, between the current file in your Visual Studio Code workspace and your instance.

**Before you begin**

Role required: admin
Procedure

1. Click the Sync icon from the menu on the top-right corner of the Visual Studio Code IDE.
   You can also use a keyboard shortcut Control+Shift+P in Windows and Command+Shift+P in MacOS to open the command palette and choose Now: Sync Current File from the list.
   - If the changes occur either on the server or on the client, the extension synchronizes the file successfully without showing up any errors.
   - If there are no differences between the local and server versions, then the message No changes detected appears on the bottom of the page.
   - If the same file is modified both on the client and the server, then the system displays the conflicts in a Conflicting Files dialog box.

2. If a conflict list is displayed in a Conflicting Files dialog box, check the conflicts.
   - Compare the Server and Client version using the Diff window, and evaluate the changes.
   - Override the Server or Client changes.

3. Check for the differences in the Conflicting Files list.

A dialog box displays the following options:
- Open Diff: Check for the differences between two versions and make the necessary changes.
- Mark Resolved: Resolve the differences and sync the versions.
• Overwrite Server: Choose if you want to override the server version with the client version.

• Overwrite Local: Choose **Override Local** to override the local version with the server version.

4. Click **Open Diff**.
   You can see two versions of the file with the differences highlighted.

5. Make changes to the server version from the client version and save the file.

6. Click **Mark as Resolved** under **Conflicting Files**.
   The changes are successfully synchronized upon the next synchronization.
   When the changes are merged successfully, the message **Sync completed successfully** appears at the bottom of the page.

Synchronize the current project between a Visual Studio Code workspace and a ServiceNow instance

Synchronize files between the Visual Studio Code workspace (client/local) and the instance (server) bi-directionally.

**Before you begin**
Create your project and start editing your applications.

**About this task**
The changes made to the application files in the Visual Studio Code workspace are initially stored in the local file system. When you run the **Sync** command, the local changes made to the application files are sent to the server for persistence.
Procedure

1. Click Sync on the status bar on the bottom of the Visual Studio Code IDE. You can also use a keyboard shortcut, Control+Shift+P on Windows or Command+Shift+P on MacOS, to open the command palette and choose Now: Sync Current Project from the list.

![Sync current project](image)

- If the changes occur either on the server or on the client, the extension synchronizes the file successfully without showing up any errors.
- If there are no differences between local and server versions, then the message No changes detected appears on the bottom of the page.
- If the same file is modified both on client and server, then the system shows up the conflicts.

2. If a conflict list is displayed, right-click on the conflicting file to open the context menu and select from the context menu. Alternatively, select the file and click Open Diff menu from the top of the page.

![Conflicting files display](image)
• Choose **Override Server** if you want to overwrite the server version with the client version

• Choose **Override Local** to overwrite the client version with the server version.

• Choose **Mark as resolved** to remove the flag indicating a conflict. The server version will be overwritten in the next synchronization.

3. Retain the desired changes in the client file and save.

4. once you have resolved all file conflicts, click **Mark as Resolved** under **Conflicting Files**.

   The changes are synchronized on the next sync. When the changes are merged successfully, the message **Sync completed successfully** appears in the bottom of the page.

   **Note:** The files are checked for syntax errors at the beginning of synchronization process. Any errors found are presented in the problem tab at the bottom of the screen.

**What to do next**

All the changes are tagged to the update set in the status bar. When a project is loaded or selected, the default update set is displayed in the status bar. Click the update set picker to choose the current update set (valid until the IDE or project is closed). If you do not explicitly select an update set, all writes happen to the default update set.

**Clear instance credentials in Visual Studio Code**

Clear the stored credentials of the current project from the system. User credentials (instance URL, user name, password) of a project are stored in the operating system credentials vault so that the user does not need to log in each time.
About this task
Once you clear credentials from the current instance, the ServiceNow Extensions for Visual Studio Code extension prompts for authentication the next time you open VS Code. You can continue working in the current session.

ℹ️ Note: The password is not stored in the Visual Studio Code settings.

Procedure

1. Navigate to View > Command Palette.
   You can also use a keyboard shortcut, Control+Shift+P on Windows or Command+Shift+P on MacOS to open the command palette.

2. Choose Now: Clear Credentials from the command palette.

   ![Now: Clear credentials command]

   The credentials of the current project are cleared.

3. Optional: Navigate to Code > Preferences > Settings > Workspace > Extensions > ServiceNow to check whether the credentials and the instance URL have been deleted.

Reset a project in Visual Studio Code

Reset the project to the state on the server by discarding all the local changes if you encounter any serious sync issues.

About this task

When you reset a project to its server state, all unsynchronized changes are lost.
Procedure

1. Navigate to View > Command Palette in.
   You can also use a keyboard shortcut, Control+Shift+P on Windows or Command+Shift+P on MacOS, to open the command palette.

2. Choose Now: Reset Project from the drop-down list.

3. Click Yes in the dialog box.

Results

The project is reset to its original state.

Note: This option should be used only when something goes wrong, for example, if the project is corrupted or you are facing sync issues.

Create a project in VS Code

Add custom file types in Visual Studio Code

If you have work with file types other than the default types provided, you can add additional file types to your instance and edit them in ServiceNow extension for Visual Studio Code.

Before you begin

Role required: admin

Procedure

1. Create a new file type in your ServiceNow instance and inherit it from the application file.

2. Add custom columns of the type Script and String, and enter some data.

   You can also use a keyboard shortcut, Control+Shift+P on Windows or Command+Shift+P on MacOS, to open the command palette.

4. Choose Now: Add Custom File Types from the command palette.
   The command fetches all the existing tables in the current application and opens the Add new file type wizard.

5. Select the file type you created in your ServiceNow instance from the list.

6. At the Select tags prompt, select the tags you created in the instance.
   All tags are selected by default. Click a tag’s check box to deselect it.
The new file type is successfully added to the app.config.json file. You can also add the desired file types manually to the app.config.json file under your project. See the example below.

7. Absorb this new file type to the current project using the **Now: Configure File Types** command from the command palette.

8. Select the file type you created from the list of file types and click **OK**. The selected file type is ready for editing in the ServiceNow Extensions for Visual Studio Code extension.

**Example:**
The following is an example for app.config.json

```json
"CustomFileTypes": {
   "sc_ic_aprvl_type_defn": {
      "superCoverName": "Miscellaneous",
      "coverName": "Approval Type Definition",
      "tags": {
         "approver_script": "js",
         "approver_html": "html",
      }
   }
}
```

- superCoverName is a name of the super parent directory (Should always point to Miscellaneous).
- coverName is a descriptive name of the table.
- sc_ic_aprvl_type_defn is a table identifier.
• tags represent the set of scriptable columns in the table
• approver_script is a name of the table column / xml tag
• js is an extension of the file (js | html | css | json)

Create a file in VS Code

Use the ServiceNow extension to create a new file for your application with your project.

Before you begin
Import an application in your VS Code project to create a file within your project.

Procedure

1. Open the VS Code project containing your application.

2. Click the Create File on the status bar on the bottom of the VSCode IDE.
   You can also use a keyboard shortcut, Control+Shift+P on Windows or Command+Shift+P on MacOS, to open the command palette and choose Now: Create New File from the list.

3. Select the file group from Select File Group list.
4. Select the file type from the **Select File Type** list from the command palette at the top of the screen.

5. Enter a name for the file in the Create New File dialog box. The extension creates a file in your application on your local file system. The new file is added to your instance when you synchronize your workspace.

**Search files on your instance in VS Code**

Search and download any script files on your instance using the ServiceNow Extensions for VS Code extension.
Procedure

1. Open a project in VS Code containing your application.

2. Click the **File Search** on the status bar on the bottom of the VSCode IDE. You can also use a keyboard shortcut, Control+Shift+P in Windows or Command+Shift+P on MacOS, to open the command palette and choose **Now: Global Search** from the list.

3. Select the file group from the **Select File Group** list in the command palette on the top of the screen.
Select File Group list

4. Select the file type from the Select a File Type list in the command palette on the top of the screen.

Select a file type list

5. Select files from the Select files to download list.
Select files to download list

You can select and download multiple files at a time.
The selected files are downloaded to the scratch folder of your application.
You can edit the selected files.

Related information
Create a file in VS Code
Run background scripts using VS Code
Run scripts from your ServiceNow instance in VS Code using the ServiceNow Extensions for VS Code.

Before you begin
Role required: admin
**Procedure**

1. While writing the script in the VS Code IDE, select the script in the text file and right-click on the script.

2. Select **Run Background Script - Current** or **Run Background Script - Global** from the context menu. The background scripts runner tab opens in VS Code and shows the location where the script is executed in the server.

**IntelliSense in VS Code**

The IntelliSense code editing feature in the ServiceNow Extensions for VS Code extension provides intelligent code completions which provide auto-completion options to make writing code faster and more efficient.

When you start scripting in the VS Code, the IntelliSense feature shows auto-completion options suitable for your code context at the top of the list.

**IntelliSense for GlideSystem**

<table>
<thead>
<tr>
<th>gs</th>
</tr>
</thead>
<tbody>
<tr>
<td>getSelection</td>
</tr>
<tr>
<td>GlideSchedule</td>
</tr>
<tr>
<td>GlideScopedEvaluator</td>
</tr>
<tr>
<td>GlideScriptableInputStream</td>
</tr>
<tr>
<td>GlideScriptedProcessor</td>
</tr>
<tr>
<td>GlideServletRequest</td>
</tr>
<tr>
<td>GlideServletResponse</td>
</tr>
<tr>
<td>GlideSession</td>
</tr>
<tr>
<td>g_user</td>
</tr>
<tr>
<td>g_list</td>
</tr>
<tr>
<td>getMessage</td>
</tr>
</tbody>
</table>

The auto-completion options available are:

- Auto-completion of methods and properties for client and server scripts.
- Auto-completion of methods and properties for standard JS APIs
- Auto-completion of Jelly tags and attributes.
- Code completion in commonly used standards.

The extension supports snippets (templates) for commonly used code patterns and loads snippets defined by the user in Macros table of the Syntax Editor on an instance. Snippets appear in IntelliSense when you type `Space` along with other suggestions. Alternatively, snippets can also be inserted using the **Insert Snippet** command from the command palette in VS Code.
Telemetry in ServiceNow Extensions for VS Code

ServiceNow Extensions for VS Code collects information on its various usage patterns such as the commands run with the help of Now Telemetry.

Now Telemetry helps in the following:

- Debug issues
- Analyse most used functions or features
- Capture user actions
- Improve the extension

ℹ️ Note: Telemetry collects anonymous information related to usage and does not capture any personal information such as name and email ID of the users. Data is accessible to ServiceNow only and is not shared with anyone.

Telemetry is enabled by default for the ServiceNow extension. If you do not wish to send usage data, you can set the `now.telemetry.enableTelemetry` user setting to false. Alternatively, select **File** (Windows) or **Code** (Mac) and navigate to **Preferences > Settings > Extensions > Now** and clear **Now Telemetry** check box to disable the feature.

ℹ️ Note: The usage data will be sent until you disable the setting. The extension abides by the global telemetry setting `telemetry.enableTelemetry`. If that is set to false, Now telemetry is disabled.
Legacy application creator

Application developers have options when creating applications.

⚠️ **Note:** As of the New York release, Guided Application Creator is the default way to set up applications on the Now Platform. There is no migration path from the legacy application creator to Guided Application Creator.

You can add a property to force legacy application creator to open instead of Guided Application Creator. For more information, see Activate the legacy application creator.

Sample application creation options

To start creating an application, navigate to System Applications > Studio and click Create Application. Select one of the available options.

- Start from scratch.
- Create custom application.
- Start from an existing service (available only when the Service Creator plugin is activated).
- Start from a template.
- Start from global.

The application creation method determines the application scope.
After you create an application, it appears on the applications list (System Applications > Applications) and is set as the current application in the application picker.

**Activate the legacy application creator**

The legacy application creator is replaced by Guided Application Creator in the New York release. You can add a property to force the legacy application creator to open instead of Guided Application Creator.

**Before you begin**
Role required: admin

**About this task**
The system property `sn_g_app_creator.use.legacy.appcreator` is set to `false` by default. If you set the property to `true`, the legacy application creator opens when you create an application in the Application Manager or Studio; Guided Application Creator is no longer available.

> Note: The legacy application creator platform opens by default if you are using Internet Explorer 11 or older.

**Procedure**

1. Add a property with the following settings.
   - Name: `sn_g_app_creator.use.legacy.appcreator`
   - Type: true | false
   - Value: true

2. Click Submit.

**Legacy: Start from scratch**

You can create an empty application using the Start from scratch option.

**Before you begin**
Complete the steps in Activate the legacy application creator.

Role required: admin

**About this task**
This option is good for applications that only use one configuration record, such as a workflow or script-based application.
Note: As of the New York release, Guided Application Creator is the default way to set up applications on the Now Platform. There is no migration path from the legacy application creator to Guided Application Creator.

Procedure
1. From the Start from scratch row, click Create.
2. Enter a Name for the application.
3. Create Create.
4. In the Confirm Application dialog box, click OK.

Legacy: Create a custom application
You can create an application with UI and data elements using the Create custom application option.

Before you begin
Complete the steps in Activate the legacy application creator.
Role required: admin

About this task
This option is good for applications that require UI elements and tables.

Note: As of the New York release, Guided Application Creator is the default way to set up applications on the Now Platform. There is no migration path from the legacy application creator to Guided Application Creator.

Procedure
1. From the Create custom application row, click Create.
2. Enter a Name for the application.
3. Optional: Modify any of these fields if the default values do not meet your needs.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Menu</td>
<td>The application menu users can use to access the application.</td>
</tr>
<tr>
<td>User Role</td>
<td>The role a user must have to access the application.</td>
</tr>
</tbody>
</table>
4. **Optional:** Select **Create Table** and provide table details.
   
   (Optional) If you do not create a table using this option, you must manually define a table before you can store any application data.

5. Click **Create**.

6. On the Confirm Application dialog box, click **OK**.
   The system creates the application and provides an **Edit App** option.

---

**Legacy: Start from an existing service**

You can convert an existing service to an application if service creator is active.

**Before you begin**

Complete the steps in **Activate the legacy application creator**.

**Role required:** admin

**About this task**

⚠️ **Note:** As of the New York release, Guided Application Creator is the default way to set up applications on the Now Platform. There is no migration path from the legacy application creator to Guided Application Creator.

You may want to convert successful services into full applications to take advantage of features only available to applications such as contextual security, data or UI policies, UI actions, and auditing.

When converting a service that exists on a production instance, you should pull the service to a non-production instance and convert the service to an application in that environment. After completing the conversion, you can push the new application to the production environment.

**Procedure**

1. From the **Start from a service** row, click **Create**.

2. In the **Create from service** field, select a published service.

3. **Optional:** Change the application details and catalog item details if the default values do not meet your needs.

4. **Optional:** Select **Replace original service** to deactivate the catalog item for the service and replace it with an equivalent catalog item for the application.
   
   (Optional) When replacing an existing service with an application, the application preserves the same end-user experience for submitting and
fulfilling requests. Any service requests that were made prior to the conversion are converted to requests within the application.

5. Click **Create**.

6. Click **OK**.

**Legacy: Conversion mapping**

The conversion process uses the following service creator elements to create application records.

### Service Creator conversion mapping

<table>
<thead>
<tr>
<th>This Service Creator element</th>
<th>Becomes this application element</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service category table</td>
<td>Application table</td>
</tr>
<tr>
<td>Service name</td>
<td>Table label</td>
</tr>
<tr>
<td>Service form layout</td>
<td>Application table form layout</td>
</tr>
<tr>
<td>Service catalog policies</td>
<td>Application table UI policies</td>
</tr>
<tr>
<td>Service catalog item</td>
<td>Application catalog item</td>
</tr>
<tr>
<td>Service catalog variable</td>
<td>Fields on the application table</td>
</tr>
<tr>
<td>Category form layout</td>
<td>Table form layout</td>
</tr>
<tr>
<td>Service task workflow</td>
<td>Application table workflow</td>
</tr>
</tbody>
</table>

**Legacy: Start from a template**

You can create service management applications from a template using the **Start from a template** option if service management is active.

**Before you begin**

Complete the steps in **Activate the legacy application creator**.

Role required: **admin**

**About this task**

This option is good for applications that need to track the status of requests or task-driven records.
Note: As of the New York release, Guided Application Creator is the default way to set up applications on the Now Platform. There is no migration path from the legacy application creator to Guided Application Creator.

Procedure
1. From the Start from a Template row, click Create.
2. Enter a Name for the application.
3. Optional: Click Configure from the section containing the process you want to use, and select the configuration options you want to use.
4. Click Create from the section containing the process you want to use.
5. In the Confirm Application dialog box, click OK.
   The system creates the application and provides an Edit App option.

Legacy: Start from global
You can create a legacy application in the global scope using the Start from global option.

Before you begin
Complete the steps in Activate the legacy application creator.

Role required: admin

About this task
Applications created in the global scope do not benefit from application scope protections. Use this option to support legacy applications from previous versions.

Note: As of the New York release, Guided Application Creator is the default way to set up applications on the Now Platform. There is no migration path from the legacy application creator to Guided Application Creator.

Procedure
1. From the Start from global row, click Create.
2. Enter a Name for the application.
   The default value for the Scope field is global and cannot be changed.
3. Optional: Modify any of these fields if the default values do not meet your needs.
### Option Description

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Menu</strong></td>
<td>The application menu users can use to access the application.</td>
</tr>
<tr>
<td><strong>User Role</strong></td>
<td>The role a user must have to access the application.</td>
</tr>
</tbody>
</table>

**4. Optional:** Select **Create Table** and provide table details.

(Optional) If you do not create a table using this option, you must manually define a table before you can use the application.

**5. Click Create.**

**6. On the Confirm Application dialog box, click OK.**

The system creates the application and provides an **Edit App** option.

### Related information

- Add a property using `sys_properties.list`

### APIs and scripts

APIs are used in scripts to change functionality and to provide new features and applications to your instance.

Using extension points to extend application functionality

Use extension points to extend the functionality of an application without altering the original application code. You can use pre-existing extension points available in selected Now Platform applications, or you can add extension points when you develop custom applications in your own instance.

Using extension points

By using extension points, you can integrate customizations without actually altering the core components in the application code. Extension points can prevent your custom code interactions from breaking, which often occurs after an upgrade if you directly embed the custom code into the application code.

Extension points that are embedded in the application code act as out-points, where data passes to the custom code, and as in-points that handle the returned results. When creating an application, the returned data or objects must conform to the requirements that you define for the extension point.

Types of extension points

You can create extension points to process the custom code that uses the following types of artifacts:

**Scripted extension points**

Extension points in server-side script includes that store JavaScript functions and object classes. To learn about scripts includes and how to implement scripted extension points in the application and custom code, see:

- Script includes
- Creating and adding a scripted extension point
- Registering custom script includes against the scripted extension points

**UI extension points**

Extension points that are used in server-side UI macros such as HTML extensions.
UI macros are discrete scripted components that you can add to the user interface. You use them to add custom content to a UI page, without having to directly modify the page. For example, you can use UI macros to add headers and footers to the standard Knowledge Base View (kb_view) UI page in which KB articles appear.

To learn about UI macros and how to implement UI extension points in the application and custom code, see:

- UI Macros
- Creating and adding a UI extension point
- Registering custom UI macros against the UI extension points

Client extension points

Extension points that are used in client-side UI scripting, typically for modifying forms.

UI scripts enable you to package client-side JavaScript into a reusable form, which is similar to how script includes store server-side JavaScript. You can create UI scripts and run them from client scripts, from other client-side script objects, and from HTML code.

To learn about UI scripts and how to implement client extension points in application and custom code, see:

- UI scripts
- Creating and adding a client extension point
- Registering custom UI scripts against the client extension points

When you use extension points to process customizations, you create a defined structure for integrating custom data or functionality into an application. Custom server-side script includes, UI macros such as HTML extensions, and client-side UI scripts are all external to the application code and only interact with it at specified extension points.

Application code

The term application code refers to:

Standard application code

Standard, or base, application code that comprises the Now Platform.

Pre-defined extension points are already embedded in certain applications, such as Customer Service Management and Field Service Management. To learn more about the Now Platform...
applications that contain pre-defined extension points, see the following:

**Internally developed custom applications for your enterprise**

You can add extension points to handle the registration of custom artifacts that are used to modify or extend the functionality of an application. When developers create custom code, they register, or pair, specific custom artifacts with specific extension points. Adding extension points enables integration of future customizations without having to change your base code.
Creating an extension point in the application code

You want to ensure that the internally developed applications that you create for your enterprise can be properly customized, combined, and upgraded as needed. Extension points enable you to modify the functionality and user interface for an application without editing its core components. Use of extension points also creates a highly defined structure for functionality extensions.

When you create an extension point, you can restrict its use to the application scope in which it is defined or specify that the extension point can run in all scopes globally. If the application scope is restricted, customizations that are registered against the extension point can only run in the designated application scope. Before designing and building an application that includes extension points, you should:

• Identify where to place extension points in the application code to accommodate custom script includes, UI macros, or UI scripts.
• Determine the content and structure for an extension point. This definition should describe how a customization should be structured, how it interacts with the application code, and how the data that is returned by a customization at the extension point is processed.

To create extension points and embed them in the application code, perform the following tasks:
1. Create an extension point and define its custom interface. This is an example of a scripted extension point.

2. Designate specific places in the application code where data or objects can be sent to a customization, and where data is returned.
3. Create an artifact, such as script includes, UI macros, or UI scripts, with the appropriate API call. The API call identifies the extension point at which registered custom artifacts execute in the application code.

Enabling debugging and logging

When you create an extension point, you should also enable debugging and logging. Debugging and logging help you to identify and fix issues that are related to the use of custom artifacts with an extension point. When you enable the debugger, you can set break points in script includes, UI macros, or UI scripts. You can check the logs to see the following details:

- When an extension point finds active extension instances, including the total number of extension instances found and the time each extension instance was found.
- When an extension point executes extension instances, including the total number of custom artifacts executed and the time of each executed. It also includes the total number that failed to execute and the time at which each extension instance failed.
Note: To learn more about how to enable debugging and how it works, see:

- Script Debugger and Session Log
- Debugging applications
- Writing to the debug log

Registering a custom artifact against an extension point

When you are customizing an application, you extend the base functionality by using custom artifacts, such as server-side script includes, UI macros, or client-side UI scripts. To design and build custom artifacts, perform the following tasks:

1. Review the listing of available extension points that are appropriate to the specific type of custom artifact that you are creating.
   - These listings include extension points that you created and any pre-defined extension points that are embedded in the Now Platform functions.
   - Each listing includes information about an extension point in the application code that calls a custom artifact and what data or objects should be returned to it.

2. Select an extension point.

3. Determine how to structure the custom artifact. The structure should be based on the extension point descriptions. The descriptions include the requirements for using the artifact with the custom code and where the artifact will located in the base application code.

4. Create the custom artifact and code when you register it against the selected extension point. Through registration, you create an extension instance record that links the extension point definition to its implementation in the custom artifact.

How registered custom artifacts are processed

When the application code executes and finds an embedded API call containing an extension point, it:

1. Uses the extension point in the API call to determine which custom artifacts are registered against it.

2. Sends the appropriate data or objects to the registered custom artifacts.

3. Collects the returned output from each custom artifact.

4. Processes and incorporates the returned results into the base application.
Using scripted extension points in server-side scripts

Use the scripted extension points in the server-side script includes that store JavaScript functions and object classes. By using extension points, you can integrate customizations without actually altering the core components in the application code.

You create the scripted extension points and add them to the script includes in the base application code. When customizing a base application, you implement the scripted extension points by creating the custom script includes and registering them against the scripted extension points.

⚠️ Note: For an example of a scripted extension point and to learn more about this process, see Using extension points to extend application functionality.

Creating and adding a scripted extension point

When developing an application, create scripted extension points and add them to the script includes in the application code. Use a scripted extension point to designate the specific location where data or objects can be sent to a registered custom script include and where returned results are processed.

⚠️ Note: For an example of a scripted extension point, see Using extension points to extend application functionality.

Create a scripted extension point

Create a scripted extension point that can be placed in a script include in the base application code. By placing the scripted extension point, you designate the specific location in the application code where data or objects can be sent to a customization and where data is returned.

Before you begin

Role required: You must have the specific role for the developer or administrator of the application, or you must have the admin role.

⚠️ Note: To learn about application-specific administrator roles and delegated development, see Access control rules in application administration apps and Delegated development and deployment.

About this task

Define the content and structure for an extension point. This definition should describe how a customization should be structured, how it interacts with the application code, and how the data that is returned by a customization at the extension point is processed.

By creating a good definition, you provide a structure for the extensions.
Procedure

1. Navigate to System Extension Points > Scripted Extension Points.
2. Click New.
3. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Unique name for the extension point. The name can be up to 100 alphanumeric characters, including special characters.</td>
</tr>
<tr>
<td>API Name</td>
<td>Name of the extension point API that is pre-pended with the application scope to which it applies. This is a system-assigned name and cannot be changed.</td>
</tr>
<tr>
<td>Application</td>
<td>Application scope against which the extension point is assigned. This is system-assigned and cannot be changed. For more information about the protections that are offered by the use of scoping, see Application scope.</td>
</tr>
<tr>
<td>Restrict to this scope</td>
<td>Option for restricting the extension point to the application scope only.</td>
</tr>
<tr>
<td>Description</td>
<td>Requirements for the custom script include, such as how the UI script should be structured and how it should operate with the application code.</td>
</tr>
<tr>
<td>Example</td>
<td>Example of how a custom script include that interacts with this extension point should be structured so it operates with the application code.</td>
</tr>
</tbody>
</table>

4. Click Submit.
Add a scripted extension point in the base application code

Add the scripted extension point into a script include in the base application code. To add the extension point, place an API call that identifies the location at which registered custom artifacts execute.

Before you begin

You must first create a scripted extension point before you can add it to a script include in the application code. Role required: You must have the specific role for the developer or administrator of the application, or you must have the admin role.

Note: To learn about application-specific administrator roles and delegated development, see Access control rules in application administration apps and Delegated development and deployment.

Procedure

1. In the application code, access the existing script include that you want to add a scripted extension point to, or create a new script include. To learn more about creating script includes, see Script includes.

2. In the script include, add a line of code at the location that you expect to collect and process the custom script output.

The code must contain the `getExtensions` command that identifies the extension point against which the custom script includes are registered. For example:

```java
var canReserve = true;
try {
    var eps = new GlideScriptedExtensionPoint().getExtensions("CanReserve");
    eps.forEach(function(ep) {
        if (ep.handles(thing)) {
            canReserve = ep.canReserve(thing, from, until, by);
        }
    });
} catch (ex) {
    gs.error("Error running ShouldAllow extension points!");
}
```

Note: It is also a good practice to deliver error messages for application customizers when their custom scripts run in an extension instance. If something fails when the function returns arguments to the extension point, the error messages include information about how to troubleshoot the custom script.
Registering custom script includes against the scripted extension points

Register custom script includes against a selected scripted extension point in the application code.

By registering the custom script, you create an extension instance record that links the scripted extension point definition to its implementation in the custom script include.

Register a custom script include

Create a custom script include and code when you register it against a selected scripted extension point. Through registration, you create an extension instance record that links the extension point definition to its implementation in the custom artifact.

Before you begin

Role required: You must have the specific role for the developer or administrator of the application, or you must have the admin role.

Note: To learn about application-specific administrator roles and delegated development, see Access control rules in application administration apps and Delegated development and deployment.

Procedure

1. Navigate to System Extension Points > Scripted Extension Points.
2. In the Extension Point [sys_extension_point] table, select the scripted extension point that you want to register a custom script include against.

Note: This listing includes the scripted extension points that you created and any pre-defined scripted extension points that are embedded in Now Platform functions (for example, Customer Service Management and Field Service Management).

To learn more about the functions that contain the pre-defined extension points, see the Related Topics links in Using extension points to extend application functionality.

3. In the Extension Point record, click the Create Implementation related link to create a new custom script include and register it against the selected scripted extension point.
4. In the Script Include form, create the custom code.
   To learn more about creating script includes, see Script includes.
5. Click Update.
Results
The custom script include is created and registered against the scripted extension point.

Review scripted extension instances
Review the listing of custom script includes that are registered against a scripted extension point. Extension instances indicate the application scope in which registered custom script include are used, and provides a link to each. You can also activate or inactive an extension instance.

Before you begin
Role required: You must have the specific role for the developer or administrator of the application, or you must have the admin role.

Note: To learn about application-specific administrator roles and delegated development, see Access control rules in application administration apps and Delegated development and deployment.

Procedure
1. Navigate to System Extension Points > Scripted Extension Points.
2. In the Extension Point [sys_extension_point] table, select the scripted extension point.
3. In the Implementations related list of the Extension Point record, select a scripted extension instance.
   The system displays the Extension Instance record.

Extension Instance record

4. Click **Submit**.

### Add a UI extension point in the base application code

Add the UI extension point into a UI macro or HTML extension in the base application code. To add the extension point, place an API call that identifies the location at which registered custom artifacts execute.

**Before you begin**

You must first create a UI extension point before you can add it to a UI macro or UI page in the application code. Role required: You must have the specific role for the developer or administrator of the application, or you must have the admin role.

**Note:** To learn about application-specific administrator roles and delegated development, see Access control rules in application administration apps and Delegated development and deployment.

**Procedure**

1. In the application code, access the existing UI macro that you want to add a scripted extension point to or create a new one. To learn more about creating UI macros with jelly tags, see UI Macros and Jelly tags.

2. In the UI macro, add a jelly tag with a line of code at the location that you expect to collect and process custom UI macro output. Typically, this line of code contains:
• A call_extension command that identifies the name of the UI extension point (for example, extension="global.KMArticle.ViewHeader") against which the custom UI macros are registered.

This line of code is similar to what is in an application code script include for scripted extension points. For an example, see Register a custom script include.

• Arguments that are passed into the UI macro when it is rendered. For example, for a Knowledge Base article, knowledgerecord="${knowledgeRecord}" passes in the current knowledge record.
• (Optional) If there are multiple implementations of this extension point, using a `limit` command specifies that x number of implementations should be returned (for example, `limit="1"`). This figure shows a UI macro that contains these commands.
<-- MB Extension point call to customize footer -->
<call_extension extension="global.KWArticleViewFooter" knowledgeRecord="#knowledgeRecord" limit="1" />

<!--  -->
<if test="#isMobileView = true">  
  <div class="mobile">  
    <inline template="kb_view_common_body"/>
  </div>
  </if>  
  </if>  
  </if>  
  </if>

Protection policy: None
Registering custom UI macros against the UI extension points

Register custom UI macros against a selected UI extension point in the application code.

By registering custom UI macros, you create an extension instance record that links the UI extension point definition to its implementation in the custom UI macro.

Register a custom UI macro

Create a custom UI macro and code when you register it against a selected UI extension point.

Before you begin

Role required: application-specific developer, application-specific admin, or admin

Note: To learn about application-specific administrator roles and delegated development, see Access control rules in application administration apps and Delegated development and deployment.

Procedure

1. Navigate to System Extension Points > UI Extension Points.

2. In the UI Extension Point [sys_ui_extension-point] table, select the extension point that you want to register a custom UI macro against.

   Note: This listing includes UI extension points that you created and any pre-defined UI extension points that are embedded in Now Platform functions (for example, Customer Service Management and Field Service Management).

   To learn more about functions that contain pre-defined extension points, see the Related Topics links in Using extension points to extend application functionality.

3. In the UI Extension Point record, click the Create Implementation related link to create a new custom UI macro and register it against the selected UI extension point.

4. In the UI Macro form, create the custom code.

   To learn more about creating UI macros, see UI Macros.

5. Click Update.

Results

The custom UI macro is created and registered against the UI extension point.
Review UI extension instances

Review the listing of custom UI macros that are registered against a UI extension point. Extension instances indicate the application scope in which registered custom UI macros are used and provides a link to each. You can also activate or inactivate an extension instance.

Before you begin
Role required: You must have the specific role for the developer or administrator of the application, or you must have the admin role.

⚠️ Note: To learn about application-specific administrator roles and delegated development, see Access control rules in application administration apps and Delegated development and deployment.

Procedure

1. Navigate to System Extension Points > UI Extension Points.
2. In the UI Extension Point [sys_ui_extension_point] table, select the UI extension point that you want to view extensive instances for.
3. In the Implementations related list of the UI Extension Point record, select a UI extension instance.
   The system displays the UI Extension Instance record.

### Add a client extension point in the base application code

Add the UI extension point into a UI script in the base application code. To add the extension point, place an API call that identifies the location at which registered custom artifacts execute.

#### Before you begin

You must first create a UI extension point before you can add it to a UI script in the application code. Role required: You must have the specific role for the developer or administrator of the application, or you must have the admin role.

⚠️ **Note:** To learn about application-specific administrator roles and delegated development, see Access control rules in application administration apps and Delegated development and deployment.

#### Procedure

1. In the application code, access the existing UI script that you want to add a scripted extension point to, or create a new one. To learn more about creating UI scripts, see UI scripts.

2. In the UI script, add a line of code at the location that you expect to collect and process the custom UI script output. The code must contain the `getExtension` command that identifies the client extension point against which the custom UI scripts are registered. This line of code is similar to what is in an application code script include for scripted extension points. For an example, see Register a custom script include.

### Registering custom UI scripts against the client extension points

Register custom UI scripts against a selected UI extension point in the application code.
By registering custom UI scripts, you create an extension instance record that links the client extension point definition to its implementation in the custom UI script.

Register a custom UI script
Create a custom UI script and code when you register it against a selected client extension point.

Before you begin
Role required: You must have the specific role for the developer or administrator of the application, or you must have the admin role.

Note: To learn about application-specific administrator roles and delegated development, see Access control rules in application administration apps and Delegated development and deployment.

Procedure
1. Navigate to System Extension Points > Client Extension Points.
2. In the Client Extension Point [sys_client_extension_point] table, select the client extension point that you want to register the custom UI script against.

Note: This listing includes the client extension points that you define and the pre-defined client extension points that are embedded in Now Platform® functions (for example, Customer Service Management and Field Service Management).

To learn more about functions that contain the pre-defined extension points, see the Related Topics links in Using extension points to extend application functionality.

3. In the Client Extension Point record, click the Create Implementation related link to create a new custom UI script and register it against the selected client extension point.
4. In the UI Script form, create the custom code.
   To learn more about creating UI scripts, see UI scripts.
5. Click Update.

Results
A custom UI script is created and registered against the client extension point.

Review client extension instances
Review the listing of custom UI scripts that are registered against a client extension point. Extension instances indicate the application scope in which
registered custom UI scripts are used, and provides a link to each. You can also activate or inactive an extension instance.

**Before you begin**
Role required: You must have the specific role for the developer or administrator of the application, or you must have the admin role.

ℹ️ **Note:** To learn about application-specific administrator roles and delegated development, see Access control rules in application administration apps and Delegated development and deployment.

**About this task**
A listing of the custom script UI scripts that are registered against the client extension point appear at the bottom of the Extension Point record. It includes links to each extension instance, custom UI script, and application scope in which the registered custom UI script is used.

**Procedure**

1. Navigate to System Extension Points > Client Extension Points.
2. In the Client Extension Point [sys_client_extension_point] table, select the client extension point.
3. In the Implementations related list of the Client Extension Point record, select a client extension instance.

**Client Extension Instance record**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point</td>
<td>Unique name for the client extension point. The name can have up to 100 alphanumeric characters, including special characters.</td>
</tr>
<tr>
<td>Class</td>
<td>Base code UI script in which the client extension point is implemented.</td>
</tr>
<tr>
<td>Application</td>

Using extension points to extend application functionality

JavaScript API reference

Use JavaScript APIs in scripts you write to change the functionality of applications, or when you create new applications.

AbstractDBObject - Global

Provides common methods for classes based on records in the database.
Use this script include as a base class to create your own database object class.

AbstractDBObject - isValid()

Determines if the current database record is valid.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the database record is valid, false otherwise.</td>
</tr>
</tbody>
</table>

The following example is from the AbstractDBObject definition in the Script Includes [sys_script_include] table.

```javascript
AbstractDBObject.prototype = {
    /*
    * Gets the record specified by the given source and table name. If the source is an
    * instance of GlideRecord, it is
    * simply returned. If the source is a string, then it is used as a sysID to find the
    * correct record, which is then
    * returned. If anything is wrong, a null will be returned.
    */
    _getRecord: function(source, tableName) {
        if (!source)
            return null;
    }
};
```
else if (source instanceof GlideRecord)
    return (source.getTableName() == tableName) ? source : null;
else {
    var gr = new GlideRecord(tableName);
    return gr.get('sys_id', source) ? gr : null;
}

isValid: function() {
    return this.valid;
},

/*AbstractDBObject*/

AbstractReconciler - Global

Use this script include as a base class to create your own Discovery reconciler.

This is an abstract base class for reconciling newly discovered data in an
XMLMemoryTable to a related list in the database. AbstractReconciler
implements the common logic and helper methods for reconciling related
lists for a particular CMDB item against discovered information present in a
MemoryTable instance.

Most of this logic is very straightforward, but one bit may not be: the resolution
of references to previously reconciled records. This feature works by collecting
information while reconciling one related list, then passing that information on
to the reconciler for another related list. For example, while switch partitions
are being reconciled, information is gathered (in a map instance) that maps
an interface number for a partition to the sys_id of the partition's record in
the partition table. Then later when the switchports are being reconciled, a
reference to the switch partition that contains the switchport can be resolved by
using this map.

AbstractReconciler - getReconciliationKey()

Gets the string value of the field to be used as a key to look up a record in the
newly discovered data.

This value will be used to attempt to find a record in the discovered data, using
the column returned by the getReconciliationKey() method.

Mandatory method, must be overridden in all concrete subclasses.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Value to use as a key into the discovered data.</td>
</tr>
</tbody>
</table>

AbstractReconciler - getReconciliationField()

Determines if the newly discovered data is different than the data already in the database for the current item.

This method is only invoked for items that have been rediscovered.
Mandatory method, must be overridden in all concrete subclasses.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the data has changed.</td>
</tr>
</tbody>
</table>

AbstractReconciler - hasChanged()

Returns true if the newly discovered data is different than the data already in the database for this item.

This method is only invoked for items that have been rediscovered.
Mandatory method, must be overridden in all concrete subclasses.
AbstractReconciler - process()

Reconciles the newly discovered data with the data already present in the database and resolves references to previously reconciled data.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the discovered data is different than the data already in the database.</td>
</tr>
</tbody>
</table>

AbstractReconciler - markAbsent()

Marks CIs as absent by setting the install status to "Absent"; other tables are marked by setting the (presumed present) field "absent" to true.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
AbstractReconciler - markPresent()

Marks CIs as present by setting the install status to "Installed"; other tables are marked by setting the (presumed present) field "absent" to false.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

AbstractReconciler - readDatabaseFields()

Reads the current memory table record of newly discovered data and checks its validity.

Mandatory method, must be overridden in all concrete subclasses.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

Boolean  True if the data is valid.
AbstractReconciler - readDiscovered()

Reads the current memory table record of newly discovered data and checks its validity.

Mandatory method, must be overridden in all concrete subclasses.

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the data is valid.</td>
</tr>
</tbody>
</table>

AbstractReconciler - resolveReferenceFields()

Reads the fields in the current database record into instance member fields.

Mandatory method, must be overridden in all concrete subclasses.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

AbstractReconciler - track(String sys_id)

Optional method to override in concrete subclasses that need to resolve reference fields.

This method is invoked after valid discovered data is read. Generally implementations will use some of this discovered data as a key into a map (passed into the concrete reconciler class when it was instantiated) that will
return the sys_id of the database record holding the referenced information. However, implementations are not required to use this approach.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sys_id</td>
<td>String</td>
<td>The sys_id of the current database record.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

### AbstractReconciler - setDatabaseFields()

Sets the database fields for the current record to the values in the newly discovered information.

This method is invoked both for new database records and for existing database records when the discovered data has changed.

Mandatory method, must be overridden in all concrete subclasses.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

### AbstractReconciler - setup()

Optional override for concrete subclasses that require special setup.
AbstractScriptProcessor - Global
Base JavaScript processor class that other JavaScript processors extend. Extend this class to create your own JavaScript processors.

AbstractScriptProcessor - initialize(String request, String response, String process)
Called by the Prototype JavaScript Framework during object construction.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>request</td>
<td>String</td>
<td>The request</td>
</tr>
<tr>
<td>response</td>
<td>String</td>
<td>The response</td>
</tr>
<tr>
<td>process</td>
<td>String</td>
<td>The process</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

AbstractScriptProcessor - process()
Called by the Prototype JavaScript Framework during object processing. Do not call this method directly.
### AbstractTimelineSchedulePage - Global

A helper class to facilitate working with the data displayed on timelines.

Processing the data displayed within a timeline starts by executing the corresponding function of the specified script include. Like other script includes, the language syntax is JavaScript and follows the default security constraints of this type of resource. However, because the different types of display options are complex, a helper class was created. To display a timeline, extend the `AbstractTimelineSchedulePage` class and pair it with its corresponding schedule page. At a minimum, extending classes should override the `getItems()` method, as this is the primary event handler for returning items to be displayed on the client.

The client processes the data that `AbstractTimelineSchedulePage` returns in two phases. The first phase makes the actual updates to the timeline. Immediately after (if configured), the second phase displays a success message box, error message box, or dialog message prompt. In phase one, the available options for manipulating data include:

- **Do Not Update Any Items** - This is the default behavior. Do not perform any of the remaining steps in phase one.
- **Update With Specific Items** - This is done using: `add()`.
- **Render The Timeline Using the `getItems()` Function** - This is done using:
  ```javascript
  setDoReRenderTimeline(true);
  ```

**Note:** If both `TimelineItems` are returned and `setDoReRenderTimeline` is set to `true`, the system will ignore the `setDoReRenderTimeline` property and explicitly show only the `TimelineItems` that were added via the `add()` function.

The available options in phase two include:
• Do Not Display Any Message Boxes - This is the default behavior.
• Display a Success Dialog Box - This is done using: `setStatusSuccess()`.
• Display an Error Dialog Box - This is done using: `setStatusError()`.
• Display a Dialog Confirm Box - This is done using: `setStatusPrompt()`.

**Note:**

A script include class that extends `AbstractTimelineSchedulePage` automatically receives all Uri parameters from the original Url whose prefix begins with `sysparm_timeline_`. To access the values of these, use: `this.getParameter("sysparm_timeline_VARIABLE");` inside your extended class.

This is useful if you need to display a schedule page from a dynamic element, such as from a context menu from a list. By passing in dynamic data via the Url the schedule page will auto-include these parameters inside the Ajax calls and therefore will be accessible inside the `AbstractTimelineSchedulePage` Script includes.

### AbstractTimelineSchedulePage - add(Object ObjTimeline)

Adds a `TimelineItem` object that will be returned to the client and appropriately displayed on the timeline.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ObjTimeline</td>
<td>Object</td>
<td>The <code>TimelineItem</code> object to add to the timeline.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

### AbstractTimelineSchedulePage - addSeparator()

Adds a horizontal frame separator into the list of timeline items. All future items added via `add()` will be added into the subsequent timeline frame.

All future items added via `add()` will be added into the subsequent timeline frame.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

// Inside of a script include that extends AbstractTimelineSchedulePage
   this.addSeparator();

### AbstractTimelineSchedulePage - elementMoveX(String spanSysId, String newStartDateTimeMs)

Event handler for when a timeline span moves horizontally.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>spanSysId</td>
<td>String</td>
<td>The sys ID of the current span being adjusted.</td>
</tr>
<tr>
<td>newStartDateTimeMs</td>
<td>String</td>
<td>The new start time of the span in milliseconds. Make sure to parse the string using parseInt() before performing any numerical comparisons.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

### AbstractTimelineSchedulePage - elementMoveY(String spanSysId, String itemSysId, String newItemSysId)

Event handler for when a timeline span moves vertically.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>spanSysId</td>
<td>String</td>
<td>The sys ID of the current span being adjusted.</td>
</tr>
<tr>
<td>itemSysId</td>
<td>String</td>
<td>The sys ID of the timeline item associated with the current span.</td>
</tr>
<tr>
<td>newItemSysId</td>
<td>String</td>
<td>The sys ID of the timeline item (a row) that the current span was dragged into.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

AbstractTimelineSchedulePage - elementMoveXY(String spanSysId, String itemSysId, String newItemSysId, String newItemSysId, String newStartDateTimeMs)

Event handler for when a timeline span moves both horizontally and vertically.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>spanSysId</td>
<td>String</td>
<td>The sys ID of the current span being adjusted.</td>
</tr>
<tr>
<td>itemSysId</td>
<td>String</td>
<td>The sys ID of the timeline item associated with the current span.</td>
</tr>
<tr>
<td>newItemSysId</td>
<td>String</td>
<td>The sys ID of the timeline item (a row) that the current span was dragged into.</td>
</tr>
<tr>
<td>newStartDateTimeMs</td>
<td>String</td>
<td>The new start time of the span in milliseconds. Make sure to parse the string using parseInt() before performing any numerical comparisons.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
AbstractTimelineSchedulePage - elementSuccessor(String spanSysId, String newSuccSpanId)

Event handler for when a timeline relationship has been created between two spans.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>spanSysId</td>
<td>String</td>
<td>The sys ID of the current span which will be a predecessor for the newly created relationship.</td>
</tr>
<tr>
<td>newSuccSpanId</td>
<td>String</td>
<td>The sys ID of the successor span from the relationship created.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td>ReturnValue</td>
</tr>
</tbody>
</table>

AbstractTimelineSchedulePage - elementTimeAdjustStart(String spanSysId, String newStartDateTimeMs)

Event handler for when a timeline span's start date was modified.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>spanSysId</td>
<td>String</td>
<td>The sys ID of the current span that is being adjusted.</td>
</tr>
<tr>
<td>newStartDateTimeMs</td>
<td>String</td>
<td>The new start time of the span in milliseconds. Make sure to parse the string using parseInt() prior to performing any numerical comparisons.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
AbstractTimelineSchedulePage - elementTimeAdjustEnd(String spanSysId, String newEndDateTimeMs)

Event handler for when a timeline span's end date was modified.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>spanSysId</td>
<td>String</td>
<td>The sys ID of the current span that is being adjusted.</td>
</tr>
<tr>
<td>newEndDateTimeMs</td>
<td>String</td>
<td>The new end time of the span in milliseconds. Make sure to parse the string using parseInt() prior to performing any numerical comparisons.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

AbstractTimelineSchedulePage - getItems()

Event handler for returning schedule items to display on the timeline.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

AbstractTimelineSchedulePage - inputBox(String strInputText)

Event handler for when a string was typed into the left pane input box.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>strInputText</td>
<td>String</td>
<td>The text that was entered in the input box in the left pane.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

AbstractTimelineSchedulePage - itemMove(String itemSysId, String newItemSysId)

Event handler for when a timeline row item was moved and dragged into another row item.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>itemSysId</td>
<td>String</td>
<td>The sys ID of the timeline item associated with the current span.</td>
</tr>
<tr>
<td>newItemSysId</td>
<td>String</td>
<td>The sys ID of the timeline item (a row) that the current span was dragged into.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

AbstractTimelineSchedulePage - setDoReRenderTimeline(Boolean b)

Specifies whether or not to re-render all of the timeline items using the `getItems()` function.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>b</td>
<td>Boolean</td>
<td>If true, re-render the timeline by making a new event call to the server's <code>getItems()</code> handler.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

AbstractTimelineSchedulePage - setPageTitle(String strTitle)

Specifies the text to display as the title of the timeline.

The page title can be set (and updated) from any interactive event; however, is recommended to be set during the `getItems()` event.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>strTitle</td>
<td>String</td>
<td>The text to be displayed on the timeline title.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

AbstractTimelineSchedulePage - setStatusError(String strTitle, String strMessage)

Sets the current event request to an error status with a specified title and message to display in phase two of the `GlideTimeline` event processing.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>strTitle</td>
<td>String</td>
<td>The text to be displayed in the dialog box title.</td>
</tr>
<tr>
<td>strMessage</td>
<td>String</td>
<td>The text to be displayed within the dialog box. The text can contain HTML formatting.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
AbstractTimelineSchedulePage - setStatusPrompt(String strTitle, String strOkFunction, String strCancelFunction, String strCloseFunction)

Sets the current event request to a prompt error status with a specified title and message to display in a confirmation dialog box during phase two of the GlideTimeline event processing. The confirmation box displays an **OK** and **Cancel** button that each generate new events that will call the functions specified the parameter arguments. The custom defined functions for **OK**, **Cancel**, and **Close** receive the same parameter arguments as those for the current event.

The confirmation box displays an **OK** and **Cancel** button that each generate new events that will call the functions specified the parameter arguments.

⚠️ **Note:** The custom defined functions for **OK**, **Cancel**, and **Close** receive the same parameter arguments as those for the current event.

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>strTitle</td>
<td>String</td>
<td>The text to display in the dialog box. The text can contain HTML formatting.</td>
</tr>
<tr>
<td>strOkFunction</td>
<td>String</td>
<td>The function to call in the current script include class if the users clicks the <strong>OK</strong> button.</td>
</tr>
<tr>
<td>strCancelFunction</td>
<td>String</td>
<td>The function to call in the current script include class if the user clicks the <strong>Cancel</strong> button.</td>
</tr>
<tr>
<td>strCloseFunction</td>
<td>String</td>
<td>The function to call in the current script include class if the user clicks the <strong>Close</strong> button.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>void</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var MyTimelineScriptIncludeClass = Class.create();
    MyTimelineScriptIncludeClass.prototype =
    Object.extendsObject(AbstractTimelineSchedulePage, { }

    getItems: function() {
        //...
    },
```

_myCloseHandlerFunction: function(spanSysId, newEndDateTimeMs) { // ... }

AbstractTimelineSchedulePage - setStatusSuccess(String strTitle,
String strMessage)

Sets the current event request to a success status with a specified title and
message to display in phase two of the GlideTimeline event processing.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>strTitle</td>
<td>String</td>
<td>The text to be displayed in the dialog box title.</td>
</tr>
<tr>
<td>strMessage</td>
<td>String</td>
<td>The text to be displayed within the dialog box. The text can contain HTML formatting.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

AccAgentsAPI API - Scoped

The AccAgentsAPI Script include enables performing management actions on available agents.
This API requires the Agent Client Collector Framework (sn_agent) store application and is provided within the \textit{sn_agent} namespace. For more information, refer to Agent Client Collector.

For the REST API solution, refer to Agent Client Collector API.

This API includes methods that enable the following:

- Getting extensive information of one or more agents.
- Submitting a request to grab an agent log and retrieving information about the request progress.
- Starting or stopping data collection.
- Restarting an agent.
- Running discovery on an agent.

\textbf{AccAgentsAPI - AccAgentsAPI()}

Creates an AccAgentsAPI instance.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

The following example shows how to initialize AccAgentsAPI.

```javascript
var agentsApi = new sn_agent.AccAgentsAPI();
```

\textbf{AccAgentsAPI - checkGrabLogRequestProgress(String requestId)}

Checks the status of a grab log request.

Run the \texttt{submitGrabLogRequest()} method to get a request ID.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>requestId</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;Object&gt;</code></td>
<td>JSON object containing the grab log request status.</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&quot;status&quot;: Number,</td>
</tr>
<tr>
<td></td>
<td>&quot;output&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>status</td>
<td>Number indicating status of the grab log request. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• 0: Grab log request is complete.</td>
</tr>
<tr>
<td></td>
<td>• 1: Grab log request in progress.</td>
</tr>
<tr>
<td></td>
<td>• 2: Grab log request timed out.</td>
</tr>
<tr>
<td></td>
<td>• 3: Grab log request has an error.</td>
</tr>
<tr>
<td></td>
<td>• 4: Grab log request was not found.</td>
</tr>
<tr>
<td>output</td>
<td>Information describing the status.</td>
</tr>
</tbody>
</table>

The following example shows how to use a request ID to get the status of a grab log request.

```javascript
var agentsApi = new sn_agent.AccAgentsAPI();
var logRequestStatus = agentsApi.checkGrabLogRequestProgress("<request_ID>");
gs.info(JSON.stringify(logRequestStatus, null, 2));
```

Output:

```javascript
{
   "status": 2,
   "output": "Grab Log Request Timed Out"
}
```

**AccAgentsAPI - getAgent(String agentID)**

Gets the information of a specified agent.

To get a list of agent IDs:
• Run the `getAgentsList()` method.
• Check the Agent ID column of the Agent Client Collectors [sn_agent_cmdb_ci_agent] table.
• Run the Agent Client Collector GET list REST API.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agentID</td>
<td>String</td>
<td>Unique ID of an agent listed in the Agent ID column of the Agent Client Collectors [sn_agent_cmdb_ci_agent] table.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Object&gt;</td>
<td>Object containing extended agent information.</td>
</tr>
<tr>
<td></td>
<td>```</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>error</td>
<td>Error message. Null if there is no error.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>agent</td>
<td>```</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>agent.agent_id</td>
<td>ID of the agent as submitted.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>Properties</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>agent.data_collection</td>
<td>Data collection indicates whether scheduled checks are to be run. These checks are a part of the policies scheduled for this agent to run. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• 0: On – Checks run as scheduled.</td>
</tr>
<tr>
<td></td>
<td>• 1: Off (manual) – Checks have been disabled manually.</td>
</tr>
<tr>
<td></td>
<td>• 2: Off (auto) – Checks have been disabled automatically due to high CPU consumption by the agent.</td>
</tr>
<tr>
<td>Data type: Number</td>
<td></td>
</tr>
<tr>
<td>agent.ip_address</td>
<td>Agent IP address.</td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
<tr>
<td>agent.is_duplicate</td>
<td>Flag that indicates whether this agent is a duplicate of another. There should be only a single agent on a given host. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: The agent has the same host as an Alive/Up agent with a different agent ID. Turn off or uninstall the duplicate</td>
</tr>
<tr>
<td></td>
<td>• false: This agent has no duplicates in the Alive/Up state.</td>
</tr>
<tr>
<td>Data type: Boolean</td>
<td></td>
</tr>
<tr>
<td>agent.is_restart_enabled</td>
<td>Flag that indicates whether restart is enabled. Agent restart is not configurable. It depends on the OS and the version of the OS the agent is running on. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: Restart is enabled for this agent.</td>
</tr>
<tr>
<td></td>
<td>• false: Restart is disabled for this agent.</td>
</tr>
<tr>
<td>Data type: Boolean</td>
<td></td>
</tr>
<tr>
<td>agent.name</td>
<td>Name of the agent.</td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agent.number_of_running_checks</td>
<td>The number of checks the agent is scheduled to run. These checks are a part of the policies scheduled for this agent to run. Data type: Number</td>
</tr>
<tr>
<td>agent.status</td>
<td>Status of the agent. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• 0: Alive/Up – The agent is active.</td>
</tr>
<tr>
<td></td>
<td>• 1: Warning – The agent has not received a keep-alive message in the past few minutes.</td>
</tr>
<tr>
<td></td>
<td>• 2: Down – The agent has not received a keep-alive message in a long time.</td>
</tr>
<tr>
<td></td>
<td>• 3: Restarting – The agent is restarting.</td>
</tr>
<tr>
<td>agent.up_since</td>
<td>UTC time since the agent’s status became alive/up. The value is in GlideDateTime format. Data type: String</td>
</tr>
<tr>
<td>agent.version</td>
<td>Version of Agent Client Collector the agent is running. Data type: String</td>
</tr>
</tbody>
</table>

The following example shows how to display an agent’s status.

```javascript
var agentsApi = new sn_agent.AccAgentsAPI();
var agentInfo = agentsAPI.getAgent("<agent_ID>");

if (!gs.nil(agentInfo.error))
gs.error(agentInfo.error);
else
  gs.info("agent status: " + agentInfo.agent.status);
```

Output:

agent status: 2

The following example shows how to get all agent details.
var agentsApi = new sn_agent.AccAgentsAPI();
var agentInfo = agentsAPI.getAgent("<agent_ID>" );
gs.info(JSON.stringify(agentInfo, null, 2));

Output:

```json
{
  "error": null,
  "agent": {
    "name": "win2016-dc-64bit",
    "status": 0,
    "agent_id": "<agent_ID>",
    "ip_address": "10.222.333.42",
    "number_of_running_checks": 1,
    "data_collection": 0,
    "is_restart_enabled": true,
    "is_duplicate": false,
    "up_since": "2021-03-24 11:04:38",
    "version": "2.4.0"
  }
}
```

AccAgentsAPI – getAgentsList(String encodedQuery, Number limit)

Gets a list of agents with related information.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>encodedQuery</td>
<td>String</td>
<td>Encoded query string in standard Glide format. See Encoded query strings.</td>
</tr>
<tr>
<td>limit</td>
<td>Number</td>
<td>Optional. Restricts results to a maximum number of agents. Use null or undefined for both if they are not required. Default/Max: 20,000</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Array&gt;</td>
<td>Array of JSON objects containing extended agent information.</td>
</tr>
</tbody>
</table>

| status                    | Status of the agent.  
|                           | Possible values:  
|                           | • 0: Alive/Up – The agent is active.  
|                           | • 1: Warning – The agent has not received a keep-alive message in the past few minutes.  
|                           | • 2: Down – The agent has not received a keep-alive message in a long time.  
|                           | • 3: Restarting – The agent is restarting.  
|                           | Data type: Number                                                                                                                                                                                          |
| up_since                  | UTC time since the agent’s status became alive/up. The value is in GlideDateTime format.  
                                                                                                                                                         |
## Returns (continued)

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>Version of Agent Client Collector the agent is running. Data type: String</td>
</tr>
</tbody>
</table>

The following example shows how to restrict results by query and number. The query returns all agents that are not in the down state with a maximum of two results.

```javascript
var agentsApi = new sn_agent.AccAgentsAPI();
var agentList = agentsApi.getAgentsList("agent_extended_info.status!=2", 2);

gs.info(JSON.stringify(agentList, null, 2));
```

**Output:**

```
[
  {
    "name": "007-175",
    "status": 0,
    "agent_id": "007-175",
    "ip_address": "11.222.63.66",
    "number_of_running_checks": 0,
    "data_collection": 0,
    "is_restart_enabled": false,
    "is_duplicate": false,
    "up_since": "2021-03-24 14:36:45",
    "version": "2.4.0"
  },
  {
    "name": "win2016-dc-64bit",
    "status": 0,
    "agent_id": "007-64",
    "ip_address": "10.222.333.42",
    "number_of_running_checks": 1,
    "data_collection": 0,
    "is_restart_enabled": true,
    "is_duplicate": false,
    "up_since": "2021-03-24 11:04:38",
    "version": "2.4.0"
  }
]```
The following example shows how to list every agent in the system. This example uses no query and no maximum number of results.

```javascript
var agentsApi = new sn_agent.AccAgentsAPI();
var agentList = agentsApi.getAgentsList(null, 0);
gs.info(JSON.stringify(agentList, null, 2));
```

The following example shows how to iterate over the results provided and displays each agent ID.

```javascript
var agentsApi = new sn_agent.AccAgentsAPI();
var agentsList = agentsApi.getAgentsList(null, 0);
for (var i = 0; i < agentsList.length; i++)
    gs.info("agent with id: " + agentsList[i].agent_id);
```

Output:

```
sn_agent: agent with id: 000a00e0aa1aa3a4
sn_agent: agent with id: 000a00e1aa1aa3a4
sn_agent: agent with id: 000a00e2aa1aa3a4
```

**AccAgentsAPI - restartAgent(String agentID)**

Restarts a specified agent with alive/up status.

If Agent Client Collector performance issues occur, you can restart the agent. Manual restart is supported in the following environments:

- Linux-based agents using **systemd**
- Windows agents

To get a list of agent IDs:

- Run the `getAgentsList()` method.
- Check the Agent ID column of the Agent Client Collectors [sn_agent_cmdb_ci_agent] table.
- Run the **Agent Client Collector GET list** REST API.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agentID</td>
<td>String</td>
<td>Unique ID of an agent listed in the Agent ID column of the Agent Client Collectors [sn_agent_cmdb_ci_agent] table.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Error message if applicable, null otherwise.</td>
</tr>
</tbody>
</table>

The following example shows how to restart an agent.

```javascript
var agentsApi = new sn_agent.AccAgentsAPI();

var err = agentsApi.restartAgent("<agent_ID>");
if (!gs.nil(err))
gs.error(err);
```

**AccAgentsAPI - runDiscovery(String agentID)**

Runs a discovery check to locate CIs related to an agent. The specified agent must be in alive/up status.

To get a list of agent IDs:
- Run the `getAgentsList()` method.
- Check the Agent ID column of the Agent Client Collectors [sn_agent_cmdb_ci_agent] table.
- Run the Agent Client Collector GET list REST API.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agentID</td>
<td>String</td>
<td>Unique ID of an agent listed in the Agent ID column of the Agent Client Collectors [sn_agent_cmdb_ci_agent] table.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Error message if applicable, null otherwise. For example, Agent With ID: &lt;agentID&gt; Is Not Up: no thrown error.</td>
</tr>
</tbody>
</table>

The following example shows how to run discovery on an agent with alive/up status.

```
var agentsApi = new sn_agent.AccAgentsAPI();

var err = agentsApi.runDiscovery("<agent_ID>");

if (!gs.nil(err))
  gs.error(err);
```

AccAgentsAPI - setDataCollectionStatus(String agentID, Boolean status)

Set the given data collection status (true/false if enabled or not) for a specified agent.

To get a list of agent IDs:
- Run the `getAgentsList()` method.
- Check the Agent ID column of the Agent Client Collectors [sn_agent_cmdb_ci_agent] table.
- Run the Agent Client Collector GET list REST API.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agentID</td>
<td>String</td>
<td>Unique ID of an agent listed in the Agent ID column of the Agent Client Collectors [sn_agent_cmdb_ci_agent] table.</td>
</tr>
</tbody>
</table>
| status | Boolean      | Flag that indicates whether data collection is enabled for the agent. Valid values:  
  • true: Enables data collection for this agent.  
  • false: Disables data collection for this agent.  
  Default: true |
### AccAgentsAPI - submitGrabLogRequest(String agentId)

Requests the log of a specified agent with alive/up status.

**Note:** To retrieve the log and check its progress, pass the request ID returned to the `checkGrabLogRequestProgress()` method.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agentID</td>
<td>String</td>
<td>Unique ID of an agent listed in the Agent ID column of the Agent Client Collectors [sn_agent_cmdb_ci_agent] table.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Object&gt;</td>
<td>JSON object containing the request ID and any error information.</td>
</tr>
</tbody>
</table>

```javascript
var agentsApi = new sn_agent.AccAgentsAPI();
var err = agentsApi.setGrabLogRequest("<agentID>";' true);
if (!gs.nil(err))
    gs.error(err);
```

The following example shows how to turn on agent data collection.

```javascript
var agentsApi = new sn_agent.AccAgentsAPI();
var err = agentsApi.setDataCollectionStatus("<agentID>", true);
if (!gs.nil(err))
    gs.error(err);
```

The following example shows how to turn off agent data collection.

```javascript
var agentsApi = new sn_agent.AccAgentsAPI();
var err = agentsApi.setDataCollectionStatus("<agentID>", false);
if (!gs.nil(err))
    gs.error(err);
```
Returns (continued)

<table>
<thead>
<tr>
<th>Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>error</td>
<td>Error message. Null if there is no error. Data type: String</td>
</tr>
<tr>
<td>request_id</td>
<td>Sys_id of a request in the Agent Client Collector Requests [sn_agent_request] table. You can use this ID to get the status of the request using GET /agents/{request_id}/. Data type: String</td>
</tr>
</tbody>
</table>

The following example shows how to get a log request ID.

```javascript
var agentsApi = new sn_agent.AccAgentsAPI();
var submittedRequest = agentsApi.submitGrabLogRequest("<agentID>");
if (!gs.nil(submittedRequest.error))
    gs.error(submittedRequest.error);
else
    gs.info("Request ID: " + submittedRequest.request_id);
```

Output:

Request ID: <sys_id>

AccCheckDefsAPI API - Scoped

The AccCheckDefsAPI script include enables managing check definitions and associated parameters.

This API requires the Agent Client Collector Framework (sn_agent) store application and is provided within the sn_agent namespace. This API requires the agent_client_collector_admin role. For more information, refer to Agent Client Collector.

This API does not have a constructor for creating an instance. Call each method using the AccCheckDefsAPI static class in the following format:

```javascript
sn_agent.AccCheckDefsAPI.<method>
```

For the REST API solution, refer to Agent Client Collector API.

This API includes methods that enable the following:
• Get a specified check definition
• Get a list of check definitions
• Update checks and check parameters

AccCheckDefsAPI - getCheck(String checkDefId, Boolean withParams)

Gets a specified check definition with details.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>checkDefId</td>
<td>String</td>
<td>Sys_id of the check definition listed in the Check Definitions [sn_agent_check_def] table.</td>
</tr>
<tr>
<td>withParams</td>
<td>Boolean</td>
<td>Flag that indicates whether existing check parameter details are returned. Information for each standard and secure check parameter is included in a JSON object. Valid values: • true: Return check parameter details. • false: Do not return check parameter details. Default: False</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>check</td>
<td>Details of the specified check definition.</td>
</tr>
</tbody>
</table>

"check ": {
    "background": Boolean,
    "check_group": "String",
    "check_type": "String",
    "command": "String",
    "error": "String",
    "name": "String",
    "params": [Array],
    "plugins": [Array],
    "proxy_valid": Boolean,
    "secure_params": [Array],
    "sys_id": "String",}
<table>
<thead>
<tr>
<th>Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;timeout&quot;: Number</td>
<td></td>
</tr>
</tbody>
</table>
| check.background         | Flag that indicates whether this check definition is a background check. A background check is a check which the agent starts execution of and doesn’t wait for it to finish running. Valid values:
- true: This check definition is a background check.
- false: This check definition is not a background check.
Data type: Boolean |
| check.check_group        | Group specified for this check definition. Data type: String |
| check.check_type         | Type of check. Possible values:
- Events – Check results are transformed into an Event Management event.
- Metrics – Values from the check result are transformed to metrics.
Data type: String |
| check.command            | Command that the Agent Client Collector executes. Data type: String |
| check.error              | Message if there is an error. Null otherwise. Data type: String |
| check.name               | Name of the check. Data type: String |
| check.params             | List of parameter definitions associated with the check definition. These results are only included if the withParams parameter is set to true. |

AccCheckDefsAPI - getChecksList(String encodedQuery, Number limit, Boolean withParams)

Gets a list of check definitions with details.

See also Checks and policies.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>encodedQuery</td>
<td>String</td>
<td>An encoded query string to filter the check definition result list. Use null for an unfiltered list of check definitions in the system.</td>
</tr>
<tr>
<td>limit</td>
<td>Number</td>
<td>Limits the number of returned records. Set to null to use the default value. Default: 20,000</td>
</tr>
</tbody>
</table>
| withParams       | Boolean| Flag that indicates whether existing check parameter details are returned. Information for each standard and secure check parameter is included in a JSON object. Valid values:  
• true: Return check parameter details.  
• false: Do not return check parameter details. Default: False |

**Returns**

<table>
<thead>
<tr>
<th>Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>check definitions</td>
<td>List of check definition and details provided as JSON objects.</td>
</tr>
</tbody>
</table>

## Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| **command** | Command that the Agent Client Collector executes.  
Data type: String |
| **name** | Name of the check.  
Data type: String |
| **params** | List of parameter definitions associated with the check definition. These results are only included if the `withParams` parameter is set to true.  

```
"params": [  
{
    "active": Boolean,
    "default_value": "String",
    "mandatory": Boolean,
    "name": "String",
    "sys_id": "String"
}
]
```

Data type: Array |

| **params.active** | Flag that indicates whether the check parameter is active.  
Valid values:  
• true: The check parameter is active.  
• false: The check parameter is inactive.  
Data type: Boolean |
| **params.default_value** | Specifies the default value for this check parameter.  
Data type: String |
| **params.mandatory** | Flag that indicates whether the check parameter is required.  
Valid values:  
• true: The check parameter is required.  
• false: The check parameter is optional.  
Data type: Boolean |
| **params.name** | Name of the check parameter. |

**AccCheckDefsAPI - updateCheck(String checkDefId, Object updateJson)**

Enables changing one or more field values of a specified check definition.

See also Checks and policies.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>checkDefId</td>
<td>String</td>
<td>Sys_id of the check definition listed in the Check Definitions [sn_agent_check_def] table.</td>
</tr>
</tbody>
</table>
| updateJson    | Object  | Map of check definition fields to be updated to their new values. Refer to the data dictionary for a comprehensive list of Check Definition fields and types.  

```json
{
    "background": Boolean,
    "check_group": "String",
    "check_type": "String",
    "command": "String",
    "name": "String",
    "plugins": [Array],
    "proxy_valid": Boolean,
    "timeout": Number
}
```

| updateJson.active | Number | Indicates whether this check definition is active. Valid values:  
|-------------------|--------|--------------------------------------------------------------------------|
|                   |        | • 0: This check definition is inactive.  
|                   |        | • 1: This check definition is active.  

| updateJson.background | Boolean | Flag that indicates whether this check definition is a background check. A background check is a check which the agent starts execution of and doesn’t wait for it to finish running. Valid values:  
|-----------------------|---------|--------------------------------------------------------------------------|
|                       |         | • true: This check definition is a background check.  
|                       |         | • false: This check definition is not a background check.  

| updateJson.check_group | String | Group specified for this check definition.  
|------------------------|--------|--------------------------------------------------------------------------|
| updateJson.check_type   | String | Type of check.

### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>updateJson.command</td>
<td>String</td>
<td>Command that the Agent Client Collector executes.</td>
</tr>
<tr>
<td>updateJson.name</td>
<td>String</td>
<td>Name of the check.</td>
</tr>
<tr>
<td>updateJson.plugins</td>
<td>Array</td>
<td>List of Agent Client Collector plugins associated with this check.</td>
</tr>
<tr>
<td>updateJson.proxy_valid</td>
<td>Boolean</td>
<td>Flag that indicates whether the check definition policy is set to work as a proxy. Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: This check definition policy is set to work as a proxy.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: This check definition policy is not set to work as a proxy.</td>
</tr>
<tr>
<td>updateJson.timeout</td>
<td>Number</td>
<td>Timeout in seconds.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>Error message if unsuccessful.</td>
</tr>
</tbody>
</table>

The following example shows how to deactivate a check definition.

```javascript
var checkJson = sn_agent.AccCheckDefsAPI.getCheck(activeCheckDefs[0].sys_id, true);
if (!gs.nil(checkJson.error))
  gs.error(checkJson.error);

var updateJson = {active: "0"); // deactivate the check definition
sn_agent.AccCheckDefsAPI.updateCheck(checkJson.check.sys_id, updateJson);
```
AccCheckDefsAPI - updateCheckParam(String checkDefParamId, Object updateJson)
Enables changing one or more field values of a specified check parameter.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>checkDefParamId</td>
<td>String</td>
<td>Sys_id of the check parameter listed in the Check Parameter Definitions [sn_agent_check_param_def] table.</td>
</tr>
<tr>
<td>updateJson</td>
<td>Object</td>
<td>Map of check parameter fields to be updated to their new values. Refer to the data dictionary for a comprehensive list of Check Secure Parameter Definition fields and types.</td>
</tr>
<tr>
<td>updateJson.active</td>
<td>Boolean</td>
<td>Flag that indicates whether the check parameter is active. Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: The check parameter is active.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: The check parameter is inactive.</td>
</tr>
<tr>
<td>updateJson.default_value</td>
<td>String</td>
<td>Specifies the default value for this check parameter.</td>
</tr>
<tr>
<td>updateJson.mandatory</td>
<td>Boolean</td>
<td>Flag that indicates whether the check parameter is required. Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: The check parameter is required.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: The check parameter is optional.</td>
</tr>
<tr>
<td>updateJson.name</td>
<td>String</td>
<td>Name of the check parameter.</td>
</tr>
</tbody>
</table>
The following example shows how to activate a check parameter.

```javascript
var checkParmSysId = "cd922ce6dba530106f4810284b961966";
var updateJson = {"active": "true"};
sn_agent.AccCheckDefsAPI.updateCheckSecureParam(checkParmSysId, updateJson);
```

**AccCheckDefsAPI - updateCheckSecureParam(String checkDefSecureParamId, Object updateJson)**

Enables changing one or more field values of a specified check secure parameter.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>checkDefSecureParamId</td>
<td>String</td>
<td>Sys_id of the secure parameter listed in the Check Secure Parameter Definitions [sn_agent_check_secure_param_def] table.</td>
</tr>
<tr>
<td>updateJson</td>
<td>Object</td>
<td>Map of check secure parameter fields to be updated to their new values. Refer to the data dictionary for a comprehensive list of Check Secure Parameter Definition fields and types.</td>
</tr>
<tr>

</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>Error message if unsuccessful.</td>
</tr>
</tbody>
</table>

The following example shows how to activate a check secure parameter.

```javascript
var checkSecParmSysId = "<sys_id>";
var updateJson = {"active": "true"};
sn_agent.AccCheckDefsAPI.updateCheckSecureParam(checkSecParmSysId, updateJson);
```

### ActivityHistoryRecord - Global

A data object that is a member of the WorkflowModelManager class; ActivityHistoryRecord methods facilitate interacting with the WorkflowModelManager object.

The ActivityHistoryRecord is basically a copy of the data from a GlideRecord on table wf_history. There are some helper methods defined for this class as well. There are no accessors or mutator to the simple data elements of this class.

**ActivityHistoryRecord - addArrivedActivityToJoin(String Array activityIds)**

Changes the `arrivedState` of already known ids to `true`.

As soon as this method changes the `arrivedState` of known ids to `true`, it tests to see if the join is satisfied. If it is, the model walk can continue; if not, it should continue to next appropriate transition. This is called during playback, as expected `wf_activities` flow to the join.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>activityIds</td>
<td>String Array</td>
<td>Array of <code>wf_activity.sys_ids</code> that are headed towards join.</td>
</tr>
</tbody>
</table>
ActivityHistoryRecord - addJoinFromActivityIds(String Array activityIds)

Seeds all the expected wf_activity sys_ids that are expected to pass through this join and sets their arriveState = false.

This state is flipped to **true** as each expected activity transitions to this instance of the Join. This method is called as part of building the cached model in memory, and is not called during playback.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>activityIds</td>
<td>String Array</td>
<td>Array of wf_activity.sys_ids that are headed towards join.</td>
</tr>
</tbody>
</table>

ActivityHistoryRecord - addTransition(Object InTransition)

As model is cached by `_getExecutedTransitions()`, this method adds transitions that have gone FROM this activity towards the .to activity.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>InTransition</td>
<td>Object</td>
<td>ExecutedTransition Javascript object to add to this activity.</td>
</tr>
</tbody>
</table>
ActivityHistoryRecord - debugDump( )
Prints debug information.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

ActivityHistoryRecord - doesJoinContainActivity( )
Tests the incoming wf_activity sys_id, presumed to be seeded in this history record. If it is, it is tested to see if it is an activity that would come through this join.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

ActivityHistoryRecord - getLogString( )
Returns the log string from the history record.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td>None</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The log string.</td>
</tr>
</tbody>
</table>

**ActivityHistoryRecord - getSatisfiedJoinActivities()**

Returns the sys_ids of the history records that transition to this Join activity that have already come through.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td>None</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Array of sys_ids of the history records that transition to this Join activity.</td>
</tr>
</tbody>
</table>

**ActivityHistoryRecord - getTransitionCount()**

Returns the transition count for this activity.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td>None</td>
</tr>
<tr>
<td>Returns</td>
<td></td>
<td></td>
</tr>
<tr>
<td>---------</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>Number</td>
<td>Number of transitions from this activity.</td>
<td></td>
</tr>
</tbody>
</table>

**ActivityHistoryRecord - getUnSatisfiedJoinActivities( )**

Returns the sys_ids of the history records that transition to this Join activity that the join is still waiting for.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

**ActivityHistoryRecord - isARollback( )**

Determines if this activity is one of the Rollback activities.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Boolean</td>
</tr>
</tbody>
</table>

**ActivityHistoryRecord - isIdADestination(String ahrSys_id)**

Determines if the sys_id passed in is a destination of any of the transitions associated with this instance of an ActivityHistoryRecord.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ahrSys_id</td>
<td>String</td>
<td>Activity history sys_id from table wf_history.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True, if the sys_id passed in is a destination of any of the transitions.</td>
</tr>
</tbody>
</table>

### ActivityHistoryRecord - isJoin( )

Determines if this activity is a join.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True, if the activity is &quot;Join&quot;.</td>
</tr>
</tbody>
</table>

### ActivityHistoryRecord - isJoinSatisfied( )

Examines the value of the arriveState.

Called during playback when the transition to sys_id of a transition points to an activity that is a join.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True, if the join is satisfied.</td>
</tr>
</tbody>
</table>

ActivityHistoryRecord - isJoinWaitingForActivity(String Array activityIds)
Tests the incoming wf_activity sys_id, presumed to be seeded in this history record.

If it is, it is tested to see if it has already been through; if it has, then this join is not waiting on this activity and it should look further downstream for the one that is waiting. This test is called in sequence as the model is walked, so it does presume in the instances of rollbacks and loops. If the sys_id is in here and the flag is true, this waiting Join is further up the sequence. This sort of check is required as the history records of Joins are removed from the history table, and so it is possible for a record to be in the transition table with no match in the corresponding history table, but is still an appropriate match for an earlier executed instance of the same Join.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>activityIds</td>
<td>String Array</td>
<td>Array of wf_activity.sys_ids that are headed towards join.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True, if the activity has already been through.</td>
</tr>
</tbody>
</table>

ActivityHistoryRecord - isRolledBack( )
Determines if this workflow was rolled back.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True, if this workflow was rolled back.</td>
</tr>
</tbody>
</table>

**ActivityHistoryRecord** - `isTurnstile()`

Determines if this activity is a turnstile.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True, if this activity is a turnstile.</td>
</tr>
</tbody>
</table>

**action** - Scoped, Global

Enables handling data for URLs in a UI action script.

Use the `action` API to configure UI actions with which users can interact. Use these scripts in the UI Action [sys_ui_action] table. For information, see UI actions. Methods for this API are referred to by the variable name 'action' in any server-side JavaScript. To learn more, see Creating interactions with UI actions.

**action** - `getGlideURI()`

Gets a GlideURI object to determine the user view.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>GlideURI object representing the URI parameter of the user view.</td>
</tr>
</tbody>
</table>
The following example shows how to get the user view and set the redirect URL to the service catalog home page.

```javascript
var uri = action.getGlideURI();
var path = 'catalog_home.do';

uri.set('sysparm_view', 'catalog_default');
action.setRedirectURL(uri.toString(path));
```

### action - getReturnURL()

Gets the URL of the return page in view after a UI action is complete.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>URL of the return page in view after a UI action is complete.</td>
</tr>
</tbody>
</table>

```javascript
action.getReturnURL();
```

### action - getURLParameter(String parameterName)

Gets the value of a URL parameter.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>parameterName</td>
<td>String</td>
<td>Name of the URL parameter name to be queried for the URL parameter value.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>URL parameter value.</td>
</tr>
</tbody>
</table>

```javascript
action.getURLParameter('sysparm_query');
```

**action - openGlideRecord(Object gr)**

Opens a page with a GlideRecord in the user view.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gr</td>
<td>GlideRecord</td>
<td>GlideRecord of the page to be opened in the user view.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to include the caller name and incident description created from an interaction record. For more details, see Set up custom UI actions in Workspace.

```javascript
if(current.update()){
    var inc = new GlideRecord("incident");
    inc.newRecord();
    inc.caller_id = current.opened_for;
    inc.short_description = current.short_description;
    action.openGlideRecord(inc);
}
```

**action - setNoPop(Boolean noPop)**

Indicates whether to enable or disable pop-up windows on the page in the current view.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>noPop</td>
<td>Boolean</td>
<td>Flag indicating whether to enable or disable pop-up windows on the page:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Disables pop-up windows.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Default. Enables pop-up windows.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to disable pop-up windows for a UI action.

```java
action.setNoPop(true);
```

**action - setRedirectURL(Object URL)**

Sets the redirect URI for this transaction, which determines the next page the user sees.

For use cases:

- Create a UI routing action
- Create knowledge articles from HR cases
- Define task relationships with UI actions

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>URL</td>
<td>Object</td>
<td>URL to set as the redirect. You can provide the URL as a string or a GlideRecord. If you pass the URL as a GlideRecord, this value takes the focus to that record's form.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
The following example shows how to redirect a user to a URL from a UI action using the `current` variable.

```javascript
var fixchg = new GlideRecord("change_request");
fixchg.short_description= current.short_description;
fixchg.comments= current.comments.getHTMLValue();
// fixchg.parent = current.sys_id;
fixchg.insert();
FixChange();

gs.addInfoMessage("Change "+ fixchg.number+" created");
action.setRedirectURL(current);
action.setReturnURL(fixchg);

function FixChange(){
  var m2m = new GlideRecord('task_rel_task');
m2m.initialize();
m2m.child= current.sys_id;
m2m.parent= fixchg.sys_id;
m2m.type.setDisplayValue("Fixes::Fixed by");
m2m.insert();}
```

The following example shows how to create a new incident record and redirect to the new incident after a UI action completes.

```javascript
var reqItem = current.u_item;
var requestedFor = current.u_requested_for;
var location = current.location;

if(current.u_incident_request == 'Incident'){  
  //Create a new incident record and redirect to the new incident
  var rec = new GlideRecord('incident');
  rec.initialize();
  rec.caller_id = requestedFor;
  rec.location = location;
  rec.insert();
  action.setRedirectURL(rec);
}

if(current.u_incident_request == 'Request'){  
  //Build the url and route the user to the request item
  var url = '';
  if(current.u_item.sys_class_name == 'sc_cat_item_guide'){
```
url = 'com.glideapp.servicecatalog_cat_item_guide_view.do?sysparm_initial=true&sysparm_guide=' + reqItem + '&sysparm_user=' + requestedFor + '&sysparm_location=' + location;
}
else{
    url = 'com.glideapp.servicecatalog_cat_item_view.do?sysparm_id=' + reqItem + '&sysparm_user=' + requestedFor + '&sysparm_location=' + location;
}
action.setRedirectURL(url);

**action - setReturnURL(Object URL)**

Sets the return URI for this transaction after a UI action is complete. You can use this method to determine what page the user has in view when they return from submit.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>URL</td>
<td>Object</td>
<td>URI to set as the return location after a UI action is complete. You can provide the URL as a string or a GlideRecord.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

The following example enables the user to select the UI action to create a change record using information from the problem record and the change template. After the change, the user returns to current view. For more information, see [Scripted templates](#). For more use cases, see [Define task relationships with UI actions](#).

```javascript
var change = new GlideRecord("change_request");
change.initialize();
change.short_description = current.short_description;
change.description = current.u_details;
change.cmdb_ci = current.u_service;
change.priority = current.priority;
change.requested_by = current.caller_id;
```
change.assignment_group.setDisplayValue('Change & Release');
change.u_status = 'New';
change.parent = current.number;
change.applyTemplate("standard/rfc");
current.rfc = change.insert();
current.comments = 'Change ' + change.number + ' created';;

var mySysID = current.update();

gs.addInfoMessage("Change " + change.number +" created");

action.setRedirectURL(change);
action.setReturnURL(current);

**action - setURLParameter(String parameterName, String parameterValue)**
Sets a URL parameter name and value.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>parameterName</td>
<td>String</td>
<td>Name of the URL parameter.</td>
</tr>
<tr>
<td>parameterValue</td>
<td>String</td>
<td>Value of the parameter.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

action.setURLParameter('sysparm_query', 'priority=2^active=true');

**Agent - Global**

Provides methods for getting or setting agent presence and channel availability.
The **Agent** API is provided within the `sn_awa` namespace.

Requires the following:

- Advanced Work Assignment plugin (com.glide.awa)
- Role: awa_integration_user or admin

**Agent - get(String user_sys_id)**

Gets an agent by sys_id.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_sys_id</td>
<td>String</td>
<td>The sys_id of the user listed in sys_user table.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the user exists, false otherwise.</td>
</tr>
</tbody>
</table>

```javascript
var agent = sn_awa.Agent.get("<user_sys_id>");
var presence = agent.getPresence();
```

Agent – getPresence()

Gets the current presence state and channel availability of a provided agent.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Presence state sys_id, presence state name, and channel information. Error message otherwise.</td>
</tr>
</tbody>
</table>

```javascript
var agent = sn_awa.Agent.get("<user_sys_id>");
var presence = agent.getPresence();
```

Agent – setPresence(Object setRequest)

Sets the state of a provided agent’s presence and sets the agent’s channel availability for that state.
## Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>setRequest</td>
<td>Object</td>
<td>Contains setRequest.sys_id and setRequest.channels.</td>
</tr>
<tr>
<td>setRequest.sys_id</td>
<td>String</td>
<td>Represents presence_sys_id from awa_presence_state table</td>
</tr>
</tbody>
</table>
| setRequest.channels   | name/value pair | Optional  
  - sys_id – channel_sys_id from the awa_service_channel table  
  - available – Agent availability to receive work for this channel (true or false) |

## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if successful, false otherwise.</td>
</tr>
</tbody>
</table>

```javascript
var agent = sn_awa.Agent.get("<user_sys_id>");
var presence = agent.setPresence({  
   sys_id: <presence_sys_id>,  
   channels: [][]  
   sys_id: "<channel_sys_id>",  
   available: true // or false  
 });
```

### AgentNowHandler API - Scoped

The AccCheckDefsAPI script include enables running check definitions on demand, checking the status of on demand executions and test check executions and for stopping background checks that were executed on demand.

This API requires the Agent Client Collector Framework (sn_agent) store application and is provided within the `sn_agent` namespace. For more information, refer to Agent Client Collector.

For the REST API solution, refer to Agent Client Collector API.

#### AgentNowHandler - AgentNowHandler()

Creates an AgentNowHandler instance.
The following example shows how to initialize `AgentNowHandler`.

```javascript
var handler = new sn_agent.AgentNowHandler();
```

**AgentNowHandler - `getRequestStatus(String requestId)`**

Gets status of the request with the given ID.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>requestId</td>
<td>String</td>
<td>A check request ID generated by calling the <code>runCheckForCis()</code> method.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Status of the request and any applicable error message.</td>
</tr>
<tr>
<td>status</td>
<td>Request status. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• done – Check is successful.</td>
</tr>
<tr>
<td></td>
<td>• failure – Check has failed. See error message for details.</td>
</tr>
<tr>
<td></td>
<td>• mid_flow – Request output is being handled by the MID server.</td>
</tr>
<tr>
<td></td>
<td>• processing – Check is in progress.</td>
</tr>
<tr>
<td></td>
<td>• timeout – Check processing exceeded time limit set in the <code>runCheckForCis()</code> method.</td>
</tr>
<tr>
<td>err_msg</td>
<td>Error message if any. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• No agents found for relevant CIs.</td>
</tr>
<tr>
<td></td>
<td>• No background check request with given ID.</td>
</tr>
</tbody>
</table>
## Returns (continued)

<table>
<thead>
<tr>
<th>Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• No request with given ID.</td>
<td></td>
</tr>
<tr>
<td>• No test result with given ID.</td>
<td></td>
</tr>
<tr>
<td>• Request timeout.</td>
<td></td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to get the status of a request.

```javascript
var handler = new sn_agent.AgentNowHandler();
var check = {checkDefId: "158279505372b30034b8ddeeff7b1270"};
var computerGr = new GlideRecord("cmdb_ci_computer");
computerGr.query();
var requestId = handler.runCheckForCis(computerGr, check, 0, 60);
var reqStatusJson = handler.getRequestStatus(requestId);
gs.info(JSON.stringify(reqStatusJson));
```

### AgentNowHandler - getTestResultStatus(String testResultId)

Gets the test check status of the given test result.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>testResultId</td>
<td>String</td>
<td>A test result ID generated by creating a test check request.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>status</td>
<td>Status of the test results. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• 0: Pending</td>
</tr>
<tr>
<td></td>
<td>• 1: In progress</td>
</tr>
<tr>
<td></td>
<td>• 2: Complete</td>
</tr>
<tr>
<td></td>
<td>• 3: No test result with given ID</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>output</td>
<td>Output describing the status.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

The following example shows how to get result status of a completed test check request:

```javascript
var testCheckStatusJson = handler.getTestResultStatus("testResultId");
gs.info(JSON.stringify(testCheckStatusJson));
```

**AgentNowHandler - runCheckForCis(Object cis, Object check, Number priority, Number timeout)**

Runs a check against the given configuration item.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cis</td>
<td>GlideRecord</td>
<td>GlideRecord of any CMDB table (any application, host, or agent) that the check is working against.</td>
</tr>
<tr>
<td>check</td>
<td>Object</td>
<td>Contains the check ID and optional check parameters.</td>
</tr>
<tr>
<td>check.checkDefId</td>
<td>String</td>
<td>Sys_id of a check definition in the Check Definitions [sn_agent_check_def] table.</td>
</tr>
<tr>
<td>check.params</td>
<td>Object</td>
<td>Optional. Map of parameter names and values. These settings can be used to override the parameter records of the check definition and its specified values.</td>
</tr>
<tr>
<td>priority</td>
<td>Number</td>
<td>Priority of the request to be set on the ECC queue.</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Possible values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 0: interactive</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 1: expedited</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 2: standard</td>
</tr>
<tr>
<td>timeout</td>
<td>Number</td>
<td>Value of the timeout for the request in seconds.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys_id of the generated background check request.</td>
</tr>
</tbody>
</table>

The following example shows how to run a background check and get its request ID.

```javascript
var handler = new sn_agent.AgentNowHandler();
var check = {checkDefId: "028fcd5067c80010b7b72dbd2685ef4f");
var computerGr = new GlideRecord("cmdb_ci_computer");
computerGr.query();
var requestId = handler.runCheckForCis(computerGr, check, 0, 60);
gs.info(requestId);
```

Output:

```
b9cf14aedb5e30106f4810284b961990
```

AgentNowHandler - stopBackgroundCheck(String requestId)

Stops a background check.

To start a background check, use the runCheckForCis() method.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>requestId</td>
<td>String</td>
<td>The ID of a background check request generated by calling the runCheckForCis() method.</td>
</tr>
</tbody>
</table>
The following example shows how to stop executing a background check.

```java
handler.stopBackgroundCheck(backRequestId);
```

## AgentMetrics - Global

Processes inbound MID server metrics.

Updates these tables:
- ECC Agent Counter Metric
- ECC Agent Memory Metric
- ECC Agent RGR Metric
- ECC Agent Scalar Metric

Use these methods in server scripts.

### AgentMetrics - AgentMetrics()

Creates an instance of AgentMetrics.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### AgentMetrics - handleCounter(String metric, String name, String midId)

Handles counter metrics from the agent by putting them into an array that can be used to update the ECC Agent Counter Metric table (ecc_agent_counter_metric).

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metric</td>
<td>String</td>
<td>The counter object from the agent</td>
</tr>
</tbody>
</table>
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The device name</td>
</tr>
<tr>
<td>midId</td>
<td>String</td>
<td>The MID server sys_id</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var amtc = new AgentMetrics();
amtc.handleCounter('count', 'server_name', '1098888bbb9483abcd89981ffaeff');
```

#### AgentMetrics - handleMemory(String metric, String name, String midId)

Updates the memory metrics for the given agent.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metric</td>
<td>String</td>
<td>The memory object from the agent</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>The device name</td>
</tr>
<tr>
<td>midId</td>
<td>String</td>
<td>The MID server sys_id</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var amtc = new AgentMetrics();
amtc.handleMemory('mem_obj', 'server_name', '1098888bbb9483abcd89981ffaeff');
```

#### AgentMetrics - handleRGR(String metric, String name, String midId)

Handles metric information from a remote glide record by putting it into an array.

```javascript
var amtc = new AgentMetrics();
amtc.handleRGR('mem_obj', 'server_name', '1098888bbb9483abcd89981ffaeff');
```
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metric</td>
<td>String</td>
<td>The remote object from the agent</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>The device name</td>
</tr>
<tr>
<td>midId</td>
<td>String</td>
<td>The MID server sys_id</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var amtc = new AgentMetrics();
amtc.handleRGR('remote_obj', 'server_name', '109888bbb9483abcd89981ffaeff');
```

**AgentMetrics - handleScalar(String metric, String name, String midId)**

Handles scalar values from the agent by putting them into an array.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metric</td>
<td>String</td>
<td>The counter object from the agent</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>The device name</td>
</tr>
<tr>
<td>midId</td>
<td>String</td>
<td>The MID server sys_id</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var amtc = new AgentMetrics();
amtc.handleScalar('scalar', 'server_name', '109888bbb9483abcd89981ffaeff');
```
AgentMetrics - updateMetric(String tableName, String values, String metric, String midID)

Updates the specified metrics table with the new metric information.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>The metrics table to update</td>
</tr>
<tr>
<td>values</td>
<td>String</td>
<td>The object containing the values to add to the table</td>
</tr>
<tr>
<td>metric</td>
<td>String</td>
<td>The metric type to add to the table</td>
</tr>
<tr>
<td>midID</td>
<td>String</td>
<td>The MID server sys_id</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var amtc = new AgentMetrics();
amtc.handleMemory('memory', 'server_name', '1098888bbb9483abcd89981ffaeff');
amtc.updateMetric('ecc_agent_memory_metric', 'm_values', 'memory', '1098888bbb9483abcd89981ffaeff');
```

APCHandler - Global

Handles SNMP classification and identification for UPSs, environmental monitors, and PDUs made by APC.

Use this API for SNMP classification and identification.

APCHandler - classifyAndIdentify()

Classifies and identifies APC devices.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
ApcPduOutletReconciler - Global
Reconciles outlets for power distribution units.
Use this API for SNMP-related discovery.

ApcPduOutletReconciler - getReconciliationField()
Returns the reconciliation field.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The reconciliation field</td>
</tr>
</tbody>
</table>

ApcPduOutletReconciler - getReconciliationKey()
Returns the reconciliation key.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The reconciliation key</td>
</tr>
</tbody>
</table>
ApcPduOutletReconciler - hasChanged()
Determines if the outlet state has changed.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the outlet state has changed; otherwise, false.</td>
</tr>
</tbody>
</table>

ApcPduOutletReconciler - readDatabaseFields()
Reads the outlet database fields.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

ApcPduOutletReconciler - readDiscovered()
Reads the discovered outlet database fields.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
**ApcPduOutletReconciler - setDatabaseFields()**

Sets the outlet database fields.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**api - UI Builder**

The `api` API provides methods that you can use when developing client scripts in the UI Builder.

This API is exposed to client scripts, also known as page scripts. Client scripts are executed in response to something happening on a page, such as:

- User interaction events/actions, such as a button click.
- Lifecycle events, such as a data broker execution started.

These scripts do not have to return anything to the framework and can be written as an asynchronous function.

This API is also exposed to scripted property values. These scripts are executed whenever the framework-runtime needs to calculate a value, such as:

- Passing to a component property.
- Determining component visibility.
- Emitting an event with a payload.

These scripts cannot be written as an asynchronous function. They also cannot invoke side-effect methods on the api object, such as, `api.emit()`, `api.setState()`, and `api.data.<data_resource_id>.*()`.
The api object contains both configuration dependent and configuration independent properties that you can access within the context of the associated page or component. You cannot directly modify the properties within this object. Modification can only be made through the available methods.

**api - api.context.props.<page_property_name>**

Page properties can be configured within UI Builder. The configuration values depend on the context in which the page is used.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;page_property_name&gt;</td>
<td>Any</td>
<td>Available values are dependant on the client script implementation. To access these properties, use the following: api.context.props.&lt;page_property_name&gt;. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>// A record page with property table could be accessed with function isActivityStreamVisible({api}) { return api.context.props.table === 'incident'; }</td>
</tr>
</tbody>
</table>

**Note:** These property values are read-only. Mutating nested object values from scripts is not supported.

**api - api.context.session.<session_property>**

Context session properties associated with the current user.

**Available session properties**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| isLoggedIn | Boolean | Flag that indicates whether the current user is logged in to the system. Possible values:
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>properties.awaEnabled</td>
<td>String</td>
<td>The system property glide.awa.enabled that indicates whether the auto assignment for work items for Advanced Work Assignment (AWA) is enabled for the current user. Possible values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: AWA is enabled for the user.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: AWA is not enabled for the user.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For additional information, see Components installed with Advanced Work Assignment.</td>
</tr>
<tr>
<td>properties.forgetMe.value</td>
<td>String</td>
<td>The property glide.ui.forgetme that indicates whether to remove the Remember Me check box from the login page to prevent login information from being cached. Possible values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Remove the Remember Me check box.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Display the Remember Me check box.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For additional information, see Remove remember me.</td>
</tr>
<tr>
<td>properties.sessionTimeLeft.value</td>
<td>String, Number coerced to string</td>
<td>The system property glide.ui.session_timeleft that determines the amount of time left before the current session times</td>
</tr>
</tbody>
</table>
### Available session properties (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>properties.sessionTimeout.value</td>
<td>String, Number coerced to string</td>
<td>The system property glide.ui.session_timeout that determines the initial session timeout value. Unit: Minutes. Values greater than 1440 minutes are treated as one day. For additional information, see <a href="#">Session activity timeout</a>.</td>
</tr>
<tr>
<td>user.avatar</td>
<td>String</td>
<td>URL of the current user's avatar.</td>
</tr>
<tr>
<td>user.dateFormat</td>
<td>String</td>
<td>Default date format.</td>
</tr>
<tr>
<td>user.domain</td>
<td>String</td>
<td>Domain path for the current user.</td>
</tr>
<tr>
<td>user.firstName</td>
<td>String</td>
<td>First name of the current user.</td>
</tr>
<tr>
<td>user.fullName</td>
<td>String</td>
<td>First and last name of the current user.</td>
</tr>
<tr>
<td>user.initials</td>
<td>String</td>
<td>Initials of the current user.</td>
</tr>
<tr>
<td>user.language</td>
<td>String</td>
<td>Primary language spoken by the current user.</td>
</tr>
<tr>
<td>user.preferences</td>
<td>Array of objects</td>
<td>Name-value pairs that describe the user preferences. These</td>
</tr>
</tbody>
</table>
Available session properties (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>user preferences are stored as records in the User Preference [sys_user_preference] table, and are updated each time the user changes their settings. For additional information, see User preferences.</td>
</tr>
<tr>
<td>user.roles</td>
<td>Array</td>
<td>Comma-separated list of roles assigned to the current user.</td>
</tr>
<tr>
<td>user.sys_id</td>
<td>String</td>
<td>Sys_id of the user in the User [sys_user] table.</td>
</tr>
<tr>
<td>user.timeFormat</td>
<td>String</td>
<td>Default time format to use for the user.</td>
</tr>
<tr>
<td>user.timeZone</td>
<td>String</td>
<td>Time zone of the current user.</td>
</tr>
<tr>
<td>user.timeZoneOffset</td>
<td>String</td>
<td>Time zone offset of the current user.</td>
</tr>
</tbody>
</table>

api - api.data.<data_resource_id>.addErrorMessage(Object payload)

Displays the specified error message at the top of the current form.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_resource</td>
<td>String</td>
<td>Unique identifier of the associated data resource. The data resource for this method must be based off of Glide Form (gform.) The available data resource instances are configuration-dependent and defined when you add the data resource to your page in UI Builder.</td>
</tr>
<tr>
<td>payload</td>
<td>Object</td>
<td>Object that describes the error message to display.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;payload&quot;: {</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;message&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>}</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>payload.message</td>
<td>String</td>
<td>Error message to display.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

```
api.data.gform.addErrorMessage({message: 'Error message'});
```

**`api - api.data.<data_resource_id>.addInfoMessage(Object payload)`**

Displays the specified informational message at the top of the current form.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_resource_id</td>
<td>String</td>
<td>Unique identifier of the associated data resource. The data resource for this method must be based off of Glide Form (gform.) The available data resource instances are configuration-dependent and defined when you add the data resource to your page in UI Builder.</td>
</tr>
<tr>
<td>payload</td>
<td>Object</td>
<td>Object that describes the informational message to display.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;payload&quot;: {</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;message&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td>payload.message</td>
<td>String</td>
<td>Informational message to display.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

```
api.data.gform.addInfoMessage({message: 'Test message'});
```
api - api.data.<data_resource_id>.addOption(Object payload)

Adds an option to the specified choice type field.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_resource_id</td>
<td>String</td>
<td>Unique identifier of the associated data resource. The data resource for this method must be based off of Glide Form (gform.) The available data resource instances are configuration-dependent and defined when you add the data resource to your page in UI Builder.</td>
</tr>
<tr>
<td>payload</td>
<td>Object</td>
<td>Object that describes the field value to update.</td>
</tr>
<tr>
<td>payload.choiceIndex</td>
<td>String</td>
<td>Optional. Index into the choice list at which to insert the option. Default: End of the choice list.</td>
</tr>
<tr>
<td>payload.choiceLabel</td>
<td>String</td>
<td>Label of the option to add to the specified field.</td>
</tr>
<tr>
<td>payload.choiceValue</td>
<td>String</td>
<td>Value of the option to add to the specified field.</td>
</tr>
<tr>
<td>payload.fieldName</td>
<td>String</td>
<td>Name of the choice type form field to add the specified option to.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

/api.data.gform.addOption({fieldName: 'priority', choiceLabel: 'Extremely High', choiceValue: '10'});

api - api.data.<data_resource_id>.addWarningMessage(Object payload)

Displays the specified warning message at the top of the current form.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_resource_id</td>
<td>String</td>
<td>Unique identifier of the associated data resource. The data resource for this method must be based off of Glide Form (gform.) The available data resource instances are configuration-dependent and defined when you add the data resource to your page in UI Builder.</td>
</tr>
<tr>
<td>payload</td>
<td>Object</td>
<td>Object that describes the warning message to display.</td>
</tr>
<tr>
<td>payload.message</td>
<td>String</td>
<td>Warning message to display.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
api.data.gform.addWarningMessage({message: 'Test message'});
```

**api - api.data.<data_resource_id>.clearMessage()**

Removes all informational and error messages from the top of the current form.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_resource_id</td>
<td>String</td>
<td>Unique identifier of the associated data resource. The data resource for this method must be based off of Glide Form (gform.) The available data resource instances are configuration-dependent and defined when you add the data resource to your page in UI Builder.</td>
</tr>
</tbody>
</table>
### api.data.<data_resource_id>.clearOptions(Object payload)

Clears all options from the specified choice type field.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_resource_id</td>
<td>String</td>
<td>Unique identifier of the associated data resource. The data resource for this method must be based off of Glide Form (gform.) The available data resource instances are configuration-dependent and defined when you add the data resource to your page in UI Builder.</td>
</tr>
<tr>
<td>payload</td>
<td>Object</td>
<td>Object that describes the choice type field whose options are to be cleared.</td>
</tr>
</tbody>
</table>

```json
"payload": {
  "fieldName": "String"
}
```

| payload.fieldName | String  | Name of the choice type field whose options are to be cleared. |

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
api.data.gform.clearOptions({fieldName: 'priority'});
```

### api.data.<data_resource_id>.executeUiAction(Object payload)

Executes the specified UI action.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_resource_id</td>
<td>String</td>
<td>Unique identifier of the associated data resource. The data resource for this method must be based off of Glide Form (gform.) The available data resource instances are configuration-dependent and defined when you add the data resource to your page in UI Builder.</td>
</tr>
<tr>
<td>payload</td>
<td>Object</td>
<td>Object that describes the UI action to execute.</td>
</tr>
<tr>
<td>payload.actionSysId</td>
<td>String</td>
<td>Sys_id of the UI action to execute. Located in the UI Action [sys_ui_action] table.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
api.data.gform.executeUiAction({actionSysId: '60615ff90f730010ac7de6f8c4767e9a'});
```

**api** - **api.data.<data_resource_id>.execute(Object inputValues)**

Triggers an execute operation on the specified data resource.

This method is only available if the data resource is one of the following types:
- Composite
- GraphQL
- REST
- Scriptlet
- Transform

ℹ️ Note: This method is only exposed if the `mutates_server_data` field is set to `true` on the corresponding data resource (sys_ux_data_broker_* table) record. It is accessible under `api.data.<data_resource_Id>.refresh()`.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_resourceId</td>
<td>String</td>
<td>Unique identifier of the associated data resource. The available data resource instances are configuration-dependent and defined when you add the data resource to your page in UI Builder.</td>
</tr>
<tr>
<td>inputValues</td>
<td>Object</td>
<td>Object to pass to the specified data resource. This object must conform to the data resource’s input parameters.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

This code example shows a page script that is invoked when the **Submit** button on the page is clicked. The page is configured with a Server Data Resource that creates a new record.

```javascript
function handler({api}) {
  if (api.state.movieYear === 2020) {
    // The data resource used in this case specifies two input parameters: name and year
    api.data.create_movie_record.execute({
      name: api.state.movieName,
      year: api.state.movieYear
    });
  }
}
```

**api - api.data.<data_resource_id>.hideFieldMessage(Object payload)**

Hides the oldest message next to the specified field or clears all messages associated with the field.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_resourceId</td>
<td>String</td>
<td>Unique identifier of the associated data resource. The data resource for this method must be based off of Glide Form (gform.)</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>payload</td>
<td>Object</td>
<td>Object that describes the field message to hide.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;payload&quot;: {</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;clearAll&quot;: Boolean,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;fieldName&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>}</td>
</tr>
</tbody>
</table>
| payload.clearAll | Boolean | Optional. Flag that indicates whether to clear all messages associated with the specified form field. Valid values:
|               |         | • true: Clear all messages associated with the specified field.                                |
|               |         | • false: Do not clear all messages associated with the specified field.                        |
|               |         | Default: false                                                                                |
| payload.fieldName | String  | Name of the form field for which to hide the oldest message or clear all associated messages. |

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

api.data.gform.hideFieldMessage({fieldName: 'short_description'});

api - api.data.<data_resource_id>.hideRelatedList(Object payload)

Hides the specified related list on the current form.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_resource_id</td>
<td>String</td>
<td>Unique identifier of the associated data resource. The data resource for this method must be based off of Glide Form (gform.) The available data resource instances are configuration-dependent and defined when you add the data resource to your page in UI Builder.</td>
</tr>
<tr>
<td>payload</td>
<td>Object</td>
<td>Object that describes the related list to hide.</td>
</tr>
<tr>
<td>&quot;payload&quot;: {</td>
<td></td>
<td>&quot;listTableName&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td>payload.listTableName</td>
<td>String</td>
<td>Name of the related list to hide. Located in the Related List [sys_ui_related_list] table. If the list to hide is through a relationship, provide the sys_id of the list instead of the name.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
api.data.gform.hideRelatedList({listTableName:'incident.parent_incident'});
```

**api - api.data.<data_resource_id>.hideRelatedLists()**

Hides all related lists on the current form.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_resource_id</td>
<td>String</td>
<td>Unique identifier of the associated data resource. The data resource for this method must be based off of Glide Form (gform.) The available data resource instances are configuration-dependent and defined when you add the data resource to your page in UI Builder.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
api.data.gform.hideRelatedLists();
```

**api - api.data.<data_resource_id>.lifecycle.lastFetchSucceeded**

Boolean flag that indicates whether the last fetch attempt for the specified data resource instance finished successfully.

If the value is true, the last fetch attempt for the data resource instance finished successfully; otherwise, false.

**Field**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_resource_id</td>
<td>String</td>
<td>Unique identifier of the associated data resource. The data resource for this</td>
</tr>
<tr>
<td></td>
<td></td>
<td>method must be based off of Glide Form (gform.) The available data resource</td>
</tr>
<tr>
<td></td>
<td></td>
<td>instances are configuration-dependent and defined when you add the data</td>
</tr>
<tr>
<td></td>
<td></td>
<td>resource to your page in UI Builder.</td>
</tr>
</tbody>
</table>

**api - api.data.<data_resource_id>.refresh()**

Triggers a refresh operation for the specified non-mutating data resource instance.

Call this method if the underlying data being fetched by the data resource changes. A data resource is considered non-mutating if the `mutates_server_data` field on the record is set to false.

This method is asynchronous and emits an internal event to trigger the refresh of the specified data resource instance. The UI Builder allows you to trigger client scripts in response to data resource lifecycle events, such as `DATA_FETCH_SUCCEEDED` and `DATA_FETCH_FAILED`. For additional information on these events, see Event mapping.

This method is only available if the data resource is one of the following types:

- Composite
- GraphQL
• REST
• Scriptlet
• Transform

Note: This method is only exposed if the `mutates_server_data` field is set to `false` on the corresponding data resource (sys_ux_data_broker_* table) record.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_resource_id</td>
<td>String</td>
<td>Unique identifier of the associated data resource. The available data resource instances are configuration-dependent and defined when you add the data resource to your page in UI Builder.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

This code example shows a page script that is invoked when a dropdown item is selected in a page. The page is configured with two Server Data Resources that query problem and incident tables.

```javascript
function handler({api, event}) {
    const value = event.payload.value[0];
    if (value === 'problem')
        api.data.problem_list_1.refresh();
    else if(value === 'incident')
        api.data.incident_list_1.refresh();
}
```

api - `api.data.<data_resource_id>`.reload()

Reloads the current form using the same table and sys_id.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_resource</td>
<td>String</td>
<td>Unique identifier of the associated data resource. The data resource for this method must be based off of Glide Form (gform.) The available data resource instances are configuration-dependent and defined when you add the data resource to your page in UI Builder.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
api.data.gform.reload();
```

**api - api.data.<data_resource_id>.removeOption(Object payload)**

Removes an option from the specified choice type field.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_resource</td>
<td>String</td>
<td>Unique identifier of the associated data resource. The data resource for this method must be based off of Glide Form (gform.) The available data resource instances are configuration-dependent and defined when you add the data resource to your page in UI Builder.</td>
</tr>
<tr>
<td>payload</td>
<td>Object</td>
<td>Object that describes the choice type field to update.</td>
</tr>
<tr>
<td>payload.choiceValue</td>
<td>String</td>
<td>Value of the option to remove from the specified choice type field.</td>
</tr>
</tbody>
</table>
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>payload.fieldName</code></td>
<td><code>String</code></td>
<td>Name of the choice type form field from which to remove the specified value.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
api.data.gform.removeOption({fieldName: 'priority', choiceValue: '1'});
```

#### `api - api.data.<data_resource_id>.save()`

Triggers form submission using the `Save` UI action.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>data_resource_id</code></td>
<td><code>String</code></td>
<td>Unique identifier of the associated data resource. The data resource for this method must be based off of Glide Form (<code>gform</code>). The available data resource instances are configuration-dependent and defined when you add the data resource to your page in UI Builder.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
api.data.gform.save();
```

#### `api - api.data.<data_resource_id>.setMandatory(Object payload)`

Sets whether the specified form field is mandatory.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_resource_id</td>
<td>String</td>
<td>Unique identifier of the associated data resource. The data resource for this</td>
</tr>
<tr>
<td></td>
<td></td>
<td>method must be based off of Glide Form (gform.)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The available data resource instances are configuration-dependent and defined</td>
</tr>
<tr>
<td></td>
<td></td>
<td>when you add the data resource to your page in UI Builder.</td>
</tr>
<tr>
<td>payload</td>
<td>Object</td>
<td>Object that describes the field whose mandatory information to update.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;payload&quot;: {</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;fieldName&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;mandatory&quot;: Boolean</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>payload.field</td>
<td>String</td>
<td>Name of the form field whose mandatory value is to be set.</td>
</tr>
<tr>
<td>payload.mandatory</td>
<td>Boolean</td>
<td>Flag that indicates the specified form field is mandatory, meaning the</td>
</tr>
<tr>
<td></td>
<td></td>
<td>form cannot be saved without this field containing a valid value.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Field is mandatory.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Field is optional.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

```
api.data.gform.setMandatory({fieldName: 'short_description', mandatory: false});
```

**api - api.data.<data_resource_id>.setReadOnly(Object payload)**

Sets the read/write capabilities of the specified form field.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_resource_id</td>
<td>String</td>
<td>Unique identifier of the associated data resource. The data resource for this method must be based off of Glide Form (gform.) The available data resource instances are configuration-dependent and defined when you add the data resource to your page in UI Builder.</td>
</tr>
<tr>
<td>payload</td>
<td>Object</td>
<td>Object that describes the field whose readability information to update.</td>
</tr>
<tr>
<td>payload.fieldName</td>
<td>String</td>
<td>Name of the form field whose readability is to be set.</td>
</tr>
<tr>
<td>payload.readonly</td>
<td>Boolean</td>
<td>Flag that indicates the read/write capabilities of the specified form field. Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Field is read only.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Field is read/write.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
api.data.gform.setReadOnly({fieldName: 'short_description', readonly: false});
```

**api -api.data.<data_resource_id>.setvalue(Object payload)**

Updates a specified GlideForm field with the specified value. Optionally, you can also update the display value with the same specified value.

Only the value on the form is updated. The value is not saved in the database.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_resource_id</td>
<td>String</td>
<td>Unique identifier of the associated data resource. The data resource for this method must be based off of Glide Form (gform.) The available data resource instances are configuration-dependent and defined when you add the data resource to your page in UI Builder.</td>
</tr>
<tr>
<td>payload</td>
<td>Object</td>
<td>Object that describes the field whose value to update.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;payload&quot;: {</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;displayValue&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;fieldName&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;value&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>}</td>
</tr>
<tr>
<td>payload.displayValue</td>
<td>String</td>
<td>Optional. Name of the display value to update. If left blank, the display value is not modified.</td>
</tr>
<tr>
<td>payload.fieldName</td>
<td>String</td>
<td>Name of the form field to update.</td>
</tr>
<tr>
<td>payload.value</td>
<td>String</td>
<td>Value to update the field with.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
api.data.gform.setValue({fieldName: 'short_description', value: 'short description'});
```

**api - api.data.<data_resource_id>.setVisible(Object payload)**

Sets the visibility of the specified form field.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_resource_id</td>
<td>String</td>
<td>Unique identifier of the associated data resource. The data resource for this method must be based off of Glide Form (gform.)</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>payload</td>
<td>Object</td>
<td>Object that describes the field on which to set visibility.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;payload&quot;: {</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;fieldName&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;visibility&quot;: Boolean</td>
</tr>
<tr>
<td></td>
<td></td>
<td>}</td>
</tr>
</tbody>
</table>

| payload.field | String   | Name of the form field whose visibility is to be set.                                                                 |
| payload.visibility | Boolean | Flag that indicates whether the associated field is visible on the current form. Valid values:                                      |
|                |          | • true: Field will display on the form.                                                                                               |
|                |          | • false: Field will not display on the form.                                                                                          |

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
api.data.gform.setVisible({'fieldName': 'short_description', 'visibility': false});
```

api - api.data.<data_resource_id>.showFieldMessage(Object payload)

Displays the specified message next to the specified field.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_resource</td>
<td>String</td>
<td>Unique identifier of the associated data resource. The data resource for this method must be based off of Glide Form (gform.)</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>The available data resource instances are configuration-dependent and defined when you add the data resource to your page in UI Builder.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>payload</td>
<td>Object</td>
<td>Object that describes the field message to display.</td>
</tr>
<tr>
<td>payload.fieldName</td>
<td>String</td>
<td>Name of the field next to which the message should appear.</td>
</tr>
<tr>
<td>payload.message</td>
<td>String</td>
<td>Message to display.</td>
</tr>
<tr>
<td>payload.type</td>
<td>String</td>
<td>Optional. Type of message to display. Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• error</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• info</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• warning</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default: info</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
api.data.gform.showFieldMessage({fieldName: 'short_description', message: 'Error message', type: 'error'});
```

`api - api.data.<data_resource_id>.showRelatedList(Object payload)`

Displays the specified related list on the current form.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_resource_id</td>
<td>String</td>
<td>Unique identifier of the associated data resource. The data resource for this method must be based off of Glide Form (gform.) The available data resource instances are configuration-dependent and defined when you add the data resource to your page in UI Builder.</td>
</tr>
<tr>
<td>payload</td>
<td>Object</td>
<td>Object that describes the related list to display.</td>
</tr>
<tr>
<td>payload.listTableName</td>
<td>String</td>
<td>Name of the related list to display. Located in the Related List [sys_ui_related_list] table. If the list to display is through a relationship, provide the sys_id of the list instead of the name.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
api.data.gform.showRelatedList({'listTableName': 'incident.parent_incident'});
```

**api - api.data.<data_resource_id>.showRelatedLists()**

Displays all related lists associated with the current form.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_resource_id</td>
<td>String</td>
<td>Unique identifier of the associated data resource. The data resource for this method must be based off of Glide Form (gform.) The available data resource instances are configuration-dependent and defined when you add the data resource to your page in UI Builder.</td>
</tr>
</tbody>
</table>
### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
api.data.gform.showRelatedLists();
```

#### api - api.data.<data_resource_id>.submit()
Triggers form submission using the specified UI action.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_resource_id</td>
<td>String</td>
<td>Unique identifier of the associated data resource. The data resource for this method must be based off of Glide Form (gform.) The available data resource instances are configuration-dependent and defined when you add the data resource to your page in UI Builder.</td>
</tr>
<tr>
<td>payload</td>
<td>Object</td>
<td>Object that describes the UI action to use to submit the current form.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>{&quot;payload&quot;: { &quot;submitActionName&quot;: &quot;String&quot; }}</td>
</tr>
</tbody>
</table>

```javascript
api.data.gform.submit({submitActionName:'sysverb_ws_save'});
```

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
api.data.gform.submit({submitActionName:'sysverb_ws_save'});
```

#### api - api.emit(String eventName, Object payload)
Emits an event with the specified name and payload.
The event name being emitted must be part of the associated page definition’s dispatched events list, which is stored in the UX Macroponent Definition [sys_ux_macroponent] table. Any `api.emit` call that dispatches events not declared in this table are ignored.

For additional information on events, see Work with events.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>eventName</td>
<td>String</td>
<td>Name of the event to emit. This name should follow the UI Framework action naming guidelines:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Should be upper snake case, such as ITEM_CHANGED. All letters in upper case and all spaces replaced with underscores.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Should be past tense, such as BUTTON_CLICKED or USER_SELECTED.</td>
</tr>
<tr>
<td>payload</td>
<td>Object</td>
<td>Optional. Object that contains the data to send with the emitted event. This object is free-form and can contain whatever data is necessary by the entity receiving the data.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note:</strong> Payloads of primitive type work, but could result in inconsistent behavior.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following code example shows emitting an event called `NOW_UXF_PAGE#ADD_NOTIFICATIONS` with an associated `items` payload.

```javascript
function handler({api}) {
    api.emit('NOW_UXF_PAGE#ADD_NOTIFICATIONS', {
        items: [
            
```
api - setState(String stateParm, Any value)

Sets the value of the specified client state parameter.

Use client state parameters to maintain a shared state on a page. The shared state can then be passed as values to properties of components used on the page. You can also access and update client states in multiple page scripts. A common use case is to keep track of values input by users in multiple form controls on a page. When the form is submitted, a client script could then use all of the values stored in client state parameters to create a new record with a data broker. A page can have one or more client state parameters, which you can declare for a page through the UI Builder. You can then bind a client state parameter to one or more components to share or act on the client state parameter.

api.setState() calls are executed asynchronously and do not necessarily update the UI immediately. If the value to set depends on the currentValue of the client state parameter, or any of the properties provided in the api object, you should use this variant of the api.setState() method to avoid using outdated values.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stateParm</td>
<td>String</td>
<td>Name of the client state parameter to update. This name must be declared in the client state parameters of the associated page. For additional information on declaring client state parameters, see Work with client state parameters.</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>Any - Must be the same as the client state parameter declaration.</td>
<td>Value to set the specified client state parameter to.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

This example shows a script that could be executed to update the email client state parameter when an input value is set on a now-input component.

```javascript
function handler({api, event}) {
    api.setState('email', event.payload.value);
}
```

api - `setState(String stateParam, Function callbackFn)`

Sets the value of the specified client state parameter to the value returned by the specified callback function.

The callback function is invoked with an object that has two properties: `currentValue` and `api`. The function should never mutate the `currentValue` property or the `api` object directly.

Use client state parameters to maintain a shared state on a page. The shared state can then be passed as values to properties of components used on the page. You can also access and update client states in multiple page scripts. A common use case is to keep track of values input by users in multiple form controls on a page. When the form is submitted, a client script could then use all of the values stored in client state parameters to create a new record with a data broker. A page can have one or more client state parameters, which you can declare for a page through the UI Builder. You can then bind a client state parameter to one or more components to share or act on the client state parameter.
api.setState() calls are executed asynchronously and do not necessarily update the UI immediately. If the value to set depends on the `currentValue` of the client state parameter, or any of the properties provided in the api object, you should use this variant of the `api.setState()` method to avoid using outdated values.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stateParm</td>
<td>String</td>
<td>Name of the client state parameter to update. This name must be declared in the client state parameters of the associated page. For additional information on declaring client state parameters, see <a href="#">Work with client state parameters</a>.</td>
</tr>
<tr>
<td>callbackFn</td>
<td>Function</td>
<td>Callback function to execute to obtain the value.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to use `api.setState` to log users into a page.

```javascript
function handler({api, event}) {
    const {name, value} = event.payload;
    if (name === 'username' || name === 'password') {
        // Update the loginParameters state object with the username/password value
        api.setState('loginParameters', ({currentValue}) => {
            return {
                ...currentValue,
                [name]: value
            };
        });
    }
}
```

### api - api.state.<client_state_parameter_name>

Current value of the specified client state parameter.
### Field

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;client_state_parameter_name&gt;</code></td>
<td>Any. The available client state parameters are dependent on the page configuration.</td>
<td>Name of the client state parameter. Available client states are dependant on the client script implementation. To access the available client states, use the following: <code>api.state.&lt;client_state_name&gt;</code>. For example:</td>
</tr>
</tbody>
</table>

```javascript
function showRelatedLists({api}) {
  return !api.state.isCustomListSelected;
}
```

**Note:** These property values are read-only. To update a client state parameter, use `api.setState()`. Mutating nested object values from scripts is not supported.

### ArrayUtil - Global

ArrayUtil API is a script include with useful functions for working with JavaScript arrays.

These methods are available to any server-side script.

### ArrayUtil - concat(Array parent, Array child)

Merge two arrays.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>parent</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>child</td>
<td>Array</td>
<td>An array to merge</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>An array of elements from both input arrays. Duplicates are not removed.</td>
</tr>
</tbody>
</table>

```javascript
var arrayUtil = new ArrayUtil();
var a1 = new Array("a", "b", "c");
var a2 = new Array("c", "d", "e");

gs.print("concat a1, a2: " + arrayUtil.concat(a1, a2));
```

Output: concat a1, a2: a,b,c,c,d,e

**ArrayUtil - contains(Array array, Object element)**

Searches the array for the specified element. Returns true if the element exists in the array, otherwise returns false.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>array</td>
<td>Array</td>
<td>Array to search.</td>
</tr>
<tr>
<td>element</td>
<td>Object</td>
<td>Element to search for.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag indicating whether the element was found in the array. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: Element found in array.</td>
</tr>
<tr>
<td></td>
<td>• false: Element not found in array.</td>
</tr>
</tbody>
</table>
var arrayUtil = new ArrayUtil();
var a1 = new Array("a", "b", "c");

gs.print("Contains b: " + arrayUtil.contains(a1, "b");
gs.print("Contains x: " + arrayUtil.contains(a1, "x");

Output:
Contains b: true
Contains x: false

ArrayUtil - convertArray(Object a)
Converts a Java object to an array.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>Object</td>
<td>Object to convert.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>Array created from the object.</td>
</tr>
</tbody>
</table>

This example converts a Java object to an array.

var arrayUtil = new ArrayUtil();
// Returns a JavaObject with the logged in user's groups
var groupObj = gs.getUser().getMyGroups();
gs.print('groupObj: ' + Object.prototype.toString.call(groupObj));

var groupArr = arrayUtil.convertArray(groupObj);
gs.print('groupArr: ' + Object.prototype.toString.call(groupArr));

Output

groupObj: [object JavaObject]
groupArr: [object Array]

ArrayUtil - diff(Array a, Array b)
Finds the differences between two or more arrays.
Any number of arrays can be provided as parameters.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>Array</td>
<td>An array</td>
</tr>
<tr>
<td>b</td>
<td>Array</td>
<td>An array</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>Returns an array of items from array a that were not found in either array b or c, or other input arrays. Duplicates are removed from the result.</td>
</tr>
</tbody>
</table>

```javascript
var arrayUtil = new ArrayUtil();
var a1 = new Array("a", "b", "c");
var a2 = new Array("c", "d", "e");
gs.print(arrayUtil.diff(a1, a2));
```

Output: a,b

### ArrayUtil - ensureArray(Object object)

Returns an array from the specified object.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object</td>
<td>Object</td>
<td>Object from which to create an array.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>Array created from the object.</td>
</tr>
</tbody>
</table>

```javascript
var arrayUtil = new ArrayUtil();
var o1 = {a: "1", b: "2", c: "3");
gs.print('o1 is array: ' + Array.isArray(o1));
gs.print('o1 stringified: ' + JSON.stringify(o1));
```
```javascript
var a1 = arrayUtil.ensureArray(o1);
gs.print('a1 is array: ' + Array.isArray(a1));
gs.print('a1 stringified: ' + JSON.stringify(a1));
```

**Output:**

```
o1 is array: false
o1 stringified: {"a":"1","b":"2","c":"3"}
a1 is array: true
a1 stringified: [{"a":"1","b":"2","c":"3"}]
```

**ArrayUtil - `indexOf(Array array, Object element)`**

Searches the array for the element. Returns the element index if found, -1 otherwise.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>array</td>
<td>Array</td>
<td>The array to search</td>
</tr>
<tr>
<td>element</td>
<td>Object</td>
<td>The element to search for</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The index where the element was found, -1 otherwise.</td>
</tr>
</tbody>
</table>

```javascript
var arrayUtil = new ArrayUtil();
var a1 = new Array("a", "b", "c");

gs.print("indexOf b: ", + arrayUtil.indexOf(a1, "b");
gs.print("indexOf x: ", + arrayUtil.indexOf(a1, "x"));
```

**Output:**

```
indexOf b: 1
indexOf x: -1
```

**ArrayUtil - `indexOf(Array array, Object element, Number startIndex)`**

Searches the array for the specified element starting at the specified index. Returns the element index or -1 if not found.
## Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>array</td>
<td>Array</td>
<td>Array to search.</td>
</tr>
<tr>
<td>element</td>
<td>Object</td>
<td>Element to search for.</td>
</tr>
<tr>
<td>startIndex</td>
<td>Number</td>
<td>Index to start searching from.</td>
</tr>
</tbody>
</table>

## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Position of the element in the array, or -1 if the element is not in the array.</td>
</tr>
</tbody>
</table>

```javascript
var arrayUtil = new ArrayUtil();
var a1 = new Array("a", "b", "c", "d", "e");
gs.print("indexOf b starting at 0: " + arrayUtil.indexOf(a1, "b", 0));
gs.print("indexOf b starting at 2: " + arrayUtil.indexOf(a1, "b", 2));
```

Output:

indexOf b starting at 0: 1
indexOf b starting at 2: -1

## ArrayUtil - intersect(Array a, Array b)

Finds the elements present in all arrays.

Any number of arrays can be provided as parameters.

## Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>Array</td>
<td>An array</td>
</tr>
<tr>
<td>b</td>
<td>Array</td>
<td>An array</td>
</tr>
</tbody>
</table>
### ArrayUtil - intersect(Array a, Array b)

An array of elements from array a that were found in all of the other input arrays. Duplicates are removed.

```javascript
var arrayUtil = new ArrayUtil();
var a1 = new Array("a", "b", "c");
var a2 = new Array("c", "d", "e");
gs.print(arrayUtil.intersect(a1, a2));
```

Output: c

### ArrayUtil - union(Array a, Array b)

Merge two or more arrays.

Any number of arrays can be provided as parameters.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>Array</td>
<td>An array</td>
</tr>
<tr>
<td>b</td>
<td>Array</td>
<td>An array</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>An array of items from all the input arrays. Duplicates are removed.</td>
</tr>
</tbody>
</table>

```javascript
var arrayUtil = new ArrayUtil();
var a1 = new Array("a", "b", "c");
var a2 = new Array("c", "d", "e");
gs.print(arrayUtil.union(a1, a2));
```

Output: a,b,c,d,e

### ArrayUtil - unique(Array a)

Removes duplicate items from an array.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>Array</td>
<td>The array to check for duplicate elements.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>An array of unique items from the input array.</td>
</tr>
</tbody>
</table>

```javascript
var arrayUtil = new ArrayUtil();
var a1 = new Array("a", "b", "c", "c", "b");
gs.print(arrayUtil.unique(a1));
```

Output: a,c,b

**AssessmentCreation - Global**

The `AssessmentCreation` class provides methods that administrators can use to generate assessments and surveys.

There are multiple ways to call the `createAssessments` method. You must set the `typeID` parameter in all cases to identify a metric type or survey definition.

Some of the factors that influence how the method behaves include:

- Whether the target is an assessment or survey
- Whether the assessment schedule type is on-demand or scheduled
- Survey schedule periods
- Parameters provided

For example, when the method is called with only the `typeID` parameter set, the method searches for stakeholders or survey users to send invitations to. In contrast, when the method is called with the `typeID` and `userID` parameters set, it attempts to send invitations to the specified users.

**AssessmentCreation - createAssessments (String typeID, String sourceRecordID, String userID)**

Creates one or more assessments or surveys for the specified metric type or survey definition.
## Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>typeID</td>
<td>String</td>
<td>The sys_id of the metric type or survey definition for which to generate assessments or surveys.</td>
</tr>
<tr>
<td>sourceRecordID</td>
<td>String</td>
<td>One or more comma-separated survey definition sys_ids to include in the assessments generated. There must be an assessable record associated with the specified metric type for each source record. If this parameter is left blank, the assessments generated includes all assessable records for the specified type. This parameter is for use with assessments only.</td>
</tr>
<tr>
<td>userID</td>
<td>String</td>
<td>One or more comma-separated sys_ids of users to which to send assessment or survey instances. If this parameter is left blank, the assessment stakeholders or survey users receive instances. This parameter is required for on-demand assessments.</td>
</tr>
</tbody>
</table>

## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>If the method is successful, it returns a comma-separated string such as 7a2ad2253784200044e0bfc8bcbe5de1, 10, b7e8b5d4c0a80169008b49e468920048 (Instance ID, number of instances, Group ID) with the following values:</td>
</tr>
<tr>
<td></td>
<td>• instanceID: Sys_id of the assessment or survey instance created, if there is only one. Sys_id of one of the instances, if there are multiple. If there are multiple instances, use the group ID to retrieve data.</td>
</tr>
<tr>
<td></td>
<td>• #instances: Number of assessment or survey instances created.</td>
</tr>
<tr>
<td></td>
<td>• groupID: Sys_id of the assessment group that contains the assessment or survey instances created.</td>
</tr>
<tr>
<td></td>
<td>If the method is unable to generate assessments or surveys, it returns one of the error codes.</td>
</tr>
</tbody>
</table>

### Error Codes

- isscheduled - Indicates that the userID or sourceRecordID parameter should not have been used. When the typeID value represents a metric type with the Schedule type field set to Scheduled, the typeID parameter is the only parameter that may be used.
<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>draft_state</td>
<td>Indicates that the <code>typeID</code> value is a metric type or survey definition that is not published. Publish the metric type or survey definition.</td>
</tr>
<tr>
<td>invalidtype</td>
<td>Indicates that there is no existing metric type that matches the <code>typeID</code> value.</td>
</tr>
<tr>
<td>inactive</td>
<td>Indicates that the <code>typeID</code> value is a metric type or survey definition that is not active. Navigate to the metric type or survey definition and select the <strong>Active</strong> check box.</td>
</tr>
<tr>
<td>not_available</td>
<td>Indicates that the <code>typeID</code> value is a metric type or survey definition that has no metrics or survey questions. Add at least one metric or survey question.</td>
</tr>
<tr>
<td>notyet</td>
<td>Indicates that at least one of the users in the <code>userID</code> value is assigned a survey instance for the specified survey definition, that has yet to expire. The error code returns the expiration date.</td>
</tr>
<tr>
<td>wip</td>
<td>Indicates that at least one of the users in the <code>userID</code> value is already assigned a survey instance for the survey.</td>
</tr>
<tr>
<td>not_authorized</td>
<td>Indicates that at least one of the users in the <code>userID</code> value is not authorized to take the survey. Verify that one of the following is true:</td>
</tr>
<tr>
<td></td>
<td>◦ There are no survey users for the specified survey definition.</td>
</tr>
<tr>
<td></td>
<td>◦ All the users in the <code>userID</code> value are saved as survey users for the specified survey definition.</td>
</tr>
<tr>
<td>completed</td>
<td>Indicates that the <code>typeID</code> value is a survey definition with the Schedule period field set to Only Once and that at least one of the users in the <code>userID</code> value has already completed a survey instance for that survey definition.</td>
</tr>
<tr>
<td>nousers</td>
<td>Indicates that the <code>userID</code> parameter was not used and that one of the following is true:</td>
</tr>
<tr>
<td></td>
<td>◦ There are no stakeholders associated with the specified metric type. Set the <code>userID</code> parameter or create at least one stakeholder.</td>
</tr>
<tr>
<td></td>
<td>◦ There are no survey users associated with the specified survey definition. Set the <code>userID</code> parameter or create at least one survey user.</td>
</tr>
</tbody>
</table>
### Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• nosources</td>
<td>Indicates that the <code>typeID</code> value is a metric type with the Schedule type field set to On demand and that neither the <code>userID</code> nor <code>sourceRecordID</code> parameter was used. Set at least one of these parameters.</td>
</tr>
</tbody>
</table>

### AuthCredential - Scoped

The `AuthCredential()` API provides methods that enable you to build credentials for a REST request.

Generate outbound signing requests using these APIs in the following order:

1. `HttpRequestData`: Build the API request.
2. `AuthCredential`: Create a credential object or update an existing one. Use the credential to sign the request through the `RequestAuthAPI` class.
3. `RequestAuthAPI`: Sign the request and return an `HttpRequestAuthedData` object.
4. `HttpRequestAuthedData`: Get information about the signed request.
5. `GlideHTTPRequest`: Send the signed request.

Before using these APIs, you must configure an authentication algorithm to sign the request and associate it with the credential used to authenticate the request.

You can create an empty AuthCredential object, instantiate an existing AuthCredential object, or use the `StandardCredentialsProvider` class to instantiate an AuthCredential object using a Credential record from the Credentials [discovery_credentials] table. If you create an empty AuthCredential object, use the `setAttribute()` method to add properties to the object.

See the following example to instantiate an AuthCredential using `StandardCredentialsProvider`:

```javascript
// Return an AuthCredential object using a Credential sys_id
var credential = new
    sn_cc.StandardCredentialsProvider().getAuthCredentialByID("5b61c16f73533300f662cff8af6a74b");
```

Use the `AuthCredential` API in scoped scripts with the `sn_auth` namespace identifier.
## AuthCredential - AuthCredential(Object authCredential)

Instantiates a new AuthCredential object, or modifies an existing one.

You can create an empty AuthCredential object, instantiate an existing AuthCredential object, or use the `StandardCredentialsProvider` class to instantiate an AuthCredential object using a Credential record from the Credentials [discovery_credentials] table. If you create an empty AuthCredential object, use the `setAttribute()` method to add properties to the object.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>authCredential</td>
<td>Object</td>
<td>Optional. Include this parameter to update an existing AuthCredential object.</td>
</tr>
</tbody>
</table>

## AuthCredential - getAttribute(String key)

Returns the value of an AuthCredential attribute.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>String</td>
<td>Key of the attribute to return the value for. If you created an empty AuthCredential object, you must use the <code>setAttribute()</code> method to add properties to the object. If you used a credential record to instantiate the AuthCredential object, pass a field name from the Credential [discovery_credentials] table to access the value.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
// Define the HttpRequestData object
var endpoint = "https://third-party-endpoint";
var httpRequestData = new sn_auth.HttpRequestData();
httpRequestData.setEndpoint(endpoint);
httpRequestData.setService('s3');
httpRequestData.setRegion('us-east-1');
httpRequestData.setHttpMethod("PUT");
```
var content = "Action=SendMessage&MessageBody=This is a test message";
httpRequestData.setContent(content);
httpRequestData.addHeader('x-amz-acl', 'public-read');

// Get AuthCredential object and set an attribute
var credential = new sn_auth.AuthCredential();
credential.setAttribute("user_name", "admin");

// Sign the request and return an AuthCredential attribute value
var signingAPI = new sn_auth.RequestAuthAPI(httpRequestData, credential);
var signingCredential = signingAPI.getAuthCredential();
name = signingCredential.getAttribute("name");

AuthCredential - setAttribute(String key, String value)
Sets an attribute for an AuthCredential object.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>String</td>
<td>Name of the attribute to set. If you created an empty AuthCredential object, you must use this method to add properties to the object. If you used a credential record to instantiate the AuthCredential object, pass a field name from the Credential [discovery_credentials] table to set the value.</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>Value of the attribute.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

// Define the HttpRequestData object
var endpoint = "https://third-party-endpoint";
var httpRequestData = new sn_auth.HttpRequestData();
httpRequestData.setEndpoint(endpoint);
httpRequestData.service('s3');
httpRequestData.setRegion('us-east-1');
httpRequestData.setHttpMethod("PUT");
var content = "Action=SendMessage&MessageBody=This is a test message";
httpRequestData.setContent(content);
httpRequestData.addHeader('x-amz-acl', 'public-read');
```javascript
// Get AuthCredential object and set an attribute
var credential = new sn_auth.AuthCredential();
credential.setAttribute("user_name", "admin");
```

**AutomationException - Global**

Provides generic exception wrapping for automation. Include this in automation code to implement error handling.

**AutomationException - getMessage()**

Retrieves the error message.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The error message</td>
</tr>
</tbody>
</table>

```javascript
var ae = new AutomationException("This is an error message");
gs.print(ae.getMessage());
```

Output: This is an error message

**BusinessServiceManager - Global**

Unify service management by converting manually-created services to application services, populating application services, and adding/removing CIs and connections.

Use BusinessServiceManager methods in global server scripts. You must have the Application Service administrator [app_service_admin] role.

**BusinessServiceManager - addCI(String service_id, String source_id, String target_id)**

Adds a CI to a manually-created application service.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>service_id</td>
<td>String</td>
<td>Sys ID of the application service to add a CI to. Must be of type cmdb_ci_service_discovered.</td>
</tr>
<tr>
<td>source_id</td>
<td>String</td>
<td>Sys ID of the CI whose outgoing connection joins the target CI.</td>
</tr>
<tr>
<td>target_id</td>
<td>String</td>
<td>Sys ID of the CI to add to the service. Cannot be an excluded item. Excluded items are CIs added to the sa.mapping.user.manual.citype.blacklist system property that are excluded from specific operations.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
//Application service is 'PeopleSoft Portals'
//Source CI is windows server 'PS Apache01'
//Target CI is 'SAP WEB01'

var bsManager = new SNC.BusinessServiceManager();
var appService = bsManager.addCI('2fce42d80a0a0bb4004af34d7e3984c8', '3a27d4370a0a0bb4006316812bf45439', '3a6cadc1c0a8ce01001f1e5d0d7d68fa');
```

**BusinessServiceManager - addManualConnection(String source_id, Object manual_endpoint, String service_id)**

Adds a manually created connection to an application service.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source_id</td>
<td>String</td>
<td>Sys ID of the CI to add to the connection.</td>
</tr>
<tr>
<td>manual_endpoint</td>
<td>Object</td>
<td>GlideRecord object in the cmdb_ci_endpoint_manual table to add to the application service.</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>service_id</td>
<td>String</td>
<td>Sys ID of the application service to add the connection to.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var now_GR = new GlideRecord("cmdb_ci_endpoint_manual");
now_GR.initialize();
now_GR.name='myEndpoint';
now_GR.insert();

var bsManager = new SNC.BusinessServiceManager();
var appService = bsManager.addManualConnection("3a307c930a0a0bb400353965d0b8861f", now_GR, "2fce42d80a0a0bb4004af34d7e3984c8");
```

**BusinessServiceManager - BusinessServiceManager()**

Instantiates a BusinessServiceManager object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var bsManager = new SNC.BusinessServiceManager();
```

**BusinessServiceManager - migrateManualToApplicationService(String service_id)**

Converts a manual service to an application service.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>service_id</td>
<td>String</td>
<td>Sys ID of the manual service to convert.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the migration to an application service succeeds.</td>
</tr>
</tbody>
</table>

```javascript
var bsManager = new SNC.BusinessServiceManager();
var appService = bsManager.migrateManualToApplicationService("451047c6c0a8016400de0ae6df9b9d76");
```

**BusinessServiceManager - populateApplicationService(String service_id, Number levels, String blacklisted_relation_types)**

Populates an application service with relations and CIs from the designated entry point.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>service_id</td>
<td>String</td>
<td>Sys ID of the application service to populate.</td>
</tr>
<tr>
<td>levels</td>
<td>Number</td>
<td>Number of levels of CIs to add from the CMDB.</td>
</tr>
<tr>
<td>blacklisted_relation_types</td>
<td>String</td>
<td>Relation types to exclude when populating the application service.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the operation is successful.</td>
</tr>
</tbody>
</table>

```javascript
var bsManager = new SNC.BusinessServiceManager();
var appService = bsManager.populateApplicationService("5bf65ebeedb91300964f6fa662989533", 10, "Depends on::Used by");
```

**BusinessServiceManager - removeCI(String service_id, String target_id)**

Removes a manually created CI from an application service.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>service_id</td>
<td>String</td>
<td>Sys ID of the application service to remove a CI from.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note:</strong> Passing a GlideRecord object is also supported.</td>
</tr>
<tr>
<td>target_id</td>
<td>String</td>
<td>Sys ID of the CI to remove from the application service.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note:</strong> Passing a GlideRecord object is also supported.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var bsManager = new SNC.BusinessServiceManager();
var appService = bsManager.removeCI("2fce42d80a0a0bb4004af34d7e3984c8", "3a290cc60a0a0bb400000bdb386af1cf");
```

### BusinessServiceManager - removeManualConnection(String source_id, String endpoint_id, String service_id)

Removes a manually created connection and the connected CI from an application service.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source_id</td>
<td>String</td>
<td>Sys ID of the CI connected to the endpoint.</td>
</tr>
<tr>
<td>endpoint_id</td>
<td>String</td>
<td>Sys ID of the manually created connection to remove from the application service</td>
</tr>
<tr>
<td>service_id</td>
<td>String</td>
<td>Sys ID of the application service to remove the connection from.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
var bsManager = new SNC.BusinessServiceManager();
var appService = bsManager.removeManualConnection("3a307c930a0a0bb400353965d0b8861f",
  "60ce3176ed91300964f6fa6629895d1", "2fce42d80a0a0bb4004af34d7e3984c8");

**Cabrillo JS constants**
These are the constants used by Cabrillo JS.

**Cabrillo JS button styles**
Constants to use when setting the style of a button.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cabrillo.viewLayout.MORE_MENU_BUTTON_STYLE</td>
<td>String</td>
<td>Indicates that the button appears in the navigation bar's overflow button menu.</td>
</tr>
<tr>
<td>cabrillo.viewLayout.REPLACE_BACK_BUTTON_STYLE</td>
<td>String</td>
<td>Replaces the native back button with a Cabrillo button.</td>
</tr>
</tbody>
</table>

**Note:** Use this style with caution. If the webpage does not restore the native back button after using the Cabrillo replacement, the user may not be able to navigate back.

**Cabrillo JS close button styles**
Constants to use when setting the close button style of modal interfaces.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cabrillo.modal.CLOSE_BUTTON_STYLE_CANCEL</td>
<td>String</td>
<td>The modal has a localized cancel button to close the modal.</td>
</tr>
<tr>
<td>cabrillo.modal.CLOSE_BUTTON_STYLE_CLOSE</td>
<td>String</td>
<td>The modal has a localized close button to close the modal.</td>
</tr>
</tbody>
</table>
Properties (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cabrillo.modal.CLOSE_BUTTON_STYLE_DONE</td>
<td>String</td>
<td>The modal has a localized done button to close the modal.</td>
</tr>
</tbody>
</table>

**Cabrillo JS modal presentation styles**

Constants to use when setting the presentation style of modal interfaces.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cabrillo.modal.MODAL_PRESENTATION_STYLE_FULL_SCREEN</td>
<td>String</td>
<td>The modal is presented full screen.</td>
</tr>
<tr>
<td>cabrillo.modal.MODAL_PRESENTATION_STYLE_FORM_SHEET</td>
<td>String</td>
<td>The modal is presented as a form sheet, but may adapt to full screen on small devices.</td>
</tr>
</tbody>
</table>

**Cabrillo JS data types**

These are common data types used by Cabrillo JS APIs.

**Cabrillo.Attachment**

Defines an attachment.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>content_type</td>
<td>String</td>
<td>The attachment content type.</td>
</tr>
<tr>
<td>ext</td>
<td>String</td>
<td>The attachment file extension.</td>
</tr>
<tr>
<td>file_name</td>
<td>String</td>
<td>The full file name of the attachment including the extension.</td>
</tr>
<tr>
<td>sys_created_by</td>
<td>String</td>
<td>The user name of the user that created the attachment.</td>
</tr>
<tr>
<td>sys_id</td>
<td>String</td>
<td>The attachment record sys_id.</td>
</tr>
<tr>
<td>sys_updated_on</td>
<td>String</td>
<td>The date the attachment record was updated.</td>
</tr>
</tbody>
</table>
### Property (continued)

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table_name</td>
<td>String</td>
<td>Name of the table containing the record to which the attachment is attached.</td>
</tr>
<tr>
<td>table_sys_id</td>
<td>String</td>
<td>The sys_id of the record that to which the attachment is attached.</td>
</tr>
<tr>
<td>thumbnail</td>
<td>String</td>
<td>The URL for the image thumbnail of the attachment. Only applies to image attachments.</td>
</tr>
</tbody>
</table>

### Cabrillo.Button

Defines a button. Different interface contexts may support a subset of a button's properties.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>title</td>
<td>String</td>
<td>Title of the button. The string should be localized.</td>
</tr>
<tr>
<td>enabled</td>
<td>Boolean</td>
<td>Indicates whether the button is enabled.</td>
</tr>
<tr>
<td>badgeCount</td>
<td>Number</td>
<td>Number value to display on the button's badge.</td>
</tr>
<tr>
<td>backgroundColor</td>
<td>String</td>
<td>Background color of the button or badge. A string containing hex, RGB, HSL an x11 named color.</td>
</tr>
<tr>
<td>textColor</td>
<td>String</td>
<td>The text color of the badge or button. A string containing hex, RGB, HSL an x11 named color.</td>
</tr>
<tr>
<td>buttonStyle</td>
<td>String</td>
<td>Used to customize the style of the button.</td>
</tr>
<tr>
<td>imageName</td>
<td>String</td>
<td>Specifies an image. Possible values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• add: Displays an add button.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• back: Displays a back arrow image to navigate back.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• cart: Displays a shopping cart.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• close: Displays an X image to navigate back.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• edit: Displays an edit button.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• filter: Displays a filter button.</td>
</tr>
</tbody>
</table>
## Property (continued)

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
|          |      | - menu: Displays a menu button.  
|          |      | - search: Displays a search button.  |

### Cabrillo.ListSelection

Describes a selected list item.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>String</td>
<td>The value of the selected item. Default is the sys_id of the record, or the value of a custom reference key.</td>
</tr>
<tr>
<td>displayValue</td>
<td>String</td>
<td>The display value of the selected item.</td>
</tr>
</tbody>
</table>

### Cabrillo.Location

Contains geographical information, latitude, longitude, and direction.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>altitude</td>
<td>Number</td>
<td>The altitude in meters.</td>
</tr>
<tr>
<td>coordinate</td>
<td>Cabrillo.LocationCoordinate</td>
<td>The geographical coordinates.</td>
</tr>
<tr>
<td>direction</td>
<td>Number</td>
<td>Measured in degrees beginning at due north.</td>
</tr>
<tr>
<td>speed</td>
<td>Number</td>
<td>Measured in meters per second.</td>
</tr>
<tr>
<td>timestamp</td>
<td>String</td>
<td>The date that the location was last updated.</td>
</tr>
</tbody>
</table>
Cabrillo.LocationCoordinate
Contains a geographical coordinate.

Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>latitude</td>
<td>Number</td>
<td>The latitude in degrees.</td>
</tr>
<tr>
<td>longitude</td>
<td>Number</td>
<td>The longitude in degrees.</td>
</tr>
</tbody>
</table>

Cabrillo.ModalResponse
Contains the result passed from a modal window that was dismissed.

Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>results</td>
<td>Object</td>
<td>The result from the dismissed modal window.</td>
</tr>
</tbody>
</table>

Cabrillo.NavigationRequest
Specifies a request to navigate to a list or record.

Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>String</td>
<td>The table to navigate to. Required for both list and record navigation.</td>
</tr>
<tr>
<td>sysId</td>
<td>String</td>
<td>The sys_id of the record to navigate to. Required for record navigation.</td>
</tr>
<tr>
<td>query</td>
<td>String</td>
<td>An encoded query for the requested list. Can be used to seed values for record navigation requests.</td>
</tr>
<tr>
<td>view</td>
<td>String</td>
<td>The list or record view.</td>
</tr>
</tbody>
</table>
**Cabrillo.Rect**
Contains the location and dimensions of a rectangle.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>Number</td>
<td>The x origin of the rectangle.</td>
</tr>
<tr>
<td>y</td>
<td>Number</td>
<td>The y origin of the rectangle.</td>
</tr>
<tr>
<td>width</td>
<td>Number</td>
<td>The width in points.</td>
</tr>
<tr>
<td>height</td>
<td>Number</td>
<td>The height in points.</td>
</tr>
</tbody>
</table>

**cabrillo - Client**
Cabrillo JS is a client side JavaScript API for accessing capabilities inside ServiceNow native mobile applications.

Use Cabrillo JS to build a custom mobile experience in ServiceNow native mobile applications. Cabrillo JS provides APIs to use native device capabilities, native mobile UI, and other ServiceNow mobile functionality.

Cabrillo JS is available in AngularJS as an injectable parameter. For example, you can inject Cabrillo JS in a Service Portal widget client script.

```javascript
function(cabrillo) {
    var c = this;

    // Used to determine if Cabrillo is executing in ServiceNow's native mobile apps.
    c.isNative = cabrillo.isNative();
}
```

Cabrillo JS APIs are only supported when executing in ServiceNow native mobile applications. Use the `cabrillo.isNative()` API to determine if the script is executing in a native context.

⚠️ **Note:** Cabrillo JS APIs are unavailable in GlideForm client scripts.

**cabrillo - isNative()**
Boolean value indicating if Cabrillo JS is executing a ServiceNow native mobile application.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Returns true if Cabrillo JS is running in a native context; otherwise, false.</td>
</tr>
</tbody>
</table>

```javascript
var isNative = cabrillo.isNative();
```

cabrillo.attachments - Client

The name space for Cabrillo JS attachment functions. This enables adding and viewing attachments.

cabrillo.attachments - addFile(String tableName, String sysId, Object params, String options)

 Presents a document picker and uploads the selected file.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>Table name of the record to which to attach the attachment.</td>
</tr>
<tr>
<td>sysId</td>
<td>String</td>
<td>The sys_id of the record to which to attach the attachment.</td>
</tr>
<tr>
<td>params</td>
<td>Object</td>
<td>Reserved for future use. Set to null.</td>
</tr>
<tr>
<td>options</td>
<td>String</td>
<td>Reserved for future use. Set to null.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>promise</td>
<td>If successful a Cabrillo.Attachment object. If the operation fails, an error.</td>
</tr>
</tbody>
</table>
var table = 'incident';
var sysID = 'a9e30c7dc61122760116894de7bcc7bd';

cabrillo.attachments.addFile(table,
    sysID,
    null,
    null
).then(function(attachment) {
    if (attachment) {
        console.log('Added a new file.', attachment);
    } else {
        console.log('User cancelled adding an attachment.');
    }
}, function(error) {
    console.log('Failed to attach new file.', error);
});

cabrillo.attachments -viewFile(Cabrillo.Attachment attachment, Cabrillo.Rect sourceRect, String sourceBase64Image)

Presents a document picker and uploads the selected file.

⚠️ **Note:** Scaling using a sourceRect parameter with a sourceBase64 image is only supported on iOS. Android ignores these parameters and opens the image without a scaling animation.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attachment</td>
<td>Cabrillo.Attachment</td>
<td>Describes the attachment to view.</td>
</tr>
<tr>
<td>sourceRect</td>
<td>Cabrillo.Rect</td>
<td>Optional. Describes the source rectangle of the image to scale up.</td>
</tr>
<tr>
<td>sourceBase64Image</td>
<td>String</td>
<td>Optional. A base64 representation of the source image to scale up.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>promise</td>
<td>If successful, is undefined; otherwise an error.</td>
</tr>
</tbody>
</table>
To scale an image that was tapped into a native image viewer, the `viewFile()` method accepts optional arguments for the image's rectangle on the page as well as a base64 encoded thumbnail of the image. The thumbnail is scaled into the full size image with an animation.

```javascript
// Grab image metadata from an image that was tapped
var imageMetadata = imageMetadataFromEvent(event);

// Optional rect of image on page
var imageRect = imageMetadata.rect;

// Optional base64 encoded image to scale up into native viewer
var base64EncodedImage = imageMetadata.base64;

// A Cabrillo.Attachment dictionary to view
var attachment = {
    sys_id: '8e99daa3ff133100ba13fffffffffff2d',
    content_type: 'image/jpeg',
    path: '8e99daa3ff133100ba13fffffffffff2d.iix'
}

cabrillo.attachments.viewFile(attachment,
    imageRect,
    base64EncodedImage
).then(function() {
    // It worked. Nothing to do here.
}, function(error) {
    console.log('Failed to view file.', error);
});
```
console.log('Failed to view file.', error);
});

**cabrillo.flowControl - Client**

Cabrillo JS flow control functions.

**cabrillo.flowControl - flowEnded(optional String flowName)**

Ends the current flow.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>flowName</td>
<td>String</td>
<td>Optional. Name for the flow to end.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```
cabrillo.flowControl.flowEnded('TestFlow');
```

**cabrillo.message - Client**

Cabrillo JS functions to provide access to the native UI banner.

**cabrillo.message - showMessage(String style, String title)**

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>style</td>
<td>String</td>
<td>Style of the banner. Possible values are described in the message styles section below.</td>
</tr>
<tr>
<td>title</td>
<td>String</td>
<td>Title to show in the banner.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
**Message Styles**

Constants to use when setting the message style.

<table>
<thead>
<tr>
<th>Style</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cabrillo.message.SUCCESS_MESSAGE_STYLE</td>
<td>Message will have Success styling.</td>
</tr>
<tr>
<td>cabrillo.message.ERROR_MESSAGE_STYLE</td>
<td>Message will have Error styling</td>
</tr>
</tbody>
</table>

```javascript
 cabrillo.message.showMessage(cabrillo.message.SUCCESS_MESSAGE_STYLE, 'This is a sample message');
```

**cabrillo.modal - Client**

Cabrillo JS functions for presenting web content inside of native modals.

**cabrillo.modal - presentModal( String title, String url, String closeButtonStyle, String modalPresentationStyle)**

Presents content in a native modal interface.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>title</td>
<td>String</td>
<td>Title of the modal interface.</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>The URL to open the modal. This must be an internal instance URL (fully qualified or relative; a relative URL is preferred).</td>
</tr>
<tr>
<td>closeButtonStyle</td>
<td>String</td>
<td>Must be one of cabrillo.modal.CLOSE_BUTTON_STYLE_CANCEL,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>cabrillo.modal.CLOSE_BUTTON_STYLE_CLOSE, or</td>
</tr>
<tr>
<td></td>
<td></td>
<td>cabrillo.modal.CLOSE_BUTTON_STYLE_DONE.</td>
</tr>
<tr>
<td>modalPresentationStyle</td>
<td>String</td>
<td>Must be cabrillo.modal.MODAL_PRESENTATION_STYLE_FULL_SCREEN, or</td>
</tr>
<tr>
<td></td>
<td></td>
<td>cabrillo.modal.MODAL_PRESENTATION_STYLE_FORM_SHEET.</td>
</tr>
</tbody>
</table>
Present a native modal that loads a custom URL. This presents a custom Service Portal page in a form sheet style modal. The promise is fulfilled when the modal is dismissed. See the `dismissModal()` function for custom dismissal capabilities.

```javascript
cabrillo.modal.presentModal('Portal Page',
   '/$sp.do?id=my_modal_page',
   cabrillo.modal.CLOSE_BUTTON_STYLE_CLOSE,
   cabrillo.modal.MODAL_PRESENTATION_STYLE_FORM_SHEET
 ).then(function(response) {
   // The results from the modal are in a results key on the response object.
   var results = response && response.results ? response.results : null;

   if (results) {
     console.log('Modal dismissed with results.', results);
   } else {
     console.log('Modal dismissed without results.');
   }
}, function(error) {
   console.log(error);
});
```

cabrillo.navigation - Client

Cabrillo JS functions for forward and backward navigation.

cabrillo.navigation - goBack()

Enables backward navigation.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Returns true if Cabrillo JS will navigate backward; otherwise false.</td>
</tr>
</tbody>
</table>

```javascript
cabrillo.navigation.goBack();
```

### `cabrillo.navigation - goto(String url, Cabrillo.NavigationRequest request)`

Enables forward navigation.

Use the request parameter not the url parameter for list or record navigation.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>String</td>
<td>An URL to navigate to. This should be used for custom URL navigation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Optional.</td>
</tr>
<tr>
<td>request</td>
<td>Cabrillo.NavigationRequest</td>
<td>Describes the list or record to navigate to.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Optional.</td>
</tr>
</tbody>
</table>

```javascript
cabrillo.navigation.goto('/$sp.do?id=my_custom_page');
```

Navigate to a list. The request parameter is preferred over the url parameter for list navigation.

```javascript
// A Cabrillo.NavigationRequest dictionary that specifies a list of active incidents.
var request = {
  table: 'incident',
  query: 'active=true',
};
cabrillo.navigation.goto(null, request);
```
Navigate to a record. The request parameter is preferred over the url parameter for record navigation.

var request = {
    table: 'incident',
    sysId: 'a9e30c7dc61122760116894de7bcc7bd'
};
cabrillo.navigation.goto(null, request);

Navigate to a new record.

// The new record will be seeded with the encoded query.
var request = {
    table: 'incident',
    sysId: '-1',
    query: 'short_description=This is a new incident.'
};
cabrillo.navigation.goto(null, request);

cabrillo.viewLayout - Client

Cabrillo JS functions to provide access to native UI elements like buttons and spinners.

cabrillo.viewLayout - hideSpinner()

Hides a native spinner in the current interface.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
**cabrillo.viewLayout - setBottomButtons( Array buttons, Function handler)**

Set buttons at the bottom of the current interface.

Images and badges are not supported in bottom buttons.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>buttons</td>
<td>Array of Cabrillo.Button objects</td>
<td>Describes the buttons to set. A maximum of one button is currently supported.</td>
</tr>
<tr>
<td>handler</td>
<td>Function</td>
<td>The function to call when a button is tapped. The function has no return value and takes the selected button index as its only parameter. The function must have a single parameter that is a Number.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>promise</td>
<td>If successful, is undefined; otherwise, an error.</td>
</tr>
</tbody>
</table>

**Set bottom buttons**

```javascript
var buttons = [
    {
        title: 'Add to Cart',
        enabled: true,
        backgroundColor: '#3091F9',
        textColor: '#FFFFFF'
    }
];

cabrillo.viewLayout.setBottomButtons(buttons, function(buttonIndex) {
    console.log('Received an event from the button.');
}).then(function() {
    console.log('Buttons were set.');
}, function() {
    console.log('Failed to register buttons.');
});
```

**Clear bottom buttons**
cabrillo.viewLayout.setBottomButtons();

cabrillo.viewLayout.setTitle(String title)
Set the current interface title.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>title</td>
<td>String</td>
<td>The title of the interface.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

cabrillo.viewLayout.setTitle('My Title');

cabrillo.viewLayout.setNavigationBarButtons(Array buttons, Function handler)
Set buttons in the navigation bar of the current interface.

Images and badges for buttons that appear in the overflow button menu are omitted. For this reason, it's best to provide a title and an image name when setting an image button in the navigation bar.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>buttons</td>
<td>Array of Cabrillo.Button objects</td>
<td>Describes the buttons to set. Buttons may overflow into an additional menu as needed.</td>
</tr>
<tr>
<td>handler</td>
<td>Function</td>
<td>The function to call when a button is tapped. The function has no return value and takes the selected button index as its only parameter. The function must have a single parameter that is a Number.</td>
</tr>
</tbody>
</table>

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>promise</td>
<td>If successful is undefined; otherwise an error.</td>
</tr>
</tbody>
</table>

Set navigation bar buttons.

```javascript
var buttons = [
    {
        title: 'Save',
        enabled: true
    }
];

cabrillo.viewLayout.setNavigationBarButtons(buttons, function(buttonIndex) {
    console.log('Received an event from the button.');
}).then(function() {
    console.log('Buttons added.');
}, function() {
    console.log('Failed to register buttons.');
});
```

Handle multiple buttons.

```javascript
var buttons = [
    {
        title: 'Save',
        enabled: true
    },
    {
        title: 'Delete',
        enabled: true
    }
];

cabrillo.viewLayout.setNavigationBarButtons(buttons, function(buttonIndex) {
    switch (buttonIndex) {
        case 0:
            console.log('Received an event from the Save button.');
            break;
        case 1:
            console.log('Received an event from the Delete button.');
            break;
    }
});
```
Buttons placed in the navigation bar can be represented by an image.

```javascript
var buttons = [
    {
        title: 'Compose',
        imageName: 'compose',
        enabled: true
    }
];

cabrillo.viewLayout.setNavigationBarButtons(buttons, function(buttonIndex) {
    console.log('Received an event from the button.');
}).then(function() {
    console.log('Buttons were set.');
}, function() {
    console.log('Failed to register buttons.');
});
```

A native back button is shown in the native app by default, but you can replace the back button with a Cabrillo button by setting a button’s `buttonStyle` property.

```javascript
var buttons = [{
    title: 'Cancel',
    imageName: 'close',
    buttonStyle: cabrillo.viewLayout.REPLACE_BACK_BUTTON_STYLE,
    enabled: true
}, {
    title: 'Done',
    enabled: true
}];

cabrillo.viewLayout.setNavigationBarButtons(buttons, function(buttonIndex) {
    switch (buttonIndex) {
        case 0:
            c.log('Cancel button was clicked.');
            break;
        case 1:
            c.log('Done button was clicked.');
    }
});
```
Buttons are placed in the overflow button menu as needed. To force a button into the overflow button menu, set the button's buttonStyle property.

```javascript
var buttons = [
    { 
        title: 'Save', 
        buttonStyle: cabrillo.viewLayout.MORE_MENU_BUTTON_STYLE, 
        enabled: true 
    }
];

cabrillo.viewLayout.setNavigationBarButtons(buttons, function(buttonIndex) {
    console.log('Received an event from the button.'); 
}).then(function() { 
    console.log('Buttons were set.'); 
}, function() { 
    console.log('Failed to register buttons.'); 
});
```

Buttons may have a badge when placed in the navigation bar. This example sets a button with a shopping cart icon and a badge count of 3. The badge has a blue background with white text.

```javascript
var buttons = [
    { 
        title: 'Cart',
        imageName: 'cart',
        badgeCount: 3,
        backgroundColor: '#3091F9',
        textColor: '#FFFFFF',
        enabled: true
    }
];

cabrillo.viewLayout.setNavigationBarButtons(buttons, function(buttonIndex) {
    console.log('Received an event from the button.'); 
}).then(function() { 
    console.log('Buttons were set.'); 
}, function() { 
    console.log('Failed to register buttons.'); 
});
```
console.log('Buttons were set.');

}, function() {
    console.log('Failed to register buttons.');
});

Clear navigation bar buttons.

cabrillo.viewLayout.setNavigationBarButtons();

cabrillo.viewLayout - showSpinner()

Shows a native spinner in the current interface.

```
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

Returns

```
<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
```

cabrillo.viewLayout.showSpinner();

CartJS - Scoped

CartJS API enables you to access the shopping cart for a user.

To use this class in a scoped application, use the `sn_sc` namespace identifier. The Service Catalog Scoped API plugin (ID: com.glideapp.servicecatalogScoped.api) that is enabled by default is required to access the CartJS API.

CartJS - addToCart(Map request)

Adds the request for a catalog item to the current cart.

```
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>request</td>
<td>Map</td>
<td>A JSON object that contains the details of the catalog item to be added to the cart.</td>
</tr>
</tbody>
</table>
```
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>item_id</td>
<td>sys_id of the item to be added to the cart</td>
<td></td>
</tr>
<tr>
<td>item_quantity</td>
<td>Number of items to be added. Default value is 1.</td>
<td></td>
</tr>
<tr>
<td>var_name</td>
<td>Name of the question.</td>
<td></td>
</tr>
<tr>
<td>var_value</td>
<td>Value of the answer (Not the display value).</td>
<td></td>
</tr>
</tbody>
</table>

The structure of the request object is:

```
{
  'sysparm_id': item_id,
  'sysparm_quantity': item_quantity,
  'variables':{
    'var_name': 'var_value',
    ...
  }
}
```

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JSON</td>
<td>Structure of the current cart.</td>
</tr>
</tbody>
</table>

```
{
  'subtotal': value,
  'items':[
    {
      itemName:'',
      quantity:'',
      price:'',
      recurring_price:''
    }
  ]
}
```

This example shows how you can add multiple items to the cart. Note that `var cart = new sn_sc.CartJS();` is inside the loop. You must call `sn_sc.CartJS()` multiple times to be able to add multiple items to the cart.

```javascript
for (i = 0; i < 2; i++) {
  var cart = new sn_sc.CartJS();
```
var item =
{
'sysparm_id': '0d08837237153000158bbfc8bcbe5d02',
'sysparm_quantity': '1',
'veariables':{
'carrier': 'at_and_t_mobility',
'data_plan': '500MB',
'duration': 'eighteen_months',
'color': 'slate',
'storage': 'sixtyfour'
}};
var cartDetails = cart.addToCart(item);
gs.info(JSON.stringify(cartDetails));
}

Output

//The cart after the first item is added
{
"cart_id": "c0f5828a1b476010593876a61a4bcb71",
"subtotal": "$599.99",
"items": [
{
"catalog_item_id": "0d08837237153000158bbfc8bcbe5d02",
"quantity": "1",
"localized_price": "$599.99",
"price": "$599.99",
"recurring_frequency": "Monthly",
"localized_recurring_price": "$30.00",
"recurring_price": "$29.00",

}
]

CartJS - CartJS(String cartName)

Creates an instance of the CartJS class with the name of a defined cart for the user who is currently logged in.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cartName</td>
<td>String</td>
<td>Optional. Name of a defined cart for the user who is currently logged in.</td>
</tr>
</tbody>
</table>

var cart = new sn_sc.CartJS(cart1);

CartJS - checkoutCart()

Performs the cart checkout. If the two-step checkout is enabled, returns the order summary. If the two-step checkout is disabled, the cart is submitted and details of the generated request are returned.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JSON</td>
<td>If the two-step checkout is enabled, the summary of the items in the cart is returned.</td>
</tr>
</tbody>
</table>

```
{
  "subtotal_price": "$2,748.49",
  "subtotal_recurring_frequency": "",
  "delivery_address": "",
  "special_instructions": "",
  "total_title": "Total",
  "requested_for_user": "System Administrator",
  "requested_for": "6816f79cc0a8016401c5a33be04be441",
  "daily": [{"frequency_subtotal": "", "items": [{}, {}, ...], ...}, ...],
  "monthly": [{"frequency_subtotal": "", "items": [{}, {}, ...], ...}, ...],
  "annually": [{"frequency_subtotal": "", "items": [{}, {}, ...], ...}, ...],
  "none": [{"frequency_subtotal": "", "items": [{}, {}, ...], ...}, ...]
}
```

If the two-step checkout is disabled:

```
{
  "request_id": "sys_id of the generated request",
  "request_number": "Number of the generated request"
}
```

Example

```javascript
var cart = new sn_sc.CartJS();
var checkoutInfo = cart.checkoutCart();
gs.info(checkoutInfo);
```

Output

If two step checkout enabled:

```json
{"subtotal_price": "$2,748.49", "subtotal_recurring_frequency": ",", "delivery_address": ",", "special_instructions": ",", "total_title": "Total", "requested_for_user": "System Administrator", "requested_for": "6816f79cc0a8016401c5a33be04be441", "weekly": {"subtotal_price": "$399.50", "subtotal_recurring_frequency": "Weekly", "subtotal_recurring_price": "$0.00", "total_title": "Total", "items": [{"catalog_item_id": "e90a07237153000158bbfc8bcbe5d7f", "variable
```
CartJS - empty()

Deletes the current cart.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
var cart = new sn_sc.CartJS();
cart.empty();

CartJS - getCartID()
Returns the ID of the current cart.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys_id for the current cart.</td>
</tr>
</tbody>
</table>

Returns the sys_id of the current cart.

```javascript
var cart = new sn_sc.CartJS();
var cartId = cart.getCartID();
gs.info(cartId);
```

Output

```
039c516237b1300054b6a3549dbe5dfc
```

CartJS - getCartItems()
Returns a GlideRecord object containing records for items in the current cart.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideRecord</td>
<td>GlideRecord object including records and fields from the Item [sc_cart_item] table that describe an item in the current cart.</td>
</tr>
</tbody>
</table>
Returns quantity and Catalog Item field values for items in the current cart.

```javascript
var cart = new sn_sc.CartJS();

var cartItems = cart.getCartItems();
while (cartItems.next()) {
    gs.info(cartItems.getElement('quantity').getDisplayValue()
            + " x "
            + cartItems.getElement('cat_item').getDisplayValue());
}
```

Output

```
1 x Apple iPhone 6s Plus
1 x Apple iPhone 6s
1 x Apple MacBook Pro 15"
```

**CartJS - getDeliveryAddress()**

Returns the delivery address for the current cart.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Delivery address for the current cart.</td>
</tr>
</tbody>
</table>

Sets and then returns the delivery address for the current cart.

```javascript
var cart = new sn_sc.CartJS();
cart.setDeliveryAddress("Brasilia, Brasil");
var deliveryAddress = cart.getDeliveryAddress();
gs.info(deliveryAddress);
```

Output

```
Brasilia, Brasil
```
CartJS - getRequestedFor()

Returns the sys_id of the user for whom the cart is requested.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys_id of the user record for whom the cart is requested; located in the User [sys_user] table.</td>
</tr>
</tbody>
</table>

Returns the user sys_id associated with the cart.

```javascript
var cart = new sn_sc.CartJS();
cart.setRequestedFor("039c516237b1300054b6a3549dbe5dfc")
var userId = cart.getRequestedFor();
gs.info(userId);
```

Output

```
039c516237b1300054b6a3549dbe5dfc
```

CartJS - getRequestedForDisplayName()

Returns the name of the user for whom the current cart is requested.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Name of the user for whom the current cart is requested; located in the User [sys_user] table.</td>
</tr>
</tbody>
</table>

Returns the name of the user associated with the cart.
var cart = new sn_sc.CartJS();
var userName = cart.getRequestedForDisplayName();
gs.info(userName);

Output

Abel Tuter

**CartJS - getSpecialInstructions()**

Returns the special instructions for the current cart.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Special instructions for the current cart.</td>
</tr>
</tbody>
</table>

This example shows how to set and retrieve the special instructions for the current cart.

```javascript
var cart = new sn_sc.CartJS();
cart.setSpecialInstructions("Delivery before 8 AM.");
var specInstruction = cart.getSpecialInstructions();
gs.info(specInstruction);
```

Output

Delivery before 8 AM.

**CartJS - orderNow(Map request)**

Orders a single item. If two-step checkout is enabled, the method adds the specified item to the cart and returns the sys_id of the cart. If two-step checkout is disabled, the method completes the purchase of the specified item and returns the sys_id of the generated request.
## Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>request</td>
<td>Map</td>
<td>JSON object that contains details of the catalog item to order.</td>
</tr>
<tr>
<td>request.delivery_address</td>
<td>String</td>
<td>Address to which to deliver the items. Default: Address of user</td>
</tr>
<tr>
<td>request.sysparm_id</td>
<td>String</td>
<td>Required. The sys_id of the item to purchase.</td>
</tr>
<tr>
<td>request.special_instructions</td>
<td>String</td>
<td>Instructions to follow when processing the order.</td>
</tr>
<tr>
<td>request.sysparm_quantity</td>
<td>String</td>
<td>Quantity of the specified item to purchase. Default: 1</td>
</tr>
<tr>
<td>request.sysparm_requested_for</td>
<td>String</td>
<td>The sys_id of the user for whom the item is requested. Default: Session user</td>
</tr>
<tr>
<td>request.variables</td>
<td>Array</td>
<td>Questions and customer answers associated with the item.</td>
</tr>
<tr>
<td>request.variables.var_name</td>
<td>String</td>
<td>Name of the question.</td>
</tr>
<tr>
<td>request.variables.var_value</td>
<td>String</td>
<td>Customer's response to the associated question.</td>
</tr>
</tbody>
</table>

## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JSON key/value pairs</td>
<td>Output if two-step checkout is enabled:</td>
</tr>
</tbody>
</table>
|                             | {{
|                             |   'cart_id' : '<sys_id of the cart to which the items were added>'
|                             | }}                                                                           |
|                             | Output if two-step checkout is disabled:                                    |
|                             | {{
|                             |   'request_id' : '<sys_id of the generated request>'
|                             | }}                                                                           |
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'request_number'</td>
<td>'&lt;Number of the generated request&gt;'</td>
</tr>
</tbody>
</table>

**Example**

```javascript
var cart = new sn_sc.CartJS();
var request = {
  'sysparm_id': '0d08837237153000158bbfc8bcbe5d02',
  'sysparm_quantity': '1',
  'variables':{
    'carrier': 'at_and_t_mobility',
    'data_plan': '500MB',
    'duration': 'eighteen_months',
    'color': 'slate',
    'storage': 'sixtyfour'
  }
}
var cartDetails = cart.orderNow(request);
gs.info(cartDetails);
```

**Output**

```
// If two-step checkout is enabled:
{"cart_id":"55384df3c322320076173b0ac3d3aec5"}

// If two-step checkout is disabled:
{"request_id":"4c690137c322320076173b0ac3d3ae03", "request_number": "REQ0010003"}
```

**CartJS - setDeliveryAddress(String address)**

Sets the delivery address for the current cart.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>address</td>
<td>String</td>
<td>Delivery address for the current cart.</td>
</tr>
</tbody>
</table>
CartJS - setSpecialInstructions(String specialInstructions)
Sets the special instructions for the current cart.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>specialInstructions</td>
<td>String</td>
<td>Special instructions for the current cart.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

CartJS - submitOrder(Map request)
Updates special instructions, requested for, and delivery address from the request parameter and performs the cart checkout. Use this API to modify the mentioned parameters of the cart and perform the cart checkout simultaneously. Missing parameters in the request object will have their default value.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>request</td>
<td>Map</td>
<td>A JSON object that contains details of the cart to be submitted.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The structure of the request object is:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>`{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'special_instructions' : 'instructions',</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'sysparm_requested_for' : requested_for,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'delivery_address' : 'address'</td>
</tr>
<tr>
<td></td>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• instructions: Special instructions for the request.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• requested_for : sys_id of the requested_for user.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• address: Delivery address for the request.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JSON</td>
<td>Structure of the cart.</td>
</tr>
<tr>
<td></td>
<td>`{</td>
</tr>
<tr>
<td></td>
<td>'request_id' : 'sys_id of the generated Request',</td>
</tr>
<tr>
<td></td>
<td>'request_number' : 'Number of the generated Request'</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
</tbody>
</table>

### Example

```javascript
var cart = new sn_sc.CartJS();
var request =
{
   'special_instructions' : 'Delivery only in working hours',
   'requested_for' : '62826bf03710200044e0bfc8bcbe5df1',
   'delivery_address' : "Brasilia, Brasil",
};
var requestDetails = cart.submitOrder(request);
gs.info(requestDetails);
```

### Output

```javascript
{"request_id":"6eed229047801200e0ef563dbb9a71c2", "request_number": "REQ0000001"}
```
CartJS - `updateItem(Map request, String cart_item_id)`

Updates an item in the cart.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>request</td>
<td>Map</td>
<td>A JSON object that contains details of the catalog item to be updated.</td>
</tr>
<tr>
<td>cart_item_id</td>
<td>String</td>
<td>sys_id of the cart item to be modified.</td>
</tr>
</tbody>
</table>

The structure of the request object is:

```json
{
    'sysparm_quantity': item_quantity,
    'sysparm_requested_for': requested_for,
    'variables': {
        'var_name': 'var_value',
        ...
    }
}
```

- **item_quantity**: Number of items to be added. Default value is 1.
- **var_name**: Name of the question.
- **var_value**: Value of the answer (Not the display value).

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JSON</td>
<td>Details of the cart.</td>
</tr>
</tbody>
</table>

```json
{
    'subtotal': value,
    'items': [
    {
        'item_name': '',
        'quantity': '',
        'price': '',
        'recurring_price': ''
    }
    ...
}
```
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>...</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
</tbody>
</table>

Example

```javascript
var cart = new sn_sc.CartJS();
var request = {
    'sysparm_quantity': '1',
    'variables':{
        'carrier': 'at_and_t_mobility',
        'data_plan': '500MB',
        'duration': 'eighteen_months',
        'color': 'slate',
        'storage': 'sixtyfour'
    }
};
var cart_item_id = "4d69b672c322320076173b0ac3d3ae79";
var cartDetails = cart.updateItem(request, cart_item_id);
gs.info(cartDetails);
```

Output

```javascript
{
    "cart_id":"35ec9e8947a13200e0ef563dbb9a7109",
    "items":[
        { "cart_item_id":"35ec9e8947a13200e0ef563dbb9a710a",
            "catalog_item_id":"0d0883723715300158bbfc8bcbe5d02", "item_name":"Apple iPhone 5",
            "localized_price":"$799.99", "localized_recurring_price":"$30.00", "price":"$799.99",
            "quantity":1, "recurring_frequency":"Monthly", "recurring_price": "$29.00" } ]
    "subtotal":"$799.99" }
```

**CartJS - canViewRF()**

Specifies if the current user has the required role to edit the **Request for** field.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean | Flag that indicates whether the user has the required role to edit the requested for field. Valid values:  
|         | • true: user has the required role                                           |
|         | • false: user does not have the required role                                |

This example checks if the user has the role needed to edit the requested for field.

```javascript
var cart=new sn_sc.CartJS();
console.log(cart.canViewRF());
```

Output:

```javascript
true
```

**CartJS - getCartDetails()**

Returns the cart details.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Object pointing to the current cart details.</td>
</tr>
</tbody>
</table>

Example:

```javascript
var cart=new sn_sc.CartJS();
console.log (cart.getCartDetails());
```

Output:
CartJS - setRequestedFor(String user)
Sets the sys_id in the sys_user record of the user for whom the cart is requested.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user</td>
<td>String</td>
<td>sys_id to be set in the sys_user record of the user for whom the cart is requested.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

Example

```javascript
var cart = new sn_sc.CartJS();
cart.setRequestFor("039c516237b1300054b6a3549dfe5dfe")
```
CatalogJS - Scoped

The CatalogJS API enables you to use methods to check and retrieve catalog-specific properties.

To use this class in a scoped application, use the sn_sc namespace identifier. The Service Catalog Scoped API plugin (com.glideapp.servicecatalogScoped.api) that is enabled by default is required to access the CatalogJS API.

CatalogJS - Catalog(GlideRecord now_GR)

Creates an instance of the catalog class for the specified glide record object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>now_GR</td>
<td>Object</td>
<td>Glide Record pointing to the sc_catalog table.</td>
</tr>
</tbody>
</table>

This example shows how to create a new instance of the catalog class.

```javascript
var now_GR = new GlideRecord('sc_catalog');
now_GR.addQuery('sys_id','e0d08b13c3330100c8b837659bba8fb4');
now_GR.query();
var catalog = new sn_sc.Catalog(now_GR);
```

CatalogJS - Catalog(String sys_id)

Creates an instance of the Catalog class with the specified sys_id.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sys_id</td>
<td>String</td>
<td>Sys_id of the catalog.</td>
</tr>
</tbody>
</table>

This example shows how to create an instance of the Catalog class with the specified sys_id.

```javascript
new sn_sc.Catalog(catalog_sys_id);
var catalog = new sn_sc.Catalog("31bea3d53790200044e0bfc8bcbe5dec");
```

CatalogJS - canView(Boolean mobile, String userId)

Determines whether a user can view the current category on a mobile device or desktop.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mobile</td>
<td>Boolean</td>
<td>Flag that indicates whether to check if the user can view the current catalog on a mobile view or desktop view. Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Mobile view</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Desktop view</td>
</tr>
<tr>
<td>userId</td>
<td>String</td>
<td>Optional. Sys_id of the user to check if they can view the catalog. Default: Current user</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the catalog is viewable by the user. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Catalog is viewable by the user.</td>
</tr>
<tr>
<td></td>
<td>• false: Catalog is not viewable by the user.</td>
</tr>
</tbody>
</table>

Example:

```javascript
var catalog = new sn_sc.Catalog("e0d08b13c3330100c8b837659bba8fb4");
gs.info(catalog.canView(true));
```

Output:

true

**CatalogJS - getAvailableCatalog()**

Returns the available active catalog.

If only one active catalog exists, then the method returns that catalog. Otherwise, it returns the earliest catalog created from the list of the catalogs that the user can view. If no catalog is available, the method returns null.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Object pointing to the earliest catalog that the user can view, or null if no catalog is available.</td>
</tr>
</tbody>
</table>

This example returns the catalog that is available to the current user.

```javascript
var catalog = sn_sc.Catalog.getAvailableCatalog()
```

### CatalogJS - getBackgroundColor()

Returns the catalog background color.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Background color of the catalog.</td>
</tr>
</tbody>
</table>

This example returns the background color for the associated catalog.

```javascript
var catalog = new sn_sc.Catalog("0f910a2ac3112200b12d9f2974d3ae3c");
gs.info("Catalog background: "+ catalog.getBackgroundColor());
```

**Output:**

```
Catalog background: white
```

### CatalogJS - getCatalogCount()

Returns the number of catalogs active in the catalog table.
**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>Number of catalogs available in the catalog table.</td>
</tr>
</tbody>
</table>

**Example:**

```javascript
console.log(sn_sc.Catalog.getCatalogCount());
```

**Output:**

3

---

**CatalogJS - getCategories()**

Returns the categories for the current catalog.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ArrayList</td>
<td>Returns the categories for the current catalog.</td>
</tr>
</tbody>
</table>

This example returns the categories available in the current catalog object.

```javascript
var catalog=new sn_sc.Catalog("e0d08b13c3330100c8b837659bba8fb4");
catalog.log(catalog.getCategories());
```

**Output:**

0

:  
  {header_image: "", sys_id: "e15706fc0a0a0aa7007fc2e1ab70c2f", description: "Your IT gateway. Report issues and submit requests.", title: "Can We Help You?");
CatalogJS - getCategoryIds()

Specifies the sys_ids of the categories in the current catalog.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ArrayList</td>
<td>Returns the sys_ids of the categories in the current catalog.</td>
</tr>
</tbody>
</table>

This example returns the sys_ids of the categories available in the current catalog.

```javascript
var catalog=new sn_sc.Catalog("e0d08b13c3330100c8b837659bba8fb4");
console.log(catalog.getCategoryIds());
```
CatalogJS - getDescription()

Returns the description of the current catalog.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Catalog description.</td>
</tr>
</tbody>
</table>

This example returns the name of the current catalog.

```javascript
var catalog=new sn_sc.Catalog("e0d08b13c3330100c8b837659bba8fb4");
console.log(catalog.getDescription());
```

**Output:**

Service Catalog - IT Now

CatalogJS - getDesktopImageSRC()

Returns the catalog desktop image file name.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Catalog desktop image file name.</td>
</tr>
</tbody>
</table>

This example returns the current catalog desktop image file name.

```javascript
var catalog = new sn_sc.Catalog("e0d08b13c3330100c8b837659bba8fb4");
console.log(catalog.getDesktopImageSRC());
```

Output:

```
adbcc271475211002ee987e8dee49001.iix
```

**CatalogJS - getGr()**

Returns the current catalog's GlideRecord.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideRecord</td>
<td>GlideRecord of the current catalog.</td>
</tr>
</tbody>
</table>

This example returns the GlideRecord for the specified catalog.

```javascript
var catalog = new sn_sc.Catalog("e0d08b13c3330100c8b837659bba8fb4");
data.history = catalog.getGr();
```

**CatalogJS - getHeaderIconSRC()**

Returns the current catalog's header icon.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Catalog header icon.</td>
</tr>
</tbody>
</table>

This example shows how to obtain the name of the catalog header icon.

```javascript
var catalog = new sn_sc.Catalog("e0d08b13c3330100c8b837659bba8fb4");
gs.info(catalog.getHeaderIconSRC());
```

Output:

```
service_catalog_header.png
```

CatalogJS - `getId()`

Returns the sys_id of the current catalog.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

This example returns the sys_id of the current catalog.

```javascript
var catalog = new sn_sc.Catalog("e0d08b13c3330100c8b837659bba8fb4");
console.log(catalog.getId());
```

Output:

```
e0d08b13c3330100c8b837659bba8fb4
```

CatalogJS - `getTitle()`

Returns the title of the current catalog.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Title of the current catalog.</td>
</tr>
</tbody>
</table>

This example returns the title of the current catalog.

```javascript
var catalog=new sn_sc.Catalog("e0d08b13c3300100c8b83759bba8fb4");
gs.info(catalog.getTitle());
```

**Output:**

```
Service Catalog
```

### CatalogJS - hasCategories()

Specifies if the current catalog has categories.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean | Flag that indicates whether the current catalog has categories. Valid values:  
- true: Catalog has categories.  
- false: Catalog does not have categories. |

This example shows how to determine if the current catalog contains categories.

```javascript
var catalog=new sn_sc.Catalog("e0d08b13c3300100c8b83759bba8fb4");
gs.info(catalog.hasCategories());
```
**CatalogJS - hasItems()**

Specifies if the current catalog has catalog items.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the current catalog has catalog items. Valid values: • true: Catalog has catalog items. • false: Catalog does not have catalog items.</td>
</tr>
</tbody>
</table>

**Example:**

```javascript
var catalog=new sn_sc.Catalog("e0d08b13c3330100c8b837659bba8fb4");
gs.info(catalog.hasItems());
```

**Output:**

```
true
```

**CatalogJS - isWishlistEnabled()**

Specifies if the wish list is enabled for the current catalog.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the current catalog supports wish lists.</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Catalog supports wish lists.</td>
</tr>
<tr>
<td></td>
<td>• false: Catalog does not support wish lists.</td>
</tr>
</tbody>
</table>

This example shows how to check if a wish lists are enabled for the current catalog.

```javascript
var catalog = new sn_sc.Catalog("e0d08b13c3330100c8b837659bba8fb4");
gs.info(catalog.isWishlistEnabled());
```

Output:

```
true
```

CatalogSearch - Scoped

CatalogSearch API enables you to search catalog item.

To use this class in a scoped application, use the `sn_sc` namespace identifier. The Service Catalog Scoped API plugin (ID: com.glideapp.servicecatalogScoped.api) that is enabled by default is required to access the CatalogSearch API.

Scoped CatalogSearch - CatalogSearch()

Creates an instance of the CatalogSearch class.

```javascript
var catSearchGR = new sn_sc.CatalogSearch().search('', '', 'Apple', false, true);
catSearchGR.query();
while(catSearchGR.next()) {
    gs.info(catSearchGR.getValue('name'));
}
```
Scoped CatalogSearch - search (String catalogID, String categoryID, String term, Boolean mobile, Boolean noDepthSearch)

Searches a catalog item based on a search term. The search can be narrowed down to a catalog category level.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>catalogID</td>
<td>String</td>
<td>Identifier of the catalog to search.</td>
</tr>
<tr>
<td>categoryID</td>
<td>String</td>
<td>Identifier of the catalog category to search.</td>
</tr>
<tr>
<td>term</td>
<td>String</td>
<td>Search term.</td>
</tr>
<tr>
<td>mobile</td>
<td>Boolean</td>
<td>Flag that indicates whether catalog items exposed for mobile are searched.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Search for mobile catalog items.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Do not search for mobile catalog items.</td>
</tr>
<tr>
<td>noDepthSearch</td>
<td>Boolean</td>
<td>Flag that indicates whether to search subcategories.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Do not search subcategories.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Search subcategories.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideRecord</td>
<td>Returns the GlideRecord on sc_cat_item matching the search result.</td>
</tr>
</tbody>
</table>

This example shows how to search all catalogs and all categories for term: ServiceNow.

```javascript
var now_GR = new sn_sc.CatalogSearch().search('', '', 'ServiceNow', false, false);
now_GR.query();
while(now_GR.next()) {
    gs.log(now_GR.name);
}
```

**Output**
CatalogItemVariable - Scoped

CatalogItemVariable API enables you to create and modify service catalog item variables using scripts.

CatalogItemVariable - create(Boolean standardUpdate)

Inserts the specified catalog item variable.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>standardUpdate</td>
<td>Boolean</td>
<td>Flag that indicates whether to enable the running of engines and workflow.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Enable engines and workflow.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Do not enable engines and workflow.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Return the sys_id of the inserted variable record.</td>
</tr>
</tbody>
</table>

CatalogItemVariable - deleteRecord(Boolean standardUpdate)

Deletes the defined catalog item variable.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>standardUpdate</td>
<td>Boolean</td>
<td>Flag that indicates whether to enable the running of engines and workflow.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Enable engines and workflow.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Do not enable engines and workflow.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

CatalogItemVariable - read(Object columns, Boolean standardUpdate)

Returns a mapping of catalog item variable attribute values.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columns</td>
<td>Object</td>
<td>Set of columns for which to return values.</td>
</tr>
<tr>
<td>standardUpdate</td>
<td>Boolean</td>
<td>Flag that indicates whether to enable the running of engines and workflow.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Enable engines and workflow.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Do not enable engines and workflow.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>An object mapping column names to values.</td>
</tr>
</tbody>
</table>

CatalogItemVariable - setAttributes(Object attributes)

Defines attribute values for this catalog item variable.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attributes</td>
<td>Object</td>
<td>An object mapping column names to values.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
CatalogItemVariable - update(Object columnValues, Boolean standardUpdate)

Updates current catalog item variable with set values.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnValues</td>
<td>Object</td>
<td>An object mapping column names to values.</td>
</tr>
<tr>
<td>standardUpdate</td>
<td>Boolean</td>
<td>Flag that indicates whether to enable the running of engines and workflow.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Enable engines and workflow.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Do not enable engines and workflow.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

CatalogClientScript - Scoped

CatalogClientScript API enables you to create, modify, or delete catalog client script records.

To use this class in a scoped application, use the `sn_sc` namespace identifier. The Service Catalog Scoped API plugin (ID: `com.glideapp.servicecatalogScoped.api`) that is enabled by default is required to access the CatalogClientScript API.

Scoped CatalogClientScript - addScript(String script)

Adds a script to the catalog client script.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>script</td>
<td>String</td>
<td>Script to be added to the catalog client script.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

Example

```javascript
var catalogClientScript = new sn_sc.CatalogClientScript();
catalogClientScript.addScript("function onLoad(){Enter the script}");
```

### Scoped CatalogClientScript - appliesToCatalogItem(Boolean flag)
Specifies if the catalog client script runs on a catalog item.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>flag</td>
<td>Boolean</td>
<td>If true, the catalog client script runs on the catalog item. If false, the catalog client script does not run on the catalog item.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

Example

```javascript
var catalogClientScript = new sn_sc.CatalogClientScript();
catalogClientScript.appliesToCatalogItem(true);
```

### Scoped CatalogClientScript - appliesToCatalogTask(Boolean flag)
Specifies if the catalog client script runs on a catalog task.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>flag</td>
<td>Boolean</td>
<td>If true, the catalog client script runs on the catalog task. If false, the catalog client script does not run on the catalog task.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

Example

```javascript
var catalogClientScript = new sn_sc.CatalogClientScript();
catalogClientScript.appliesToCatalogTask(true);
```

**Scoped CatalogClientScript - appliesToRequestedItem(Boolean flag)**

Specifies if the catalog client script runs on a requested item.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>flag</td>
<td>Boolean</td>
<td>If true, the catalog client script runs on the requested item. If false, the catalog client script does not run on the requested item.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

Example

```javascript
var catalogClientScript = new sn_sc.CatalogClientScript();
catalogClientScript.appliesToRequestedItem(true);
```

**Scoped CatalogClientScript - appliesToTargetRecord(Boolean flag)**

Specifies if the catalog client script runs on a requested item.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>flag</td>
<td>Boolean</td>
<td>If true, the catalog client script runs on the target record. If false, the catalog client script does not run on the target record.</td>
</tr>
</tbody>
</table>
## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

## Example

```java
var catalogClientScript = new sn_sc.CatalogClientScript();
catalogClientScript.appliesToTargetRecord(true);
```

### Scoped CatalogClientScript - CatalogClientScript()

Creates an instance of the CatalogClientScript class.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```java
var catalogClientScript = new sn_sc.CatalogClientScript();
```

### Scoped CatalogClientScript - create(Boolean standardUpdate)

Inserts the defined catalog client script in the catalog_script_client table.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>standardUpdate</td>
<td>Boolean</td>
<td></td>
</tr>
</tbody>
</table>

Flag that indicates whether to enable the running of engines and workflow. Valid values:

- true: Enable engines and workflow.
- false: Do not enable engines and workflow.

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys_id of the catalog client script.</td>
</tr>
</tbody>
</table>

### Example
var catalogClientScript = new sn_sc.CatalogClientScript();
catalogClientScript.setAttributes({"name": "My Catalog Item", "applies_to": "item",  
"ui_type": "desktop", "type": "onLoad"});
catalogClientScript.appliesToCatalogItem(true);
catalogClientScript.appliesToRequestedItem(true);
catalogClientScript.appliesToCatalogTask(true);
catalogClientScript.appliesToTargetRecord(true);
var catalogClientScriptId = catalogClientScript.create();
gs.info(catalogClientScriptId);

Output

039c516237b1300054b6a3549dbe5dfc

Scoped CatalogClientScript - deleteRecord(String sys_id, Boolean standardUpdate)

Deletes the defined catalog client script.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sys_id</td>
<td>String</td>
<td>Sys_id of the catalog client script.</td>
</tr>
</tbody>
</table>
| standardUpdate | Boolean  | Flag that indicates whether to enable the running of engines and workflow. Valid values:  
- true: Enable engines and workflow.  
- false: Do not enable engines and workflow. |

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to delete a catalog client script.

var sys_id = "039c516237b1300054b6a3549dbe5dfc";
var catalogClientScript = new sn_sc.CatalogClientScript();
catalogClientScript.deleteRecord("039c516237b1300054b6a3549dbe5dfc");
Scoped CatalogClientScript - setAttributes(Map attributes)
Defines attribute values for the catalog client script.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attributes</td>
<td>Map</td>
<td>A JSON object that has mapping for the field and value pairs.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

Example

```javascript
var catalogClientScript = new sn_sc.CatalogClientScript();
catalogClientScript.setAttributes({"name": "My Catalog Item", "applies_to": "catalog_item", "ui_type": "desktop", "type": "onLoad"});
```

Scoped CatalogClientScript - setCatalogItem(String sys_id)
Associates a catalog item with the catalog client script.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sys_id</td>
<td>String</td>
<td>Sys_id of the catalog item.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to associate a catalog item with the current catalog client script.

```javascript
var catalogClientScript = new sn_sc.CatalogClientScript();
catalogClientScript.setCatalogItem("039c516237b1300054b6a3549dbe5dfc");
```
Scoped CatalogClientScript - setOnChangeVariable(String sys_id)
Runs the catalog client script when a variable value is updated.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>------</td>
</tr>
<tr>
<td>sys_id</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>void</td>
</tr>
</tbody>
</table>

Example
```
var catalogClientScript = new sn_sc.CatalogClientScript();
catalogClientScript.setOnChangeVariable("039c516237b1300054b6a3549dbe5dfc");
```

Scoped CatalogClientScript - setVariableSet(String sys_id)
Associates a variable set with the catalog client script.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>------</td>
</tr>
<tr>
<td>sys_id</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>void</td>
</tr>
</tbody>
</table>

Example
```
var catalogClientScript = new sn_sc.CatalogClientScript();
catalogClientScript.setVariableSet("039c516237b1300054b6a3549dbe5dfc");
```

CatalogItemVariableSet - Scoped

CatalogItemVariableSet API enables you to create and modify service catalog item variable sets using scripts.
CatalogItemVariableSet - create(Boolean standardUpdate)

Inserts the defined catalog item variable set.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>standardUpdate</td>
<td>Boolean</td>
<td>Flag indicating whether to enable the running of engines and workflow.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Enable the running of engines and workflow.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Do not enable the running of engines and workflow.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys_id of the inserted variable record.</td>
</tr>
</tbody>
</table>

// Given an existing catalog item
var catItemSysId = "e0d08b13c3330100c8b837659bba8fb4";
addVariableSets(catItemSysId);

function addVariableSets(catItemSysId) {
    // List of all variable sets to attach
    var myVarSets = [];

    // Create variable set
    var myVarSetAttrs = {"name": "Requester details", "order": "100"};
    var myVarSet = new sn_sc.CatalogItemVariableSet();
    myVarSet.setAttributes(myVarSetAttrs);
    var myVarSetId = myVarSet.create(true);
    myVarSets.push(myVarSetId);
}

CatalogItemVariableSet - deleteRecord(Boolean standardUpdate)

Deletes the defined catalog item variable.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>standardUpdate</td>
<td>Boolean</td>
<td>Flag that indicates whether to enable the running of engines and workflow.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Enable engines and workflow.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Do not enable engines and workflow.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**CatalogItemVariableSet - read(Object columns, Boolean standardUpdate)**

Returns a mapping of catalog item variable set attribute values.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columns</td>
<td>Object</td>
<td>Specify the set of columns that you would like the values for.</td>
</tr>
<tr>
<td>standardUpdate</td>
<td>Boolean</td>
<td>Flag that indicates whether to enable the running of engines and workflow.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Enable engines and workflow.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Do not enable engines and workflow.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>An object mapping column names to values.</td>
</tr>
</tbody>
</table>

**CatalogItemVariableSet - setAttributes(Object attributes)**

Defines attribute values for this catalog item variable set.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attributes</td>
<td>Object</td>
<td>An object mapping column names to values.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

CatalogItemVariableSet - update(Object columnValues, Boolean standardUpdate)

Updates current catalog item variable set with set values.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnValues</td>
<td>Object</td>
<td>An object mapping column names to values.</td>
</tr>
</tbody>
</table>
| standardUpdate | Boolean    | Flag that indicates whether to enable the running of engines and workflow. Valid values:  
• true: Enable engines and workflow.  
• false: Do not enable engines and workflow. |

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

CatalogItemVariableSetM2M - Scoped

CatalogItemVariableSetM2M API enables you to create and modify service catalog item variable set many-to-many (M2Ms) using scripts.

CatalogItemVariableSetM2M - create(Boolean standardUpdate)

Inserts the defined catalog item variable set M2M.
### CatalogItemVariableSetM2M - deleteRecord(Boolean standardUpdate)

Deletes the defined catalog item variable set M2M.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| standardUpdate| Boolean | Flag that indicates whether to enable the running of engines and workflow. Valid values:  
• true: Enable engines and workflow.  
• false: Do not enable engines and workflow. |

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys_id of the inserted variable record.</td>
</tr>
</tbody>
</table>

### CatalogItemVariableSetM2M - read(Object columns, Boolean standardUpdate)

Returns a mapping of catalog item variable set M2M attribute values.
## Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columns</td>
<td>Object</td>
<td>Set of columns that you would like the values for.</td>
</tr>
</tbody>
</table>
| standardUpdate| Boolean    | Flag that indicates whether to enable the running of engines and workflow. Valid values:  
  • true: Enable engines and workflow.  
  • false: Do not enable engines and workflow. |

## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>An object mapping column names to values.</td>
</tr>
</tbody>
</table>

### CatalogItemVariableSetM2M - setAttributes(Object attributes)

Defines attribute values for this catalog item variable set M2M.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attributes</td>
<td>Object</td>
<td>An object mapping column names to values.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

### CatalogItemVariableSetM2M - update(Object columnValues, Boolean standardUpdate)

Updates current catalog item variable set M2M with set values.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnValues</td>
<td>Object</td>
<td>An object mapping column names to values.</td>
</tr>
</tbody>
</table>
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| standardUpdate  | Boolean  | Flag that indicates whether to enable the running of engines and workflow.  
|                 |          | Valid values:  
|                 |          | • true: Enable engines and workflow.  
|                 |          | • false: Do not enable engines and workflow.                                                                                           |

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

### CatCategory - Scoped

`CatCategory` API enables you to create and modify service catalog categories using scripts.

### CatCategory - availableForUserCriteria(String action, Array criteriaIDs)

Adds the **Available For** user criteria to the current catalog category.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| action   | String | Action to perform.  
|          |        | • add: Adds the user criteria to the **Available For** list.  
|          |        | • delete: Deletes the user criteria from the **Available For** list.       |
| criteriaIDs | Array | Array of the user criteria sys_ids.                                        |

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var item = new sn_sc.CatCategory("31bea3d53790200044e0bfc8bcbe5dec");
item.availableForUserCriteria("add", ["0c441abbc6112275000025157c651c89"]);  
```
CatCategory - canView(Boolean isMobile, String userSysId)
Determines whether a specified user can view a specified category on a mobile device or desktop.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>isMobile</td>
<td>Boolean</td>
<td>Flag that indicates whether to verify the user for access on a mobile device or desktop.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Validate for mobile.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Validate for desktop.</td>
</tr>
<tr>
<td>userSysId</td>
<td>String</td>
<td>Sys_id of the user to validate.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the user can view the associated category.</td>
</tr>
<tr>
<td></td>
<td>• true: User can view the category.</td>
</tr>
<tr>
<td></td>
<td>• false: User cannot view the category.</td>
</tr>
</tbody>
</table>

```javascript
var scopedCategoryObj = new sn_sc.CatCategory('7b1262b9530033007444ddeeff7b12ae');
scopedCategoryObj.canView(false, '62826bf03710200044e0bfc8bcbe5df1');
```

CatCategory - create(Boolean standardUpdate)
Insert the defined category.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>standardUpdate</td>
<td>Boolean</td>
<td>Flag that indicates whether to enable the running of engines and workflow.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Enable engines and workflow.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Do not enable engines and workflow.</td>
</tr>
</tbody>
</table>
## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys_id of the inserted variable record.</td>
</tr>
</tbody>
</table>

```javascript
var categoryCreate = new sn_sc.CatCategory();
categoryCreate.setAttributes({"title": "test a scoped category", "sc_catalog": "e0d08b13c3330100c8b837659bba8fb4"});
var categorySysId = categoryCreate.create();
var isValidSysId = categorySysId.match(/^[0-9a-fA-F]{32}$/) === null ? false : true;
global.Assert.assertEquals(true, isValidSysId,"CategorySysId: [" + categorySysId + "] is not valid", true, isValidSysId);
```

### CatCategory - deleteRecord(Boolean standardUpdate)

Deletes the category record on which the CatCategory class was initially instantiated.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>standardUpdate</td>
<td>Boolean</td>
<td>Flag that indicates whether to enable the running of engines and workflow. Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Enable engines and workflow.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Do not enable engines and workflow.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var categoryDelete = new sn_sc.CatCategory(categorySysId);
categoryDelete.deleteRecord();
var category = new sn_sc.CatCategory(categorySysId);
values = category.read({"title": "", "sc_catalog":""}, false);
global.Assert.assertEquals("", values.title,"Category should title");
```
CatCategory - `notAvailableForUserCriteria(String action, Array[] criteriaIDs)`

Adds the **Not Available For** user criteria to a catalog category.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>String</td>
<td>Action to perform.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>add</strong>: Adds the user criteria to the <strong>Not Available For</strong> list.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>delete</strong>: Deletes the user criteria from the <strong>Not Available For</strong> list.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
var item = new sn_sc.CatCategory("31be3d53790200044e0bfc8bcbe5dec");
item.notAvailableForUserCriteria("add", ["0c441abbc6112275000025157c61c89"]);
```

CatCategory - `read(Object columns, Boolean standardUpdate)`

Returns a mapping of the category.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columns</td>
<td>Object</td>
<td>Set of columns that you would like the values for.</td>
</tr>
<tr>
<td>standardUpdate</td>
<td>Boolean</td>
<td>Flag that indicates whether to enable the running of engines and workflow. Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>true</strong>: Enable engines and workflow.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>false</strong>: Do not enable engines and workflow.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Mapping of column names to values.</td>
</tr>
</tbody>
</table>
```javascript
var category = new sn_sc.CatCategory("a96277509f300200b407b89a442e704e");
var values = category.read({"title": ""}, true);
gs.log(values.title);
```

**CatCategory - setAttributes(Object attributes)**

Defines the attribute values for this category.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attributes</td>
<td>Object</td>
<td>Attributes for the new field and value pairs.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var categoryCreate = new sn_sc.CatCategory();
categoryCreate.setAttributes({"title": "test a scoped category", "sc_catalog": "e0d08b13c3330100c8b837659bba8fb4"});
var categorySysId = categoryCreate.create();
var isValidSysId = categorySysId.match(/^[0-9a-fA-F]{32}$/) == null ? false : true;
global.Assert.assertEquals(true, isValidSysId,"CategorySysId: [" + categorySysId + "] is not valid", true, isValidSysId);
```

**CatCategory - setTableName(String tableName)**

Defines the table name for this category.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>Name of the table that extends sc_category.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
```javascript
var categoryRead = new sn_sc.CatCategory(categorySysId);
categoryRead.setTableName("test_category");
var values = categoryRead.read({"title": "," , "sc_catalog": "," , "test": ","}, false);
gs.info(categorySysId);
gs.info(values.title);
gs.info(values.test);
global.Assert.assertEquals("testValue", values.test,"Category extends sc_category and stores its extended value");
```

**CatCategory - update(Object columnValues, Boolean standardUpdate)**

Updates the current category with the specified name-value pairs.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnValues</td>
<td>Object</td>
<td>Mapping of column names to values.</td>
</tr>
<tr>
<td>standardUpdate</td>
<td>Boolean</td>
<td>Flag that indicates whether to enable the running of engines and workflow.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Enable engines and workflow.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Do not enable engines and workflow.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var categoryUpdate = new sn_sc.CatCategory(categorySysId);
categoryUpdate.update({"title": "test changed scoped category"}, true);
values = categoryUpdate.read({"title": "," , "sc_catalog": ","}, false);
global.Assert.assertEquals("test changed scoped category", values.title,"Category should title");
```

**CatCategory - getID()**

Returns the sys_id of the current category.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys_id of the current category.</td>
</tr>
</tbody>
</table>

Example:

```javascript
var cart = new sn_sc.CatCategory("2809952237b1300054b6a3549dbe5dd4");
var categoryID = cart.getID();
gs.info(categoryID);
```

Output:

```
2809952237b1300054b6a3549dbe5dd4
```

CatItem - Scoped

CatItem API enables you to create and modify service catalog items using scripts.

CatItem - availableForUserCriteria(String action, Array criteriaIDs)

Adds the Available For user criteria to the current catalog item.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>String</td>
<td>Action to perform.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• add: Adds the user criteria to the Available For list.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• delete: Deletes the user criteria from the Available For list.</td>
</tr>
<tr>
<td>criteriaIDs</td>
<td>Array</td>
<td>Array of the user criteria sys_ids.</td>
</tr>
</tbody>
</table>
This example shows how to add the specified **Available For** user criteria.

```javascript
var item = new sn_sc.CatItem("31bea3d53790200044e0bfc8bcbe5dec");
item.availableForUserCriteria("add", ["0c441abbc6112275000025157c651c89"]);
```

**CatItem - canViewOnSearch(boolean isMobile)**

Determines if the user has access to view the catalog item on global search.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>isMobile</td>
<td>Boolean</td>
<td>Flag that indicates whether to perform the search for the mobile or desktop view.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Perform the search for the mobile view.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Perform the search for the desktop view.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the user has access to view the catalog item on global search.</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: User has access to view the catalog item on global search.</td>
</tr>
<tr>
<td></td>
<td>• false: User does not have access to view the catalog item on global search.</td>
</tr>
</tbody>
</table>

This code example shows how to check if the user has access to view the catalog item on global search in desktop view.

```javascript
var catItem = new sn_sc.CatItem("04b7e94b4f7b4200086eeed18110c7fd");
var canView = catItem.canViewOnSearch('false');
gs.info("Can view on global search: " + canView);
```
Output:

| Can view on global search: true |

**CatItem - canViewInDomain()**

Verifies whether the current catalog item is viewable in the selected domain (domain selected in the domain picker).

Catalog items in the global domain are available across all domains.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean | Flag that validates whether the current catalog item is viewable in the selected domain. Valid values:  
true: Catalog item is viewable in the domain  
false: Catalog item is not viewable in the domain |

This example shows how to verify whether a catalog item is viewable in the currently selected domain.

```javascript
var catItem = new sn_sc.CatItem("060f3afa3731300054b6a3549dbe5d3e");
gs.info(catItem.canViewInDomain());
```

**CatItem - create(Boolean standardUpdate)**

Inserts the defined catalog item.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>standardUpdate</td>
<td>Boolean</td>
<td>Flag that indicates whether to enable the running of engines and workflow. Valid values:</td>
</tr>
</tbody>
</table>
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| standardUpdate   | Boolean | Flag that indicates whether to enable the running of engines and workflow. Valid values:  
  • true: Enable the running of engines and workflow.  
  • false: Do not enable the running of engines and workflow.  

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| String | Sys_id of the newly created catalog item.        

This code example shows how to create a new catalog item.

```javascript
var catalogItem = new sn_sc.CatItem();
catalogItem.setAttributes({"name":"My FirstCatItem");
catalogItem.setCatalogs(catalogSysId); // Service catalog
catalogItem.setCategories(categorySysId); // Use scoped category

var catItemSysId = catalogItem.create(true); // Returns sys_id of created item
```

**CatItem - deleteRecord(Boolean standardUpdate)**

Deletes the defined catalog item.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| standardUpdate| Boolean | Flag that indicates whether to enable the running of engines and workflow. Valid values:  
  • true: Enable the running of engines and workflow.  
  • false: Do not enable the running of engines and workflow.  

This code example shows how to delete a catalog item.

```javascript
var catItem = new sn_sc.CatItem("a96277509f300200b407b89a442e704e");
catItem.deleteRecord(false);
```

**CatItem - getFirstAccessibleCategoryForSearch(String catalogId)**

Returns the first category that the user can view in a catalog.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>catalogId</td>
<td>String</td>
<td>Sys_id of the catalog.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys_id of the first category that the user can view in a catalog.</td>
</tr>
</tbody>
</table>

**Example:**

```javascript
var CatItem=new sn_sc.CatItem("04b7e94b4f7b42000866ed18110c7fd");
console.log(CatItem.getFirstAccessibleCategoryForSearch("e0d08b13c3330100c8b837659bba8fb4"));
```

**Output:**

d258b953c611227a0146101fb1be7c31

**CatItem - getInvalidDelegatedUsers(Array requestForUsers)**

Returns an array of users for whom the associated item cannot be delegated (requested on behalf of).

The method verifies each of the users passed in the array.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>requestForUsers</td>
<td>Object</td>
<td>Array of user sys_ids to check whether the associated user can acquire the current item and that the item can be requested on behalf of them. User sys_ids are located in the Users [sys_user] table.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>List of user names (Name column from Users [sys_user] table) for whom the item cannot be requested for by a delegate.</td>
</tr>
</tbody>
</table>

This example shows how to obtain a list of user names for whom the item cannot be requested for by a delegate.

```javascript
function getInvalidDelegatedUsers(itemId, userIds) {
    var catItem = new sn_sc.CatItem(itemId);
    var invalidUsers = catItem.getInvalidDelegatedUsers(userIds);
    return invalidUsers;
}
```

**Output:**

```
[
    "Joe Smith",
    "Jenny Brown",
    "Fred Bennet",
    "Alice Jones"
]
```

---

**CatItem - getRecordClass()**

Returns the class name for the current catalog item record.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Class name for the current catalog item record.</td>
</tr>
</tbody>
</table>

Example:

```javascript
var CatItem = new sn_sc.CatItem("04b7e94b4f7b4200086eeed18110c7fd");
console.log(CatItem.getRecordClass());
```

Output:

```javascript
sc_cat_item
```

**CatItem - isDelegationAllowed(String delegatedUser)**

Verifies whether the specified delegated user has acquisition rights to the current service catalog item.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>delegatedUser</td>
<td>String</td>
<td>Optional. Sys_id of the user to request the service catalog item for (delegate). The method verifies whether the user has acquisition rights to the item. Default: Checks whether the calling user has acquisition rights to the item.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean | Flag that indicates whether the user has acquisition rights to the current service catalog item. Valid values:  
  • true: User has acquisition rights to the item.  
  • false: User does not have acquisition rights to the item. |

This code example shows how to determine if delegation is allowed for the catalog item.

```javascript
function canRequestFor(itemId, user) {
    var catItem = new sn_sc.CatItem(itemId);
    var delegatedUser = user;  
    var _result = catItem.isDelegationAllowed(delegatedUser);
    return result;
}
```
var result = catItem.isDelegationAllowed(user);
return result;
}

Output: true

CatItem - isVisibleServicePortal()
Determines if the current catalog item is available in service portal.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the catalog item is available in the Service Portal. Valid values: • true: Available on Service Portal. • false: Not available on Service Portal.</td>
</tr>
</tbody>
</table>

Example:

var catItem = new sn_sc.CatItem("04b7e94b4f7b4200086e6ed18110c7fd");
var catItemAvail = catItem.isVisibleServicePortal();
gs.info("Is item available on Service Portal: " + catItemAvail);

Output:

Is item available on Service Portal: true

CatItem - notAvailableForUserCriteria(String action, Array criteriaIDs)
Adds the Not Available For user criteria to a catalog item.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>String</td>
<td>Action to perform.</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>add</td>
<td></td>
<td>Adds the user criteria to the <strong>Not Available For</strong> list.</td>
</tr>
<tr>
<td>delete</td>
<td></td>
<td>Deletes the user criteria from the <strong>Not Available For</strong> list.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to add the specified **Not Available For** user criteria.

```javascript
var item = new sn_sc.CatItem("31bea3d53790200044e0bfc8bcbe5dec");
item.notAvailableForUserCriteria("add", ["0c441abbc6112275000025157c651c89"]);```

**CatItem - read(Object columns, Boolean standardUpdate)**

Returns a mapping of catalog item attribute values.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| columns          | Object  | Name-value pairs of columns for which to return values \.
| standardUpdate   | Boolean | Flag that indicates whether to enable the running of engines and workflow.  |
|                  |         | Valid values:                                                               |
|                  |         | • true: Enable the running of engines and workflow.                          |
|                  |         | • false: Do not enable the running of engines and workflow.                  |

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Mapping column names to values.</td>
</tr>
</tbody>
</table>

This code example shows how to read a catalog item.
```javascript
var catItem = new sn_sc.CatItem("a96277509f300200b407b89a442e704e");
var values = catItem.read({"name" : "," , "price" : ","}, true);
gs.info("Catalog item name: " + values.name);
gs.info("Catalog item price: " + values.price)
```

**Output:**

Catalog item name: Standard Laptop  
Catalog item price: 1100

---

**CatItem - setAttributes(Object attributes)**  
Defines attribute values for this catalog item.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attributes</td>
<td>Object</td>
<td>Name-value pairs of the columns for which to set.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This code example shows how to set the attribute for a new price field.

```javascript
var catItem = new sn_sc.CatItem();
catItem.setAttribute({"price2" : "12.50"});
```

---

**CatItem - setCatalogs(String catalogs)**  
Defines the catalogs that this catalog item is associated with.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>catalogs</td>
<td>String</td>
<td>Comma-separated list of sys_ids of the catalogs to associate with the item the item.</td>
</tr>
</tbody>
</table>
This example shows how to associate two catalogs to an item.

```javascript
var catItem = new sn_sc.CatItem("060f3afa3731300054b6a3549dbe5d3e");
catItem.setCatalogs("af443cfa5f130100a9ad2572f2b47747", 
"d467125fd7500200d74460affd6103a1");
```

CatItem - setCategories(String categories)

Defines the categories that this catalog item is associated with.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>categories</td>
<td>String</td>
<td>Comma-separated list of sys_ids of the categories to associate with the item the item.</td>
</tr>
</tbody>
</table>

This example shows how to associate two categories to an item.

```javascript
var catItem = new sn_sc.CatItem("060f3afa3731300054b6a3549dbe5d3e");
catItem.setCatagories("af443cfa5f130100a9ad2572f2b47747", 
"d467125fd7500200d74460affd6103a1");
```

CatItem - setImage(String dbImageSysId, String type)

Sets the image of a catalog item to the specified database image record.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbImageSysId</td>
<td>String</td>
<td>Sys_id of the database image.</td>
</tr>
<tr>
<td>type</td>
<td>String</td>
<td>Type of image.</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• picture</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• icon</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to associate an image to a catalog item.

```javascript
var catItem = new sn_sc.CatItem("060f3afa3731300054b6a3549dbe5d3e");
catItem.setImage("d467125fd7500200d74460affd6103a1", "picture");
```

CatItem - setTableName(String tableName)

Defines the table name for this catalog item.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>Name of the table that extends Catalog Item [sc_cat_item].</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to set the name of an extended table.

```javascript
var catItem = new sn_sc.CatItem();
catItem.setTableName("New_catalog_table");
```

CatItem - update(Object columnValues, Boolean standardUpdate)

Updates the current catalog item fields with a specified set of values.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnValues</td>
<td>Object</td>
<td>Name-value pairs of the fields to update and their associated values.</td>
</tr>
<tr>
<td>standardUpdate</td>
<td>Boolean</td>
<td>Flag that indicates whether to enable the running of engines and workflow.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Enable the running of engines and workflow.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Do not enable the running of engines and workflow.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to update the price of an existing catalog item.

```javascript
var catItem = new sn_sc.CatItem("04b7e94b4f7b4200086eeed18110c7fd");
var values = catItem.read({"name" : ", "price" : ", false);
gs.info("Catalog item name: " + values.name);
gs.info("Catalog item price: " + values.price)
catItem.update({"price" : "1100"}, false);
var values = catItem.read({"price" : ", false);
gs.info("Catalog item price: " + values.price)
```

Output:

- Catalog item name: Standard Laptop
- Catalog item price: 1400
- Catalog item price: 1100

### Cell - Scoped, Global

Creates a Cell object as a cell in a table. You can use this API to format the cell and include additional blocks, such as paragraphs and images.

This API is part of the ServiceNow PDF Generation Utilities plugin (com.snc.apppdfgenerator) and is provided within the sn_pdfgeneratorutils namespace. The plugin is activated by default.
This API is a component used with the Document API to generate a PDF.

**Cell - Cell(Number rowspan, Number colspan)**

Instantiates a new `Cell` object. Creates a cell which takes a custom amount of cell spaces in the table.

ℹ️ **Note:** If you provide a negative number for either parameter, the value sets to 1.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rowspan</td>
<td>Number</td>
<td>Number of rows this cell is to occupy.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default: 0</td>
</tr>
<tr>
<td>colspan</td>
<td>Number</td>
<td>Number of columns this cell is to occupy.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default: 0</td>
</tr>
</tbody>
</table>

The following example shows how to create a `Cell` object spanning a single row and single column.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 1);
```

**Cell – addImage(Image image)**

Adds an image to a table cell.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>image</td>
<td><code>Image</code></td>
<td>Image to add to a table cell.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to instantiate an existing image attachment and add it to a cell in a table. For a document usage example, see Document API.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 1);
```
Cell – addParagraph(Paragraph paragraph)

Adds text to a table cell.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>paragraph</td>
<td>Paragraph</td>
<td>Text to add to a table cell.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to instantiate paragraph objects and add the content cells in a table. For a document usage example, see Document API.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var para = new sn_pdfgeneratorutils.Paragraph("Paragraph text.");
cell.addParagraph(para);
```

Cell – addStyle(Style style)

Applies a predefined style to table cells.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>style</td>
<td>Style</td>
<td>Style to apply to this element.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to apply a style to a table cell. For a document usage example, see Document API.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var style = new sn_pdfgeneratorutils.Style("My Style");
cell.addStyle(style);
```
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var style = new sn_pdfgeneratorutils.Style();
style.setBold();

```
cell.addStyle(style);
```

**Cell – addTable(Table table)**

Adds a table to a cell.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>Table</td>
<td>Table to add to a cell.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to instantiate a table object and add it to a cell. For a document usage example, see Document API.

```
var cell = new sn_pdfgeneratorutils.Cell(1, 1);

var columnWidths = [100, 50, 50];

var table = new Table(columnWidths, false);

var cell = new sn_pdfgeneratorutils.Cell(1, 3);

var style = new sn_pdfgeneratorutils.Style();

```

```
cell.addStyle(style);
```

```
cell.addTable(table);
```

**Cell – getColumn()**

Gets the number of the column in which the cell is located.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Number of the column position for a cell.</td>
</tr>
</tbody>
</table>

The following example shows how to get the number of a column position for a cell.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 1);
var columnWidths = [100, 50, 50];
var table = new sn_pdfgeneratorutils.Table(true, columnWidths, false);
table.addCell(cell);
var colNum = cell.getColumn();
gs.info("The column position for cell is ", colNum);
```

Output:

The column position for cell is 1

**Cell – getRow()**

Gets the number of rows in which the cell is located.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Number of the row position for a cell.</td>
</tr>
</tbody>
</table>

The following example shows how to get the number of a row position for a cell.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 1);
var rowWidths = [100, 50, 50];
```
var table = new sn_pdfgeneratorutils.Table(true,rowWidths,false);

table.addCell(cell);

var rowNum = cell.getRow();

gs.info("The row position for cell is " + rowNum);

Output:

The row position for cell is 4927

**Cell – setBackGroundColor(Color color)**

Specifies a background color for the cell.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>color</td>
<td>Color</td>
<td>Background color.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to set cell background color. For a document usage example, see Document API.

```
var cell = new sn_pdfgeneratorutils.Cell(1, 3);

var color = new sn_pdfgeneratorutils.Color([1, 0.9, 0.9]); // provided as array of RGB float values

cell.setBackGroundColor(color);
```

**Cell – setBorder(Number width)**

Sets a border for all four edges of a cell.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>width</td>
<td>Number</td>
<td>Cell border width in points.</td>
</tr>
</tbody>
</table>
The following example shows how to set a cell border of one point to all four edges of a cell. For a document usage example, see Document API.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var width = 1.0;
cell.setBorder(width);
```

**Cell – setBorderBottom(Number width)**

Sets a border for the lower limit of a cell.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>width</td>
<td>Number</td>
<td>Cell border width in points.</td>
</tr>
</tbody>
</table>

The following example shows how to set a cell border. For a document usage example, see Document API.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var width = 1.0;
cell.setBorder(width);
```

**Cell – setBorderLeft(Number width)**

Sets a border for the left limit of a cell.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>width</td>
<td>Number</td>
<td>Cell border width in points.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to set a left-side cell border. For a document usage example, see Document API.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var width = 1.0;
cell.setLeftBorder(width);
```

### Cell – `setBorderRight(Number width)`

Sets a border for the right limit of a cell.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>width</td>
<td>Number</td>
<td>Cell border width in points.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to set a right-side cell border. For a document usage example, see Document API.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var width = 1.0;
cell.setRightBorder(width);
```
Cell – setBorderTop(Number width)
Sets a border for the upper limit of a cell.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>width</td>
<td>Number</td>
<td>Cell border width in points.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to set a top cell border. For a document usage example, see Document API.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var width = 1.0;
cell.setBorderTop(width);
```

Cell – setColoredBorder(Color color, Number width)
Sets a colored border for all four edges of a cell.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>color</td>
<td>Color</td>
<td>Cell border color.</td>
</tr>
<tr>
<td>width</td>
<td>Number</td>
<td>Cell border width in points.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to set a colored cell border. For a document usage example, see Document API.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var width = 1.0;
var color = 'blue';
cell.setColoredBorder(color, width);
```
var cell = new sn_pdfgeneratorutils.Cell(1, 3);

var borderColor = new sn_pdfgeneratorutils.Color([0.8,0.8,0.8]);
var width = 1.0;

cell.setColoredBorderBottom(borderColor, width);

**Cell – setColoredBorderBottom(Color color, Number width)**

Sets a colored border for the lower limit of a cell.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>color</td>
<td>Color</td>
<td>Cell border color.</td>
</tr>
<tr>
<td>width</td>
<td>Number</td>
<td>Cell border width in points.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to set a colored lower cell border. For a document usage example, see Document API.

var cell = new sn_pdfgeneratorutils.Cell(1, 3);

var borderColor = new sn_pdfgeneratorutils.Color([0.8,0.8,0.8]);
var width = 1.0;

cell.setColoredBorderBottom(borderColor, width);

**Cell – setColoredBorderLeft(Color color, Number width)**

Sets a colored border for the left limit of a cell.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>color</td>
<td>Color</td>
<td>Cell border color.</td>
</tr>
<tr>
<td>width</td>
<td>Number</td>
<td>Cell border width in points.</td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
<td></td>
</tr>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to set a colored left cell border. For a document usage example, see Document API.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var borderColor = new sn_pdfgeneratorutils.Color([0.8,0.8,0.8]);
var width = 1.0;

cell.setColoredBorderLeft(borderColor, width);
```

**Cell – setColoredBorderLeft(Color color, Number width)**

Sets a colored border for the left limit of a cell.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>color</td>
<td>Color</td>
<td>Cell border color.</td>
</tr>
<tr>
<td>width</td>
<td>Number</td>
<td>Cell border width in points.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to set a colored right cell border. For a document usage example, see Document API.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var borderColor = new sn_pdfgeneratorutils.Color([0.8,0.8,0.8]);
var width = 1.0;

cell.setColoredBorderRight(borderColor, width);
```

**Cell – setColoredBorderRight(Color color, Number width)**

Sets a colored border for the right limit of a cell.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var borderColor = new sn_pdfgeneratorutils.Color([0.8,0.8,0.8]);
var width = 1.0;

cell.setColoredBorderTop(borderColor, width);
```

**Cell – setColoredBorderTop(Color color, Number width)**

Sets a colored border for the upper limit of a cell.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>color</td>
<td>Color</td>
<td>Cell border color.</td>
</tr>
<tr>
<td>width</td>
<td>Number</td>
<td>Cell border width in points.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to set a colored top cell border. For a document usage example, see Document API.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var borderColor = new sn_pdfgeneratorutils.Color([0.8,0.8,0.8]);
var width = 1.0;
cell.setColoredBorderTop(borderColor, width);
```

**Cell – setHeight(Number height)**

Sets the height of a cell.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>Number</td>
<td>Cell height in points.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how set a cell height of 10 points. For a document usage example, see Document API.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var height = 10;
```
Cell – setHorizontalAlignment(String alignment)

Sets the horizontal alignment for this cell.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>alignment</td>
<td>String</td>
<td>Horizontal alignment setting. Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• center: Align contents to the center.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• left: Align contents to the left.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• right: Align contents to the right.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to set horizontal alignment on a cell. For a document usage example, see Document API.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var alignment = "center";
cell.setHorizontalAlignment(alignment);
```

Cell – setMaxHeight(Number value)

Sets the maximum height of a cell.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>Number</td>
<td>Maximum cell height in points.</td>
</tr>
</tbody>
</table>

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var alignment = "center";
cell.setHorizontalAlignment(alignment);
```
The following example shows how to set a maximum cell height of 409 points. For a document usage example, see Document API.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var height = 409;
cell.setMaxHeight(height);
```

**Cell – setMaxWidth(float value)**
Sets the maximum width of a cell.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>Number</td>
<td>Maximum cell width in points.</td>
</tr>
</tbody>
</table>

The following example shows how to set a maximum cell width of 1530 points. For a document usage example, see Document API.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var width = 1530;
cell.setMaxWidth(width);
```

**Cell – setMinHeight(Number value)**
Sets the minimum height of a cell.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>Number</td>
<td>Minimum cell height in points.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how set a minimum cell height of 12.75 points. For a document usage example, see Document API.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var height = 12.75;
cell.setMinHeight(height);
```

Cell – setMinWidth(Number value)

Sets the minimum width of a cell.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>Number</td>
<td>Minimum cell width in points.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how set a minimum cell width of 50.58 points. For a document usage example, see Document API.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var width = 50.58;
cell.setMinWidth(width);
```
Cell – setOpacity(Number opacity)

Sets the opacity of cell content, borders, and background.

⚠️ Note: This setting affects all child elements of the cell.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>opacity</td>
<td>Number</td>
<td>Float decimal value from 0 through 1, in which 0 is transparent and 1 is fully opaque. Default: 0</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to set the opacity of a cell.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var opacity = 0.5;
cell.setOpacity(opacity);
```

Cell – setPadding(Number padding)

Sets the padding of all four sides of a cell to the same width.

See also:

- setPaddingBottom()
- setPaddingLeft()
- setPaddingRight()
- setPaddingTop()

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>padding</td>
<td>Number</td>
<td>Padding width in points as a decimal value.</td>
</tr>
</tbody>
</table>
The following example shows how to set the bottom cell to one point. For a document usage example, see Document API.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var padding = 1.0;
cell.setPaddingBottom(padding);
```

**Cell – setPaddingBottom(Number padding)**

Sets the value of the bottom padding width of a cell.

See also:
- `setPadding()`
- `setPaddingLeft()`
- `setPaddingRight()`
- `setPaddingTop()`

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>padding</td>
<td>Number</td>
<td>Padding width in points as a decimal value.</td>
</tr>
</tbody>
</table>

The following example shows how to set bottom cell padding to one point. For a document usage example, see Document API.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var padding = 1.0;
```
cell.setPaddingBottom(padding);

**Cell – setPaddingLeft(Number padding)**

Sets the value of the left padding width of a cell.

See also:
- setPadding()
- setPaddingBottom()
- setPaddingRight()
- setPaddingTop()

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>padding</td>
<td>Number</td>
<td>Padding width in points as a decimal value.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to set left cell padding to one point. For a document usage example, see Document API.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var padding = 1.0;
cell.setPaddingLeft(padding);
```

**Cell – setPaddingRight(Number padding)**

Sets the value of the right padding width of a cell.

See also:
- setPadding()
- setPaddingBottom()
- setPaddingLeft()
- setPaddingTop()
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>padding</td>
<td>Number</td>
<td>Padding width in points as a decimal value.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to set right cell padding to one point. For a document usage example, see [Document API](#).

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var padding = 1.0;
cell.setPaddingRight(padding);
```

**Cell – setPaddingTop(Number padding)**

Sets the value of the top padding width of a cell.

See also:
- `setPadding()`
- `setPaddingBottom()`
- `setPaddingLeft()`
- `setPaddingRight()`

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>padding</td>
<td>Number</td>
<td>Padding width in points as a decimal value.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
The following example shows how to set top cell padding to one point. For a document usage example, see Document API.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var padding = 1.0;

cell.setPaddingTop(padding);
```

**Cell – setTextAlignment(String alignment)**

Sets the text alignment of this cell.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| alignment | String | Text alignment position. Valid values:
|           |        | • text-center: Aligns text to the center.
|           |        | • text-justified: Modifies the space between characters to completely fill text between the left and right sides. The final line is left-aligned.
|           |        | • text-justified-all: Justifies text alignment including the final line.
|           |        | • text-left: Align text to the left.
|           |        | • text-right: Align text to the right. |

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to set the cell text to left alignment.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var alignment = "text-left";

cell.setTextAlignment(alignment);
```
Cell – setVerticalAlignment(String alignment)
Sets the vertical alignment for this cell.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>alignment</td>
<td>String</td>
<td>Vertical alignment setting. Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• bottom: Aligns contents to the bottom.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• mid: Aligns contents to the center.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• top: Aligns contents to the top.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to set vertical alignment on a cell. For a document usage example, see Document API.

```javascript
var cell = new sn_pdfgeneratorutils.Cell(1, 3);
var alignment = "mid";
cell.setVerticalAlignment(alignment);
```

CertificateEncryption - Scoped

APIs available for encrypting certificates in scoped applications.

Use these methods to generate a hash for the certificate, sign data using a private key, and generate a message authentication code.

Instantiates a CertificateEncryption object in a scoped application.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
CertificateEncryption - generateMac(String key, String algorithm, String data)

Generates the Message Authentication Code (MAC), which is used to authenticate a message.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>String</td>
<td>Key to use to sign the message. Must be Base64 encoded.</td>
</tr>
<tr>
<td>algorithm</td>
<td>String</td>
<td>Algorithm to use to generate the MAC: HmacSHA256, HmacSHA1, HmacMD5, and so on.</td>
</tr>
<tr>
<td>data</td>
<td>String</td>
<td>Data to process.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>MAC in base64 format.</td>
</tr>
</tbody>
</table>

Example

```javascript
var mac = new CertificateEncryption;
var key = "sample_key";
key = gs.base64Encode(key);
mac.generateMac(key, "HmacSHA256", "sample_data");
```

CertificateEncryption - getThumbPrint(String certificateID, String algorithm)

Generates a hash (SHA-1, SHA-256, and so on) for the certificate from Trust Store Cert.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>algorithm</td>
<td>String</td>
<td>SHA-1, SHA-256, and so on</td>
</tr>
<tr>
<td>Returns</td>
<td></td>
<td></td>
</tr>
<tr>
<td>---------</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>String</td>
<td>Thumbprint in base64 format.</td>
<td></td>
</tr>
</tbody>
</table>

**CertificateEncryption - getThumbPrintFromKeystore(String certificateID, String alias, String algorithm)**

Generates a hash (SHA-1, SHA-256, and so on) for the certificate from the keystore entry.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>alias</td>
</tr>
<tr>
<td>algorithm</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

**CertificateEncryption - sign(String certificateID, String alias, String aliaspassword, String algorithm, String datatosign)**

Signs the data using the private key and the specified algorithm.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>alias</td>
</tr>
<tr>
<td>aliaspassword</td>
</tr>
<tr>
<td>algorithm</td>
</tr>
</tbody>
</table>
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>• NONEwithRSA</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• MD2withRSA</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• MD5withRSA</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SHA1withRSA</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SHA224withRSA</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SHA256withRSA</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SHA384withRSA</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SHA512withRSA</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• NONEwithDSA</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SHA1withDSA</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SHA224withDSA</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SHA256withDSA</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SHA512withECDSA</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SHA1withECDSA</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SHA224withECDSA</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SHA256withECDSA</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SHA384withECDSA</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SHA512withECDSA</td>
</tr>
</tbody>
</table>

| datatosign | String | Data to sign. |

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Signed data in base64 format.</td>
</tr>
</tbody>
</table>

```javascript
var ce = new CertificateEncryption;
ce.sign("recordID", "alias", "password", "SHA1withRSA", "sign this data");
```

### ChangeCollisionHelper - Global

Helper functions found in the Change Management Collision Detector Plugin.
Use these methods in server side scripts, or when using AJAX calls on the client. You must have the Change Management Collision Detector Plugin installed to use these methods.

**ChangeCollisionHelper - addCiToChangeAffectedCis(String ci, String changeld)**

Adds the CI to the change's affected CI list.

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td><strong>Type</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>ci</td>
<td>String</td>
<td>The sys_id of the configuration item</td>
</tr>
<tr>
<td>changeld</td>
<td>String</td>
<td>The change record's sys_id</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td><strong>Description</strong></td>
<td></td>
</tr>
<tr>
<td>void</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**ChangeCollisionHelper - getAffectedCisByChangeld(String changeld)**

Returns the Affected CI sys_ids for the given change.

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td><strong>Type</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>changeld</td>
<td>String</td>
<td>A change record's sys_id</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td><strong>Description</strong></td>
<td></td>
</tr>
<tr>
<td>Array</td>
<td>An array of sys_ids of affected CIs.</td>
<td></td>
</tr>
</tbody>
</table>

**ChangeCollisionHelper - getBlackoutsByDate(GlideDateTime startDate, GlideDateTime endDate)**

Returns any blackout that overlap the period defined by startDate and endDate.

© 2021 ServiceNow, Inc. All rights reserved. ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>startDate</td>
<td>GlideDateTime</td>
<td>The beginning date</td>
</tr>
<tr>
<td>endDate</td>
<td>GlideDateTime</td>
<td>The ending date</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>An array of blackouts (blackoutId:stringSpan).</td>
</tr>
</tbody>
</table>

**ChangeCollisionHelper - getChangesWithAffectedCi(String ci, GlideDateTime startDate, GlideDateTime endDate)**

Returns changes scheduled in the timespan (defined by startDate and endDate) that have the given CI in their Affected CIs list.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ci</td>
<td>String</td>
<td>The configuration item's sys_id</td>
</tr>
<tr>
<td>startDate</td>
<td>GlideDateTime</td>
<td>The beginning date</td>
</tr>
<tr>
<td>endDate</td>
<td>GlideDateTime</td>
<td>The ending date of the time span</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>An array of change record's sys_ids</td>
</tr>
</tbody>
</table>

**ChangeCollisionHelper - getChangesWithCi(String ci, GlideDateTime startDate, GlideDateTime endDate)**

Returns the changes that are in the timespan (startDate, endDate) and that are linked to the given CI.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ci</td>
<td>String</td>
<td>The configuration item’s sys_id</td>
</tr>
<tr>
<td>startDate</td>
<td>GlideDateTime</td>
<td>The beginning date</td>
</tr>
<tr>
<td>endDate</td>
<td>GlideDateTime</td>
<td>The ending date of the time span</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>An array of sys_ids for change records</td>
</tr>
</tbody>
</table>

**ChangeCollisionHelper - getCiMaintenanceSchedule(String ci)**

Returns the Maintenance Schedule for a CI.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ci</td>
<td>String</td>
<td>The configuration item’s sys_id</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**ChangeCollisionHelper - getDependants(String ci)**

Returns all the CIs that depend on the given CI.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ci</td>
<td>String</td>
<td>A configuration item’s sys_id</td>
</tr>
</tbody>
</table>
### ChangeCollisionHelper - getDependencies(String ci)

Returns all the CIs that the given CI depends on.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ci</td>
<td>String</td>
<td>The configuration item's sys_id</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>An array of CIs</td>
</tr>
</tbody>
</table>

### ChangeCollisionHelper - isCiInAffectedCis(String ci, String changecId)

Check if an CI is already in the change's affected CIs list.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ci</td>
<td>String</td>
<td>The sys_id of the configuration item</td>
</tr>
<tr>
<td>changecId</td>
<td>String</td>
<td>The change record's sys_id</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the CI already is in the change's affected CI list.</td>
</tr>
</tbody>
</table>

### ChangeCollisionHelper - isDateInCiMaintenanceWindows(GlideDateTime startDate, GlideDateTime endDate, String maintenanceWindow)

Checks if the time span defined by startDate and endDate falls in the CI's maintenance window.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>startDate</td>
<td>GlideDateTime</td>
<td>The beginning date</td>
</tr>
<tr>
<td>endDate</td>
<td>GlideDateTime</td>
<td>The ending date</td>
</tr>
<tr>
<td>maintenanceWindow</td>
<td>String</td>
<td>The configuration item's sys_id</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the time span is in the CI's maintenance window</td>
</tr>
</tbody>
</table>

**ChangeConflict - Global**

Helper functions found in the Change Management Collision Detector Plugin. Use these methods in server side scripts, or when using AJAX calls on the client. You must have the Change Management Collision Detector Plugin installed to use these methods.

**ChangeConflict(String cild, String changeld, Number type)**

Creates an instance of ChangeConflict.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cild</td>
<td>String</td>
<td>A configuration item's sys_id</td>
</tr>
<tr>
<td>changeld</td>
<td>String</td>
<td>A change request's sys_id</td>
</tr>
<tr>
<td>type</td>
<td>Number</td>
<td>A value from the conflict's type choice list</td>
</tr>
</tbody>
</table>

**ChangeConflict - toString()**

Returns a string representation of the conflict.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
## ChangeConflictHandler - Global

Helper functions found in the Change Management Collision Detector Plugin. Use these methods in server side scripts, or when using AJAX calls on the client. You must have the Change Management Collision Detector Plugin installed to use these methods.

### ChangeConflictHandler - addChangeConflict(String chgConflict)

Adds the Change Conflict to a Change Conflict Container.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>chgConflict</td>
<td>String</td>
<td>The sys_id of the change conflict</td>
</tr>
</tbody>
</table>

### ChangeConflictHandler - changeConflictHandler()

Creates an instance of ChangeConflictHandler.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### ChangeConflictHandler - deleteConflictsByChangeId(String changeld)

Deletes conflicts that are associated with the same change request (by sys_id).

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>changeld</td>
<td>String</td>
<td>The sys_id of the change request</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**ChangeConflictHandler - getConflicts()**

Returns an array of Change Conflicts from a Change Conflict Container.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>An array of change conflicts</td>
</tr>
</tbody>
</table>

**ChangeConflictHandler - saveConflicts()**

Writes out the Change Conflicts in a Change Conflict Container array to individual Change Conflict records.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>

CheckDefinitionTestBuilder API - Scoped

The `CheckDefinitionTestBuilder` script include enables building test check requests on check definitions.

This API requires the Agent Client Collector Framework (sn_agent) store application and is provided within the `sn_agent` namespace. For more information, refer to Agent Client Collector.

For the REST API solution, refer to Agent Client Collector API.

This API includes methods that enable the following:

- Set the check definition to test
- Set the configuration item to run the test against

You can also specify one of the following identifiers to use during the test:

- Credential sys_id
- Credential alias id
- Credential name

**CheckDefinitionTestBuilder - CheckDefinitionTestBuilder()**

Creates an `CheckDefinitionTestBuilder` instance.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>---</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

The following example shows how to initialize `CheckDefinitionTestBuilder`.

```csharp
var builder = new sn_agent.CheckDefinitionTestBuilder();
```

**CheckDefinitionTestBuilder - build()**

Builds the test check request with the arguments set.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>---</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>JSON object with two attributes – the test result record ID and an error. If the build is successful, the test result ID returns and error is null. If an error occurs during the build, the test result ID is null and the error displays.</td>
</tr>
</tbody>
</table>

The following example shows how build a test check request:

```javascript
var checkId = "158279505372b30034b8ddee7f7b1270";
var ciId = "cc0dcc855374301062d1ddee7f7b12b0";
var builder = new sn_agent.CheckDefinitionTestBuilder();

var testResultJson = builder.withCheckId(checkId).withCiId(ciId).build();

if (!gs.nil(testResultJson.error))
gs.error(testResultJson.error);
```

**CheckDefinitionTestBuilder - withCheckId(String checkId)**

Sets the sys_id of the check definition to test.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>checkId</td>
<td>String</td>
<td>Sys_id of the check definition listed in the Check Definitions [sn_agent_check_def] table.</td>
</tr>
</tbody>
</table>

The following example shows how create a test check:

```javascript
var checkId = "158279505372b30034b8ddee7f7b1270";
var ciId = "cc0dcc855374301062d1ddee7f7b12b0";
var builder = new sn_agent.CheckDefinitionTestBuilder();
var testResultJson = builder.withCheckId(checkId).withCiId(ciId).build();
if (!gs.nil(testResultJson.error))
gs.error(testResultJson.error);`
CheckDefinitionTestBuilder - withCiId(String ciId)
Sets the sys_id of the configuration item to run the test against.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ciId</td>
<td>String</td>
<td>Sys_id of a CMDB Configuration Item.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CheckDefinitionTestBuilder</td>
<td>The builder instance the method was invoked for.</td>
</tr>
</tbody>
</table>

The following example shows how to create a test check request with:

```javascript
var checkId = "158279505372b30034b8ddeeff7b1270";
var ciId = "cc0dcc855374301062d1ddeeff7b12b0";
var builder = new sn_agent.CheckDefinitionTestBuilder();
var testResultJson = builder.withCheckId(checkId).withCiId(ciId).build();
if (!gs.nil(testResultJson.error))
  gs.error(testResultJson.error);
```

CheckDefinitionTestBuilder - withCredentialsAliasId(String credentialsAliasId)
Sets the credentials alias sys_id to use during the test.

⚠️ Note: Running this removes any previous assignment done by calling withCredentialsName, withCredentialsAliasId or withCredentialsAliasName.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>credentialsAliasId</td>
<td>String</td>
<td>Sys_id of a credentials record.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CheckDefinitionTestBuilder</td>
<td>The builder instance the method was invoked for.</td>
</tr>
</tbody>
</table>

The following example shows how create a test check and set the credentials alias ID.
var checkId = "158279505372b30034b8ddee7b1270";
var credAlias = "<sys_id>";
var builder = new sn_agent.CheckDefinitionTestBuilder();
var testResultJson =
    builder.withCheckId(checkId).withCredentialsAliasId(credAlias).build();
if (!gs.nil(testResultJson.error))
    gs.error(testResultJson.error);

CheckDefinitionTestBuilder - withCredentialsAliasName(String credentialsAliasName)

Sets the credentials alias name to use during the test. If the given value matches the name of multiple credentials aliases records, then one of them is chosen randomly.

Note: Running this removes any previous assignment done by calling withCredentialsName, withCredentialsAliasId or withCredentialsAliasName.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>credentialsAliasName</td>
<td>String</td>
<td>Name of a credentials alias.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CheckDefinitionTestBuilder</td>
<td>builder instance the method was invoked for.</td>
</tr>
</tbody>
</table>

The following example shows how create a test check and set the credentials alias name.

var checkId = "158279505372b30034b8ddee7b1270";
var credentialsAliasName = "credentialsAliasName";
var builder = new sn_agent.CheckDefinitionTestBuilder();
var testResultJson =
    builder.withCheckId(checkId).withCredentialsAliasName(credentialsAliasName).build();
if (!gs.nil(testResultJson.error))
    gs.error(testResultJson.error);

CheckDefinitionTestBuilder - withCredentialsId(String credentialsId)

Sets the credentials sys_id to use during the test.
**Note:** Running this removes any previous assignment done by calling `withCredentialsName`, `withCredentialsAliasId` or `withCredentialsAliasName`.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>credentialsId</td>
<td>String</td>
<td>Sys_id of a credentials record.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CheckDefinitionTestBuilder</td>
<td>The builder instance the method was invoked for.</td>
</tr>
</tbody>
</table>

The following example shows how create a test check and set the credentials ID.

```javascript
var checkId = "158279505372b30034b8d2eef7b1270";
var credID = "<sys_id>";
var builder = new sn_agent.CheckDefinitionTestBuilder();
var testResultJson = builder.withCheckId(checkId).withCredentialsId(credID).build();
if (!gs.nil(testResultJson.error))
    gs.error(testResultJson.error);
```

**CheckDefinitionTestBuilder - withCredentialsName(String credentialsName)**

Sets the credentials name to use during the test. If the given value is the name of several credentials records, then one of them is chosen randomly.

**Note:** Running this removes any previous assignment done by calling `withCredentialsName`, `withCredentialsAliasId` or `withCredentialsAliasName`.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>credentialsName</td>
<td>String</td>
<td>Name of the credentials record.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CheckDefinitionTestBuilder</td>
<td>The builder instance the method was invoked for.</td>
</tr>
</tbody>
</table>
The following example shows how to create a test check and set the credentials name.

```javascript
var checkId = "158279505372b30034b8dfeeff7b1270";
var credname = "credentialsName";
var builder = new sn_agent.CheckDefinitionTestBuilder();
var testResultJson = builder.withCheckId(checkId).withCredentialsName(credName).build();
if (!gs.nil(testResultJson.error))
gs.error(testResultJson.error);
```

**CheckInstanceTestBuilder API - Scoped**

The `CheckInstanceTestBuilder` script includes enables building test check requests on check instances.

This API requires the Agent Client Collector Framework (sn_agent) store application and is provided within the `sn_agent` namespace. For more information, refer to `Agent Client Collector`.

For the REST API solution, refer to `Agent Client Collector API`.

This API includes methods that enable the following:

- Set the check instance to test
- Set the configuration item to run the test against

You can also specify one of the following identifiers to use during the test:

- Credential sys_id
- Credential alias id
- Credential name

**CheckInstanceTestBuilder - CheckInstanceTestBuilder()**

Creates an `CheckInstanceTestBuilder` instance.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to initialize `CheckInstanceTestBuilder`.

```javascript
var builder = new sn_agent.CheckInstanceTestBuilder();
```
CheckInstanceTestBuilder - build()
Builds the test check request with the arguments set.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>JSON object with two attributes – the test result record ID and an error. If the build is successful, the test result ID returns and error is null. If an error occurs during the build, the test result ID is null and the error displays.</td>
</tr>
</tbody>
</table>

The following example shows how build a test check request:

```java
var checkId = "158279505372b30034b8ddeeff7b1270";
var ciId = "cc0dcc855374301062d1ddeeff7b12b0";
var builder = new sn_agent.CheckInstanceTestBuilder();

var testResultJson = builder.withCheckId(checkId).withCiId(ciId).build();

if (!gs.nil(testResultJson.error))
    gs.error(testResultJson.error);
```

CheckInstanceTestBuilder - withCheckId(String checkId)
Sets the sys_id of the check definition to test.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>checkId</td>
<td>String</td>
<td>Sys_id of the check definition listed in the Check Definitions [sn_agent_check_def] table.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CheckInstanceTestBuilder</td>
<td>builder instance the method was invoked for.</td>
</tr>
</tbody>
</table>
The following example shows how to create a test check.

```javascript
var checkId = "158279505372b30034b8ddee77b1270";
var ciId = "cc0dcc855374301062d1ddee77b12b0";
var builder = new sn_agent.CheckInstanceTestBuilder();
var testResultJson = builder.withCheckId(checkId).withCiId(ciId).build();
if (!gs.nil(testResultJson.error))
    gs.error(testResultJson.error);
```

**CheckInstanceTestBuilder - withCiId(String ciId)**

Sets the sys_id of the configuration item to run the test against.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ciId</td>
<td>String</td>
<td>Sys_id of a CMDB Configuration Item.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CheckInstanceTestBuilder</td>
<td>builder instance the method was invoked for.</td>
</tr>
</tbody>
</table>

The following example shows how to create a test check request with

```javascript
var checkId = "158279505372b30034b8ddee77b1270";
var ciId = "cc0dcc855374301062d1ddee77b12b0";
var builder = new sn_agent.CheckInstanceTestBuilder();
var testResultJson = builder.withCheckId(checkId).withCiId(ciId).build();
if (!gs.nil(testResultJson.error))
    gs.error(testResultJson.error);
```

**CheckInstanceTestBuilder - withCredentialsAliasId(String credentialsAliasId)**

Sets the credentials alias sys_id to use during the test.

⚠️ **Note:** Running this removes any previous assignment done by calling withCredentialsName, withCredentialsAliasId or withCredentialsAliasName.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>credentialsAliasId</td>
<td>String</td>
<td>Sys_id of a credentials alias record.</td>
</tr>
</tbody>
</table>
The following example shows how to create a test check and set the credentials alias ID.

```javascript
var checkId = "158279505372b30034b8ddee0ff7b1270";
var credAlias = "<sys_id>";
var builder = new sn_agent.CheckInstanceTestBuilder();
var testResultJson =
    builder.withCheckId(checkId).withCredentialsAliasId(credAlias).build();
if (!gs.nil(testResultJson.error))
    gs.error(testResultJson.error);
```

---

**CheckInstanceTestBuilder - withCredentialsAliasName(String credentialsAliasName)**

Sets the credentials alias name to use during the test. If the given value matches the name of multiple credentials aliases records, then one of them is chosen randomly.

ℹ️ **Note:** Running this removes any previous assignment done by calling `withCredentialsName`, `withCredentialsAliasId` or `withCredentialsAliasName`.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>credentialsAliasName</td>
<td>String</td>
<td>Name of a credentials alias.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CheckInstanceTestBuilder</td>
<td>builder instance the method was invoked for.</td>
</tr>
</tbody>
</table>

The following example shows how to create a test check and set the credentials alias name.

```javascript
var checkId = "158279505372b30034b8ddee0ff7b1270";
var credentialsAliasName = "credentialsAliasName";
var builder = new sn_agent.CheckInstanceTestBuilder();
```
```javascript
var testResultJson = 
  builder.withCheckId(checkId).withCredentialsAliasName(credentialsAliasName).build();
if (!gs.nil(testResultJson.error))
  gs.error(testResultJson.error);
```

**CheckInstanceTestBuilder - withCredentialsId(String credentialsId)**

Sets the credentials sys_id to use during the test.

⚠️ **Note**: Running this removes any previous assignment done by calling
`withCredentialsName`, `withCredentialsAliasId` or `withCredentialsAliasName`.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>credentialsId</td>
<td>String</td>
<td>Sys_id of a credentials record.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CheckInstanceTestBuilder</td>
<td>builder instance the method was invoked for.</td>
</tr>
</tbody>
</table>

The following example shows how create a test check and set the credentials ID.

```javascript
var checkId = "158279505372b30034b8d9eff7b1270";
var credID = "<sys_id>";
var builder = new sn_agent.CheckInstanceTestBuilder();
var testResultJson = builder.withCheckId(checkId).withCredentialsId(credID).build();
if (!gs.nil(testResultJson.error))
  gs.error(testResultJson.error);
```

**CheckInstanceTestBuilder - withCredentialsName(String credentialsName)**

Sets the credentials name to use during the test. If the given value is the name of
several credentials records, then one of them is chosen randomly.

⚠️ **Note**: Running this removes any previous assignment done by calling
`withCredentialsName`, `withCredentialsAliasId` or `withCredentialsAliasName`. 
The following example shows how to create a test check and set the credentials name.

```javascript
var checkId = "158279505372b30034b8ddee7b1270";
vartestResultJson = builder.withCheckId(checkId).withCredentialsName(credName).build();
if (!gs.nil(testResultJson.error))
gs.error(testResultJson.error);
```

**CheckInstanceTestBuilder - withProxyAgentId(String agentId)**

Sets the agent to run the test. Allowed only in case the tested check instance and policy are proxy.

The following example shows how to create a test check and set the proxy agent ID.

```javascript
var checkId = "158279505372b30034b8ddee7b1270";
varagentId = "<agentId>";
```
var builder = new sn_agent.CheckInstanceTestBuilder();
var testResultJson = builder.withCheckId(checkId).withAgentId(agentId).build();
if (!gs.nil(testResultJson.error))
  gs.error(testResultJson.error);

CIData - Global

Utility class for working with CI data structures in JavaScript.

Instances of this class represent a CI (both its base record and any related lists), and the provided methods allow loading from or storing both the base record and related lists.

This class acts as a container for simple classes acting as maps of property name/value pairs. This class contains three kinds of such maps.

• A single map representing the base CI table entry (such as one row cmdb_ci_linux_server and its superclasses). This map can be retrieved with the `getData()` method.

• Arrays of maps representing the instances of related lists, with each array representing a single related list and each element of such an array representing a single row of that related list. These arrays can be retrieved with the `getRelatedList()` method.

• Arrays of maps representing the instances of many-to-many tables, with each array representing a single many-to-many table and each element of such an array representing a single row of that many-to-many table. These arrays can be retrieved with the `getM2MTable()` method.

Use with any server-side discovery script.

CIData - addRelatedList(Array relatedList)

Adds the specified related list to this instance.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>relatedList</td>
<td>Array</td>
<td>Related list to add.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
This example creates and adds a related list to the CIData object.

```javascript
var ciDataObj = new CIData();
var rl = new CIRelatedList('cmdb_serial_number', 'cmdb_ci');
var sr = {};
  sr['serial_number_type'] = "bios";
  sr['serial_number'] = "1BC5E4z89246";
  sr['valid'] = "true";
rl.addRec(sr);
  ciDataObj.addRelatedList(rl);
```

CIData - CIData(String debugFlag)

Creates an instance of the CIData class.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| debugFlag | String | Flag that indicates whether to enable debug logging. Valid values:  
  • True: Debug logging is enabled.  
  • False: Debug logging is not enabled. |

This example creates and adds a related list to the CIData object.

```javascript
var ciDataObj = new CIData();
var rl = new CIRelatedList('cmdb_serial_number', 'cmdb_ci');
var sr = {};
  sr['serial_number_type'] = "bios";
  sr['serial_number'] = "1BC5E4z89246";
  sr['valid'] = "true";
rl.addRec(sr);
  ciDataObj.addRelatedList(rl);
```

CIData - convertRelatedList(String sensor, String tableName, String refField, String keyName)

Converts the specified related list to a related list in a given sensor.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sensor</td>
<td>String</td>
<td>The sensor</td>
</tr>
<tr>
<td>tableName</td>
<td>String</td>
<td>The table name</td>
</tr>
<tr>
<td>refField</td>
<td>String</td>
<td>The reference field</td>
</tr>
<tr>
<td>keyName</td>
<td>String</td>
<td>The key name</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

CIData - fromXML(String xml)

Initializes the current CIData instance from the specified XML string.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xml</td>
<td>String</td>
<td>An XML string</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

CIData - getData()

Gets the data map in the base CI record.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Returns</td>
<td></td>
<td></td>
</tr>
<tr>
<td>---------</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td><strong>Description</strong></td>
<td></td>
</tr>
<tr>
<td>Object</td>
<td>The data map</td>
<td></td>
</tr>
</tbody>
</table>

**CIData - getM2MTable(String table, String refField)**

Gets an array of data maps in the given many-to-many list (to this CI).

The array is not in any particular order. If this is not a many-to-many list, returns an empty array.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>String</td>
<td>The name of the table containing the related list. In the case of a many-to-many list, this is the name of the many-to-many table, not the target table.</td>
</tr>
<tr>
<td>refField</td>
<td>String</td>
<td>The name of the field in the related list that refers to this CI. In the case of a many-to-many list, this is the name of the referring field in the many-to-many table, not in the target table.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
</tr>
<tr>
<td>Array</td>
</tr>
</tbody>
</table>

**CIData - getRelatedList(String table, String refField)**

Gets an array of maps of data in the given related list (to this CI).

The array is not in any particular order. In the case of a many-to-many list, this will be an array of instances of the target table, not the many-to-many table. For example, given 'cmdb_software_instance' and 'installed_on' (a many-to-many table and the field that refers to a CI), this method will return an array of maps representing cmdb_ci_spkg (the target table) instances.
## Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>String</td>
<td>Name of the table containing the related list. In the case of a many-to-many list, this is the name of the many-to-many table, not the target table.</td>
</tr>
<tr>
<td>refField</td>
<td>String</td>
<td>Name of the field in the related list that refers to this CI. In the case of a many-to-many list, this is the name of the referring field in the many-to-many table, not in the target table.</td>
</tr>
</tbody>
</table>

## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>An array of maps of data in the specified related list.</td>
</tr>
</tbody>
</table>

### CIData - getRelatedListInstance(String table, String refField)

Returns the instance of CIRelatedList for the given list.

## Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>String</td>
<td>Name of the table containing the related list. In the case of a many-to-many list, this is the name of the many-to-many table, not the target table.</td>
</tr>
<tr>
<td>refField</td>
<td>String</td>
<td>Name of the field in the related list that refers to this CI. In the case of a many-to-many list, this is the name of the referring field in the many-to-many table, not in the target table.</td>
</tr>
</tbody>
</table>

## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Instance of the CIRelatedList for the specified list.</td>
</tr>
</tbody>
</table>

### CIData - init()

Initializes this instance in preparation for loading a new CI.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var cdta = CIData('false');
cdta.init();
```

**CIData - loadFromCI(String cmdb_ci)**

Loads the current data from a specified sys_id.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmdb_ci</td>
<td>String</td>
<td>The sys_id of the CI</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>The current data from the specified CI</td>
</tr>
</tbody>
</table>

```javascript
var cdta = CIData('false');
cdta.init();
cdta.loadFromCI('ccaf9c0a8016400b98a06818d57c7');
```

**CIData - toString()**

Converts the name of this instance to a string.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Name of the instance</td>
</tr>
</tbody>
</table>

CIData - toXML()

Returns an XML string containing a serialized version of this instance (including any related lists).

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The XML string containing a serialized version of this instance and any related lists.</td>
</tr>
</tbody>
</table>

```javascript
var cdata = CIData();
cdata.toXML();
```

CIIdentification - Global

Main class for discovery CI identification.

Use this with any server-side discovery script for CI identification.

CIIdentification - CIIdentification(String ciData, String logger)

Creates an instance of the CIIdentification class.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ciData</td>
<td>String</td>
<td>The CI data to identify</td>
</tr>
<tr>
<td>logger</td>
<td>String</td>
<td>The discovery logger</td>
</tr>
</tbody>
</table>

### CIIdentification - debug(String msg)

Logs a message to the CI Identification log if debug logging is turned on.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>msg</td>
<td>String</td>
<td>The message to log</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

### CIIdentification - process()

Identifies the CI. This is the entry point for the entire CI Identification process.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDResult</td>
<td>The result returned by the identifier</td>
</tr>
</tbody>
</table>

### CIIdentifierResult - Global

Gets the result returned by an identifier. Use with any server-side discovery script.
CIIdentifierResult - CIIdentifierResult(Array matched, Boolean matchable, Boolean terminatedChain)

Creates an instance of the CIIdentifierResult class.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>matched</td>
<td>Array</td>
<td>An array of sys_ids of matching CIs; may have any number of entries including zero.</td>
</tr>
<tr>
<td>matchable</td>
<td>Boolean</td>
<td>True if identifier had sufficient data to match</td>
</tr>
<tr>
<td>terminatedChain</td>
<td>Boolean</td>
<td>True if the identifier chain should stop processing filters. False to continue.</td>
</tr>
</tbody>
</table>

CimCIData - Global

Provides a wrapper for CIM CI data manipulation.

Use with any server-side discovery script.

CimCIData - addSerial(String type, String serial)

Adds a serial number to the current CI, by type.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>String</td>
<td>The serial number type. If out-of-box, use the CimCIData.serialType enum.</td>
</tr>
<tr>
<td>serial</td>
<td>String</td>
<td>The serial number</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The current CI</td>
</tr>
</tbody>
</table>

CimCIData - SerialRecord(String type, String serial)

Creates a new serial record.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>String</td>
<td>The serial type to assign to the CI. If out-of-box, uses the CimCIData.serialType enum.</td>
</tr>
<tr>
<td>serial</td>
<td>String</td>
<td>The serial number to assign.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

CimCIData - setMakeAndModel(String make, String model)

Sets the make and model for the current CI.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>make</td>
<td>String</td>
<td>The manufacturer</td>
</tr>
<tr>
<td>model</td>
<td>String</td>
<td>The model</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

CimIDSensor - Global

Performs identification for CIM probe results.

Use in any server-side script to perform identification of CIM probe results.

CimIDSensor - configureTriggeredProbe(String probe)

Configures a triggered probe before it is launched.
## Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>probe</td>
<td>String</td>
<td>An already configured probe that is ready to fire.</td>
</tr>
</tbody>
</table>

## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True to fire this probe, false to skip it.</td>
</tr>
</tbody>
</table>

### CimIDSensor - getInstanceHashToken()

Gets the instance hash token.

## Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The hash token</td>
</tr>
</tbody>
</table>

### CimIDSensor - prepare()

Prepares the probe results.

## Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
CimIDSensor - process(Object results, CimCIData cimData, CimIDSensor sensor)
Processes all CIM probe query results for a CIM ID sensor.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>results</td>
<td>Object</td>
<td>The query results</td>
</tr>
<tr>
<td>cimData</td>
<td>CimCIData</td>
<td>The CI data of the device being identified.</td>
</tr>
<tr>
<td>sensor</td>
<td>CimIDSensor</td>
<td>The wrapping sensor, extends CimIDSensor</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

CimIDSensor - runMultiProbeScript(String script, Object probeResult, String probeRecord)
Runs a multi-probe script against a probe result.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>script</td>
<td>String</td>
<td>The script</td>
</tr>
<tr>
<td>probeResult</td>
<td>Object</td>
<td>The probe result</td>
</tr>
<tr>
<td>probeRecord</td>
<td>String</td>
<td>The probe ID</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

CimIDSensor - updateDeviceCount()
Updates the device count.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**CimInstanceToken - Global**

 Represents the unique query identity of a CIM instance.  
Use with any server-side discovery script.

**CimInstanceToken - getHashToken(String cimomip)**

 Parses the instance token.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cimomip</td>
<td>String</td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The hash token</td>
</tr>
</tbody>
</table>

**CimInstanceToken - parse(XMLObj instance)**

 Parses the instance token.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance</td>
<td>XMLObj</td>
<td>The CIM instance</td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>---------</td>
<td>--------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>String</td>
<td>The parsed instance token, for example,</td>
<td></td>
</tr>
<tr>
<td></td>
<td>CIM_ClassName{Key1='Value1',Key2='Value2'}</td>
<td></td>
</tr>
</tbody>
</table>

**CimProbe - Global**

Maintains CIM probe meta data.

Use in any server-side script where you need to maintain a CIM probe.

**CimProbe - getNamedQueries()**

Returns all the named queries for the current CIM probe.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>void</td>
</tr>
</tbody>
</table>

**CimProbe - getQueries()**

Returns all the queries for the current CIM probe.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Array</td>
</tr>
</tbody>
</table>
CimProbe - getQueryRecords()
Returns all the records in the CIM Probe table.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideRecord</td>
<td>The query result</td>
</tr>
</tbody>
</table>

CimProbeResult - Global
Processes CIM probe results.
Use to process CIM probe results in any server-side discovery script.

CimProbeResult - getNamedInstances(String namedQueries)
Gets the named instances for the specified named queries.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>namedQueries</td>
<td>String</td>
<td>The named queries</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The named instances</td>
</tr>
</tbody>
</table>

CimProbeResult - getQueries()
Gets all the queries for the current CIM probe.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>None</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String Array</td>
<td>All Queries</td>
</tr>
</tbody>
</table>

**CIRelatedList - Global**

Utility class for working with CI Related lists.

Each instance of this class contains the details of a single list that is related to a particular CI. The details of this list and the contents of the list are included.

Use with any server-side discovery script.

**CIRelatedList - addRec(String record)**

Adds the specified record to the related list.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>record</td>
<td>String</td>
<td>The record to add</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**CIRelatedList - addRecs(String records)**

Sets the given records to the related list.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>records</td>
<td>String</td>
<td>The records to set</td>
</tr>
</tbody>
</table>
## CIRelatedList - appendXMLChildFld(String parent, String name, String datum)

Appends an XML child to a field.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>parent</td>
<td>String</td>
<td>The parent element</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>The element name</td>
</tr>
<tr>
<td>datum</td>
<td>String</td>
<td>The data to append</td>
</tr>
</tbody>
</table>

## CIRelatedList - appendXMLChildRecord(String parent, String name, String record)

Appends an XML child to a record.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>parent</td>
<td>String</td>
<td>The parent element</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>The element name</td>
</tr>
<tr>
<td>record</td>
<td>String</td>
<td>The record</td>
</tr>
</tbody>
</table>

## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
CIRelatedList - checkSysCollection()
Checks to see if this is a SysCollection table. If it is, sets the target table name and reference field name.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CIRelatedList</td>
<td>An instance of CIRelatedList for the specified list.</td>
</tr>
</tbody>
</table>

CIRelatedList - checkSysM2M()
Checks to see if this is a Sys many-to-many table. If it is, sets the target table name and reference field name.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if it is a sys many-to-many table; otherwise, false.</td>
</tr>
</tbody>
</table>

CIRelatedList - CIRelatedList(String table, String reffield, String cmdb_cname, String debugFlag)
Creates an instance of the CIRelatedList class. With no arguments, simply constructs an empty instance.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>String</td>
<td>The table containing the related list. If many-to-many, the many-to-many table.</td>
</tr>
<tr>
<td>refField</td>
<td>String</td>
<td>The reference field in the table for this related list.</td>
</tr>
<tr>
<td>cmdb_ci</td>
<td>String</td>
<td>The sys_id of the CI this list is related to.</td>
</tr>
<tr>
<td>debugFlag</td>
<td>String</td>
<td>If true, debug logging is enabled.</td>
</tr>
</tbody>
</table>

#### CIRelatedList - fromXML(String element)

Initializes this instance from the specified XML element.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>element</td>
<td>String</td>
<td>An XML element</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

#### CIRelatedList - populate()

Populates the `this.records` field of this instance.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
CIRelatedList - toString(Array result)
Makes a string representation of this instance, pushing each line onto the end of
the given result array.

This method is called from CIData.toString(), and assumes related list lines are to
be indented two spaces.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>Array</td>
<td>The result to convert</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

CIRelatedList - toXML(String document, String element)
Serializes this instance to XML in the given document and <rl> element.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>document</td>
<td>String</td>
<td>The document</td>
</tr>
<tr>
<td>element</td>
<td>String</td>
<td>The rl element</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

CIRelatedList - remove()
Removes all the related list items.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

### CIRelatedList - xmlToRecord(String records, String element)

Converts a related list from XML to record format.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>records</td>
<td>String</td>
<td>The record to create</td>
</tr>
<tr>
<td>element</td>
<td>String</td>
<td>The XML element</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

### CIUtils - Global

CIUtils is a utility class for working with configuration items.

By default, when traversing CI relationships the system will use a max depth of 10. This can be overridden in the `glide.relationship.max_depth` property.

The maximum number of items returns is 1000. This can be overridden in the `glide.relationship.threshold` property.

The CIUtils class is available to server-side scripts.

### CIUtils - servicesAffectedByCI(String CI_sys_id)

Determines which business services are affected by a specific CI.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CI_sys_id</td>
<td>String</td>
<td>The sys_id of a configuration item (cmdb_ci) to check.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>An array of sys_id values for cmdb_ci records downstream of (or affected by) the specified item.</td>
</tr>
</tbody>
</table>

This example displays the names of the services affected by the CI items with the name = Linux100.

```javascript
var CIUtil = new CIUtils();

//get a server record
var server = new GlideRecord("cmdb_ci_server");
server.addQuery("name", "Linux100");
server.query();
if (server.next()) {
    //get the affected services, array of ids
    var serviceIds = CIUtil.servicesAffectedByCI(server.getUniqueValue());
    for (var i=0; i < serviceIds.length; i++) {
        //get the service record
        var service = new GlideRecord("cmdb_ci_service");
        service.get(serviceIds[i]);
        gs.print(service.getDisplayValue());
    }
}
```

Output:

- Client Services
- IT Services
- Bond Trading

**CIUtils - servicesAffectedByTask(GlideRecord task)**

Determines which business services are affected by the specified task.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task</td>
<td>GlideRecord</td>
<td>A task GlideRecord, for example incident, change_request, or problem.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>An array of sys_id values for CIs downstream of (or affected by) the configuration item referenced by the task's cmdb_ci field.</td>
</tr>
</tbody>
</table>

This example displays the names of the services affected by the incident INC00050.

```javascript
var CIUtil = new CIUtils();

// get an incident record
var inc = new GlideRecord("incident");
inc.addQuery("number", "INC00050");
inc.query();
if (inc.next()) {
    // get the affected services, array of ids
    var serviceIds = CIUtil.servicesAffectedByTask(inc);
    for (var i=0; i < serviceIds.length; i++) {
        // get the service record
        var service = new GlideRecord("cmdb_ci_service");
        service.get(serviceIds[i]);
        gs.print(service.getDisplayValue());
    }
}
```

Output:

- IT Services
- Email
- Windows Mobile
- Electronic Messaging
- Outlook Web Access (OWA)
- Blackberry

### ClassificationSolutionStore - Global

Enables storing and retrieving solutions.
The `ClassificationSolutionStore` API requires the Predictive Intelligence plugin (com.glide.platform_ml) and is provided within the `sn_ml` namespace.

**ClassificationSolutionStore - add(Object mlSolution)**

Adds a new solution object to the store and returns a unique name.

ℹ️ **Note:** Label values do not need to be unique. For example, if you run this method with the same label 10 times, this method adds 10 different uniquely-named objects to the store.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mlSolution</td>
<td>ClassificationSolution()</td>
<td>object to add to the store.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>System-generated solution name.</td>
</tr>
</tbody>
</table>

The following example shows how to add a solution to the store. Use `ClassificationSolution - submitTrainingJob()` to run the training job after adding it to the store.

```javascript
// Create a dataset
var myData = new sn_ml.DatasetDefinition({
  'tableName': 'incident',
  'fieldNames': ['assignment_group', 'short_description', 'description'],
  'encodedQuery': 'activeANYTHING'
});

// Create a solution
var mySolution = new sn_ml.ClassificationSolution({
  'label': "my solution definition",
  'dataset': myData,
  'predictedFieldName': 'assignment_group',
  'inputFieldNames': ['short_description']
});
```
// Add the solution to the store to later be able to retrieve it.
var my_unique_name = sn_ml.ClassificationSolutionStore.add(mySolution);

ClassificationSolutionStore - deleteObject(String name)
Removes a specified solution object from the store.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the ClassificationSolution() object to be deleted.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to delete a solution from the store.

sn_ml.ClassificationSolutionStore.deleteObject("ml_sn_global_global_solution");

ClassificationSolutionStore - get(String name)
Gets a solution object from the store.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of a solution in the store.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>ClassificationSolutionVersion object. Returns an error if the object does not exist.</td>
</tr>
</tbody>
</table>

The following example shows how to get a solution object from the store using the get() method and view its training status using the ClassificationSolution - getActiveVersion() and ClassificationSolutionVersion - getStatus() methods.
// Get status
var mlSolution = sn_ml.ClassificationSolutionStore.get('ml_incident_categorization');

gs.print(JSON.stringify(JSON.parse(mlSolution.getActiveVersion().getStatus(), null, 2)));

Output:

```json
{
    "state":"solution_complete",
    "percentComplete":"100",
    "hasJobEnded":"true"
}
```

**ClassificationSolutionStore - getAllNames(Object options)**

Gets the names of all solution definition records in the store.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>options</td>
<td>Object</td>
<td>Options for restricting results within the specified properties.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>options.label</td>
<td>String</td>
<td>Optional. Label of your solution object.</td>
</tr>
<tr>
<td>options.domainName</td>
<td>String</td>
<td>Optional. Name of the domain for your solution object. Refer to <a href="https://datalabs.servicenow.com/servicenow/article/labs/doc/predictive-intelligence">Domain separation and Predictive Intelligence</a>.</td>
</tr>
<tr>
<td>options.scope</td>
<td>String</td>
<td>Optional. Name of an application scope for your solution object.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>List of strings representing solution object names in the store.</td>
</tr>
</tbody>
</table>
In the following example, the `getAllNames()` method returns a list of all names in the store.

```javascript
gs.print(JSON.stringify(JSON.parse(sn_ml.ClassificationSolutionStore.getAllNames()), null, 2));
```

Output:

```
[
  "ml_x_snc_global_global_my_solution_definition_3",
  "ml_incident_assignment",
  "ml_x_snc_global_global_my_solution_definition",
  "ml_x_snc_global_global_my_solution_definition_2",
  "ml_sn_global_global_incident_service"
]
```

In the following example, the `getAllNames()` method returns only names associated with values set in the `options` parameter.

```javascript
var options = {
  'label' : 'my solution definition',
  'domainName' : 'global',
  'scope' : 'global'
};
var solNames = sn_ml.ClassificationSolutionStore.getAllNames(options);
gs.print(JSON.stringify(JSON.parse(solNames), null, 2));
```

Output:

```
[
  "ml_x_snc_global_global_my_solution_definition"
]
```

**ClassificationSolutionStore - update(String name, Object mlSolution)**

Replaces an existing object in the store with the object passed as a parameter. The object name provided must be empty or match.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the solution to update.</td>
</tr>
<tr>
<td>mlSolution</td>
<td><code>ClassificationSr:ClassificationSolution()</code></td>
<td>object properties to update.</td>
</tr>
</tbody>
</table>
The following example shows how to update a solution object in the store.

```javascript
var solutionUpdate = new sn_ml.ClassificationSolution({
  'label': 'my solution definition',
  'dataset': myData,
  'predictedFieldName': 'assignment_group',
  'inputFieldNames': ['short_description']
});

sn_ml.ClassificationSolutionStore.update('ml_sn_global_global_incident_service',
  solutionUpdate);
```

### ClassificationSolutionVersion - Global

Scriptable object used in Predictive Intelligence stores.

The `ClassificationSolutionVersion` API requires the Predictive Intelligence plugin (com.glide.platform_ml) and is provided within the `sn_ml` namespace.
